Purpose: Previous clinical studies have shown that ferumoxtran-enhanced macrophage-MRI (m-MRI) has the potential to detect lymph node metastases (LNM) in patients with prostate cancer (PCa). This phase 3 study should confirm diagnostic performance using a confirmatory, prospective design.
To definitively assess the diagnostic accuracy of m-MRI compared with unenhanced MRI for detecting LNM in patients with newly diagnosed, intermediate- to high-risk PCa, using histopathology from extended pelvic lymph node dissection (ePLND) as the reference standard.
Methods or Background: This prospective, open-label, single-arm Phase 3 study (PROSTAPROGRESS) enrolled 160 men with newly diagnosed intermediate- or high-risk PCa at 15 European centres, all scheduled for radical prostatectomy and ePLND.
Results or Findings: Primary endpoints were met, demonstrating superior per-patient sensitivity (19,2% vs. 0,0%; $p < 0.025$) and non-inferior specificity (94.5% vs 97.6%; $p < 0,001$). The mMRI sensitivity for LNs > 2 mm was 35.3%. A high non-retrieval rate was also observed: 70.5% of m-MRI-suspicious LNs, particularly in the internal and common iliac regions, were not resected, which appears to be the most important limitation.
Conclusion: All primary endpoints were met. M-MRI has higher sensitivity than unenhanced-MRI for detecting normal-sized metastatic LNs, while maintaining high specificity. Its implementation can enhance non-invasive N-staging and improve patient management in intermediate- and high-risk PCa.
Limitations: m-MRI reading has a learning curve; moderate reader variability was observed, underscoring the importance of appropriate training to ensure reading consistency. The ‘non-retrieval’ of 71% of suspicious nodes introduces verification bias, likely underestimating the modality's true sensitivity.

Intratumoral oncolytic virotherapy in pediatric diffuse midline gliomas: early MRI and clinical correlates from a phase I clinical trial (11 min)

Carmen Mbongo; Pamplona / Spain

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: C. Mbongo, M. Calvo Imirizaldu, R. Garcia de Eulate, P. Dominguez Echavarri; Pamplona/ES
Purpose: To describe imaging and clinical outcomes following intratumoral administration of DNX-2401, a conditionally replicative oncolytic adenovirus, in children with newly diagnosed diffuse intrinsic pontine glioma (DIPG).
Methods or Background: This single-arm phase I study evaluated the safety and preliminary efficacy of DNX-2401 administered via stereotactic injection into the tumor, followed by conventional radiotherapy 2–6 weeks later. Eligible patients had radiologically confirmed DIPG. MRI follow-up included volumetric assessment and response evaluation according to RAPNO criteria. Tumor molecular profiling and immune analyses were performed.
Results or Findings: Twelve patients were enrolled. H3K27M mutations were detected in 83% and TP53 mutations in 42%. Treatment was well tolerated, with no dose-limiting or treatment related grade ≥3 toxicities. Transient perilesional edema was common on early post-injection MRI, consistent with localized inflammatory response. Reductions in enhancing tumor area were observed in 9/12 patients (75%), including three confirmed radiological responses per RAPNO criteria. Median overall survival reached 17.8 months, with three patients alive beyond 24 months.
Conclusion: Intratumoral infusion of DNX-2401 followed by radiotherapy is feasible and safe in pediatric DIPG. MRI demonstrates characteristic inflammatory changes and delayed volumetric reductions consistent with viral oncolysis and immune activation. These encouraging early imaging–clinical correlations warrant further evaluation in larger prospective studies.
Limitations: Small sample size and single-arm design, inherent to early-phase pediatric neuro-oncology trials, limit the generalizability of results.

Absence of a control group precludes definitive conclusions regarding survival benefit.

Short- and medium-term follow-up, with ongoing survivors, prevents full assessment of long-term efficacy and potential delayed toxicities.

Imaging interpretation challenges: early post-injection MRI changes (edema, enhancement) may overlap with treatment-related inflammation, complicating objective response assessment under RAPNO criteria.

Molecular heterogeneity and variable viral distribution may influence response patterns and should be explored in larger cohorts.
Funding for this study: The study took place in the setting of a clinical trial

Cancer Image Europe: general overview and milestones (15 min)
Luis Marti-Bonmati; Valencia / Spain

1. To learn about the EUCAIM project and the Cancer Image Europe platform for cancer imaging and AI development.
2. To understand the current volume and diversity of cancer imaging datasets and AI tools available through the platform.
3. To explore how the Cancer Image Europe platform enables the development, validation, and benchmarking of AI tools for precision medicine.

Key achievements on large, high-quality data findability and accessibility (15 min)
Ignacio Blanquer; Valencia / Spain

1. To learn about the EUCAIM project and the Cancer Image Europe platform for cancer imaging and AI development.
2. To understand the current volume and diversity of cancer imaging datasets and AI tools available through the platform.
3. To explore how the Cancer Image Europe platform enables the development, validation, and benchmarking of AI tools for precision medicine.

Key achievements on data holders, providers and users: EUCAIM linking European hospitals (15 min)
Katrine Riklund; Umeå / Sweden

1. To learn how many hospitals and research institutions are actively contributing data, and the types of imaging and associated data being shared.
2. To appreciate the conditions and benefits of contributing to or accessing data within the Cancer Image Europe infrastructure.
3. To explore the diversity of data providers and users, and how the platform supports academic research, clinical AI development and validation.

The future of Cancer Image Europe: key achievements towards EDIC (15 min)
Ana Miguel Blanco; Valencia / Spain

1. To learn about the future of AI-driven cancer imaging and data interoperability, and how these efforts align with the European Health Data Space and Europe's AI strategy.
2. To understand the key components of EUCAIM’s sustainability strategy.
3. To explore EUCAIM's pathway toward becoming a European Digital Infrastructure Consortium (EDIC).

Discussion (20 min)

ESOR - Shaping the future of radiology: radiologists shaping the future

Categories: Professional Issues, Research, Management/Leadership, Education

ETC Level: ALL LEVELS

Date: March 5, 2026 | 16:30 - 18:30 CET

CME Credits: 2

In 2026, the European School of Radiology (ESOR) marks a major milestone—20 years of and in action to harmonise education without borders across Europe and beyond, 20 years of supporting young radiologists, 20 years of connecting people and creating the precious ESOR community! Join us at this special session to celebrate ESOR's journey, achievements, and future!
After looking back while summarising the last 20 years making ESOR bigger, brighter and stronger, this session will turn towards the future, and several speakers who have shaped and are shaping the future of radiology will share their experience, thoughts and visions. In different presentations, the close and inseparable connection between education and leadership for a bright and shaped future of radiology will be discussed from different aspects and viewpoints. Based on the knowledge and experience gained in the past, educational models need to be continuously changed and adapted to the needs of changing environments and challenges. A new generation of educators, teachers and leaders has to improve their soft skills, AI knowledge, and should think globally. And there will be more exciting talks by luminaries from ESR, who have been part of ESOR since years/decades. Another highlight will be to hear the voices of ESOR – ESOR scholars and fellows from the early years, who will present their journeys from scholars to leaders.
Finally, already representing a tradition, this session will be the opportunity to give award certificates to the young colleagues who have been awarded with an ESOR scholarship or fellowship this year.

Geriatric oncology: moving the needle towards precision oncology for older adults with cancer (20 min)
Nicolo Battisti; London / United Kingdom

1. To learn about the challenges of managing cancer in older adults.
2. To appreciate the benefits of comprehensive geriatric assessment for older adults with cancer.
3. To understand the importance of broader multidisciplinary care input for older adults with cancer.

Impact of body composition on survival in pancreatic cancer (20 min)
Mario Ghosn; Créteil / France

1. To learn about how body composition is currently assessed and the role of imaging.
2. To appreciate the difficulties in body composition assessments and the need for robust objective measures.
3. To understand the impact of body composition on treatment strategies in pancreatic cancer.

Opportunistic evaluation of body composition in cancer patients: association with therapy-related toxicity (20 min)
Stefania Rizzo; Lugano / Switzerland

1. To learn about how body composition is currently assessed in cancer patients and the role of imaging.
2. To appreciate the effects of treatment toxicity on body composition.
3. To understand the impact of treatment-related toxicity on patient outcome as a result of altered body composition.

Beyond cancer: alternative role of PET/CT in oncology (20 min)
Egesta Lopci; Rozzano / Italy

1. To learn about how PET/CT is currently used in oncological patients beyond cancer therapy.
2. To appreciate the strengths and limitations of PET/CT in treatment-induced body modifications.
3. To understand how we should incorporate PET/CT assessments reporting findings beyond cancer in oncology.

Panel discussion (8 min)

ESR EDI 11 - EDI and meritocracy: marriage made in heaven or divorce waiting to happen?

From clinical curiosity to research question: where do I start? (15 min)
Marion Smits; Rotterdam / Netherlands

1. To learn how to translate clinical observations into clear, structured, and researchable questions.
2. To recognise the importance of curiosity and critical thinking in identifying relevant research gaps.
3. To understand the foundational steps in formulating a feasible and impactful research hypothesis.

Building skills and finding support: what every young researcher should know (15 min)
Paola Clauser; Vienna / Austria

1. To learn the basic research skills needed to get started.
2. To understand how mentorship, collaboration and institutional support can accelerate research growth.
3. To explore practical tips for finding resources, securing funding and building a professional research network.

Balancing residency and research: the resident's perspective (10 min)
Heidi Huhtanen; Turku / Finland

1. To learn practical strategies for effectively integrating research activities within the demands of residency training.
2. To recognise common challenges faced when balancing clinical responsibilities with research commitments.
3. To identify key factors contributing to clinical training and research development success.

The perspective of an emerging radiology researcher (10 min)
Joshua Rothwell; Cambridge / United Kingdom

1. To learn about common challenges faced when building a career in radiology research.
2. To appreciate the evolving impact of technology, interdisciplinary collaboration and funding opportunities on research development.
3. To understand key strategies for establishing and maintaining a sustainable academic research path.

Panel discussion: How do we inspire and empower the next generation of radiology researchers? (35 min)

ESR eHealth 11 - Privacy preservation for artificial intelligence (AI) applications

Categories: Professional Issues, Management/Leadership, Imaging Informatics, Medico-legal, Artificial Intelligence

ETC Level: LEVEL III

Date: March 5, 2026 | 16:30 - 17:30 CET

Panel discussion: Is patient data safe in the age of AI? (10 min)

ESR Undergraduate 11 - Voices of the future: a real talk on choosing radiology

Categories: Education

ETC Level: LEVEL I

Date: March 5, 2026 | 16:30 - 17:30 CET

CME Credits: 1

The session is organised as an interactive panel discussion with audience participation. Several topics and issues will be discussed, including the role of AI in the future of radiology, the number one reason why students hesitate to enter radiology, the one thing ESR offers that no medical student should miss, and the biggest misconception one encounters among medical students interested in radiology. Furthermore, the panel will address the following questions: how much does subspecialisation matter early on in radiology training, can radiologists still lead patient care, and should medical students start engaging with the ESR content as early as in the first year?

Optimisation of CT imaging in children (15 min)
Rutger A. J. Nievelstein; Utrecht / Netherlands

1. To understand the rationale for optimising CT in children.
2. To learn the technical strategies for dose reduction.
3. To understand the role of dedicated diagnostic reference levels, dose management systems and regular auditing.

Implementing evidence-based clinical decision support systems for paediatric imaging (15 min)
Bogdan-Stefan Olteanu; Bucharest / Romania

1. To understand the rationale for using clinical decision support systems in paediatric imaging.
2. To appreciate implementation strategies and the associated technical and human challenges.
3. To learn about the results observed so far in terms of improved justification and adherence to guidelines.

AI-driven optimisation in paediatric imaging (15 min)
John Damilakis; Iraklion / Greece

1. To learn about the most relevant AI-based tools available for reducing and evaluating dose exposure.
2. To appreciate the technical and ethical challenges in developing and using these tools.
3. To understand future directions of AI-driven optimisation in paediatric imaging.

Advances in hybrid imaging protocols for paediatric oncology (15 min)
Oleksandra V. V Ivashchenko; Groningen / Netherlands

1. To explain the modalities and most frequent indications for hybrid imaging in children with cancer.
2. To appreciate the strategies to optimise hybrid imaging protocols in paediatric patients.
3. To understand recent advancements and specific considerations for hybrid imaging in children.

Updated guidelines and communication strategies for radiation exposure in paediatric imaging (15 min)
Desislava Kostova-Lefterova; Sofia / Bulgaria

1. To learn about the latest international and European guidelines on radiation protection in paediatric imaging.
2. To appreciate the importance of using age and weight-specific imaging protocols, paediatric-dedicated equipment, and a child-friendly environment.
3. To understand how to communicate effectively with parents and caregivers about radiation risk in a way that builds trust and supports informed decision-making.

Panel discussion: Optimisation of imaging in children: what does the future hold? (10 min)

How to ensure effective access to AI for radiographers? (12 min)
Clare Rainey; Cork / Ireland

1. To understand the critical role radiographers play in the adoption and use of artificial intelligence (AI) across diagnostic imaging, radiotherapy, and nuclear medicine.
2. To explore the educational, infrastructural, and regulatory enablers required to ensure equitable and effective access to AI tools in radiographic practice.
3. To identify best practices and collaborative strategies that promote radiographer involvement in AI development, integration, and clinical governance.

Implementation of AI in clinical use: challenges and results (12 min)
Napapong Pongnapang; Bangkok / Thailand

1. To learn about key areas where artificial intelligence (AI) has been implemented in clinical radiography practice, and the outcomes observed.
2. To appreciate the practical challenges - including ethical, regulatory, technical, and workflow-related issues - faced during AI adoption in real-world clinical settings.
3. To understand the critical success factors and lessons learned from global case studies in AI implementation, especially from the perspective of radiographers and technologists.

Overview of international radiographer workforce challenges (12 min)
Edward Hung Tat TAT Chan; Fo Tan / Hong Kong SAR China

1. To learn about the global healthcare workforce challenge and the radiographer shortage.
2. To appreciate the result of the ISRRT survey of the WHO's strategy on human resources for health: workforce 2030.
3. To understand education gaps in radiography training worldwide and propose solutions.

Innovative opportunities to support rising demands for the radiographer workforce (12 min)
Elona Dybeli; Tirana / Albania

1. To understand the growing clinical and operational pressures on radiology services, and how radiographers can contribute to sustainable solutions.
2. To explore innovative models of care, technological advancements, and role development opportunities that support efficiency, access, and quality in radiology.
3. To evaluate the importance of interdisciplinary collaboration and continuous professional development in addressing workforce capacity and rising service demands.

ETC Level: LEVEL III

Date: March 5, 2026 | 16:30 - 18:00 CET

CME Credits: 1.5

The session aims to highlight technological advances that may influence the development of point-of-care imaging in developed and developing countries. We want to understand the clinical impact and the opportunities for better imaging delivery due to specific technological breakthroughs. The session will also address the potential benefits of these breakthroughs regarding sustainability.

Moderators:

Guy Frija; Paris / France

Alan H Matsumoto; Reston / United States

Chairpersons' introduction (5 min)

OF 11R - Radiographers' research in MRI

Categories: Radiographers, Students, Research
Date: March 5, 2026 | 16:30 - 17:30 CET
CME Credits: 1

Moderator:
Andrew England; Cork / Ireland

Chairperson's introduction (5 min)
Andrew England; Cork / Ireland

Low-field magnetic resonance imaging for musculoskeletal investigations (12 min)
Switinder Singh Ghotra; Lausanne / Switzerland

1. To explain the principles and advantages of low-field MRI technology in musculoskeletal imaging.
2. To identify key applications and limitations of low-field MRI for diagnosing musculoskeletal conditions.
3. To assess the potential research developments and clinical implications of low-field MRI in enhancing musculoskeletal diagnostic workflows.

Towards more efficient breast cancer diagnosis by combining ultrafast MRI, clinical data and artificial intelligence (12 min)
Belinda Lokaj; Geneva / Switzerland

1. To understand the principles and benefits of ultrafast breast MRI in improving diagnostic speed and patient comfort.
2. To recognise the potential of integrating clinical data and AI to enhance diagnostic accuracy and streamline breast cancer workflows.
3. To identify the radiographer's role in implementing and supporting AI-enhanced imaging protocols, ensuring quality, efficiency, and patient-centred care.

Effect of temporal resolution in resting-state functional MRI fingerprinting (12 min)
Stefano Tambalo; Rovereto / Italy

1. To understand what resting-state fMRI fingerprinting is and how it identifies individuals based on brain activity.
2. To learn how changing the temporal resolution affects the results of fMRI fingerprinting.
3. To see why this matters for improving personalised brain research and clinical use.

Open forum discussion (19 min)

RC 1103 - Pathology in and around the heart: from outside to inside

Categories: Imaging Methods, Chest, Vascular, Cardiac
ETC Level: LEVEL II+III
Date: March 5, 2026 | 16:30 - 17:30 CET
CME Credits: 1

Moderator:
Marco Francone; Rome / Italy

Chairperson's introduction (5 min)
Marco Francone; Rome / Italy

Imaging in pulmonary hypertension (PH) (15 min)
Karl-Friedrich Kreitner; Mainz / Germany

1. To outline the challenges for imaging in PH.
2. To outline the role of CT/MR imaging in the current PH guidelines.
3. To discuss CT/MR imaging features predicting PH.

Imaging in pericardial disease (15 min)
JORDI BRONCANO BRONCANO CABRERO; Córdoba / Spain

1. To discuss the different imaging modalities used to investigate pericardial disease with their strengths and limitations.
2. To describe typical image features of different pericardial diseases.
3. To outline the use of MRI and CT in the diagnostic work-up of constrictive pericarditis.

Diagnosis vs prognosis: modern non-invasive imaging of the myocardium (15 min)
Bernd J. Wintersperger; Toronto / Canada

1. To understand the role of MR in imaging the myocardium.
2. To describe the emerging role of MR in the differential diagnosis of myocardial pathologies.
3. To outline MR's role in diagnosing cardiac diseases and predicting patient outcomes.

Panel discussion: How can we use different imaging techniques best to assess disease in and around the heart? (10 min)

RECIST 11 - RECIST workshop: tips and tricks

Categories: General Radiology, Oncologic Imaging

Integrated Multi-Omics Profiling of Crohn's Disease-related Bowel Damage: Bridging Radiomics, Microbiota Dysbiosis, and Metabolic Dysregulation (6 min)
Jixin Meng; Guangzhou / China

Author Block: J. Meng, M. Wang; Zhengzhou/CN
Purpose: Crohn's disease(CD)–associated bowel damage(BD), marked by bowel structural injury and fibrosis, often necessitates surgery. Although gut microbial and metabolite changes contribute to BD, their link with magnetic resonance enterography (MRE)—the gold standard for BD evaluation remains unclarified. This multi-omics study uses MRE to dissect BD mechanisms and develop an integrated radiomic-microbial-metabolic predictive model.
Methods or Background: A prospective cohort of 230 CD patients and 30 healthy controls underwent MRE, fecal 16S rRNA sequencing, and serum/fecal untargeted metabolomics. BD was stratified using the Lémann Index. Microbial diversity and differential taxa were analyzed via Kruskal-Wallis or ANOVA; Spearman or Kendall correlations linked MRE features including T2WI, DWI, dynamic contrast enhancement (DCE) to microbiota and metabolites. Key radiomic signatures were identified through inter-observer reliability analysis. A random forest-based predictive model combining radiomic, microbial, and metabolic data was validated using ROC comparisons.
Results or Findings: BD patients exhibited distinct multi-omics profiles: (1) Radiogenomic Phenotypes: Penetrating lesions and arterial-phase DCE heterogeneity emerged as BD hallmarks, exhibiting near-perfect diagnostic agreement (κ=0.97–0.99, $P<0.001$) and correlating with fibrosis burden ($r=0.63$, $P<0.001$); (2) Microbial-Metabolic Drivers: BD patients demonstrated Blautia depletion, Escherichia-Shigella expansion, and serum ceramide (d18:2/23:1) accumulation, linked to diminished fecal IPA ($r=-0.71$) and acylcarnitine synthesis; (3) Integrated Model Superiority: The multiomics model combining MRI radiomics, taxa, and ceramides significantly outperformed single-modality predictions (AUC=0.86 vs. 0.61; DeLong's test $P<0.001$), stratifying patients into low-/high-risk BD progression groups.
Conclusion: Our study underscores the interplay between gut microbial dysbiosis, metabolic alterations, and MRE-quantified structural changes in BD patients. The integrated multi-omics model provides a promising tool for BD prediction, enabling precise CD severity stratification and personalized clinical decision-making.
Limitations: Future studies involving larger, multicenter cohorts across diverse geographical regions would enhance the validity of our results.

Integrated clinical and contrast-enhanced CT parameters for predicting therapeutic response in colorectal cancer liver metastasis treated with chemotherapy and bevacizumab (6 min)
Long Yuan; Lanzhou / China

Author Block: L. Yuan, J. Zhou; Lanzhou/CN
Purpose: To investigate the predictive value of clinical and pre- and post-treatment CT parameters for the efficacy of bevacizumab in patients with colorectal liver metastasis(CRLM) .
Methods or Background: This retrospective study included 290 patients with CRLM and 455 liver metastases treated with bevacizumab in our hospital . The morphological features of CRLM after four treatment cycles were assessed using CT images. CT values at baseline and after four treatment cycles in different phases (PS, AP, VP, and DP), and density change values (ΔCT values) before and after treatment were calculated. According to RECIST 1.1, CRLM after 12 treatment cycles was categorized into responsive and non-responsive groups. Differences between the two groups were searched for using the T-test, Mann−Whitney U, or chi-square test, and diagnostic performances of the different variables were evaluated using the receiver operating characteristic (ROC) curve.
Results or Findings: RAS mutant-type CRLM was more prevalent in the responsive group than in the wild-type group, with a significant difference (P<0.001). CRLM with a lobulated shape and heterogeneous texture after four treatment cycles showed a poorer treatment response than those with a round shape and homogeneous texture, with a significant difference (P<0.05). Additionally, CT values of AP-pre, VP-pre, DP-pre, VP-post, and ΔAP were higher in the responsive group than in the non-responsive group. The combined use of clinical and contrast-enhanced CT parameters demonstrated better efficacy (AUC >0.7) than single parameters. Parameters such as RAS, texture-post, and AP-pre combined showed higher predictive efficacy.
Conclusion: The combination of clinical parameters and contrast-enhanced CT parameters before and after treatment can effectively predict the early therapeutic response in patients with CRLM.
Limitations: It is single-center, small-sample, and retrospective nature may have affected the robustness of the results.
Funding for this study: This work was supported by grants of the National Natural Science Foundation of China (No. 82371914) and the Cuiying Scientific and Technological Innovation Program of Lanzhou University Second Hospital (CY2021-ZD-01).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the institutional ethical review board (2023A-379).

The Impact of Sarcopenia on the Risk of Gallbladder Perforation in Acute Cholecystitis: A Retrospective Analysis (6 min)

MUHAMMET VASFİ GÖKAY; Istanbul / Turkey

Author Block: M. V. GÖKAY, K. Kadirli, F. S. Bayramoğlu, H. Mutlu; Istanbul/TR
Purpose: To evaluate the association and prognostic value of CT-derived body composition parameters with gallbladder perforation in patients with acute cholecystitis.
Methods or Background: We retrospectively analyzed 80 surgically treated patients with acute cholecystitis (Jan 2018–Dec 2024). Gallbladder perforation was intraoperatively confirmed in 21 cases (26.2%), while 59 non-perforated patients, matched by age, sex, and comorbidity, served as controls. Preoperative non-contrast abdominal CTs were assessed at the L3 level. Skeletal muscles (psoas, paraspinal, abdominal wall) and visceral/subcutaneous fat were segmented semi-automatically using ImageJ v1.54m. Thresholds: –29 to +150 HU for muscle, –190 to –30 HU for fat. All areas were normalized to vertebral surface area. Measurements were repeated twice by two readers. Comorbidities were grouped as none, 1, 2, or ≥3. Collected variables included demographics, CRP, leukocytes, and time intervals (symptom–CT, symptom–admission, admission–surgery). Univariate tests identified predictors of perforation. Significant variables were entered into multivariate logistic regression (backward LR). ROC assessed diagnostic performance, and VIF tested collinearity. Variables with <20% missingness were handled via listwise deletion, leading to minor sample variations.
Results or Findings: Univariate analysis showed significantly higher IMAT/vertebra ratio in the perforation group (p=0.050). Multivariate analysis identified IMAT/vertebra ratio (OR: 4.63; 95% CI: 1.41–15.15; p=0.011) and leukocyte count (OR: 1.14; 95% CI: 1.02–1.29; p=0.026) as independent predictors. Symptom-to-CT interval showed borderline association (OR: 1.14; 95% CI: 1.00–1.29; p=0.054). Interobserver agreement was excellent (ICC = 0.89).
Conclusion: Our findings show that the IMAT/vertebra ratio is an independent predictor of gallbladder perforation in acute cholecystitis, reflecting inflammatory burden and reduced physiological reserve. Validation in larger multicenter cohorts is needed to confirm its prognostic value and support integration into routine preoperative assessment.
Limitations: Single-center, retrospective design and small sample size.
Funding for this study: None.

Prediction of Microsatellite Instability in Colorectal Cancer Using Two Internally Validated Radiomic Models (6 min)

Antonio Galluzzo; Firenze / Italy

Author Block: A. Galluzzo, L. Scalzone, C. Mugnaini, G. Danti, V. Miele; Firenze/IT
Purpose: To develop two different radiomic models (RMs) based on preoperative portal phase computed tomography (PP CT) to predict microsatellite instability (MSI) in patients with colorectal cancer (CRC) before surgery.
Methods or Background: PP CT scans of 115 CC patients were segmented using 3DSlicer (v5.6.1). Model I included images from three different scanners (GE, Siemens, Philips), while Model II used only one scanner (GE). For Model I, 80 patients were used for training and 35 for internal validation; for Model II, 46 and 24 patients were used, respectively. Data on sex, age, tumor location, and MSI genomic status were collected. Significant radiomic features (RFs) were identified using the t-test or Mann–Whitney test ($p<0.05$), and the most robust RFs were selected using the LASSO regression method. Both RMs were internally validated.
Results or Findings: Model I, based on 2 RFs and 1 clinical features (LOCATION) achieved an AUC of 0.76 (95% CI: 0.65–0.87) in the training cohort and 0.74 (95% CI: 0.56–0.92) in the validation cohort. Model II, based on 3 RFs, achieved an AUC of 0.85 (95% CI: 0.73–0.96) in the training cohort and 0.72 (95% CI: 0.50–0.94) in the validation cohort.
Conclusion: Both RMs performed well in distinguishing MSI from non-MSI tumors, potentially reducing the need for invasive histology and improving treatment timing. Despite a higher AUC, Model II showed overfitting compared to Model I, which included two RFs and one clinical feature (LOCATION). Developing models on larger, more diverse datasets is preferable to improve generalizability and limit overfitting.
Limitations: This study is limited by its retrospective design, small sample size, lack of external validation, and absence of follow-up. Future studies should use larger, prospective cohorts. Standardized imaging and multicentre trials are key for clinical implementation of radiomics.
Funding for this study: No funding was received for this study
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was conducted in accordance with the Declaration of Helsinki, and approved by the Ethics Committee of Careggi University Hospital (protocol code 13261_OSS).

Opportunistic CT-derived Assessment of Spleen volume Predicts Outcome in Patients undergoing MitraClip (6 min)

Babak Salam; Bonn / Germany

Author Block: B. Salam, M. Weber, A. M. Sprinkart, S. Nowak, M. Theis, A. Isaak, J. A. Luetkens, J. Vogelhuber, D. Kütting; Bonn/DE
Purpose: The spleen is an essential component of the immune system and closely associated with cardiac function (cardio-splenic axis). In this context, spleen volume (SV) emerges as a potential new prognostic indicator for cardiovascular risk. This study aimed to investigate the prognostic value of SV measured from routine preinterventional CT in patients undergoing MitraClip for treatment of recurrent mitral regurgitation.
Methods or Background: Consecutive patients undergoing MitraClip between February 2011 and November 2022 at the Heart Center Bonn were retrospectively evaluated. SV was determined from pre-interventional CT scans using a dedicated deep learning segmentation model for body composition analysis (TotalSegmentor).
Results or Findings: A total of 214 patients (mean age: 77.6±8.2 years, mean EuroSCORE II: 5.0±3.6%) were investigated. 1-year survivors had a significantly lower SV compared to non-survivors (0.19±0.12 cm3 vs. 0.35±0.35 cm3, P<0.001). According to their SV, patients were dichotomized by the median value and defined to have low (<0.182 cm3) and high SV (≥0.182 cm3), respectively. Following MitraClip, high SV was related to acute kidney injury (53.3% vs. 71.0%, P=0.020) as well as increased 30-day (2.8% vs. 12.1%, P=0.009), 1-year (10.3% vs. 27.1%, P=0.001), 2-year (15.0% vs. 33.6%; P=0.001), and 3-year mortality (15.9% vs. 34.6%; P=0.002). On multivariate Cox regression analysis, SV (Hazard Ratio 8.92 [95% Confidence Interval: 2.67-29.90]; P<0.001), as well as NT-proBNP (HR 1.00 [95% CI: 1.00-1.00]; P=0.015) were identified as independent predictors of 1-year mortality.
Conclusion: Our results indicate CT-derived SV as a promising new imaging biomarker, which provides additional information for risk stratification in MitraClip patients. Future studies should explore the clinical value of SV compared with other established risk stratification tools and the prognostic role of SV for other cardiovascular and oncologic diseases.
Limitations: Single-center retrospective design limits generalizability.

Tumor mutation burden drives survival outcomes in pancreatic ductal adenocarcinoma and enables noninvasive prediction via spectral CT (6 min)

Siya Shi; Guangzhou / China

Author Block: S. Shi, J. Liu, Y. Luo, S-T. Feng, W. Deng; Guangzhou/CN
Purpose: To investigate the prognostic value of tumor mutation burden (TMB) in pancreatic ductal adenocarcinoma (PDAC) and the predictive utility of dual-layer spectral CT (DLCT) for TMB assessment.
Methods or Background: This retrospective study included patients with histologically confirmed PDAC who underwent DLCT from June 2019 to December 2023. The association between TMB and progression-free survival (PFS) was analyzed using survival analysis and the optimal cutoff was calculated to group patients. The Kaplan-Meier survival curves were used to compare the PFS between both groups. Independent TMB predictors were identified through univariate and LASSO regression. Predictive performance was assessed via ROC and precision-recall (PR) curve analyses.
Results or Findings: Among 75 enrolled patients (mean age 60.4 ± 11.2 years, 41 male), 52 received combination immunotherapy. Median TMB was 2.13 mutations per megabase (mut/Mb; interquartile range: 1.00–4.26). An integer TMB cutoff of 5 mut/Mb (optimized from 5.03 for clinical practicality) stratified patients into distinct prognostic groups, with low-TMB cases demonstrating inferior PFS (median PFS: 5 vs. 7 months, p=0.02); this trend persisted in the immunotherapy subgroup (4 vs. 7 months, p=0.02). Normalized iodine concentration in the pancreatic phase (nIC_a) emerged as the sole independent TMB predictor (area under the curve [AUC] of ROC=0.901, cutoff=0.089; accuracy=0.893, sensitivity=0.818, specificity=0.906), surpassing normalized conventional CT attenuation values in the pancreatic phase (nCT_a, AUC=0.834), pancreatic tumor infiltration (AUC=0.679), and a combined model (nCTa+PTI, AUC=0.864). PR curves confirmed nIC_a's superior efficacy. Patients stratified by nIC_a-predicted TMB status exhibited significant PFS differences (7 vs. 5 months, p=0.04).
Conclusion: Low TMB is a negative prognostic biomarker in PDAC, associated with shorter PFS. DLCT-derived nIC_a enables accurate, noninvasive TMB prediction, supporting its potential role in therapeutic stratification.
Limitations: The single-center retrospective design with a limited sample size□a single vendor platform.
Funding for this study: This study has received funding by National Natural Science Foundation of China (82472096) and Natural Science Foundation of Guangdong Province (2024A1515011968) to Yanji Luo.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study design was approved by the ethics review board of our hospital and informed consent was waived owing to the retrospective nature of the study.

AI-driven longitudinal body composition analysis from routine CT imaging for predicting survival in pancreatic ductal adenocarcinoma (6 min)

Felix Herr; Munich / Germany

Author Block: F. Herr, M. Vornhülz, C. A. Dascalescu, A. E. Sint, J. Ricke, M. Ingrisch, L. K. Shiyam Sundar, J. Mayerle, S. Grosu; Munich/DE
Purpose: To evaluate the prognostic relevance of longitudinal changes in body composition derived from routine CT scans in patients with pancreatic ductal adenocarcinoma (PDAC) using fully automated image analysis.
Methods or Background: In this retrospective single-center study, 55 patients with histologically confirmed PDAC from the prospective METAPAC trial were included. All had at least one venous-phase abdominal CT within 90 days from baseline. Fully automated segmentation was used to quantify volumetric indices for visceral fat (VF), subcutaneous fat (SF), muscle (M), and compute ratios (VF/SF, SF/M). Relative changes from baseline were calculated. Optimal cutoffs were determined using maximally selected rank statistics. Associations with overall survival (OS) were analyzed via Cox regression and evaluated by Harrell's C-index and AIC.
Results or Findings: A total of 88 CT scans from 55 patients (mean age 67 ± 11 years; 28 male) were analyzed. An increase in subcutaneous fat index (SFI) (HR: 5.17; C-index: 0.60; p = .028) and a decrease in VF/SF ratio (HR: 2.70; C-index: 0.67; p = .014) were significantly associated with reduced OS. Both metrics remained prognostic in multivariable analysis (SFI: HR: 4.67; p = .0398; VF/SF: HR: 2.75; p = .0199; C-index: 0.73). Absolute baseline or follow-up values were not predictive. Kaplan–Meier analysis confirmed shorter OS in patients with SFI > 0.77 (median OS 319 days vs. not reached; p = .015) and VF/SF ≤ 0.97 (median OS 131 vs. 809 days; p = .011).
Conclusion: In PDAC patients, dynamic fat distribution changes, particularly rising SFI and falling VF/SF ratios, were associated with poorer survival. Automated body composition analysis from routine CT may serve as a non-invasive imaging biomarker for early risk stratification.
Limitations: Key limitations of our study include the small sample size and retrospective, single-center design.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This single-center retrospective study was approved by the local ethics committee (approval number 19-027).

Diffusion-based virtual MR elastography: association with pancreatic fibrosis and prediction of postoperative pancreatic fistula after pancreaticoduodenectomy (6 min)

Cai Wei; Beijing / China

Author Block: C. Wei, Y. Zhu, X. Zhao; Beijing/CN
Purpose: Preoperative prediction of clinically relevant postoperative pancreatic fistula (CR-POPF) after pancreaticoduodenectomy is crucial for implementing prevention strategies. This study aims to explore the application of virtual MR elastography (vMRE) in noninvasive assessing pancreatic fibrosis and preoperative predicting CR-POPF with inter-devices validation.
Methods or Background: Patients underwent pancreatic MRI with multiple-b-value DWI sequence were retrospectively collected, and divided into two cohorts based on different MRI scanners. Spearman correlation analysis was used to assess the relationship between shifted apparent diffusion coefficient (sADC) and standard MR elastography. Linear regression analysis was employed to constructed diffusion-based tissue shear modulus (μdiff) using optimal sADC. Association between μdiff and pancreatic fibrosis grades were evaluated. Logistic regression was used to identify the independent risk factors for CR-POPF. The predictive performance was evaluated through receiver operating characteristic (ROC) analysis.
Results or Findings: A total of 320 patients (cohort 1: 228; cohort 2: 92) were finally included. sADC generated from b values of 400 and 1500 s/mm2 was identified for fitting μdiff. μdiff was significantly associated with histopathologic fibrosis grade and demonstrated satisfactory performance for CR-POPF with area under the curve (AUC) of 0.765. The results was confirmed in cohort 2. μdiff, body mass index (BMI), and main pancreatic duct (MPD) was revealed as independent predictors of CR-POPF. Their combination further improved the predictive performance to AUC of 0.923.
Conclusion: Diffusion-based vMRE could effectively assess pancreatic fibrosis grade and provide a noninvasive biomarker for predicting CR-POPF preoperatively. The combination of μdiff, BMI, and MPD demonstrated superior predictive performance.
Limitations: This was a single-center study with a relatively small sample size. Although two b-value combination for pancreatic vMRE was validated on different MRI scanner, which completely eliminate the risk of overfitting. Multi-center studies with larger samples are warranted.
Funding for this study: Supported by National High Level Hospital Clinical Research Funding 80102022505
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective study was conducted in accordance with the Declaration of Helsinki. The study protocol was approved by the Institutional Review Board of the National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College (Approval #21/241-4521; November 10, 2021).

Automated Abdominal CT Biomarkers Predict 5 and 10 year Mortality in a Large, Multi-Hospital Cohort (6 min)

Abhinav Suri; Los Angeles / United States

Author Block: A. Suri[1], M. A. B. C. Rockenbach[2], B. C. Bizzo[2], J. Garrett[3], D. C. Elton[2], P. J. Pickhardt[3]; [1]Los Angeles, CA/US, [2]Boston, MA/US, [3]Madison, WI/US
Purpose: To investigate whether abdominal CT biomarkers explored in prior literature remain predictive of 5 and 10 year all-cause mortality in a novel, large cohort.
Methods or Background: 180,935 CT patients (with and without contrast, imaging the abdomen, one scan per patient, mean avg 56.6±17.4, 55.7% female) from our multi-hospital institution were selected for usage in this study. Automatically extractable imaging biomarkers (derived from muscle attenuation, bone mineral density, visceral & subcutaneous adipose tissue volume, and abdominal aorta Agatston score at the L3 vertebral body) were calculated on all scans. Date of death of each patient was also gathered. 80% of scans (144,748) were used to train/validate 14 different algorithms to predict 5 or 10 year all-cause mortality. The best algorithm on the training set (based on AUC over 5-fold cross-validation) was evaluated on the hold out test set.
Results or Findings: The best performing algorithm for 5-year mortality prediction was XGBoost which achieved an AUC of 0.84 on the hold out test set. The algorithm did not vary significantly in AUC for age ≤65=0.82 vs >65=0.85. The best performing algorithm for 10-year mortality prediction was Light Gradient Boosting Machines (AUC=0.79) with minimal variation according to age (AUC≤65=0.77 vs AUC>65=0.81). For both 5 and 10 year mortality prediction, the most important values relied on visceral adipose tissue attenuation followed by visceral:subcutaneous adipose tissue volume ratio. The least important feature was abdominal aorta Agatston score.
Conclusion: Automated abdominal CT biomarkers are strong predictors of all-cause mortality even in large, multi-hospital settings. These imaging biomarkers remain predictive regardless of clinical demographics such as age.
Limitations: Follow up data on patients is limited by their interaction with our institution. As a result, information on the death of patients may be incomplete.
Funding for this study: No funding sources to declare.
Has your study been approved by an ethics committee? Not applicable

Body Composition Analysis: A Quantitative Imaging Biomarker for Perioperative Risk Stratification (6 min)

Arvind Channarayapatna Srinivasa; Singapore / Singapore

Author Block: A. Channarayapatna Srinivasa[1], S. S. Poluri[2], Z. T. J. Sim[2], E. C. Z. H. Ng[2], K. Y. How[2], B. K. N. Prakash[1], C. H. Tan[2]; [1]Singapore/SG, [2]singapore/SG
Purpose: This study aims to examine the prognostic significance of abdominal body composition compartments—superficial subcutaneous adipose tissue (SSAT), deep subcutaneous adipose tissue (DSAT), visceral adipose tissue (VAT), and skeletal muscle—on perioperative outcomes in colorectal cancer surgery, and to assess the additional value of cross-sectional area (CSA) and attenuation (HU) as quantitative imaging biomarkers.
Methods or Background: We conducted a retrospective analysis of 1,499 colorectal cancer patients who underwent surgical intervention and had pre-operative abdomen CT scans at the level of the third lumbar vertebra. nnU-Net facilitated the automatic segmentation of SSAT, DSAT, VAT, and skeletal muscle. Both CSA and HU were measured. The evaluated outcomes comprised recovery duration, length of stay (LOS), readmission rates, complications (infectious, cardiovascular, surgical, paralytic ileus, wound dehiscence, anastomotic leak), and pre- and post-operative WHO performance status.
Results or Findings: SSAT and DSAT CSA and HU exhibited no significant correlations with outcomes. A diminished skeletal muscle cross-sectional area corresponded with inferior WHO performance status ($p<0.001$). Reduced muscle HU forecasted extended LOS ($\rho=-0.106$, $p\_fdr<0.001$), postponed recovery ($\rho=-0.082$, $p\_fdr=0.011$), and heightened complications (OR = 0.98perHU,$p = 0.005$). VAT exhibited a contradictory dual function: increased VAT CSA correlated with extended LOS ($p<0.001$), ileus ($p\_fdr < 0.001$), and surgical complications (OR≈1.03per+10 cm^2, $p = 0.025$), yet diminished VAT CSA and low muscle mass signified frailty ($p < 0.01$). Increased VAT HU independently forecasted a heightened risk of complications (OR=1.01perHU,$p=0.016$) and an escalation in the severity of surgical and cardiovascular incidents.
Conclusion: CT body composition yields clinically significant biomarkers. Muscle (CSA, HU) reflects frailty and functional reserve, whereas VAT has a paradoxical role; elevated VAT indicates surgical risk, whereas diminished VAT alongside low muscle suggests frailty.
Limitations: Retrospective, single-cancer cohort; absence of external validation; and lack of long-term oncological outcomes.
Funding for this study: No Funding

Signal Intensity–Derived Apparent Extracellular Volume: Can It Predict Liver Fibrosis? (6 min)

Kübra Nur Kılıçarslan; Bolu / Turkey

Author Block: A. Buz, K. N. Kılıçarslan; Bolu/TR
Purpose: This study aims to evaluate the feasibility of signal intensity–based apparent extracellular volume derived from dynamic liver MRI as a noninvasive and accessible quantitative method to improve the diagnostic reliability of liver fibrosis assessment.
Methods or Background: A total of 61 adult patients with chronic liver parenchymal disease who underwent contrast-enhanced dynamic liver MRI between July 2021 and August 2025 were included in the study. In the dynamic MRI, signal intensity measurements of the aorta and liver parenchyma from both lobes were obtained in the pre-contrast and late hepatic phases LAVA series. Patients were divided into three groups based on their FIB-4 index to explore the correlation with liver ECV. All data analyses were performed using R version 4.4.1.
Results or Findings: A total of 61 participants were included in the study, comprising 34 males and 27 females. The median age was 65 years (IQR: 12; range: 26–82 years). The median ECV was 0.291 (IQR: 0.104) in the low-risk group (n = 6), 0.316 (IQR: 0.129) in the intermediate-risk group (n = 19), and 0.283 (IQR: 0.101) in the high-risk group (n = 36). Overall, no clear trend of increasing or decreasing ECV with higher FIB-4 value was observed.
Conclusion: Signal intensity–derived liver ECV is a feasible, noninvasive measure, but it did not consistently correlate with FIB-4–based fibrosis risk in this cohort. Incorporating T1 mapping may improve its accuracy, and further studies are needed to determine its predictive value for liver fibrosis.
Limitations: Single center-retrospective study design.
Funding for this study: N/A

The effect of AI on retrospectively visible interval cancers in mammography screening – results from the randomised controlled MASAI trial (6 min)
Veronica Hernström; Lund / Sweden

Author Block: V. Hernström, H. Sartor, O. Hagberg, K. Lang; Lund/SE
Purpose: To investigate whether the distribution of interval cancer classification groups differ with or without the use of artificial intelligence (AI) in mammography screening.
Methods or Background: The MASAI trial is a randomised, controlled, non-inferiority, screening study comparing AI-supported mammography screening with standard double reading. In the intervention group, AI was used for triage to single or double reading and for detection support. Participants with interval cancers were retrospectively reviewed by a panel of breast radiologists and classified as true negative, showing minimal signs or missed at screening. The distribution of classification groups was compared between the intervention and control groups, and in relation to AI risk scores. Differences in distribution were assessed with a Chi-2 test.
Results or Findings: There were fewer interval cancers showing minimal signs (14 [17%] vs 26 [28%]) and a similar number of missed (9 [11%] vs 10 [11%]) and true negatives (59 [72%] vs 57 [61%]), in the intervention group compared to the control group. The distribution was however not statistically significantly different (p=0.22). Of the retrospectively visible interval cancers (missed or minimal signs) in the intervention group, 78% (18/23) had intermediate or high AI risk scores and 65% (15/23) were correctly localised by AI.
Conclusion: The use of AI in mammography screening yielded fewer interval cancers with minimal signs at screening compared with standard double reading, indicating its ability to aid in detecting subtle malignancies. A further reduction of interval cancer may be achievable since a substantial proportion of the retrospectively visible interval cancers were assigned elevated risk scores and were correctly localised by AI.
Limitations: Single-institution trial, single AI-system, informed review of classification groups
Funding for this study: Swedish Cancer Society, Confederation of Regional Cancer Centres, and governmental funding for clinical research.

Influence of AI-informed Disease Prevalence on Radiologist Performance: Insights from the Mammography Screening with Artificial Intelligence trial (MASAI) (6 min)
Jessie Gommers; Nijmegen / Netherlands

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: J. Gommers[1], C. Abbey[2], O. Hagberg[3], K. Lang[3]; [1]Nijmegen/NL, [2]Santa Barbara, CA/US, [3]Malmö/SE
Purpose: To investigate how knowledge of AI-informed disease prevalence influenced radiologists' screening performance by comparing outcomes across AI risk scores when reading with and without AI.
Methods or Background: This study used data from the prospective MASAI trial, designed to compare AI-supported mammography screening, where AI triaged examinations to single (AI scores 1-9) or double (AI score 10) reading and was used as decision support, with standard double reading without AI. Recall rates (RR), cancer detection rates (CDR), and false positive rates (FPR) were compared between the AI-supported group (intervention) and double reading group (control) using Fisher's exact tests with results stratified by AI risk scores. Single-reader assessments in the control group were approximated for examinations with AI scores 1-9.
Results or Findings: In total, 105,087 women were included in this study, of which 52,576 in the control group and 52,511 in the intervention group. For examinations classified as low risk (AI score 1–7), AI-supported reading led to a reduction in RR (0.50% vs 0.61%, P=.043) and FPR (0.49% vs 0.59%, P=.049), without affecting CDR (0.17‰ vs 0.22‰, P=.804), compared to standard reading. For intermediate-risk examinations (AI scores 8–9), AI-supported reading resulted in increased RR (2.29% vs 1.58%, P<.001) and FPR (1.90% vs 1.30%, P=.003), with no change in CDR (3.94‰ vs 2.75‰, P=.224). For high-suspicion examinations (AI score 10), AI-supported reading increased RR (14.41% vs 9.44%, P<.001), FPR (6.69% vs 3.40%, P<.001), and CDR (77.23‰ vs 60.34‰, P=.004).
Conclusion: Knowledge about AI-informed prevalence affects radiologists differently across AI risk categories, enhancing cancer detection in high-risk examinations and reducing false positives in low-risk examinations.
Limitations: Interval cancer data not yet included.
Funding for this study: Swedish Cancer Society, Confederation of Regional Cancer Centres, and Swedish governmental funding for clinical research.

Artificial Intelligence in Mammography Screening in Norway (AIMS Norway): a randomized controlled trial (6 min)

Solveig Hofvind; Oslo / Norway

Author Block: Å. S. Holen, M. Larsen, S. Hofvind; Oslo/NO
Purpose: The randomized controlled trial Artificial Intelligence in Mammography Screening in Norway (AIMS Norway) evaluates the performance of artificial intelligence (AI) combined with one or two radiologists, compared to standard independent double reading in BreastScreen Norway. The objective is to demonstrate that AI-assisted screening is non-inferior to the current standard in detecting breast cancer.
Methods or Background: This randomized, controlled, non-inferiority, parallel-group, single-blind trial is recruiting participants through written consent at the time of mammography screening. Participants are randomized into either a study or control group. In the study group, examinations are analyzed using Transpara® v2.1 (ScreenPoint Medical) and triaged by AI score, indicating risk of malignancy. Exams with low scores (1–7) are single-read, while those with intermediate to high scores (8–10) undergo independent double reading (standard of care). Radiologists are blinded to both the AI results and whether the exam is single- or double-read during primary reading; AI scores and AI-generated annotations are only available during consensus meetings. The control group follows standard double reading.
Results or Findings: Recruitment for the trial began in November 2024 in Western Norway and in September 2025 in the Central region. Recruitment in Northern Norway is planned to start by the end of 2025. The trial aims to enroll 140,000 women. As of October 2025, 79% of women attending the screening program in participating regions have consented participation in the study.
Conclusion: The AIMS Norway randomized controlled trial has begun recruiting participants in two health regions, with a 79% acceptance rate. Recruitment will continue until the target number of participants is reached to demonstrate non-inferiority in screen-detected cancer rates.
Limitations: None
Funding for this study: Norwegian Cancer Society (Pink Ribbon, #214931) and the Western (#F-12858-D11417), Central (#2024-36740) and Northern (#HNF1723-24) Norway Regional Health Authorities.

Improving the performance of AI on Australian screening mammograms using priors cases (6 min)

Sarah Jayne Lewis; Penrith / Australia

Author Block: S. J. Lewis[1], P. D. Trieu[2], S. Tavakoli Taba[2], M. Barron[2], Z. (. Jiang[2]; [1]Campbelltown/AU, [2]The University Of Sydney/AU
Purpose: Mammographic population-based screening programs can improve the early detection of breast cancer, but workload pressures for radiologists remain. Artificial Intelligence (AI) may mitigate this pressure but the lack of training with prior cases, which research shows is important for high specificity, is a limitation and lacks rigorous documentation. This study compares the performance of an AI trained on mammograms with, and without priors.
Methods or Background: The training dataset had 1458 cases, 729 malignant, 729 normal) all with prior mammograms from a previous screening round. Current and prior mammograms were aligned using a fully convolutional network with a multiresolution strategy. The Globally-aware Multiple Instance Classifier (GMIC) AI with transfer learning was applied to generate malignant features. A correlational neural network with 6-fold cross-validation learned the relationships between two patches corresponding to the current/prior malignant features. AI performance testing was assessed using the BreastScreen Reader Assessment Strategy dataset (374 cases, 118 malignant, 256 normal) across different cancer types with, and without priors, using one-way ANOVA test.
Results or Findings: The AI demonstrated a significant improvement in specificity (93.1% with priors; 90.4% without; p =0.037). Significant improvement in sensitivity for spiculated masses (p=0.024) and architectural distortions (p=0.012) was shown with a non-significant difference in overall sensitivity (92.6% vs 91.2%) and for calcification (p=0.26), discrete mass (p=0.19), non-specific density (p=0.08), and stellate (p=0.13) lesions.
Conclusion: AI performance was improved through training with prior screening cases, notably through specificity, and the detection of two cancer types. The importance of training with longitudinal screening rounds should be considered by AI vendors as well as a national approach to screening program data storage to advance AI technologies.
Limitations: Australian screening context with small training and testing datasets.
Funding for this study: National Breast Cancer Foundation (Australia) and the Australian Commonwealth Department of Health and Aging.

AI-only for assessing breast cancer screening mammograms – the evolution with AI as an independent reader (6 min)

Karin Elisabeth Dembrower; Stockholm / Sweden

Author Block: K. E. Dembrower[1], F. Pilblad[1], M. Arango Lievano[2]; [1]Stockholm/SE, [2]Montpellier/FR
Purpose: Since June 2023 an AI-algorithm replaced one human reader in a population based screening program for breast cancer, redefining the standard of care for this center as AI and one radiologist instead of two radiolgists. This study aims at assessing the safety of an AI only pathway for highly confidence normal examinations.
Methods or Background: If either AI or the human reader flagged an examination, it was referred to the consensus discussion where two breast radiologists finally decide to declare the woman as healthy or recall her for further work-up. The AI-algorithm generated an abnormality score (AS) from zero to one hundred where zero is no abnormality detected and one hundred is most likely cancer. Images were generated from equipment by one manufacturer. We reported which cancer cases were flagged by a human reader, by AI and if the examination was flagged because of clinical symptoms (and/or/not AI-positive). The ground truth was pathologically proven breast cancer. We analyzed the AS of all examinations to determine a safety threshold where no SDC was missed by AI.
Results or Findings: All screening mammograms between 15/01/2025 and 31/08/2025 were assessed independently by AI and one human reader. In total 25 172 women were screened. And total of 158 cancer cases were diagnosed with a score between 3.95 and 99.2. The lowest AI-score for a cancer case was set 3,95. If we set the safety threshold at AS=2, the proportion triaged images is 17,2% (4 330 examinations).
Conclusion: These results demonstrate that assessment of low score screening examinations (AI score below two) with AI only is safe for almost 20% of the screening examinations, further decreasing radiolgists' workload.
Limitations: Not applicable

Artificial intelligence reveals early mammographic signs of breast cancers diagnosed at subsequent screening (6 min)

Eleonora Di Gaetano; Treviso / Italy

Author Block: E. Di Gaetano, C. M. Weiss, R. Cerniato, E. Cattarin, G. Soppelsa, I. Vinci, G. Morana; Treviso/IT
Purpose: Artificial intelligence (AI) generates continuous risk scores (RS) and identifies regions of interest (ROI) on screening mammograms (SM). We evaluated whether baseline RS and ROI in an AI-supported screening (AISS) could predict breast cancers (BC) diagnosed at the subsequent round, and whether results were consistent across BI-RADS breast density (BD) and lesion types.
Methods or Background: We retrospectively analysed 321 women diagnosed with BC at the subsequent AISS round (November 2023–July 2025), performed on average after 777 (median 768;range 691–1,192) days following a negative SM. Side-specific RS at baseline and subsequent round were compared using the Wilcoxon signed-rank test. ROI were deemed concordant if they overlapped the tumour in at least one projection. McNemar's test assessed within-subject ROI changes, and conditional odds ratios (OR) with 95% confidence intervals (CI) were calculated. Analyses were stratified by BD and lesion type.
Results or Findings: Baseline RS was significantly higher in breasts that developed BC than in cancer-free sides (16.9vs10.1;p<0.001), and increased further at the subsequent round (47.6vs10.2;p<0.001). Concordant ROI were present at baseline in 111/321 BCs (34.6%). Mean baseline RS was similar for opacities (15.9), microcalcifications (15.8), and distortions (19.6); combined lesions had higher values (20.4). Baseline ROI concordance was found in 31.3% (50/160) of opacities, 28.8% (21/73) of microcalcifications, 40.0% (18/45) of distortions, and 51.2% (22/43) of combined lesions. When grouped by BD, concordant ROI were more frequent in BD C–D (46/122;37.7%) than in A–B (65/199;32.7%).
Conclusion: AI assigned higher RS to the breast that later developed cancer and localized one third of BCs at baseline with concordant ROI, especially in combined lesions. These findings highlight the potential of AI to anticipate BC detection in population-based screening.
Limitations: No limitations

AI risk score for a new versus old version of a CE-marked AI model for breast cancer detection (6 min)

Solveig Hofvind; Oslo / Norway

Author Block: M. Larsen, Å. S. Holen, N. Moshina, M. B. Bergan, S. Hofvind; Oslo/NO
Purpose: To explore screening examinations with and without breast cancer with the same screening mammograms, but with higher AI risk score in the new versus old version of an AI model.
Methods or Background: This retrospective cohort study used data from 117,709 screening examinations performed in BreastScreen Norway 2009-2018. The same screening mammograms were processed by two versions of the commercially available AI model, Transpara (version 1.7 and 2.1, ScreenPoint Medical). We used the categorical AI risk score assessment, AI score 1-10. Scores between 1-7 were defined as low risk, 8-9 as intermediate risk, and 10 as high risk of malignancy. Changes in risk scores below refers to the low, intermediate and high-risk groups.
Results or Findings: A total of 5.3% (6272/117,709) of all screening examinations had higher AI score in version 2.1 as in 1.7. Among the screen-detected cancer cases, 7.9% (58/737) had higher AI score in the new versus old version, while 85.6% (631/737) had stable high AI risk score. We found 1.5% (11/737) to have a lower (10 -> 1-9) and 5.0% (37/737) to have stable low or stable intermediate score (1-9 -> 1-9). Among the interval cancers, 11.5% (23/200) had higher score in the new versus old version.
Conclusion: An updated version of the AI model resulted in a higher detection of cancers in the high AI risk score group. However, the total number of examinations in the high-risk group did also increase, which resulted in a higher proportion of high AI score, but no cancer detected.
Limitations: Exploring location of AI markings and comparison with true cancer location were not included in this study.
Funding for this study: The Norwegian Cancer Society and the Pink Ribbon Campaign have supported performance of the study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Approved by the Regional Ethical Committee in South Eastern Norway

Empirically determined effect of dataset size and enrichment on threshold selection of a commercial mammography AI algorithm (6 min)

Nicholas Payne; Cambridge / United Kingdom

Author Block: N. Payne[1], J. Rothwell[1], R. Black[1], S. Hickman[2], F. Kilburn-Toppin[1], B. Kasmai[3], A. Juette[3], F. J. Gilbert[1]; [1]Cambridge/UK, [2]London/UK, [3]Norwich/UK
Purpose: To empirically show the varying precision and accuracy of selecting AI operating thresholds based on dataset size and composition in prospective use.
Methods or Background: 22,608 full-field digital consecutive mammograms from a single site and vendor (including 952 screen detected cancers (SDC) and 471 interval cancers (IC)) were scored by a commercial AI tool (Lunit INSIGHT-MMGv1.1.7) to establish 'true' performance. Nine data subsets were defined by degree of cancer enrichment (representative [8/1000 SDC, 4/1000 IC], mildly enriched [20/1000 SDC, 10/1000 IC], and heavily enriched [100/1000 SDC, 50/1000 IC]) and size (small [n=250], medium [n=1000], large [n=5000]). Each subset was used to measure area under the receiver operating characteristic curve (AUC) and to set thresholds at 90% specificity, 70% sensitivity, and 5% recall which were then applied to the full data to find their 'actual' performance. Subsampling was repeated 1000 times.
Results or Findings: 'True' AUC was 0.899. Using larger and enriched subsets increased the likelihood of an 'accurate' measure of AUC. Enrichment was beneficial for threshold setting based on sensitivity, however, even using large heavily enriched subsets, the 'actual' sensitivity ranged by >5% points. There is a detrimental impact of enrichment when threshold setting based on recall rate, as oversampling of cancer cases leads to a reduced recall rate when applied to the population. Mean recall rate of thresholds set using the representative, mildly-, and heavily enriched subsets were ~5%, ~4% and ~0.5% respectively.
Conclusion: When selecting a dataset to evaluate AI tools and set operating thresholds, larger datasets are beneficial provided they are relevant to the metric used. Enrichment allows smaller datasets to better assess AUC and sensitivity, however, it is vital to use representative datasets when assessing recall rates.
Limitations: Single site and single vendor.
Funding for this study: Funding was provided by the Future Dreams Breast Cancer charity, the National Institute for Health and Care Research (NIHR) Cambridge Biomedical Research Centre (NIHR203312) and the Cancer Research UK early detection program grant (C543/A26884). Ethics committee - additional information: This study used the Cambridge Cohort Mammography East Anglia Digital Imaging Archive ('CC-MEDIA') dataset, which has ethical approval in which informed consent is waived (Health Research Authority Research Ethics Committee 25/LO/0220, Health Research Authority Confidentiality Advisory Group 20/CAG/0009, Public Health England Research Advisory Committee BSPRAC_090).

A Fully Automated Deep Learning Framework for Lesion Segmentation and Survival Prediction in Breast Cancer Patients (6 min)

Shushan Dong; Shanghai / China

Author Block: K. Wang[1], S. Wang[1], S. Huang[2], J. Xie[3], S. Dong[2], M. Xu[1], R. Zhang[1]; [1]Hangzhou/CN, [2]Beijing/CN, [3]Shanghai/CN
Purpose: To develop and validate a fully automated deep learning framework (FA-SurvNet) that integrates lesion segmentation and survival prediction for breast cancer patients using preoperative MRI.
Methods or Background: In this retrospective study, 573 female breast cancer patients from two medical centers who underwent preoperative MRI were enrolled. We developed the FA-SurvNet model, which integrates an nnU-Net for automated tumor segmentation with a CNN-Cox regression network for survival analysis. The segmentation performance was evaluated using the Dice Similarity Coefficient (DSC), Positive Predictive Value (PPV), and Sensitivity (SEN). The prognostic performance of FA-SurvNet was compared against two baseline models: a clinical Traditional Chinese Medicine (TCM) model and a radiomics model, both based on conventional Cox regression. Model evaluation included Harrell's concordance index (C-index), time-dependent area under the curve (AUC), and decision curve analysis (DCA) for net clinical benefit.
Results or Findings: The nnU-Net segmentation model achieved high performance in the training (DSC: 0.85, PPV: 0.85, SEN: 0.88) and testing cohorts (DSC: 0.84, PPV: 0.87, SEN: 0.84). The FA-SurvNet model demonstrated excellent predictive ability for recurrence risk, with C-indexes of 0.88 (training) and 0.84 (testing). It outperformed the radiomics model (training C-index: 0.84; testing C-index: 0.75) and performed comparably to the clinical TCM model (training C-index: 0.89; testing C-index: 0.88). The time-dependent AUCs of FA-SurvNet for predicting 3- and 5-year recurrence-free survival (RFS) were 0.89 and 0.90 in the training cohort, and 0.84 and 0.87 in the testing cohort, respectively.
Conclusion: The FA-SurvNet framework successfully automates the entire prognostic pipeline from lesion segmentation to survival risk estimation, offering a powerful and efficient tool for personalizing breast cancer management.

Artificial intelligence–assisted risk stratification of atypical breast lesions: correlation of pathology, imaging features and Lunit abnormality score (6 min)

Rafael Boava Souza; São Paulo / Brazil

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: R. B. Souza, L. F. Chala, G. G. N. Mello, T. C. d. M. Tucunduva, M. Siepcich, B. A. Rocha, I. Oliveria, M. P. F. Ananias, V. L. N. Aguillar; São Paulo/BR
Purpose: Atypical breast lesions (B3), including atypical ductal hyperplasia (ADH), lobular neoplasia (LN), and flat epithelial atypia (FEA), diagnosed by stereotactic vacuum-assisted biopsy (VAB) of suspicious calcifications carry variable risk of underestimation and upgrade to ductal carcinoma in situ (DCIS) or invasive carcinoma. This study evaluated upgrade rates of B3 lesions, predictive factors, and the role of Lunit INSIGHT MMG abnormality score as an AI-based biomarker.
Methods or Background: This retrospective study included 271 women (Jan 2020–Dec 2024) with VAB-diagnosed B3; 157 underwent surgery and 114 clinical-radiological follow-up. Analyzed variables included age, personal/family history, calcification morphology and distribution, residual calcifications, and pathological subtype. Lunit scores were retrieved for 100 cases. Analyses included chi-square, Fisher's exact, Mann-Whitney U, and ROC.
Results or Findings: Overall upgrade rate was 16.6% (26/157): 73% DCIS, 27% invasive carcinoma. Pathology was the strongest predictor. Borderline ADH demonstrated the highest upgrade risk (77.8%, $p<0.001$), followed by ADH (21.9%, $p=0.012$), FEA (13%), and LN (10%). No difference was observed between isolated and multiple atypias ($p=0.801$), both lower than borderline ADH. Pleomorphic linear/branching calcifications were significantly associated with malignancy ($p=0.007$). Residual calcifications showed a non-significant trend toward higher risk (22% vs. 11.4%). Clinical variables were not predictive. Lunit scores were higher in upgraded vs non-upgraded cases (mean 36.2 vs 23.2; median 32.2 vs 11.9), though not statistically significant ($p=0.149$). ROC analysis yielded an AUC of 0.615, with optimal cut-off of approximately 29 (sensitivity 62.5%, specificity 67.9%).
Conclusion: Borderline ADH is the strongest predictor of upgrade, followed by suspicious calcification morphology. Although not statistically significant, higher Lunit scores trended toward upgraded lesions and moderate discriminatory performance. AI-assisted mammographic analysis may complement pathology and imaging in risk models, supporting individualized management of atypical calcifications.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study.

Real versus Virtual Contrast Enhancement for AI-Based Breast MRI Classification (6 min)

Tri-Thien Nguyen; Erlangen / Germany

Author Block: T-T. Nguyen, S. Heidarikahkesh, H. Schreiter, L. Brock, L. A. Kapsner, A. Liebert, A. Maier, M. Uder, S. Bickelhaupt; Erlangen/DE
Purpose: Breast MRI offers high sensitivity and specificity; however, widespread use remains limited. Contrast-free protocols and AI tools might improve accessibility, for example in screening. This study evaluated the diagnostic performance of an AI model trained on early contrast-enhanced subtraction (T1sub) images for breast cancer classification, and tested its application on both real contrast-enhanced T1sub and virtually generated contrast-enhanced (T1virtual) images from non-contrast sequences.
Methods or Background: This IRB-approved retrospective study included 1,712 women undergoing routine multiparametric 3T breast MRI, some with multiple exams. Images were split by breast side, yielding 3,685 samples, including 488 test cases. A Medical Slice Transformer was trained on T1sub images to classify BI-RADS 1–3 versus 4–6. Model performance was evaluated on both T1sub and T1virtual test images. Statistics used McNemar's test for accuracy and DeLong's test for AUC; specificity at 90%, 95%, and 97.5% sensitivity was reported. Attention map analysis assessed whether the model focused on clinically relevant regions, using a three-point Likert scale (good, moderate, poor) rated by a board-certified radiologist.
Results or Findings: The model achieved higher performance on T1sub compared with T1virtual images (AUC 0.80±0.03 vs 0.74±0.03, $p=0.035$; accuracy 0.85 vs 0.81, $p=0.0056$). At sensitivity thresholds of 90%, 95%, and 97.5%, specificity was 0.33/0.21/0.12 on T1sub and 0.21/0.13/0.09 on T1virtual. Attention maps showed similar lesion focus, with most cases rated 'Good' (55–60%) or 'Moderate' (30–35%).
Conclusion: An AI model trained on contrast-enhanced T1sub achieved 4% higher accuracy on T1sub than T1virtual, a statistically significant difference. While performance was lower on virtual contrast, the approach remains promising and warrants further validation to expand accessibility of AI-assisted breast cancer detection, particularly in screening scenarios.
Limitations: Single-center retrospective study; model trained exclusively on contrast-enhanced data and applied without re-training to virtual images.
Funding for this study: This project is partially funded by the Bavarian Ministry of Economic Affairs, Regional Development and Energy
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was approved by the Institutional Review Board of the Friedrich-Alexander-Universität Erlangen-Nürnberg (Ethik-Kommission) with waived informed consent (approval number 23-281-Br) due to its retrospective nature and use of pseudonymized data.

Can artificial intelligence detect additional cancers on screening digital breast tomosynthesis? (6 min)

Victor Dahlblom; Malmö / Sweden

Author Block: V. Dahlblom, K. Johnson, M. Dustler, A. Tingberg, S. Zackrisson; Malmö/SE
Purpose: Several studies have indicated that AI systems can detect additional cancers on screening digital mammography (DM) examinations compared with unaided radiologists, but it is less studied if this also applies for digital breast tomosynthesis (DBT). We want to investigate if a DBT AI system can detect cancers that were not detected in screening.
Methods or Background: The study is based on the Malmö Breast Tomosynthesis Screening Trial, where women were screened with double-read DBT once. Following screenings used DM only. DBT examinations from 14368 women were analysed with ScreenPoint Transpara 2.1, which gives a score between 1 and 10, where 10 means the highest cancer suspicion. The AI scores from the DBT screening examinations of women with screening-detected cancers in the two upcoming screening rounds (1.5 or 2 years interval depending on age) – or diagnosed with interval cancers, were compared with scores from women without breast cancer.
Results or Findings: The mean AI score at screening DBT was clearly higher for women with cancer diagnosed in the interval until (mean 6.1) or at the first following screening round (mean 5.9), compared to women without cancer diagnosed during the two subsequent screening rounds (mean 3.3). During the first interval and screening round, 23% (6/22) of the interval cancers and 26% (15/57) of the screening-detected cancers had score 10 at DBT screening, compared to 3.8% (527/13986) among women without cancer. For cancers in the second following screening round, the DBT examination had score 10 in 11% (3/27) of interval cancers and 10% (6/56) of screening-detected cancers.
Conclusion: AI analysis of DBT screening images could potentially detect a substantial amount of additional cancers compared to radiologist double reading of DBT.
Limitations: Single-centre, single-vendor, single-view DBT at one screening occasion.

Impact of Annotation-Free AI system for Simultaneous Detection and Diagnosis on Breast Ultrasound: A Multi-Reader Multi-Case Study across Diverse Professionals (6 min)

Hasang Park; Seoul, Republic of Korea / Korea, Republic of

Author Block: H. Park[1], K. H. Han[2], H-W. Kim[3], W. H. Kim[4], J. Kim[4], J. H. Yoon[1]; [1]Seoul, Republic of Korea/KR, [2]Seoul/KR, [3]iksan/KR, [4]Daegu/KR
Purpose: To evaluate how a deep learning-based artificial intelligence(AI) system that provides autonomous lesion detection and simultaneous differential diagnosis for breast ultrasound(US) affects the diagnostic performance of readers with diverse professional backgrounds.
Methods or Background: This study included 1,000 US images (500 cancer, 250 benign, 250 negative). Fifteen readers of various medical profession were recruited: 6 radiologists, 3 breast surgeons, 3 physicians, and 3 radiographers. Image interpretation was conducted in two sessions; session 1: without AI, and after 2-weeks washout, session 2: with AI. Reader performances were evaluated and compared between the two sessions.
Results or Findings: Overall reader-averaged area under the localization receiver operating characteristic curve(LROC) significantly increased in session 2 vs. session 1 [0.910 (95% CI: 0.888, 0.931) vs 0.864 (95% CI: 0.831, 0.898)] (P=0.002). LROC of standalone AI was 0.909 (95% CI: 0.889, 0.930). Of subgroups according to profession, radiographers showed significantly improved LROC in session 2 vs. session 1, 0.922 vs 0.868, (P=0.032). Average sensitivity and accuracy were significantly improved for all 15 readers in session 2 vs. session 1; 95.0% vs. 85.3% and 85.7% vs. 82.3%, respectively (all P<0.001). Physicians (82.3% vs. 75.7%) and radiographers (81.7% vs. 76.7%) demonstrated significant decrease of specificity in session 2 vs. session 1 (all P<0.001), respectively. Radiologists without fellowship training or <8 years of experience, showed significant improvement in sensitivity and accuracy but decreased specificity in session 2 (all P<0.05), respectively.
Conclusion: Using AI for breast US interpretation significantly enhanced the overall diagnostic performances in readers of diverse healthcare professionals. AI application may result in different consequences across readers of different levels of expertise, that should be considered in clinical application.
Limitations: Cancer enriched population was used for reader study.
Funding for this study: This study was supported by the Korea Medical Device Development Fund grant funded by the Korea government (the Ministry of Science and ICT, the Ministry of Trade, Industry and Energy, the Ministry of Health & Welfare, the Ministry of Food and Drug Safety) (Project Number: 1711197554, RS-2023-00227526).

Ethics committee - additional information: This study has been approved by the institutional review board (IRB) of three institutions (Severance Hospital, IRB No. 1-2023-0073, Wonkwang University Hospital IRB No. 2023-07-017-002, Kyungpook National University Chilgok Hospital IRB No. KNUCH 2023-11-029), with a waiver for informed consent.

Application of an artificial intelligence-assisted diagnostic system for breast ultrasound: a prospective study (6 min)

Zhi-Ying Jin; Beijing, China / China

Author Block: Z. L. Wang; Beijing/CN
Purpose: Accurate diagnosis of breast cancer is of great importance to improve the prognosis of patients. AI-assisted diagnostic system for breast ultrasound is gradually being applied in the identification of benign and malignant breast lesions. This study aimed to evaluate the diagnostic performance and optimal application of AI-assisted ultrasonography for breast lesions in clinical setting.
Methods or Background: A total of 501 consecutive patients with 679 breast lesions were prospectively included in the study. Junior and senior radiologists were asked to interpret images of lesions with and without AI assistance, respectively. Three application modes of AI were employed: AI alone, adjusted BI-RADS, and second reading mode. The diagnostic performances of these application modes were analyzed and compared.
Results or Findings: The AUC of junior radiologists increased from 0.879 to 0.921 in BI-RADSsecond reading, which was higher than that in BI-RADSadjusted (0.901), similar to that in AI alone (0.924), and lower than that obtained by senior radiologists (0.950). Using BI-RADS category 4A as the threshold, the sensitivity of junior radiologists was found to increase from 0.83 to 0.92 ($P<0.001$). Furthermore, the specificity increased from 0.79 to 0.85, which was higher than those of AI alone and BI-RADSadjusted ($P<0.001$). The unnecessary biopsy rate decreased by 14.70% ($P=0.01$). For senior radiologists, the sensitivity increased from 0.91 to 0.96 ($P=0.01$). Similar results were observed in the subgroup analysis of lesions ≤2 cm. For lesions >2 cm, only the specificity of junior radiologists increased from 0.39 to 0.52 ($P=0.03$).
Conclusion: AI-assisted ultrasound is useful for the diagnosis of breast lesions, particularly for junior radiologists and lesions ≤2 cm. The use of the second reading mode can achieve excellent diagnostic performance.
Limitations: The sample size of breast lesions >2 cm was relatively small.
Funding for this study: This work was supported by the National Natural Science Foundation of China (No. 82071925), the Military Health Project (No. 22BJZ23), and the Equipment Comprehensive Research Project (No. LB20211A010011).

Ethics committee - additional information: This prospective study was approved by the Ethics Committee of the Chinese PLA General Hospital (No. S2021-683-01), and informed
consent was obtained from all patients.

RPS 1105 - AI-radiomics and clinical data convergence across the breast cancer continuum

Categories: Oncologic Imaging, Breast, Imaging Informatics, Artificial Intelligence
Date: March 5, 2026 | 16:30 - 18:00 CET
CME Credits: 1.5

Moderator:
Annie Ng; London / United Kingdom

Same studies, different scores: how RQS, RQS2, and METRICS shape radiomics quality assessment (6 min)
Maciej Bobowicz; Gdańsk / Poland

Author Block: M. Bobowicz, M. Kosno, K. P. Brzozowski, E. Szurowska; Gdańsk/PL
Purpose: Radiomics has emerged as a powerful method for extracting quantitative insights from medical imaging, with the potential to enhance diagnostic and prognostic precision. We aimed to critically evaluate RQS, RQS2, and METRICS tools to assess their robustness, reliability, and practical utility, thereby guiding reproducible and high-quality radiomics research.
Methods or Background: A comprehensive search of PubMed, Embase, Scopus, Web of Science, and IEEE Xplore databases identified studies employing predicting pathological complete response (pCR) in breast cancer patients receiving neoadjuvant therapy based on MRI radiomics. The study quality was assessed using RQS, RQS2 and METRICS. We compared metrics across seven overarching categories: study design and protocol, imaging protocol quality, image preparation and processing, segmentation and ROI definition, feature extraction and selection, model building and validation, and reporting, transparency, and open science. Inter-reader agreement was evaluated with Cohen's κ, and overall score reliability was determined using ICC.
Results or Findings: RQS and RQS2 emphasise clinical aspects, while METRICS provides more holistic perspective. The result of this approach is reflected in the higher median score achieved by METRICS compared to RQS and RQS2. The correlation between total scores was weak to moderate. The RQS vs. RQS2 analysis yielded a result of $\rho = 0.312$ ($p \approx 0.068$). Similarly, the RQS vs. METRICS analysis produced a result of $\rho = 0.180$ ($p \approx 0.302$). Finally, the RQS2 vs. METRICS comparison yielded a result of $\rho = 0.412$ ($p = 0.014$).
Conclusion: The METRICS tool is the most equitable choice, as each supercategory addresses multiple facets of the issue. Each research problem has unique characteristics, and the effectiveness of RQS, RQS2, or METRICS may differ. Therefore, when evaluating a model's quality, at least two forms should be used.
Limitations: None

Prediction of Axillary Pathologic Complete Response after Neoadjuvant Chemotherapy in Breast Cancer Using Multiparametric MRI Radiomics and Deep Learning (6 min)
Weiyue Chen; Lishui / China

Author Block: W. Chen, G. Lin, M. Chen, J. Ji; Lishui/CN
Purpose: To assess whether multiparametric MRI radiomics combined with deep learning can predict axillary pathologic complete response (pCR) following neoadjuvant chemotherapy (NAC) in breast cancer.
Methods or Background: This retrospective two-center study included 213 patients with breast cancer who underwent NAC and axillary surgery (center 1: n=144; center 2: n=69) in the training, validation, and test cohorts. Patients were stratified into axillary pCR and non-pCR groups based on pathology. Tumor regions were segmented on T2-weighted, diffusion-weighted, and dynamic contrast-enhanced MRI. Radiomics and deep learning features were extracted; feature reduction was performed using minimum redundancy maximum relevance, and least absolute shrinkage and selection operator. Radiomics and deep learning scores were derived. Logistic regression identified independent predictors and constructed clinical, radiomics, deep learning, and combined models. Discrimination, calibration, and decision curve analysis were used to assess performance.
Results or Findings: Twelve radiomics and fourteen deep learning features were selected. The clinical N stage, radiomics score, and deep learning score were independent predictors. The combined model achieved the highest AUCs (validation cohort: 0.948; test cohort: 0.891), significantly higher than the clinical model (validation cohort: 0.675; test cohort: 0.761) and radiomics model (validation cohort: 0.838; test cohort: 0.827) (all $P < 0.05$). Calibration showed good agreement, and decision curve analysis demonstrated the greatest net clinical benefit for the combined model.
Conclusion: Multiparametric MRI models integrating radiomics, deep learning, and clinical factors enable accurate prediction of axillary pCR after NAC in breast cancer, supporting personalized treatment strategies.
Limitations: First, as a retrospective study, it is inevitably subject to choice bias and inherent errors. Second, all ROIs in our study were delineated manually, rendering inter-operator variability unavoidable, which may affect the reproducibility of features.
Funding for this study: This work was supported by the Key Project of Joint Construction by Provincial and Ministerial Authorities (WKJ-ZJ-2452 to Minjiang Chen); Public Welfare Technology Application Research Project of Lishui City (2024GYX45 to Weiyue Chen).

Diagnostic Performance of Virtual vs. True Non-Contrast Dual-Energy CT for Differentiating Hepatic Cysts from Liver Metastases in Breast Cancer (6 min)

Aynur Gökduman; Frankfurt / Germany

Author Block: A. Gökduman, I. Yel, P. Reschke, J. Gotta, S. Mahmoudi, V. Koch, M. Dimitrova, T. Vogl, C. Booz; Frankfurt/DE
Purpose: To assess the diagnostic performance and Hounsfield unit (HU) correlation between virtual non-contrast (VNC) and true non-contrast (TNC) dual-energy CT (DECT) for differentiating hepatic cysts from liver metastases in patients with breast cancer.
Methods or Background: This retrospective study included 668 liver lesions (334 cysts, 334 metastases) in patients with histologically confirmed breast cancer who underwent DECT between January 2020 and December 2022. HU values were measured in lesion-specific regions of interest (ROIs) from both TNC and VNC images. Receiver operating characteristic (ROC) analysis was performed to identify optimal cut-off values using the Youden index. Diagnostic performance was assessed using AUC, sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and overall accuracy. Correlation between TNC and VNC HU values was analyzed. The reference standard for lesion classification was either contrast-enhanced MRI or image-guided biopsy.
Results or Findings: TNC achieved an area under the curve (AUC) of 0.869, while VNC demonstrated a comparable AUC of 0.866; both results were statistically significant ($p < 0.001$). TNC showed a sensitivity of 87.7%, specificity of 63.5%, and accuracy of 75.6%. VNC yielded a sensitivity of 85.0%, specificity of 61.4%, and accuracy of 73.2%. A strong positive correlation was observed between TNC and VNC HU values ($r = 0.977$; $p < 0.001$). In this cohort, omission of the true non-contrast phase and exclusive use of VNC would have resulted in a documented CTDI reduction of approximately 40–50%.
Conclusion: VNC imaging demonstrated diagnostic performance nearly equivalent to that of TNC, with minimal clinically relevant differences. Given the strong HU correlation, replacing TNC with VNC could significantly reduce radiation exposure in oncological liver staging, streamline imaging workflows, and maintain high diagnostic performance.
Limitations: Minor attenuation discrepancies could influence lesion classification in borderline cases.

Implementation of AI in a National Breast Cancer Screening System (6 min)

Osmo Tervonen; Oulu / Finland

Author Block: O. Tervonen; Oulu/FI
Purpose: The purpose of this study was to study which mandatory steps should be achieved to implement AI as a part of a national breast cancer screening program.
Methods or Background: The study consisted of following steps: 1. Finding of an AI software ready be implemented; 2. Health care service provider commitment; 3. Compliance with Hospital IT system 4. Compliance with hospital data security quidelines; 5. Rediness of the ministry for legislation change of the national screening process; 6. National Radiology Society participation; 7. Defining the new screening process with the health care professionals; 8. Compliance with the national and EU GDPR regulation
Results or Findings: Seven out of eight required steps were achieved. We defined an impementation process, where AI process is running parallely with the present well defined two radiologist screening process, and after experience, define the new national screening process. Multiple AI software were considered applicaple and the one with an independent reader process model was selected. The health care provider was committed to co-work based on proven short and long-term benefits. The national legislator indicated readiness in starting legislation change based on the results. However, as a part of GDPR regulation, the National Office of Data Protection Ombudsman, which is the highest national authority, made a statement that all the screening data has to be removed from the archives of the AI vendor after the process, which was impossible to comply by the vendor.
Conclusion: The current GDPR regulation and how it is implemented nationally does not allow to proceed in taking AI as a part of a national screening program
Limitations: The data used for the evaluetion was based on review of the literature and assement by the board members of the study,.
Funding for this study: This study has not received external funding.

Automated Classification of Malignant versus Benign Breast Lesions on DCE-MRI: A Comparative Study of 3D Deep Learning Architectures and Input Preprocessing Strategies (6 min)

Mustafa Arda Kukal; Istanbul / Turkey

Author Block: M. A. Kukal, M. Gitmez, T. Orhan, B. Uzunoğlu, A. Hamamci, F. Celebi; Istanbul/TR
Purpose: To systematically evaluate different deep learning architectures (DL) and input preprocessing strategies for automated differentiation of malignant from benign breast lesions on dynamic contrast-enhanced MRI (DCE-MRI).
Methods or Background: This retrospective study analyzed breast DCE-MRI examinations acquired on 1.5T and 3T scanners. Post-contrast second phase dynamic T1-weighted sequences were processed using three input strategies: full image volumes, segmentation masks, and lesion-centered patches (96×96×64 voxels). Data were partitioned into training (80%) and independent test (20%) sets, with patient-stratified 5-fold cross-validation used for model selection. Five 3D convolutional neural networks were evaluated: ResNet3D-18, R(2+1)D-18, MC3-18, DenseNet3D-121, and X3D-S. All architectures were adapted for single-channel volumetric input with binary classification output. Class imbalance was addressed through stratified sampling, focal loss, and data augmentation. Performance was assessed using precision, recall, F1-score, area under the precision-recall curve (AUC-PR), and accuracy.
Results or Findings: The cohort included 163 patients (54 benign, 109 malignant lesions) with median age 44 years (IQR: 40-51) and median lesion size 12 mm (IQR: 8-20). All classifications were validated against histopathological standards. Patch-based ResNet3D-18 demonstrated the most ballanced and robust performance on the independent test set: precision 0.85, recall 0.81, F1-score 0.83, PR-AUC 0.83, and accuracy 0.80. Patch-based preprocessing consistently yielded the most robust performance across all architectures.
Conclusion: Patch-based input preprocessing demonstrated superior performance compared to full volumes and segmentation masks for automated breast lesion classification on DCE-MRI. The achieved diagnostic accuracy meets clinically acceptable standards. While improved performance is expected with larger datasets, current findings support clinical feasibility. Multi-institutional validation studies are warranted to confirm generalizability.
Limitations: Not Applicable

A Physics-Informed Neural Network for Robust Pharmacokinetic Parameter Estimation from Ultrafast Breast MRI Time-Intensity Profiles with Varying Temporal Resolution (6 min)

Gökhan Ertaş; Istanbul / Turkey

Author Block: G. Ertaş, F. Celebi, D. Yildirim; Istanbul/TR
Purpose: Ultrafast dynamic contrast-enhanced magnetic resonance imaging (DCE-MRI) achieves high temporal resolution for breast cancer assessment but yields sparsely sampled time-intensity profiles (TIPs). This study develops and validates a physics-informed neural network (PINN) that simultaneously reconstructs continuous TIPs and estimates pharmacokinetic (PK) parameters from sparse ultrafast DCE-MRI data, comparing its accuracy with conventional curve-fitting methods.
Methods or Background: The PINN comprised four fully connected layers with hyperbolic tangent activations, trained to minimize a composite loss combining data-fidelity (mean-squared error) and physics-informed terms that penalize residuals of the simplified Tofts ordinary differential equation. Ktrans and Vp were optimized jointly with network weights. Conventional nonlinear least squares (NLLS) fitting using Levenberg-Marquardt algorithm provided comparison. Both methods were evaluated on synthetic datasets with known ground-truth values: benign lesions (median Ktrans=0.013, range 0.0026–0.17; Vp=0.0022, range 0.00025–0.017) and malignant lesions (Ktrans=0.073, range 0.013–0.14;Vp=0.021, range 0.002–0.099) across temporal resolutions from 5-13 seconds at 1-second intervals. Performance was quantified using adjusted R2 (adjR2) for goodness-of-fit and median percentage absolute error (MdPAE) for parameter accuracy.
Results or Findings: Across 1000 synthetic sparse TIPs, PINN generated smooth continuous reconstructions with excellent agreement (adjR2=0.993) and low parameter errors (MdPAE: Ktrans=0.5%, Vp=1.4%). NLLS achieved superior curve fitting (adjR2=0.999) but substantially higher parameter errors (MdPAE: Ktrans=3.1%, Vp=24.7%). PINN consistently delivered more accurate PK estimates than NLLS, with greatest improvement for Vp estimation.
Conclusion: Integrating tracer-kinetic equations within neural networks enables robust TIP reconstruction and more accurate PK parameter estimates from sparse ultrafast DCE-MRI, enhancing quantitative biomarker mapping reliability in breast MRI.
Limitations: Not applicable.
Funding for this study: No funding was provided for this study.

Can large language models replace traditional textbooks in breast radiology education for medical students? (6 min)

Umitcan Yildiz; Istanbul / Turkey

Author Block: U. Yildiz, O. Adiguzel Karaoysal, A. Karadayi Buyukozsoy, N. Voyvoda; Istanbul/TR
Purpose: This study aimed to systematically assess the content validity and educational adequacy of lecture notes on breast imaging for medical students, produced by five prominent Large Language Models (LLMs), in comparison to a standard radiology textbook.
Methods or Background: Five large language models (LLMs)—GPT-4o, Claude 4 Sonnet, Gemini 2.5 Pro, DeepSeek V3, and Grok 3—were tasked with generating lecture notes on breast imaging. A rubric consisting of 14 themes and 43 subthemes was constructed based on a reference textbook. Three radiologists, each with distinct professional backgrounds, independently evaluated the outputs of these models for accuracy, scope, clarity, and educational value using the Content Validity Index (CVI) metrics.
Results or Findings: None of the LLMs achieved the recommended CVI thresholds, which are indicative of high content validity. The most effective model addressed only 34.9% of the subthemes and 78.6% of the themes, whereas the other models demonstrated inferior performance. Notably, there was significant inter-rater variability among the expert evaluators, underscoring subjective differences in assessment.
Conclusion: Current general-purpose LLMs are insufficient as standalone resources for specialised medical education purposes. While they can address some topics, performance variability necessitates domain-specific fine-tuning, advanced prompting strategies, and robust evaluation frameworks. They are best used as supplementary tools within structured, instructor-led learning environments.
Limitations: The limitations of the study are its use of a single, simple prompt that may not reflect the models' full potential and an evaluation that lacked student input. The study was also limited by its focus on a single topic, its restriction to the English language, and the uncontrolled design variations among the LLMs.
Funding for this study: No funding was received for this study.

Ethics committee - additional information: The ethics committee notification can be found under the number UID 2025/0l0.99/l8/3.

Performance evaluation of mammography AI detection software on symptomatic breast cohort (6 min)

Nisha Sharma; Leeds / United Kingdom

Author Block: N. Sharma[1], M. M. M. McMahon[1], M. Fletcher[1], D. Manuel[1], S. Rajan[1], A. Kshirsagar[2], F. Eskandari[1], J. Simpson[1]; [1]Leeds/UK, [2]Santa Clara, CA/US
Purpose: Several studies have reported standalone performance of artificial intelligence (AI) software in the screening population. The purpose of this study is to assess the performance of commercially available AI software in symptomatic population.
Methods or Background: This prospective study included a total of 308 subjects (79 with dense breasts and 229 with fatty breasts) imaged at diagnostic clinic from August 2024 to March 2025. All women with clinically suspected cancer had bilateral DBT and those recalled for a mammographic abnormality on 2D mammogram had synthetic 2D and 3D imaging of the affected breast only. The cohort contained 87 malignant cases confirmed by biopsy, 46 benign cases confirmed by biopsy and 175 cases deemed benign after follow-up imaging. Results of Genius AI® Detection 2.0 were available for each subject and were reviewed by a breast imaging expert to determine TP, TN, FP and FN by AI for each patient based on location of AI marks and the pathological outcome of the subject. Sensitivity, specificity, PPV and NPV for AI were calculated as well as ROC analysis was performed.
Results or Findings: Sensitivity of AI software to detect biopsy proven cancers was 93.1% (81/87) with a 95% CI of 85.0-97.2%. Specificity of AI software to correctly identify benign cases was 52.9% (117/221) with a 95% CI of 46.2%-59.7%. Positive predictive value of AI for this cohort was 43.8% (81/185) with a 95% CI of 36.6%-51.3%. Negative predictive value of AI for this cohort was 95.1% (117/123) with a 95% CI of 89.2%-98.0%. AI software model achieved an area under ROC curve (AUC) of 0.89 with a 95% CI of 0.85 to 0.93.
Conclusion: The AI detection software demonstrated high sensitivity and high specificity in symptomatic population.
Limitations: Single centre study
Funding for this study: None

How Fair Are We? A Systematic Review of Bias in MRI Radiomics Models for Predicting Breast Cancer Treatment Response (6 min)

Maciej Bobowicz; Gdańsk / Poland

Author Block: M. Bobowicz[1], D. A. Kessler[2], M. Kosno[1], S. Joshi[2], K. Marias[3], O. Diaz[2], K. Lekadir[2]; [1]Gdańsk/PL, [2]Barcelona/ES, [3]Heraklion/GR
Purpose: Radiomics is a widely employed technique for predicting pathological complete response (pCR) to neoadjuvant therapy in breast cancer. Despite its popularity, several problems remain related to fairness, generalizability, and methodological quality. In this review, a thorough analysis was conducted, thereby exposing the potential sources of bias and limitations in the existing studies.
Methods or Background: A comprehensive search was conducted in major bibliographic databases, including PubMed, Embase, Scopus, Web of Science, and IEEE Xplore, to identify studies that utilised MRI-based radiomics for predicting pCR in breast cancer patients undergoing neoadjuvant therapy. The methodological quality of the included studies was assessed using the METhodological RadiomICs Score (METRICS), while a custom framework adapted from the QUADAS-2 tool was used to determine fairness. Additionally, a GUI-based sample size calculator was developed, integrating the events per variable (EPV) rule and the Cox-Snell R^2 approach to evaluate the adequacy of study power.
Results or Findings: A total of 35 studies met the inclusion criteria and were thus deemed eligible for further analysis. The majority of these studies (80%) were retrospective and based on single-centre cohorts, with limited demographic detail and infrequent external validation (14%). A mere five studies (14%) assessed the model's performance across demographic or clinical subgroups. The sample sizes of the studies were often small, and 75% of the studies were underpowered based on established EPV and R^2 criteria.
Conclusion: This analysis enables us to provide practical recommendations for enhancing the reliability, generalizability, and equity of radiomics-based models for predicting pCR and potentially beyond. This is achieved by underscoring standard practices and pinpointing potential sources of bias, along with developing sample size calculators based on dual methodologies: the EPV rule and the Cox-Snell R^2 approach.
Limitations: Not specified in the abstract

Is Digital Breast Tomosynthesis (DBT)-based Artificial Intelligence (AI) Better than 2D Mammography-based AI? (6 min)

Yan Chen; Nottingham / United Kingdom

Author Block: G. J. W. Partridge[1], H. Jupp[1], J. James[1], M. Michell[2], Y. Chen[1]; [1]Nottingham/UK, [2]London/UK
Purpose: Digital Breast Tomosynthesis (DBT) has been shown to improve sensitivity and specificity for cancer detection compared with 2D digital mammography (2DDM) when interpreted by human readers. It is therefore expected that AI trained on DBT would also outperform AI based on 2DDM. In this study, we directly compare the performance of DBT-AI and 2DDM-AI using a dataset of paired DBT+2DDM cases from the UK DBT screening PROSPECTS Trial.
Methods or Background: In the UK, the multi-centre PROSPECTS randomised trial has been conducted to investigate the cost-effectiveness of replacing 2DDM with DBT in screening. Between January 2019-October 2022, 14,479 women were randomised into the intervention arm of PROSPECTS and screened with 2-view combo DBT+2DDM. Malignant cases are pathology proven and normal cases will have a negative 3-year follow-up screening episode. A DBT- and a 2DDM-based AI algorithm from the same commercial AI vendor (Lunit) will analyse the DBT and 2DDM images from this cohort, respectively. AI case scores between modalities will be compared using linear correlation and Bland-Altman plots, and ROC analysis will compare overall model performance.
Results or Findings: The eligible cases from the PROSPECTS dataset are currently being analysed by the AI algorithms. Data will be presented at ECR if accepted.
Conclusion: As the popularity of DBT based screening grows, it's important to know how the performance of DBT-based cancer detection AI systems compare to 2DDM-based counterparts. If DBT-based AI performance is superior to 2DDM, this may also support wider adoption of DBT in screening.
Limitations: Cases from the PROSPECTS Trial are from one vendor (Hologic) which may limit the generalisability of the findings. Relatively small size of evaluation test-set; low cancer prevalence (but screening setting).
Funding for this study: Lunit

Development of an Integrated Radiopathomics Signature for Oncotype DX Prediction in Breast Cancer: a pilot study (6 min)

Valentina Giannini; Turin / Italy

Author Block: V. Giannini, G. Nicoletti, A. Defeudis, E. Battista, I. Castellano, M. Durando; Torino/IT
Purpose: To evaluate the feasibility of developing an Artificial Intelligence (AI)-based integrated biomarker to predict Oncotype DX using magnetic resonance imaging(MRI) and H&E-fixed histopathological Whole Slide Images(WSI).
Methods or Background: A total of 120 patients (94 from the Duke-Breast-Cancer-MRI dataset and 26 from an internal cohort) were used for the radiomics signature, while 55 were included in the pathomics analysis; 19 were common to both. In the pathomics pipeline, H&E WSI were divided into 224×224pixel patches, and color normalized with the Macenko method. First-order and texture features were extracted with PyRadiomics and aggregated at patient level using descriptive statistics. Redundant features (Pearson correlation≥0.8) were removed. The most relevant were retained (correlation>0.3 with the output) and used to train multiple classifiers with leave-one-out cross-validation (CV). For radiomics, images were Z-score standardized, tumors manually segmented, and first-order, texture, and shape features extracted. Feature selection was performed with mRMR algorithm, and classifiers were trained with stratified CV on the Duke dataset and tested on the internal cohort.
Results or Findings: In pathomics, two features were retained, with ElasticNet yielding the best performance. In radiomics, four features were selected, with the Decision Tree performing best. On the 19 patients common to both datasets, each model reached 74% accuracy. The pathomics model misclassified five patients (two as low risk, three as high risk), while the radiomics model misclassified five (one as low risk, four as high risk). When combined into a radiopathomics signature, accuracy increased to 84%, with three misclassifications (one as low risk, two as high risk).
Conclusion: This pilot study supports the feasibility of a radiopathomics signature for Oncotype DX prediction.
Limitations: The small sample size and monocentric design of the pathomics cohort limit generalizability, highlighting the need for larger, multicentric validation.

Artificial intelligence scores as a biomarker for ductal carcinoma in situ upgrade risk (6 min)

Manisha Bahl; Cambridge / United States

Author Block: M. Bahl, A. Kniss, H. Kim, K-S. Kim, S. Do, L. Lamb; Boston, MA/US
Purpose: Artificial intelligence (AI) is increasingly used for mammography to enhance breast cancer detection. The purpose of this study was to evaluate whether AI scores for screening-detected ductal carcinoma in situ (DCIS) are associated with upgrade to invasive carcinoma at surgery.
Methods or Background: This retrospective study included consecutive screening digital breast tomosynthesis (DBT) examinations performed between 2014 and 2021 at a single academic institution. All cases were radiologist-initiated screening recalls with biopsy-confirmed pure DCIS. A commercially available, FDA-cleared AI algorithm (Genius AI® Detection 2.0; Hologic, Inc.) assigned a score (0-100) to each examination; scores ≥22 were classified as positive per vendor recommendation. Upgrade status to microinvasive (≤1 mm) or invasive (>1 mm) carcinoma was determined from surgical pathology reports. Associations between AI scores and upgrade risk were evaluated using standard statistical tests, with $p < 0.05$ considered significant.
Results or Findings: The study cohort included 344 women (mean age 62 ± 12 years) with biopsy-proven DCIS. Positive AI scores (≥22) were observed in 94.8% (326/344) of cases. At surgery, 15.1% (52/344) were upgraded to invasive carcinoma, including 25.0% (13/52) with microinvasive disease. Upgraded cases had a significantly higher mean AI score compared with nonupgraded cases (78 vs. 60, $p < 0.001$). No significant difference in AI scores was observed between upgrades to invasive carcinoma versus microinvasive disease (80 vs. 69, $p = 0.11$).
Conclusion: Higher AI scores on screening DBT were associated with DCIS cases upgraded to invasive carcinoma. These findings suggest that AI-derived scores may serve as a potential biomarker of biologically aggressive DCIS and could inform risk stratification and management strategies.
Limitations: The limitations of the study are single-center, retrospective design and use of one vendor/algorithm with a vendor-defined threshold, which may limit generalizability.
Funding for this study: Funding was provided by Hologic, Inc. The authors, none of whom are employees of Hologic, maintained full control over the data and the submitted information.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective Health Insurance Portability and Accountability Act (HIPAA)-compliant study was granted an exemption from the requirement for written informed consent by the institutional review board at the Massachusetts General Hospital (Protocol #: 2023P003130).

Influence of Mammographic Positioning Quality, BI-RADS Density, and Mammography Image Type on the Discriminatory Performance of an AI Short-Term Breast Cancer Risk Model (6 min)

Georgia Spear; Park Ridge / United States

Author Block: G. Spear[1], M. Abdolell[2], L. R. Margolies[3], K. Yao[4]; [1]Park Ridge, IL/US, [2]Halifax, NS/CA, [3]New York, NY/US, [4]Evanston, IL/US
Purpose: To evaluate how mammographic positioning quality, breast density, and image type influence the discriminatory performance of an image-based AI model for short-term breast cancer risk, with implications for deployment in clinical practice.
Methods or Background: A retrospective cohort study of 59,352 screening mammograms (1,822 cancers; 57,530 controls) acquired between May 2017 and April 2023 was performed at an urban health system. Eligible exams comprised standard four-view sets without implants; controls required a negative follow-up ≥1 year after the index exam. AI algorithms categorized positioning quality using a 12-level PGMI scale, breast density using ACR BI-RADS 5th edition categories (A–D), and Hologic image type (FFDM, C-view synthetic 2D, Intelligent 2D). Short-term risk predictions were generated with the Mirai model and evaluated by 2-year area under the ROC curve (AUC). Stratified analyses compared performance across positioning, density, and image type strata; $p<0.05$ considered statistically significant.
Results or Findings: Mirai overall 2-year model performance was AUC=0.73 but varied significantly across strata. Exams rated P+/P achieved higher discrimination (AUC=0.80) than those rated P–/G+/G/G–/M+/M/M–/I+/I/I– (AUC=0.72), p=0.02. BI-RADS A mammograms achieved higher discrimination (AUC=0.76) than denser categories B–D (AUC=0.72), p=0.05. FFDM images achieved higher accuracy (AUC=0.80) relative to synthetic 2D formats (AUC=0.72), p<0.001. Positioning quality, breast density, and image type exerted independent and measurable effects on model performance.
Conclusion: Suboptimal positioning, higher breast density, and synthetic 2D images reduce the discriminatory performance of an AI-based short-term breast cancer risk model. Ensuring optimal positioning quality, accounting for density, and recognizing modality type are critical for robust AI-driven risk assessment and successful clinical implementation.
Limitations: Single health system retrospective design; potential residual confounding. Future work will involve external validation across multiple vendors and sites to confirm generalizability and assess clinical utility.

Raphaele Marie Renard Penna; Paris / France

Biparametric and multiparametric MRI for prostate cancer detection (Gleason grade group 1, ≥2 and ≥3) – an analysis of the PRIME trial (6 min)
Alexander Ng; London / United Kingdom

Author Block: A. Ng, P. T. G. .; London/UK
Purpose: Multiparametric MRI (mpMRI) ± prostate biopsy is internationally recommended for diagnosing clinically significant prostate cancer (csPCa). However, resource limitations limit global adoption. The PRIME trial (NCT04571840) aimed to evaluate whether biparametric MRI (bpMRI) without intravenous contrast, was non-inferior to mpMRI in detecting csPCa.
Methods or Background: In a prospective, multicentre, within-patient, non-inferiority trial, biopsy naïve men with suspected PCa underwent mpMRI. Radiologists first reported bpMRI (T2-weighted and diffusion weighted imaging) blinded to the dynamic contrast enhanced (DCE) sequences. After unblinding to DCE, radiologists reported the full mpMRI.

Men with bpMRI or mpMRI suggesting PCa underwent MRI-targeted ± systematic biopsy. Men whose MRI were not suggestive of PCa, but PSA density ≥0.15 ng/mL/mL received systematic biopsy. The primary outcome was the proportion of men diagnosed with csPCa (Gleason grade group (GGG) ≥2). Secondary outcomes included the proportion of men diagnosed with clinically insignificant PCa (ciPCa) (GGG 1), and csPCa (GGG ≥3).
Results or Findings: 490 patients included in the primary outcome analysis were recruited from 22 centres across 12 countries. bpMRI detected csPCa (GGG ≥2) in 143/490 (29.2%) compared to 145/490 (29.6%) on mpMRI (adjusted difference 0.4%; 95% CI -1.2 to 0.4; p=0.5). Results were consistent on a lesion-level analysis. bpMRI detected ciPCa (GGG 1) in 45/490 (9.2%) compared to 47/490 (9.6%) on mpMRI (adjusted difference 0.4%; 95% CI -1.2 to 0.4). bpMRI detected csPCa (GGG ≥3) in 73/490 (14.9%) compared to 75/490 (15.3%) on mpMRI (adjusted difference 0.4%; 95% CI -1.2 to 0.4).
Conclusion: In men with suspected prostate cancer, bpMRI with or without targeted biopsy was non-inferior to mpMRI in the detection of GGG 1, ≥2 or ≥3 prostate cancer.
Limitations: Radiologists were generally very experienced and scans were of good quality.
Funding for this study: The PRIME trial is supported by The John Black Charitable Foundation, Prostate Cancer UK, the European Association of Urology Research Foundation and Wolfgang.Dieckmann Foundation.
Has your study been approved by an ethics committee? Yes

Modelling apparent diffusion coefficient (ADC) variability in multicentre prostate MRI to identify significant acquisition parameters and clinical factors (6 min)
Jessica Winfield; Sutton / United Kingdom

Author Block: S. Yu[1], J. Almeida[2], B. Whitcher[1], S. J. Withey[1], M. Blackledge[1], D-M. Koh[1], N. Papanikolaou[2], J. Winfield[1]; [1]London/UK, [2]Porto/PT
Purpose: Apparent diffusion coefficient (ADC) estimates from diffusion-weighted MRI (DWI) have shown good repeatability and ability to identify clinically-significant prostate cancer. Despite these findings, ADC values are not used quantitatively in clinical practice due to the lack of defined thresholds for interpretation and variation in ADC estimates between different imaging protocols. The impact of imaging protocol variations and inter-scanner differences on ADC estimates has not been quantified in large international datasets. This study aims to model ADC values of the prostate, including variation with tumour grade, in a large multicentre dataset of DWI data to identify the imaging protocol and inter-scanner differences that affect ADC estimates.
Methods or Background: Mean ADC estimates of the prostate gland of 6413 patients from the ProCAncer-I repository including tumour grade and imaging metadata are used in the analysis. The whole prostate glands were segmented using methods developed in the ProCAncer-I project. A list of potentially significant imaging protocol parameters were compiled, based on literature review. Clinical data, including age, pathological Gleason Grade, and radiological PI-RADS scores were also collected.
Results or Findings: Random forest and Lasso regression identified significant factors using repeated 5-fold cross validation, with echo time, field of view, pixel spacing and PI-RADS=5 found consistently to be the most important factors correlating with ADC values. Lasso coefficients indicate that ADC value will change by -6.78, +98.58(10-6 mm2/s) per ms and mm increase in TE and pixel spacing, and +56.87, -34.84(10-6 mm2/s) for small-field-of-view scans and PI-RADS category 5, independently.
Conclusion: Using a real-world multi-centre prostate MRI dataset has allowed us to identify significant MR parameters and clinical factors that affect ADC estimates, which can inform on future multi-centre collaborations and protocol standardisation.

Improving Prostate MRI Quality Assessment Across Diverse Evaluators and Institutional Practice Through a PI-QUAL Lecture (6 min)

Lili Xu; Hangzhou / China

Author Block: L. Xu[1], F. Giganti[2], C. M. Moore[2], H. Sun[3], X. Wang[1], L. Shi[1]; [1]Hangzhou/CN, [2]London/UK, [3]Beijing/CN
Purpose: To evaluate the impact of a Prostate Imaging Quality (PI-QUAL) v2 lecture on accuracy and inter-reader agreement of prostate MRI image quality assessment among radiologists and technologists from diverse professional backgrounds and institutions, and to evaluate its role in institutional-level quality improvement through a quality control (QC) process.
Methods or Background: Ten participants (five radiologists and five technologists) from five different hospitals independently evaluated 15 prostate MRIs before and after a standardized PI-QUAL lecture. Reference scores were established by two experienced radiologists. Assessment accuracy was evaluated by the area under the ROC curve (AUC). Inter-reader agreement was measured using percent agreement (PA) and Gwet's AC1. Subgroup analyses were conducted based on participant characteristics. For the quality assurance and QC (QA/QC), each center submitted 15 prostate MRIs before and after the lecture. Image quality was evaluated centrally to determine institutional improvement.
Results or Findings: The overall AUC improved from 0.629 to 0.842 ($p < 0.001$), with subgroup improvements across all participant types (pre: 0.500–0.688; post: 0.806–0.896). Inter-reader agreement improved from PA 57.6% to 72.6% and Gwet's AC1 from 0.214 to 0.466. Through the QA/QC process, three centers initially failed to meet PI-QUAL v2 technical criteria. After feedback, image quality markedly improved, with all post-intervention scans achieving PI-QUAL v2 scores >1.
Conclusion: A structured PI-QUAL v2 lecture significantly improved both the accuracy and inter-reader agreement of prostate MRI image quality assessments among diverse evaluators. Incorporating QA/QC further enhanced institutional image quality. PI-QUAL v2 training is a feasible strategy for standardizing prostate MRI quality.
Limitations: First, the number of cases evaluated was limited. Second, no hands-on workshop was conducted.

mpMRI Surveillance After Focal Therapy for Localized Prostate Cancer: A Comparative Analysis of TARGET and PI-FAB Scores (6 min)

Yan Mee Law; Singapore / Singapore

Author Block: G. Hang[1], R. Z. Lee[1], A. L. C. Y. Lai[1], N. Lath[1], J. Velaga[2], K. J. Tay[1], N. T. Ngo[1], Y. M. Law[1]; [1]Singapore/SG, [2]Brunswick East/AU
Purpose: The growing adoption of focal therapy (FT) for localized prostate cancer (PCa) emphasizes the need for standardized MRI-based frameworks to detect recurrent clinically significant prostate cancer (csPCa). The Transatlantic Recommendations for Prostate Gland Evaluation with MRI after Focal Therapy (TARGET) and Prostate Imaging after Focal Ablation (PI-FAB) systems have recently been proposed to guide post-FT multiparametric MRI (mpMRI) assessment. This study compared the diagnostic performance and inter-reader agreement of TARGET and PI-FAB.
Methods or Background: Patients who underwent FT for localized csPCa were recruited as part of a prospective phase II trial and an extended cohort. All patients underwent mpMRI and prostate biopsy. Two genitourinary radiologists evaluated post-FT mpMRI independently using TARGET and PI-FAB. Diagnostic metrics (sensitivity, specificity, positive predictive value [PPV], negative predictive value [NPV], accuracy) were analyzed. Inter-reader agreement was assessed using quadratic weighted Cohen's kappa (κ).
Results or Findings: Seventy-nine patients with 139 ablated sites were included. For both TARGET and PI-FAB, radiologist 1 achieved the same sensitivity 100%, specificity of 82.6%, PPV of 62%, NPV of 100%, and an accuracy of 74.8%. Radiologist 2 achieved a sensitivity of 72.4% and 78.5%, a specificity of 65.4% and 64.8%, a PPV of 52.2% and 43.1%, an NPV 90% and 92.3%, and an accuracy of 66.9 % and 67.6% in TARGET and PI-FAB, respectively. Inter-reader agreement was moderate (κ=0.59 for TARGET, κ=0.60 for PI-FAB)
Conclusion: TARGET and PI-FAB demonstrated comparable diagnostic performance in detecting in-field recurrence of csPCa following FT. Despite different reader experience, moderate agreement was achieved, supporting their role in standardized post-FT mpMRI evaluation.
Limitations: This study was conducted at a single center with a modest sample size, which limits generalizability. Only two radiologists participated, restricting assessment of variability across broader expertise levels.
Funding for this study: Dr KJ Tay received funding support from National Medical Research Council, Singapore.
Grant number - NCT04138914.

Visualizing Invasive Cribriform Architecture and Intraductal Carcinoma in Prostate Cancer via Time-Dependent Diffusion MRI (6 min)

Yanling Chen; Guangzhou / China

Author Block: Y. Chen, H. Wang, Y. Guo; Guangzhou/CN
Purpose: To investigate the feasibility of time-dependent diffusion MRI-based microstructural mapping for noninvasively characterizing the intraductal carcinoma (IDC) and invasive cribriform (Cr) histologic patterns in prostate cancer (PCa).
Methods or Background: This retrospective study enrolled men with pathologically confirmed PCa based on radical prostatectomy specimens between March 2023 and March 2025. Time-dependent diffusion MRI was performed using pulsed and oscillating gradient diffusion MRI sequences. The microstructural parameters, including cell diameter(d), extracellular diffusivity(Dex), intracellular fraction (fin), and cellularity were estimated with a two-compartment model. Apparent diffusion coefficient (ADC) maps were generated for each diffusion frequency (0 Hz, 17 Hz, 33 Hz). These parameters were compared between PCa with and without Cr/IDC patterns. Their diagnostic performance in detecting Cr/IDC architecture were assessed.
Results or Findings: A total of 81 participants were enrolled, of which 69.5% (57/81) PCa exhibited Cr/IDC patterns. Among all measurements derived from time-dependent diffusion MRI, fin and cellularity were significantly higher in the Cr/IDC-positive group compared to the negative group ($P < 0.001$ and $P = 0.002$, respectively), while ADC0Hz and ADC17Hz values were significantly lower ($P = 0.015$ and $P = 0.029$, respectively). No significant differences were observed in Dex, d and ADC33Hz ($P = 0.151$, 0.689, and 0.055, respectively). For detecting Cr/IDC morphology, fin yielded the highest area under the receiver operating characteristic curve (AUC) of 0.758 (95% CI: 0.639–0.877). Cellularity, ADC0Hz and ADC17Hz showed AUCs of 0.732 (95% CI: 0.605–0.858), 0.671 (95% CI: 0.545–0.798), and 0.654 (95% CI: 0.519–0.790), respectively.
Conclusion: Microstructural mapping via time-dependent diffusion MRI demonstrates strong potential for noninvasively characterizing histologic subtypes of PCa, showing high efficacy in identifying cribriform architecture and intraductal carcinoma.
Limitations: Sensitivity analyses adjusted for Gleason grade were not performed due to the small cohort.

Pre-treatment MRI as an Independent Prognostic Marker for Biochemical Recurrence, Metastasis, and Prostate Cancer Mortality After Radical Prostatectomy: Systematic Review and Meta-analysis (6 min)

Georgios Agrotis; Amsterdam / Netherlands

Author Block: G. Agrotis, S. Ursprung, P. Van Leeuwen, H. Van der Poel, U. van der Heide, I. G. Schoots; Amsterdam/NL
Purpose: To systematically review and meta-analyze the prognostic value of pre-treatment MRI for oncological outcomes in men undergoing radical prostatectomy.
Methods or Background: A systematic literature search of MEDLINE, Embase, and Scopus was performed from inception through March 2025.
Eligible studies evaluated pre-treatment MRI in men undergoing radical prostatectomy and reported long-term oncological outcomes, including biochemical recurrence, metastatic failure, overall survival, or cancer-specific mortality. Two reviewers independently extracted data and assessed study quality using the Quality in Prognostic Studies tool. Random-effects meta-analysis was performed to pool hazard ratios (HRs). The primary outcome was biochemical recurrence. Secondary outcomes included metastatic failure and prostate cancer–specific mortality.
Results or Findings: Forty-four studies (27,453 patients) were included. MRI-detected extracapsular extension (mT3a disease) (HR 2.16 [95% CI, 1.85–2.52]) and seminal vesicle invasion (mT3b disease) (HR 3.32 [2.68–4.12]) were strong independent predictors of biochemical recurrence. PI-RADS score (HR 2.22 [1.86–2.64]) and tumor apparent diffusion coefficient values (HR 2.39 [1.65–3.47]) also showed prognostic value. Additional MRI features associated with recurrence included tumor diameter (HR 1.04 [1.01–1.07]), tumor volume (HR 1.56 [1.20–2.02]), peripheral zone tumor location (HR 3.64 [1.71–7.72]), and MRI-detected positive lymph nodes (HR 2.33 [1.78–3.04]). For metastatic failure, MRI-detected extracapsular extension (HR 4.11 [2.24–7.571]), seminal vesicle invasion (HR 8.36 [2.21–31.6]), and tumor diameter (HR 1.04 [1.02–1.06]) were independent predictors. MRI-detected extracapsular extension was also associated with prostate cancer–specific mortality (HR 7.86 [4.51–13.7]).
Conclusion: Pre-treatment MRI provides independent prognostic value for biochemical recurrence, metastatic failure, and cancer-specific mortality in men undergoing radical prostatectomy. Integration of specific MRI-derived predictors into risk models may improve preoperative stratification, guide treatment planning, and inform post-treatment management.
Limitations: retrospective, heterogeneity of MRI protocols and variability of readers
Funding for this study: No funding to disclose

Value of additional systematic cores during MRI-guided targeted prostate biopsy in prostate cancer screening in young men – results from the PROBASE trial (6 min)

Matthias Boschheidgen; Düsseldorf / Germany

Author Block: M. Boschheidgen[1], R. Al-Monajjed[1], A. Kilaviciute[2], J. P. Radtke[1], H-P. Schlemmer[2], G. Antoch[1], P. Albers[1], L. Schimmöller[3]; [1]Düsseldorf/DE, [2]Heidelberg/DE, [3]Herne/DE
Purpose: While MRI-guided targeted biopsy (TB) is becoming an integral part for early prostate cancer (PCa) detection, its role in screening of younger men remains unclear. Here we analyse the additional value of systematic biopsy (SB) to improve detection of clinically significant PCa (csPCa).
Methods or Background: 525 men aged 45–54 years with confirmed PSA ≥3.0 ng/ml underwent mpMRI followed by combined TB and SB between February 2014 and August 2023 within a multicenter, prospective screening trial in Germany. Software-based MRI/ultrasound fusion 2-core TB combined with SB was performed transrectally or transperineally. Primary objective was to analyse differences in csPC detection rates between SB versus TB in correlation to MRI. Secondary objectives were overall PCa detection and ISUP grade group (GG) distribution by SB and/or TB.
Results or Findings: PCa was detected in 209 men (39%). 148 were csPCa (71%; ISUP GG ≥2). SB missed 24 cases of csPCa (16%) and TB missed 49 (33%). SB detected 25 more low-risk PCa than TB (n=51 vs. n=26). In 64% of the cases in which SB detected a higher ISUP GG (n=89; including ISUP GG 1) the positive cores were located within the MRI-detected lesions. 5 ISUP GG ≥3 PCa were not identified on MRI.
Conclusion: A relevant proportion of csPCa was missed by 2-core TB although they were correctly identified on MRI, suggesting limitations in targeting accuracy and/or fusion technique. Thus, SB or at least perilesional sampling should become the standard biopsy technique in PCa detection in younger men until targeting can be further optimized.
Limitations: Limitations are the lack of centralized MRI review before biopsy, variability in biopsy technique, retrospective subgroup analysis, and short follow-up.

Improving Prostate Cancer Detection with Targeted Biopsy: Focus on DWI-definition of Lesion-Core and Penumbra (6 min)

Ludovica Laschena; Rome / Italy

Author Block: L. Laschena, F. Mezzapesa, L. De Giacomo, S. Novelli, E. Messina, V. Panebianco; Rome/IT
Purpose: To explore the potential role of DWI in defining the "lesion-core" in the prostate peripheral zone and to assess whether targeting biopsies specifically on the DWI-based “lesion-core” can improve the diagnostic performance in detecting csPCa.
Methods or Background: Prospective,single-center study; patients with clinical suspicion of PCa underwent mpMRI according to PI-RADS v2.1 recommendations and those with a positive scan (PI-RADS 5, 4 and PI-RADS 3 with PSA-density ≥0.15) were directed to a transrectal-fusion-targeted-biopsy (TBx). Only peripheral zone lesions with a mismatch in terms of size or extent between DWI and T2WI were considered. During pre-biopsy lesion segmentation performed by an experienced uro-radiologist, the “lesion-core” was indicated as the most restricting area on DWI, while the “penumbra” as the exceeding area visible on T2WI.During the procedure cores from each region were collected and separately stored. Statistical analyses included McNemar’s,Wilcoxon, and ROC.
Results or Findings: 111 patients were enrolled;152 lesions identified.Overall, 12 (10.8%) had no evidence of prostate cancer, 18 (16.2%) had ciPCa, and 81 (72.8%) were diagnosed with csPCa.When stratifying by biopsy site, significant differences emerged between “lesion-core” and “penumbra".Detection of csPCa was higher in the lesion-core (107-70.3%) compared to the penumbra (79-52.0%), with a significant difference (p=0.01).Similarly, Gleason scores were higher in the lesion-core than in the penumbra.ROC analysis confirmed the superior diagnostic performance of lesion-core biopsies.The AUC for csPCa detection was 0.86 for lesion-core targeting compared to 0.66 for penumbra targeting, with the difference reaching statistical significance (p=0.031).
Conclusion: DWI-based lesion-core targeting provides higher diagnostic yield for csPCa compared to penumbra sampling. This approach refines biopsy accuracy, reduces overdiagnosis of indolent disease, and may improve patient stratification. DWI should therefore be considered the dominant sequence to guide targeted biopsy in peripheral zone lesions.
Limitations: Single-center study, sample-size

Quantitative Assessment of Inter-Observer Variability in PI-RADS Evaluation of Transition Zone Lesions: Impact of Reader Expertise on Diagnostic Performance and Cost-Effectiveness (6 min)

Giovanni Foti; Negrar / Italy

Author Block: F. Spoto[1], E. Demozzi[1], G. Sala[1], C. Cicciò[1], L. Monterubbiano[1], N. Cardobi[2], G. Cacciatori[2], M. D'Onofrio[2], G. Foti[1]; [1]Negrar/IT, [2]Verona/IT
Purpose: To quantify the impact of reader expertise on diagnostic accuracy for transition zone lesions using histopathological validation, and evaluate associated clinical and economic implications.
Methods or Background: This retrospective single-center study analyzed 315 consecutive patients with PI-RADS ≥3 transition zone lesions who underwent multiparametric MRI followed by MRI-guided in-bore biopsy between January 2018 and December 2024. Cases underwent blinded re-interpretation by either community radiologists (n=164) or expert readers at specialized center (n=151). Assessment included diagnostic accuracy metrics, PI-RADS category-specific performance, inter-observer agreement, and multivariable logistic regression. Economic impact was assessed through cost analysis and incremental cost-effectiveness ratios.
Results or Findings: Expert readers achieved superior diagnostic accuracy compared to community radiologists (47.0% versus 35.4%, p<0.001), representing 11.6% absolute improvement. Positive predictive value for clinically significant cancer improved 15.2% (43.3% versus 28.1%, p<0.001). For PI-RADS 4 lesions (56.8% of cohort), specialized centers achieved 76.9% cancer detection versus 42.6% for non-specialized centers (p<0.001), nearly doubling detection while reducing false positives by 60%. In multivariable analysis, PI-RADS score remained the strongest predictor (OR 3.06, p<0.001), while expertise effect was attenuated after adjustment (OR 1.12, p=0.68). Inter-observer agreement between experts (κ=0.603) exceeded agreement with community readers (κ=0.291, p=0.002). Economic analysis revealed €627 cost reduction per cancer detected through expert interpretation.
Conclusion: Reader expertise substantially impacts diagnostic accuracy for transition zone lesions, particularly for PI-RADS 4 lesions where specialized centers nearly double cancer detection rates while reducing false positives by 60%.
Limitations: Study limitations include retrospective design, potential selection bias, and lack of external validation. Economic analysis was limited to direct medical costs from a healthcare system perspective, without considering indirect costs or long-term treatment expenses beyond initial diagnosis.
Funding for this study: This study received no external funding.

Diagnostic accuracy and reliability of MR based Node-RADS for prostate cancer (6 min)

Raif Can Yarol; Izmir / Turkey

Author Block: R. C. Yarol, C. Sinirsiz, M. S. Ozer, I. B. Akin, O. Bozkurt, V. Sen, E. B. Tuna, K. Yorukoglu, C. Altay; Izmir/TR
Purpose: The aim of this study is to investigate the ability of the Node-RADS in predicting lymph node metastasis of prostate cancer.
Methods or Background: The Node-RADS score was provided a standized assessment of lymph nodes with scores ranging from 1 to 5, accounting size and configuration criteria. In this study, 102 patients with prostate cancer who have undergone radical prostatectomy and lymph node dissection from 2021 to 2025 were retrospectively evaluated for detection of lymph nodes and scored according to Node-RADS system. Node-RADS evaluations were performed by two radiologists based on pre-operative MR examinations. Diagnostic accuracy was assessed with receiver-operating characteristics (ROC) curve analysis, sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV). Interreader agreement was calculated using Cohen's kappa.
Results or Findings: Overall, 102 patients with a mean age of 67.26 ± 6.20 years were included. Lymph node metastasis was histopathologically proven 12 among 102 patients (11,8%). One patient with a score of 1 (1/80) and one patient with a score of 2 (1/8) had a positive node. Considering a Node RADS 4–5 positive and a Node RADS 1–2 negative, PPV was 85.7% and the NPV was 97.7%. Node-RADS achieved a sensitivity of 75% and a specificity of 98,8%. ROC curve analysis for lymph node discrimination showed an AUC of 0.897.
Conclusion: Node-RADS is a reliable and effective tool for predicting nodal metastasis in prostate cancer. Pre-operative routine use of it may enhance radiological staging and support treatment decisions.
Limitations: Retrospective nature and limited number of patients

Is It Safe to Omit Contrast in Prostate Cancer Patients on Active Surveillance? (6 min)

Ailin Dehghanpour; Rome / Italy

Author Block: A. Dehghanpour, M. Bicchetti, A. Borrelli, S. Novelli, E. Messina, V. Panebianco; Rome/IT
Purpose: Active surveillance (AS) is the recommended strategy for men with low-risk prostate cancer. The Prostate Cancer Radiological Estimation of Change in Sequential Evaluation (PRECISE) criteria were designed to standardise the reporting of tumour progression on serial MRI, and PRECISE v2 has recently refined definitions and incorporated minimum quality standards.
Multiple studies have demonstrated the non-inferiority of biparametric MRI (bpMRI) compared to multiparametric MRI (mpMRI) for the detection of csPCa. The aim of this study was to evaluate whether contrast administration can also be safely omitted in patients undergoing AS.
Methods or Background: We retrospectively analysed a prospectively maintained single-centre AS cohort of 185 men with clinically insignificant prostate cancer and ≥3 years of follow-up. 120 underwent repeat biopsy; the remainder were clinically and radiologically stable. Two expert radiologists independently reviewed all MRI examinations and assigned PRECISE v2 scores once using mpMRI and once using bpMRI. Image quality was scored with PI-QUAL v2. The reference standard was ISUP group grade on biopsy or stable follow-up. Diagnostic performance was assessed with ROC analysis for a PRECISE cut-off ≥4.
Results or Findings: For mpMRI, PRECISE ≥4 predicted ISUP upgrading with sensitivity 70%, specificity 75%, PPV 58%, NPV 84%, and accuracy 72% (AUC 0.77). In scans with PI-QUAL 3, particularly DWI score 4, bpMRI yielded comparable performance: sensitivity 66%, specificity 73%, PPV 55%, NPV 82%, accuracy 70% (AUC 0.75). When PI-QUAL was <3, bpMRI showed inferior performance with mpMRI significantly outperforming bpMRI ($p<0.05$).
Conclusion: PRECISE scoring system is an accurate tool for predicting disease progression in men on AS, both with mpMRI and bpMRI when image quality is optimal. However, in suboptimal scans mpMRI clearly outperforms bpMRI, and it is therefore not yet safe to omit contrast administration.
Limitations: Retrospective study.

Prostate Cancer: Value of volume-adjusted PSA density in recurrence assessment after HIFU (6 min)

Clara Elsner; Zürich / Switzerland

Author Block: C. Elsner, A-M. Pausch, T. Rabadi, N. Rupp, D. Eberli, A. M. Hötker; Zürich/CH
Purpose: Optimal follow-up and biopsy stratification after high-intensity focused ultrasound (HIFU) ablation of localized prostate cancer are challenging, as PSA levels are often unreliable due to inflammation and variable residual tissue. This study aimed to evaluate the diagnostic performance of the Prostate Imaging after Focal Ablation (PI-FAB) score on multiparametric MRI in combination with volume-adjusted PSA density (vaPSA-D, derived from volumetrically assessed residual vital prostate tissue) in recurrence detection.
Methods or Background: This IRB-approved, retrospective single-center study included 119 men treated with HIFU for localized prostate cancer. Follow-up mpMRI and prostate biopsies were performed at 6, 12, and 36 months. PI-FAB scores and vaPSA-D were assessed independently. Diagnostic performance was analyzed using histopathology from biopsy as the reference standard.
Results or Findings: The PI-FAB score demonstrated good diagnostic performance, particularly at 36 months (AUC 0.92). VaPSA-D likewise showed solid performance, with steadily increasing accuracy over time (AUC 0.68, 0.81, 0.84 at 6, 12, and 36 months; overall 0.78), outperforming PI-FAB at 12 months post-HIFU. Integrating vaPSA-D into PI-FAB subgroups significantly enhanced recurrence assessment: PI-FAB 1: sensitivity/specificity 75%/78% (threshold 0.14 ng/ml); PI-FAB ≥2: sensitivity/specificity 67%/85% (threshold: 0.18 ng/ml); PI-FAB 3: sensitivity/specificity 69%/90% (threshold: 0.18 ng/ml).
Conclusion: Both PI-FAB and vaPSA-D perform well in the post-HIFU setting, each with distinct strengths: PI-FAB shows excellent performance at late follow-up, while vaPSA-D ensures high sensitivity and reliable recurrence exclusion across all time points. Their combined application provides the most accurate assessment of in-field recurrence after HIFU, supporting a complementary rather than exclusive use of these tools to potentially reduce unnecessary biopsies.
Limitations: Limitations include the retrospective design, single-center setting, and an overall low recurrence prevalence.
Funding for this study: No funding for this study.

Evaluation of Diagnostic Performance and Inter-reader agreement of the Transatlantic Recommendations for Prostate Gland Evaluation with Magnetic Resonance Imaging After Focal Therapy (TAREGT) (6 min)

Yan Mee Law; Singapore / Singapore

Author Block: G. Hang[1], R. Z. Lee[1], A. L. C. Y. Lai[1], N. Lath[1], J. Velaga[2], K. J. Tay[1], N. T. Ngo[1], Y. M. Law[1]; [1]Singapore/SG, [2]Brunswick East/AU
Purpose: Architectural distortion after focal therapy (FT) presents challenges for post-treatment surveillance using multiparametric magnetic resonance imaging (mpMRI). To address this, the Transatlantic Recommendations for Prostate Gland Evaluation with Magnetic Resonance Imaging After Focal Therapy (TAREGT) scoring system—a 5-point scale—was recently developed to evaluate residual cancer or in-field recurrence at ablation sites. This study aimed to assess the diagnostic performance and inter-rater reliability of the TARGET system in post-FT mpMRI.
Methods or Background: Patients were enrolled through a phase II clinical trial and an extended prospective cohort. Eligible participants had localized clinically significant prostate cancer (csPCa) and underwent cryotherapy or irreversible electroporation (IRE) between October 2019 and January 2024. All underwent post-FT mpMRI and subsequent prostate biopsy. Two genitourinary radiologists with 11 and 5 years of experience independently assessed mpMRI using TARGET. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and accuracy were calculated. Inter-rater reliability was measured with quadratic weighted Cohen's kappa (κ).
Results or Findings: Seventy-nine patients with 139 treated sites were analyzed. Radiologist 1 achieved sensitivity 100 %, specificity 82.6 %, PPV 62 %, NPV 100 %, and accuracy 74.8 %. Radiologist 2 achieved sensitivity 72.4 %, specificity 65.4 %, PPV 52.2 %, NPV 90 %, and accuracy 66.9 %. Cohen's κ was 0.59, indicating moderate agreement.
Conclusion: The TARGET scoring system demonstrated high diagnostic accuracy in detecting in-field recurrence after FT. Despite moderate inter-reader agreement, diagnostic performance was higher for the more experienced radiologist, highlighting the influence of expertise. These findings support TARGET as a valid framework for standardized post-FT mpMRI surveillance.
Limitations: This study was conducted at a single center with a modest sample size, which may limit generalizability. Only two radiologists participated, restricting assessment of variability across broader expertise levels.
Funding for this study: Dr KJ Tay received funding support from National Medical Research Council, Singapore.

Incidental sulcal enhancement on contrast enhanced T2-FLAIR during brain metastasis evaluation: Incidence, and associated risk factors (6 min)
Nam Hoon Kim; Seoul / Korea, Republic of

Author Block: L. Joo, J. B. Lee, Y. Yim, N. H. Kim; Seoul/KR
Purpose: The purpose of this study is to characterize ISE observed in patients undergoing brain MRI for the evaluation of brain metastasis
Methods or Background: This retrospective study included patients who underwent enhanced brain MRI between November, 2023 and September, 2024 for the purpose of evaluating brain metastasis. All patients underwent CE-T2FLAIR, CE-3D MPRAGE, and CE-3D SPACE imaging. The obtained contrast-enhanced T2FLAIR images were evaluated by two independent radiologists to identify patients with sulcal enhancement, and in case of disagreement, a consensus conclusion was reached. The patients were then divided into true leptomeningeal metastasis and ISE based on imaging and clinical findings, and the incidence of ISE was investigated, and logistic regression analysis was performed to identify variables with statistically significant associations with risk factors such as age, microbleed (3 categories; 0, 1-4, 5≤), and previous brain radiation therapy (RT) history.
Results or Findings: A total of 387 patients who suspected malignancy underwent brain MRI, and 50 were excluded, resulting in 337 brain MRIs included in this analysis. Among these, 72 patients showed sulcal enhancement on CE-T2FLAIR. Of these, 11 were diagnosed as true leptomeningeal metastasis, and 61 were classified as ISE, yielding an incidence of 18.1% (61/337). Logistic regression identified age, microbleed, and previous RT history as significant risk factors. Multivariate logistic regression results showed that age, microbleed, and RT history were independent risk factors to predict ISE on CE-T2FLAIR, regardless of gender. (Odds ratio; age: 1.1, 1.0 ~ 1.1; microbleeds: 1-4: 2.9, 1.5 ~ 5.8; ≥5: 7.3, 2.6 ~ 21.0; RT: 7.7, 2.1 ~ 28.0)
Conclusion: The incidence of ILE performed to evaluate brain metastasis was 18.1% . Significant independent risk factors for detecting ILE include age, microbleed, and RT history.
Limitations: Not applicable

Metabolic, Microvascular, and Macrovascular DSC-PWI-Derived Metrics for Presurgical Differentiation of Glioblastoma and Solitary Brain Metastasis Across Different Acquisition Protocols (6 min)
Clemente García; Murcia / Spain

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: C. García[1], I. MARTINEZ-ZALACAIN[2], P. Naval-Baudin[2], D. Choque[2], A. M. Viveros Castaño[2], M. Cos Domingo[2], C. Majós[2], A. Pons Escoda[2]; [1]Murcia/ES, [2]Hospitalet de Llobregat/ES
Purpose: The aim of this study is to quantify the diagnostic performance of a multiparametric, bicompartmental perfusion analysis, and to establish technical-scenario-specific thresholds and classifiers for the presurgical differentiation between glioblastomas and metastases.
Methods or Background: Patients: Retrospective cohort with 101 glioblastomas IDH-wt (52 males, median age 61) and 52 metastases (29 males, median age 63). DSC-Perfusion: Double-acquisition protocol: 1st without pre-bolus, flip angle 75°; 2nd with pre-bolus (using prior contrast), flip angle 60°. Segmentations: Semi-automatic and 3D. Two tumor compartments: enhancing tumor and peritumoral T2-FLAIR abnormality (edema). Masks co-registered to DSC space. Perfusion metrics: Commercial AIF-based Bayesian vascular model. Voxel-wise and normalized to normal-appearing white matter. Macrovascular metrics: rCBV (relative-cerebral-blood-volume), rCBF (relative-cerebral-blood-flow), MTT (mean-transit-time). Microvascular: CTH (capillary-transit-time-heterogeneity), TTD (delay), COV (coefficient-of-variance). Metabolic: OEF (oxygen-extraction-fraction), rCMRO2 (relative-cerebral-metabolic-rate-of-oxygen). Data analysis: Computation of best single-metric/single-statistic performance per protocol and tumor compartment. Combination of metrics using logistic regressions on three-metric sets that maximized discrimination for each acquisition scenario and compartment, as well as bicompartmental models.
Results or Findings: Single-metric performance: The highest AUC was 0.78 for peritumoral rCBFmax in the second protocol. Remaining best single-metric AUCs: protocol-1/enhancing CTHp25 = 0.73; protocol-1/edema rCBFmax = 0.77; protocol-2/enhancing MTTmin = 0.74. Trivariable classifiers: Scenario-specific peak AUCs were protocol-2/enhancing 0.79 (MTTmin + TTDmean + rCMRO2mean); protocol-2/edema 0.79 (CTHmin + OEFmin + rCBFmax). Within protocols, bicompartmental models outperformed single-compartment models—protocol-1 0.82 (vs 0.75); protocol-2 0.80 (vs 0.79). All models ranged 0.75–0.83. In exploratory subanalysis, both single metrics and classifiers remained stable in lab-simulated heterogeneous settings, with AUCs 0.73–0.84.
Conclusion: Multiparametric bicompartmental perfusion analysis using innovative commercial software demonstrates excellent discriminatory power and robustness across technical settings. Strengthening biological plausibility, classifiers combining vascular and metabolic information from distinct tumor habitats achieved the highest performance.
Limitations: Single-centre, retrospective design.

EGFR Mutation Subtypes Influence MRI Patterns and Survival Outcomes in Leptomeningeal Metastasis from Lung Adenocarcinoma with Intraventricular Chemotherapy via Ommaya Reservoir (6 min)

Yizhen Jia; Nanjing / China

Author Block: Y. Jia, M. Yuan; Nanjing/CN
Purpose: Leptomeningeal metastasis (LM) is a devastating complication of advanced lung adenocarcinoma (LUAD), with high prevalence in EGFR-mutant patients. Imaging and prognostic differences among EGFR subtypes remain poorly understood, especially in those receiving intraventricular chemotherapy via Ommaya reservoir. This study investigated MRI features and survival outcomes across EGFR mutation subtypes in this context.
Methods or Background: In this multicenter retrospective study, LUAD patients with cerebrospinal fluid (CSF)-confirmed LM (November 2021–June 2024) underwent contrast-enhanced brain MRI and CSF-based next-generation sequencing (NGS). Patients were classified as EGFR exon 21 L858R (EGFR 21), exon 19 deletion (EGFR 19), or non-classic/other mutations (NCOM). Imaging features were compared using chi-square tests, and intracranial progression-free survival (iPFS) and overall survival (OS) were analyzed with Kaplan–Meier and Cox regression models.
Results or Findings: A total of 110 patients (mean age 55.6 ± 10.2 years) were included. MRI-negative LM was more frequent in EGFR 19 (65.5%) versus EGFR 21 (34.9%) and NCOM (34.2%) ($p = 0.01$). EGFR 21 was associated with localized disease (<4 lobes: 85.7%) compared with NCOM (≥4 lobes: 45.5%) ($p = 0.01$). Median iPFS and OS were longer in EGFR 21 (12.0 and 18.0 months) than in NCOM (6.5 and 10.2 months). EGFR 19 conferred no survival benefit. EGFR subtype independently predicted iPFS ($p = 0.03$), but not OS ($p = 0.12$).
Conclusion: EGFR mutation subtypes are linked to distinct MRI features and survival outcomes in LUAD patients with LM treated via Ommaya reservoir, providing insights for diagnosis, risk stratification, and treatment planning.
Limitations: This study is limited by modest sample size and lack of CSF biomarker correlation. The high proportion of MRI-negative LM in EGFR 19 underscores the need for multimodal imaging and molecular integration in future multicenter studies.

Differentiating Radiation-Induced Brain Injury from Tumor Recurrence in Brain Metastases after Radiotherapy: A Deep Learning Model Integrating MRI and Clinical Data (6 min)

Yuhan Liang; Beijing / China

Author Block: Y. Liang, Z. Chen, M. Ge, Y. Wang; Beijing/CN
Purpose: Differentiating radiation-Induced brain Injury (RIBI) from tumor recurrence (TR) in brain metastases after stereotactic radiosurgery (SRS) remains a significant clinical challenge due to their similar appearance on conventional MRI. As management strategies differ substantially, this study aims to develop a deep learning model integrating multiparametric MRI with clinical data for accurate discrimination.
Methods or Background: This retrospective study enrolled 82 patients with brain metastases treated with SRS between January 2016 and December 2024. Diagnosis was confirmed by pathology or ≥6 months of follow-up. Based on post-radiation evolution, lesions were classified as RIBI (49 lesions) if showing initial growth followed by spontaneous regression or stability >6 months, or as TR (43 lesions) if demonstrating continuous progression. Multiparametric MRI sequences (T1WI, contrast-enhanced T1WI, T2WI) were analyzed, with all lesions manually delineated by radiologists. A deep learning model was developed to fuse imaging features with embedded clinical data (including patient demographics, tumor characteristics, and treatment parameters) for end-to-end classification. Model performance was evaluated via cross-validation using accuracy, sensitivity, specificity, and AUC.
Results or Findings: The integrated model demonstrated high performance, achieving an accuracy of 91.30%, sensitivity of 84.21%, specificity of 97.14%, and AUC of 0.92. Compared to the MRI-only model (accuracy 89.13%, AUC 0.885), clinical data integration improved accuracy by 2% and AUC by 0.035, validating the added value of multi-modal fusion.
Conclusion: The deep learning model integrating MRI and clinical data shows significant potential for accurately differentiating RIBI from TR in post-SRS brain metastases, providing a high-precision, non-invasive tool for clinical decision-making that may help avoid unnecessary invasive procedures.
Limitations: Not applicable

Percentage signal recovery and relative cerebral blood volume: a dual-parameter strategy to differentiate post-stereotactic radiosurgery tumour progression from radiation necrosis in brain metastases (6 min)

Nan Mei; Shanghai / China

Author Block: V. Sawlani[1], N. Mei[2], R. Flintham[1], S. Meade[1], H. Benghiat[1], S. Nagaraju[1], U. Pohl[1], P. Sanghera[1], V. Wykes[1]; [1]Birmingham/UK, [2]Shanghai/CN
Purpose: Stereotactic radiosurgery (SRS) is widely used for brain metastases, but differentiating tumour progression from radiation necrosis on conventional MRI remains difficult. Percentage signal recovery (PSR), derived from dynamic susceptibility contrast (DSC) perfusion MRI, reflects signal recovery post-contrast and offers insights into capillary permeability. This study aimed to evaluate PSR and relative cerebral blood volume (rCBV) and assess their combined diagnostic value in post-SRS brain metastases.
Methods or Background: Patients with enlarging post-SRS brain metastases and diagnostic uncertainty were retrospectively included. PSR and rCBV were extracted from DSC-MRI and normalized to contralateral white matter. The dataset was split into training and validation cohorts using stratified sampling. Logistic regression with 5-fold cross-validation and bootstrap validation was used. Diagnostic performance was assessed by ROC analysis.
Results or Findings: Sixty-one patients (62 lesions; 26 progression, 36 necrosis) were included. Progression showed higher rCBV (2.84 vs. 0.76) and lower PSR (95% vs. 176%) (both $p < 0.001$). Both were significant in univariate analysis; PSR remained independently predictive ($p = 0.04$) in multivariate analysis. PSR outperformed rCBV in ROC analysis (AUC = 0.960 vs. 0.898); the combined model improved accuracy (95.9%) without loss of sensitivity or specificity. Bootstrap-derived thresholds were 108% (PSR) and 1.96 (rCBV). A nomogram was developed for individualized risk estimation.
Conclusion: PSR and rCBV provide complementary diagnostic information for post-SRS lesion assessment. PSR offers added value without additional scanning, and integration of both parameters enhances diagnostic confidence. Routine inclusion of PSR and rCBV in post-SRS imaging protocols is recommended.
Limitations: This retrospective single-centre study may be subject to selection bias and limited generalizability. Using maximum rCBV and PSR values likely improved sensitivity for detecting focal tumour recurrence but may introduce variability in heterogeneous lesions; prospective multicentre validation is warranted.

PSR: an accurate marker in differentiating between radionecrosis and progression of brain metastases treated with stereotactic radiosurgery (6 min)

Zhao Hui Chen Zhou; Madrid / Spain

Author Block: Z. H. Chen Zhou, A. Hilario Barrio, E. Salvador Alvarez, A. Cardenas, J. Romero Coronado, C. Lechuga Vázquez, A. Martínez De Aragón Calvo, R. D´Ambrosi, A. Ramos Gonzalez; Madrid/ES
Purpose: Stereotactic radiosurgery (SRS) is the treatment of choice for local control of isolated brain metastases. However, after SRS, it is common for metastases to show increased enhancement, making it difficult to distinguish between tumour progression and treatment-related effects. DSC perfusion is useful for evaluating haemodynamic changes, with rCBV being the most extensively studied parameter. Nevertheless, the percentage signal recovery (PSR), which is an indicator of blood–brain barrier integrity, has been assessed less frequently. This study aimed to compare the diagnostic performance of rCBV and PSR.
Methods or Background: A retrospective analysis was performed on patients with brain metastases who were treated with SRS between January 2020 and December 2024. The patients showed increased post-treatment enhancement and had available DSC perfusion. The final diagnosis of progression or radionecrosis was established by either surgical resection or clinical–radiological follow-up. Images were processed to obtain rCBV and PSR values. Statistical tests (Mann–Whitney U and Student's t-test) were applied to compare the two groups.
Results or Findings: A total of 79 treated brain metastases that subsequently grew were included in the analysis (45 cases of radionecrosis and 34 cases of progression). rCBV was significantly higher in cases of tumour progression ($p < 0.001$), while PSR was significantly lower ($p < 0.001$). Using a cut-off value of 1.7, rCBV achieved a sensitivity of 91.2%, a specificity of 60%, and an area under the curve (AUC) of 0.87. For PSR, the cutoff value was 70%. Sensitivity was 94.1%, specificity was 97.8%, and the AUC was 0.99.
Conclusion: Although traditionally overlooked, PSR is more accurate than rCBV at differentiating tumour progression from radionecrosis after radiosurgery. This establishes PSR as a highly useful diagnostic tool in clinical practice.
Limitations: Retrospectiva and single center study.
Funding for this study: No funding.

Ethics committee - additional information: The hospital's local ethics committee affirms that it complies with ethical standards and good clinical practice.

Prediction of incidental asymptomatic meningioma at high risk of tumor growth using a multiparametric MRI-based machine learning approach (6 min)

Nan Mei; Shanghai / China

Author Block: N. Mei[1], Y. Chen[2], V. Sawlani[3], X. Li[1], J. Cui[1], Z. Zheng[4], D. Wang[1], Y. Lu[1], B. Yin[1]; [1]Shanghai/CN, [2]Jiangsu/CN, [3]Birmingham/UK, [4]Shandong/CN
Purpose: Tumor growth imposes a considerable psychological impact on patients with incidental asymptomatic meningiomas. This study aimed to identify clinical, semantic, and multiparametric MRI features associated with growth potential and to develop a machine learning model for risk prediction, thereby informing personalized surveillance and management strategies.
Methods or Background: This retrospective multi-center study enrolled adult patients with incidental asymptomatic meningiomas confirmed by routine MRI. Tumors were manually segmented on CE-T1WI images. Radiomics features were extracted from CE-T1WI, T2-FLAIR, and ADC images and selected using correlation and Cox regression analyses. A random survival forest model was developed with five-fold cross-validation to predict tumor growth. Model performance was assessed by C-index and time-dependent ROC curves. Risk stratification was evaluated using Kaplan-Meier analysis.
Results or Findings: 421 patients with incidental asymptomatic meningiomas from Institution A were randomly split into training, validation, and testing sets, with an independent external validation set comprising 39 patients from Institutions B and C. Eleven significant predictors were incorporated into a random survival forest model, which demonstrated strong performance with C-indices of 0.928, 0.874, 0.872, and 0.860 in the training, validation, testing, and external validation sets, respectively. The model achieved consistently high time-dependent AUCs (> 0.80) at 1-, 2-, 3-, and 5-year follow-up, and stratified patients into significantly low and high growth-risk groups on Kaplan-Meier analysis.
Conclusion: Our MRI-based machine learning model reliably predicts growth risk in incidental asymptomatic meningiomas, enabling personalized surveillance. This may improve clinical decision-making and reduce unnecessary interventions and, importantly, patient anxiety.
Limitations: Patient inclusion was based on meningiomas identified at initial MRI, which may have led to rare misclassification of solitary fibrous tumor; however, follow-up likely minimized this risk. Only reproducible, interpretable radiomics features were included to reduce redundancy and overfitting.
Funding for this study: This work is sponsored by the Explorers Program of Shanghai (Grant no. 24TS1410800) and the National Natural Science Foundation of China (82281966).

Imaging Perspectives on Angiomatous Meningioma and Solitary Fibrous Tumor: Diagnostic Challenges and Differentiation (6 min)

Hsiao-Hsuan Chen; New Taipei City / Taiwan, Chinese Taipei

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: H-H. Chen, F-C. Chang; New Taipei City/TW
Purpose: Intracranial solitary fibrous tumors(SFT) are rare hypervascular dural based tumor, which showed overlapping imaging appearance with angiomatous meningioma(AM), another hypervascular dural based tumor. This study aim to differentiate the two different tumor on a routine MRI sequence.
Methods or Background: We retrospectively reviewed the pathology database at VGHTPE from January 2015 to September 2025, and included 20 cases of SFT and AM respectively. Preoperative MRI features was analyzed. Group comparisons were performed using chi-square or t-tests.
Results or Findings: SFT typically demonstrated T1 and T2 isointensity, while AM more often showed T1 hypointensity and T2 hyperintensity. Both tumors were hypervascular with marked enhancement and no significant restricted diffusion overall. Although AM more frequently exhibited mild restricted diffusion in peripheral region. The presence of peripheral restricted diffusion showed a sensitivity of 50%, specificity of 85%, and overall accuracy of 67.5% in identifying AM.
Conclusion: AM and SFT may exhibit overlapping imaging features but differ markedly in biological behavior and prognosis. Accurate differentiation is essential for guiding appropriate therapeutic strategies. Peripheral restricted diffusion appears to be a promising imaging marker for distinguishing AM from SFT.
Limitations: Limitations include small sample size and retrospective single-center design. Possible bias due to manual drawing and visual positioning of the ROI.

Preoperative Prediction of Brain Invasion in Meningiomas: A Comparison of Diffusion Kurtosis Imaging and Diffusion Tensor Imaging (6 min)

Qin Jing; Fuzhou city / China

Author Block: Q. Jing, K. Wang, J. Zhao, L. Lin; Fuzhou/CN
Purpose: Identifying brain invasion particularly important for meningioma patients, but there is still a lack of valuable early biomarkers. The authors aimed to investigate the value of histogram analysis of diffusion kurtosis imaging (DKI) and diffusion tensor imaging (DTI) in predicting the brain invasion of meningioma.
Methods or Background: A total of 132 meningioma patients were prospectively included and underwent magnetic resonance diffusion imaging. The whole-tumour histogram parameters were extracted from diffusion maps including Mean kurtosis (MK), fractional anisotropy (FA), and mean diffusivity (MD). The Mann-Whitney U test was used to compare the parameters of brain invasive and non-invasive meningiomas. The receiver operating characteristic (ROC) curve and multiple logistic regression analyes were performed to identify the diagnostic performance. Spearman's partial correlation was used to evaluate correlations between histogram parameters and the Ki-67 index.
Results or Findings: DKI-MK (10th, 50th, 90th percentile, maximum, mean and kurtosis), DKI-FA (minimum, maximum), DKI-MD (minimum, maximum, kurtosis and skewness), DTI-FA (maximum), DTI-MD (10th percentile, kurtosis and skewness) showed statistically significant differences between brain invasive and non-invasive meningiomas ($p < 0.05$). For all histogram parameters, the highest individual predictor was DKI-MK 90th percentile with an AUC of 0.837 and an accuracy of 75.0%. The DKI combined model can further improve the diagnostic efficiency, with an AUC of 0.914 and an accuracy of 85.6%. Significant correlations were found between various diffusion histogram parameters and the Ki-67 index (rho = -0.244-0.504, $p < 0.05$).
Conclusion: The whole-tumour DKI and DTI histogram analysis is a promising approach for predicting brain invasion in meningiomas, and the multi-parameter combined model can further improve diagnostic efficiency.
Limitations: The single-center design inherently carries selection bias and lacks external validation.

Correlation of Elastography Stiffness with ADC and Conventional MRI Sequences in Meningiomas (6 min)

Tolga Orhan; Istanbul / Turkey

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: T. Orhan, M. Oral, Z. Firat, G. Ekinci; Istanbul/TR
Purpose: To investigate the relationship between magnetic resonance (MR) elastography-derived stiffness values and diffusion (ADC) as well as conventional MR signal intensity ratios (SIR) in meningiomas
Methods or Background: We retrospectively analyzed 40 patients with histologically proven meningiomas who underwent preoperative MRI, including elastography. Elastography stiffness scores were compared with ADC values and SIRs from T1, T2, and FLAIR sequences.
Results or Findings: Elastography scores showed a significant negative correlation with ADC values ($p<0,01$), indicating that stiffer tumors tend to have lower ADC. In contrast, no significant associations were found between elastography and SIR values on T1, T2, or FLAIR sequences ($p > 0.05$ for all).
A secondary finding was noted: in the subgroup of patients with elevated T2 SIR (>1) but reduced FLAIR SIR (<1), elastography scores were higher (median = 4) compared to other patients (median = 3). This difference was statistically significant ($p<0.05$).
Conclusion: Preoperative elastography stiffness is inversely related to ADC in meningiomas, suggesting complementary roles of these imaging biomarkers. While conventional SIR values alone did not correlate with stiffness, the observation of high elastography scores in tumors with a “T2/FLAIR mismatch” may represent a promising secondary marker. Further studies with larger cohorts are warranted to validate this novel finding.
Limitations: Lack of direct correlation between the elastography stiffness values and a gold standard
Retrospective study
Small sample size
Single centred study

Association Between Facet Joint Orientation, Facet Tropism, and Degenerative Lumbar Spondylolisthesis (6 min)

Burcin Akgun; Istanbul / Turkey

Author Block: B. Akgun, E. Gülay, B. Baysal; Istanbul/TR
Purpose: Spondylolisthesis is defined as the anterior displacement of one vertebra relative to the caudal vertebra.This study aimed to evaluate the relationship between facet tropism and disc and facet joint degeneration in degenerative lumbar spondylolisthesis and to identify potential radiographic risk factors by comparison with healthy controls.
Methods or Background: Seventy patients with DLS at L3/4, L4/5, and L5/S1 and seventy controls were included.Lumbar MR images were independently assessed by two radiology resident.Intervertebral disc degeneration was graded using the Pfirrmann system, while facet joint degeneration was evaluated with Weishaupt and Fujiwara scores.Right and left facet angles and tropism were recorded.The reference plane was defined as a line through the disc midline and base of the spinous process;the facet line connected the anteromedial and posteromedial borders of the superior articular facet.Facet angle was calculated between the reference plane and facet line. Tropism was defined as an asymmetry ≥8°. Inter-observer agreement was assessed with Cohen’s Kappa; correlations were analyzed using Spearman’s test.
Results or Findings: Among patients,65.5% were male and 34.5% female. DLS involvement was 43.7% at L4-5, 40.8% at L5-S1, and 15.5% at L3-4.Pfirrmann scores at L5-S1 were significantly higher in DLS than controls($p<0.05$), while L3-4 and L4-5 showed no difference.Weishaupt and Fujiwara scores at L4-5 were significantly higher in DLS($p<0.05$); other levels showed no difference.Facet tropism prevalence did not differ significantly. Right-sided facet angle negatively correlated with Weishaupt and Fujiwara scores($p<0.05$); no significant left-sided correlation was observed.At L3-4 and L5-S1, tropism was associated with higher degeneration scores($p<0.01$).
Conclusion: Facet joint degeneration, along with facet morphology, may play important roles in DLS development.These findings suggest that facet morphology and tropism may be linked to degeneration and could serve as potential radiographic risk factors in DLS.
Limitations: No limitations were identified.
Funding for this study: No funding was provided for this study.

Diffusion tensor imaging with 3D high-resolution MRI of lumbosacral nerve roots in lumbar disc herniation with radiculopathy and its clinical correlations: A prospective study (6 min)

Wei Zeng; Chongqing / China

Author Block: W. Zeng, H. Yang; Chongqing/CN
Purpose: To optimally visualize and identify the fiber bundle abnormalities of lumbosacral nerve roots in lumbar disc herniation (LDH) with radiculopathy by diffusion tensor imaging (DTI) based on 3D high-resolution MRI.
Methods or Background: Ninety-seven patients with unilateral LDH with radiculopathy were enrolled and underwent DTI and 3D high-resolution MRI. Quantitative DTI parameters including fractional anisotropy (FA), apparent diffusion coefficient (ADC), axial diffusivity (AD), and radial diffusivity (RD) were obtained through continuous multi-point measurements from the nerve root compression level to the distal end. The correlations among DTI parameters, nerve root compression grades, and clinical scoring systems for pain and functional disability were analyzed.
Results or Findings: At the compression site, the FA and AD of the affected nerve root were significantly lower than those of the contralateral side ($p < 0.001$). The FA generally increased and the, ADC and RD decreased following the measurement points away from compressed level. The FA, ADC and AD were significantly correlated with compression severity and clinical scoring systems ($p < 0.001$ - $p = 0.038$ and $p < 0.001$ - $p = 0.042$, respectively). Specifically, the lower FA and higher ADC and RD values were associated with worse functional outcomes and greater pain ($r = -0.42$ to 0.41).
Conclusion: Anatomically-guided, multi-parametric DTI reveals complex injury patterns in LDH that may be missed by single-parameter or single-point analysis. This comprehensive approach provides robust biomarkers that reflect clinical severity and holds potential to improve patient stratification and guide therapeutic decisions.
Limitations: Not applicable
Funding for this study: Not applicable
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was performed in line with the principles of the Declaration of Helsinki. Approval was granted by the Medical Ethics Committee of the First Affiliated Hospital of Chongqing Medical University (Protocol Number: 2024-341-01). Informed consent was obtained from all individual participants included in the study.

Intraoperative MRI for Resection of Intramedullary Spinal Cord Tumors: A Case Series of 15 Patients (6 min)

Keng-Chian Lin; Taipei City / Taiwan, Chinese Taipei

Author Block: K-C. Lin, Y. Huang; Taipei City/TW
Purpose: Intraoperative MRI (ioMR) is an underutilized examination for facilitating resection of intramedullary spinal cord tumors. In the current case series, the authors present their technical and interpretation-related experiences with ioMR.
Methods or Background: A total of 15 patients who underwent ioMR for intramedullary spinal cord tumor resection from April to December 2024 were retrospectively included in this single-center series. Unique intraoperative imaging findings were evaluated (intraoperative contrast leakage [IOCL], blood product in the surgical cavity, residual high T2 signal in the spinal cord, and suspicious nodular enhancement), and ioMR imaging quality was assessed on a Likert scale. Technical details were recorded for ioMR sequences.
Results or Findings: The average scanning time was 58.9 ± 8.7 minutes. Residual tumors were identified in eight patients (53.3%), and two patients (13.3%) underwent additional resection. IOCL was the most prevalent imaging finding, observed in 73.3%–80.0% of patients, with good interobserver agreement. The median imaging quality was acceptable (Likert scale = 3), as assessed by two reviewers, with thoracic spine images exhibiting the worst quality among all segments.
Conclusion: Total resection can be achieved in patients with intramedullary spinal cord tumors under the assistance of ioMR. Radiologists should note unique imaging findings that have been previously identified, with particular attention given to IOCL, to correctly interpret intraoperative spine MRI.
Limitations: First, the relatively small number of patients with heterogeneous tumor pathology and surgical goals may render our experiences non-generalizable experience to all patients undergoing intramedullary tumor resection. Second, the average ioMR scan time was approximately 1 hour, and this time increased with patient transfer. Whether the benefits of ioMR for surgical outcomes justify the longer operating time and greater resources expended should be examined in further studies.

CoMPaSS-NMD: Unlocking genotype-phenotype associations in neuromuscular disorders on MRI with machine learning (6 min)

Lukasz Piorecki; Rybnik / Poland

Author Block: L. Piorecki[1], M. Socha[1], J. Verdú-Díaz[2], J. Diaz-Manera[2], V. Straub[2], R. Tupler[3], J. Polanska[1]; [1]Poland/PL, [2]Newcastle/UK, [3]Modena/IT

Purpose: Neuromuscular disorders (NMDs) are genetically heterogeneous and often display subtle, visually indistinct MRI patterns. Automated stratification and classification may facilitate diagnosis, enable patient grouping, and enhance understanding of genotype–phenotype associations in NMD.

Methods or Background: The original dataset consisted of 1,351 T1-weighted MRI scans of the lower limbs from 616 patients with 9 different genetically confirmed neuromuscular disorders, collected within the MYO-GUIDE project between 2023 and 2025. The dataset was cleaned, and the MRI scans were preprocessed by removing skin, subcutaneous tissue and osseous structures. The thigh region in the MR volumes was found by referencing the femur. After cleaning, the data were partitioned into training, validation, and hold-out subsets, containing 139, 47, and 51 scans, respectively, with multiple timepoints of the same patient assigned exclusively to one subset. Three feature extraction approaches were investigated: two based on radiomic descriptors and one employing a convolutional autoencoder. Feature dimensionality was reduced using Boruta and CellBRF selection algorithms. Classifier optimization was performed using four-fold cross-validation with a grid search across Logistic Regression (LR), Decision Tree (DT), Random Forest (RF), and Support Vector Machine (SVM) models, as well as their parameters, for each feature selection method. The best classifier was chosen based on the weighted AUC.

Results or Findings: For radiomic descriptors, Boruta outperformed CellBRF, whereas CellBRF performed better for autoencoder-derived features with higher dimensionality. The highest classification metrics were achieved for radiomics per pie slice feature space, reduced by Boruta and LR as the classifier. Achieving a weighted AUC metric of 0.87 and 0.90 for the validation and holdout subsets, respectively.

Conclusion: This approach suggests the potential of MRI-based automation to support differential diagnosis in neuromuscular disorders and contribute to the development of imaging biomarkers.

Limitations: Not applicable.

Funding for this study: This work was financed by CoMPaSS-NMD, Computational Models for new Patients Stratification Strategies of Neuromuscular Disorders, HORIZON RIA, Tools and Technologies for Healthy Society, ID: GAP-101080874

Imaging of focal renal lesions: what do I need to know? (15 min)
Iztok Caglič; London / United Kingdom

1. To learn practical tips and tricks for evaluating focal renal lesions with conventional imaging.
2. To appreciate the added value of multiparametric MRI (mpMRI) in the assessment of renal masses.
3. To understand how to create actionable and structured reports, and their impact on clinical decision-making and patient management.

Characterisation of adnexal masses: the good, the bad and the ugly (15 min)
Rosemarie Forstner; Salzburg / Austria

1. To learn imaging findings to discriminate between benign and malignant adnexal lesions.
2. To appreciate the added value of MRI complementary to US.
3. To understand the role of imaging in treatment planning.

Prostate MRI made easy: a practical guide for the beginners (15 min)
Luca Russo; Rome / Italy

1. To learn how to interpret prostate MRI using PI-RADS, while recognising and avoiding common pitfalls.
2. To appreciate the role of MRI in the detection, localisation and staging of prostate cancer, and its impact on clinical decision-making.
3. To understand the critical importance of image quality in ensuring accurate interpretation and diagnosis.

Panel discussion: Pearls and pitfalls in GU imaging: how to write an actionable report? (10 min)

EDiR 12 - EDiR in the spotlight: shining a light on emergency radiology cases. Win an EDiR examination place!

EDiR simulation (50 min)
Laura Oleaga Zufiria; Barcelona / Spain
Ana Blanco Barrio; Murcia / Spain

1. To engage in an immersive EDiR experience featuring multiple response questions, short cases, and clinically oriented reasoning evaluation (CORE). Cases are tailored to emergency radiology, mirroring the format of an actual exam.
2. To analyse and solve both theoretical and hands-on cases.
3. To familiarise yourself with the clue patterns embedded in EDiR questions to enhance your ability to answer effectively.
4. To explore and tackle the most challenging cases presented in this simulation, gaining valuable insights into complex diagnostic scenarios.
5. To master emergency radiology fundamentals and deepen your understanding of the subspecialty.
6. To learn about the key educational tools tailored for EDiR preparation and optimise your study approach to ensure success.
*Please note that there can only be one winner per session.

Pooling of conclusions and perceptions (5 min)
Laura Oleaga Zufiria; Barcelona / Spain
Ana Blanco Barrio; Murcia / Spain

1. To jointly summarise and review what we have learned at today's session.

EIBALL 12 - Quantitative imaging in metabolic dysfunction-associated steatohepatitis (MASH)

Categories: Abdominal Viscera
ETC Level: LEVEL III
Date: March 6, 2026 | 08:00 - 09:00 CET

Quantitative imaging biomarkers in MASH: from concept to clinical criteria (15 min)
Richard Ehman; Rochester / United States

1. To learn the principles behind quantitative imaging biomarkers and their potential role in assessing MASH.
2. To appreciate how imaging biomarkers can support diagnostic confidence and clinical decision-making in MASH.
3. To understand the criteria and challenges for validating imaging biomarkers as surrogate endpoints in clinical trials and routine care.

Monitoring MASH progression and treatment response with quantitative imaging (15 min)
Lukas Müller; Mainz / Germany

1. To learn about imaging techniques currently used to quantify liver fat, inflammation, and fibrosis in MASH.
2. To appreciate the strengths and limitations of quantitative imaging for monitoring disease evolution and therapeutic response.
3. To understand how imaging biomarkers can complement or replace biopsy in longitudinal assessment of MASH.

Quality, standardisation, and best practices in quantitative ultrasound imaging for MASH (15 min)
Giovanna Ferraioli; Pavia / Italy

1. To learn the importance of quality assurance and quality control (QA/QC) in quantitative liver imaging.
2. To appreciate the parallels between standardisation in imaging and laboratory-based diagnostics.
3. To understand current initiatives and frameworks for ensuring reproducibility and cross-centre consistency in quantitative imaging measurements.

Panel discussion: What are the barriers to implementing quantitative imaging in MASH? (10 min)

ESR/EFSUMB - The practical value of ultrasound in emergency

Categories: Musculoskeletal, General Radiology, Emergency Imaging, Paediatric, Interventional Radiology

ETC Level: LEVEL II+III

Date: March 6, 2026 | 08:00 - 09:00 CET

High-relaxivity gadolinium-based contrast agents: when do these add value? (19 min)
Giles Hannibal Roditi; Glasgow / United Kingdom

1. To learn about currently available high-relaxivity GBCA.
2. To appreciate the benefits of HR-GBCA in daily practice.
3. To understand the indications for which there is added value.

Short-chain fatty acid metabolism (FPIA) PET imaging: bench to bedside (19 min)
Eric Aboagye; London / United Kingdom

1. To learn the development of short-chain fatty acid [18F]fluoropivalate (FPIA) PET imaging.
2. To appreciate the clinical potential for FPIA imaging of brain tumours (gliomas and metastatic tumours).
3. To understand future prospects for FPIA imaging and image-guided therapy (theranostics).

Seeing beyond structure: the clinical potential of metabolic MRI (19 min)
Christoffer Laustsen; Aarhus / Denmark

1. To learn about metabolic MRI techniques, including hyperpolarised ^{13}C MRI and deuterium metabolic imaging (DMI) and their potential applications in oncology, neurology, and other areas.
2. To appreciate the technical challenges in translating metabolic MRI from research into routine clinical use, including data acquisition, post-processing, and interpretation.
3. To understand the current clinical evidence supporting metabolic MRI, its advantages over conventional imaging methods.

ESR EDI 12 - Cognitive biases: see them, name them, fight them

Categories: Professional Issues, Management/Leadership

Plain radiographs in the emergencies (25 min)
Mario P Padron; Madrid / Spain

1. To learn the injury mechanism and radiologic findings in acute elbow and wrist injuries.
2. To appreciate how to face the diagnosis and management of fractures and dislocations of the forearm with a plain film.
3. To understand the radiologist's role in the decision-making vs follow-up with other imaging modalities.

MRI of overuse injuries (25 min)
Reto Sutter; Zürich / Switzerland

1. To understand the elbow and wrist anatomical structures relevant to overuse injuries.
2. To recognise common overuse injuries of the elbow and wrist in sports.
3. To describe MRI findings of overuse injuries of the elbow and wrist bones, tendons and ligaments.

Panel discussion (5 min)

E³ 1226 - Long axial field of view (LAFOV) PET: fast and furious advances in molecular imaging technology and their clinical impact

Categories: Hybrid Imaging, Imaging Methods, Physics in Medical Imaging, Molecular Imaging, Nuclear Medicine

ETC Level: LEVEL II+III

Date: March 6, 2026 | 08:00 - 09:00 CET

CME Credits: 1

Long axial field of view (LAFOV) PET/CT is redefining imaging by combining ultrafast whole-body capture with high precision through innovation in detector sensitivity, axial resolution, and real-time data processing. This enables unprecedented imaging accuracy and diagnostic speed. Patient-friendly protocols are feasible in high-throughput clinical settings, reducing imaging time without a compromise in diagnostic quality. Novel opportunities, ranging from ultra-short dynamic imaging studies to same-day multi-tracer imaging, are designed to enhance diagnostic insight and operational efficiency, and may be potentially applied in future in everyday practice for comprehensive and rapid patient assessments.

Breast pain: is there a role for imaging? (15 min)
Matthew G. Wallis; Cambridge / United Kingdom

1. To discuss the rationale for imaging in breast pain.
2. To review the performance of imaging modalities in breast pain.
3. To understand the evidence-based guidance for evaluating the role of imaging in breast pain and review strategies for managing women with breast pain.

Imaging in the pregnant and breastfeeding patient: what do I do? (15 min)
Alexandra Athanasiou; Athens / Greece

1. To identify the safest and most effective imaging modalities during pregnancy and breastfeeding.
2. To review guidance for screening high-risk women during pregnancy and lactation.
3. To recognise the most common benign conditions and to distinguish them from pregnancy-related breast cancer.

How to navigate radiological/pathological discordance (15 min)
Isabelle Thomassin-Naggara; Paris / France

1. To recognise the causes of radiological/pathological discordance.
2. To understand the impact of discordance on patient outcomes.
3. To determine appropriate actions in radiologic/pathologic discordance cases, ensuring timely and accurate diagnosis while minimising unnecessary procedures.

Panel discussion: The diagnostic dilemma: navigating uncertainties in symptomatic breast cases (10 min)

RC 1203 - Approaching the aorta as an organ

Categories: Imaging Methods, Contrast Media, Vascular, Cardiac
ETC Level: LEVEL I+II
Date: March 6, 2026 | 08:00 - 09:00 CET
CME Credits: 1

Moderator:

Chairperson's introduction (5 min)
Hatem Alkadhi; Zürich / Switzerland

Standardised aortic imaging and assessment (15 min)
Nicola Galea; Rome / Italy

1. To describe appropriate approaches for aortic imaging.
2. To describe standardised post-processing and measurement approaches.
3. To describe methods to minimise inter-reader & inter-study variability.

Reporting and communication of aortic imaging (15 min)
Diana Litmanovich; Boston / United States

1. To describe the key aspects of every aortic imaging report.
2. To understand key elements of reports impacting patient management.
3. To know when and how to escalate report communication.

Heredetary aortopathies and postoperative changes (15 min)
Sara Boccalini; Rouen / France

1. To understand imaging approaches specific to the underlying aortopathy.
2. To learn and understand predictive findings in hereditary aortopathies.
3. To understand key elements of post-therapeutic imaging in continued surveillance.

Panel discussion: How to implement current guidelines on aortic imaging in clinical practice (10 min)

RC 1204 - Masterclass in assessing treatment response in lung cancer therapy

Categories: Oncologic Imaging, Chest, President's Choice
ETC Level: LEVEL II
Date: March 6, 2026 | 08:00 - 09:00 CET

Chairperson's introduction (6 min)
Dorith Shaham; Jerusalem / Israel

Assessment of recurrence patterns post lung cancer surgery (18 min)
Darragh Halpenny; Dublin / Ireland

1. To show the normal appearance after lung cancer surgery.
2. To present the frequency and recurrence patterns after lung cancer surgery.

Imaging after radiation therapy of lung cancer: a guide for radiologists (18 min)
Anna Rita Larici; Rome / Italy

1. To show the normal findings after radiation therapy.
2. To describe delayed complications of radiation therapy.
3. To give the clues to diagnose recurrence after radiation therapy.

Response assessment post immunotherapy for non-small cell lung cancer (18 min)
Anna Sharman; Cheshire / United Kingdom

1. To review the response criteria in lung cancer treated with immunotherapy.
2. To describe the limitations in assessing response after immunotherapy.

RC 1208 - Structured approach to skull base and temporal bone imaging

Categories: Neuro, Head and Neck
ETC Level: ALL LEVELS
Date: March 6, 2026 | 08:00 - 09:00 CET

Chairperson's introduction (5 min)
Timothy Beale; London / United Kingdom

A structured approach and report of the temporal bone CT (15 min)
Riste Saat; Tallinn / Estonia

1. To understand the complex anatomy of the temporal bone and its key structures visible on CT and learn a systematic, structured method to evaluate temporal bone CT images, starting with axial and coronal planes and including evaluation of pneumatisation, middle and inner ear structures, and critical neurovascular canals.
2. To recognise common surgically relevant anatomical variants on CT imaging.
3. To develop skills for clear, comprehensive CT reporting in different clinical settings.

Imaging of the post-operative skull base (15 min)
Davide Farina; Brescia / Italy

1. To understand the typical postoperative imaging appearances of skull base reconstructions following various surgical approaches, including open and endoscopic techniques.
2. To identify and distinguish normal reconstructive tissues from recurrent or residual neoplastic disease on CT and MRI.
3. To recognise common postoperative complications such as infection, haemorrhage, and graft-related changes, and understand their imaging characteristics.
4. To gain practical knowledge of interpreting altered anatomy after skull base surgery to optimise patient follow-up and management.

Imaging of pulsatile tinnitus (15 min)
Steve Connor; London / United Kingdom

1. To understand the pathophysiology and clinical significance of pulsatile tinnitus and its relationship to vascular and temporal bone abnormalities.
2. To learn the imaging modalities and protocols best suited for evaluating patients with pulsatile tinnitus, emphasising CT and MRI techniques.
3. To identify common and less common causes of pulsatile tinnitus on imaging.
4. To develop a systematic approach to image interpretation to guide diagnosis and clinical management of pulsatile tinnitus.

Panel discussion: Tips and pitfalls in skull base and temporal bone imaging. What I wish someone had told me (10 min)

RC 1212 - Imaging complications of prematurity: bronchopulmonary dysplasia (BPD), intraventricular haemorrhage (IVH) and periventricular leukomalacia (PVL), necrotising enterocolitis (NEC)

Spyridon Prountzos; Athens / Greece

Chairperson's introduction (5 min)
Spyridon Prountzos; Athens / Greece

Lungs bronchopulmonary dysplasia (BPD) (15 min)
Alistair D Calder; London / United Kingdom

1. To describe and understand the pathophysiology of BPD.
2. To list the imaging patterns of BPD development.
3. To discuss the role of different imaging techniques in BPD.

Cerebral IVH, PVL (15 min)
Vasileios G Xydis; Ioannina / Greece

1. To learn about the mechanisms of injury in IVH and PVL.
2. To describe how IVH and PVL can be diagnosed in neonates and young children.
3. To show how accurate detection and staging are clinically relevant.

Abdominal complications (15 min)
Damjana Ključevšek; Ljubljana / Slovenia

1. To illustrate the radiological signs, with emphasis on radiographs and ultrasound.
2. To list the most common complications of prematurity in the abdomen.
3. To show examples of imaging findings important for clinical management.

Panel discussion: How can imaging guide clinical management? (10 min)

RC 1214 - Ethics and integrity in radiography: urgent questions for contemporary practice

Back to the basics in radiography ethics (10 min)
Szilvia Anett Nagy; Pecs / Hungary

1. To define the core ethical principles (autonomy, beneficence, non-maleficence, and justice) as they apply to radiographic practice.
2. To recognise common ethical dilemmas in radiography and identify appropriate professional responses.
3. To reinforce the importance of patient consent, confidentiality, and professional integrity in daily imaging procedures.

Demands versus ethics: impacts of pressure on radiographers' clinical work (10 min)
Yvonne Susan Thackray; Chelmsford / United Kingdom

1. To recognise how time and workload pressures can challenge ethical decision-making in radiography practice.
2. To identify common ethical dilemmas radiographers face when balancing efficiency with patient-centred care.
3. To explore practical strategies to uphold ethical standards under clinical and organisational pressures.

The impact of generative AI on our evidence-base (10 min)
Jonathan Mcnulty; Dublin / Ireland

1. To understand how generative AI tools are influencing the creation, interpretation, and dissemination of clinical evidence.
2. To identify potential risks to evidence integrity, including misinformation, bias, and lack of transparency in AI-generated content.
3. To explore strategies for critically appraising AI-influenced sources to maintain a trustworthy and ethical evidence base.

Quo vadis on ethics in radiography education, practice and research (10 min)
Graciano Paulo; Coimbra / Portugal

1. To identify key ethical principles in radiography by recognising and understanding patient confidentiality, informed consent, and professional integrity
2. To evaluate the ethical challenges in radiography education and practice, analysing real-world ethical dilemmas such as balancing patient care with technological advancements.
3. To discuss the future of ethics in radiography research: explore emerging ethical issues in radiography research, such as the use of AI and data privacy.

Panel discussion: Pushing harder ethics in all domains of radiography (15 min)

RPS 1201 - Technical advances in abdominal imaging

Enhancing Image Quality and Diagnostic Confidence through AI-Based Spectral Reconstruction in Abdominal Imaging (6 min)
Lina Hieronymi; Cologne / Germany

Author Block: L. Hieronymi[1], J. Lueckel[1], S. Skornitzke[2], N. Große Hokamp[1], D. Maintz[1]; [1]Cologne/DE, [2]Hamburg/DE
Purpose: To evaluate a prototype deep learning–based spectral reconstruction algorithm (SAI, Philips) for spectral detector dual-energy CT (sdDECT) in abdominal imaging. The algorithm aims to reduce image noise while preserving texture in both conventional and virtual monoenergetic images (VMI), addressing known limitations of low-keV VMI.
Methods or Background: This retrospective study included 67 patients undergoing contrast-enhanced abdominal sdDECT. Conventional images were reconstructed with hybrid-iterative (HI-R) and spectral algorithm (SAI-R). VMI (40–200keV) were generated accordingly (HI-VMI, SAI-VMI). Quantitative analysis involved 22 ROIs in the liver, pancreas, spleen, kidneys, psoas muscle, and fat. Signal-to-noise and contrast-to-noise ratios (SNR/CNR) were calculated. Two blinded radiologists compared randomized, patient-matched images (HI-R/VMI vs. SAI-R/VMI, 40–70keV) across liver, pancreas, and kidney, rating image quality, noise, texture, lesion conspicuity, and diagnostic confidence using a two-alternative forced choice design. Statistical analysis was performed with ANOVA and Tukey's post hoc test.
Results or Findings: Attenuation was higher in low-keV VMI (40–60keV) compared to conventional reconstructions ($p \leq 0.05$). Noise increased with decreasing keV, with SAI-VMI showing lower noise than HI-VMI at all levels (e.g., muscle at 40keV: 14.39±4.88HU vs. 16.15±4.90HU; $p \leq 0.05$). Importantly, SAI-VMI demonstrated lower noise at low-keV compared to HI-VMI at higher keV, highlighting superior noise performance at lower energy levels (e.g., liver: SAI at 40keV 12.17±3.71HU vs. HI at 60keV 13.10±3.34HU; $p \leq 0.05$). SNR and CNR were significantly higher with SAI-R and SAI-VMI, particularly at low-keV (e.g. liver CNR at 40 keV: SAI-VMI 8.18±2.67 vs. HI-VMI 7.15±2.41; $p \leq 0.05$). Reader preference strongly favored SAI-R/VMI (averaged: HI-R 0.83%±1.31% vs. SAI-R 31.67%±4.97%; $p \leq 0.05$). SAI-VMI at 40keV was preferred over all other reconstructions (97.92%±2.36%, $p \leq 0.05$).
Conclusion: AI-based spectral reconstruction improves abdominal sdDECT by reducing noise and enhancing SNR/CNR, while further increasing diagnostic benefits of VMI.
Limitations: The study is limited by its retrospective design.
Funding for this study: This work was funded by Philips Healthcare. The funding source had no involvement in study design, collection or interpretation of data.

Improved visualization of pancreas and tumor boundaries using high-frequency kernels with deep-learning image reconstruction at high-strength level (6 min)
Nobuyuki Kawai; Gifu / Japan

Author Block: N. Kawai, Y. Noda, T. Kaga, K. Matsuoka, S. OMATA, Y. Takai, M. Asano, H. Kato, M. Matsuo; Gifu/JP
Purpose: The combination of high-frequency reconstruction kernels and deep-learning image reconstruction (DLIR) may enhance structure edges while maintaining image quality in abdominal CT. This study aimed to investigate the feasibility of combining high-frequency reconstruction kernels and DLIR at high-strength level (DLIR-H) for improving visualization of the pancreas and tumor boundaries on pancreatic protocol CT.
Methods or Background: This retrospective study included 30 patients (median age, 75 years; 16 women; median body mass index, 22 kg/m²) who underwent pancreatic protocol CT for assessing pancreatic tumors from January 2024 to July 2024. Four image sets were reconstructed using DLIR-H in combination with either standard, bone, bone-plus, or lung kernels. Edge sharpness between the pancreas and retroperitoneal fat tissue (pancreas-to-fat) and between the pancreas and pancreatic ductal adenocarcinoma (pancreas-to-PDAC) was quantitatively assessed using edge rise slope (ERS) measurements. Two radiologists qualitatively examined the sharpness of the pancreas, tumor boundary, and overall image quality.
Results or Findings: Pancreas-to-fat ERS was greater in lung kernel images than in standard and bone kernel images ($P = 0.001$). Pancreas-to-PDAC ERS was greater in lung kernel images than in other kernel images ($P < 0.001$). Sharpness of the pancreas and tumor boundaries was better in lung kernel images than in other kernel images ($P < 0.001$ for both). Overall image quality in lung kernel images was comparable to the standard and superior to the bone kernel ($P < 0.001$).
Conclusion: The combination of lung kernel and DLIR-H in pancreatic protocol CT improves both quantitative and qualitative sharpness of the pancreas and tumor boundaries while maintaining the overall image quality.
Limitations: Limitations include small sample size, lower body mass index than Western populations, no diagnostic performance assessment, and restriction to one vendor and DLIR-H.
Funding for this study: No funding was received for this study.

Assessing Technical Performance of 3T Spin-Echo EPI Liver MR Elastography: Insights from a Large Tertiary Cohort (6 min)

Ahmet Yasin Yitik; Vienna / Austria

Author Block: A. Y. Yitik, R. Ambros, S. Ba-Ssalamah, S. Pötter-Lang, N. Bastati-Huber, A. Kristic, V. Vetchy, U. I. Attenberger, A. Ba-Ssalamah; Vienna/AT
Purpose: To evaluate determinants of technical failure of 3T liver MR elastography (MRE) using a 2D spin-echo EPI sequence in a large tertiary cohort.
Methods or Background: This retrospective study included 2,731 consecutive patients (mean age 55 ± 6 years; 52% male) who underwent 3T MRE between January 2020 and December 2023. Exams were performed with a 2D spin-echo EPI sequence. Two radiologists independently analyzed MRE and anatomic images. Liver iron concentration (LIC) and proton density fat fraction (PDFF) were measured on a 3D multi-echo GRE sequence. Technical failure was defined as the absence of pixels with >95% confidence index and/or lack of visible shear waves. Logistic regression was used to identify predictors of failure.
Results or Findings: The overall failure rate was 8% (205/2,731). On univariate analysis, higher body mass index (BMI), liver iron deposition, massive ascites, T1-mapping values, MELD, APRI, and ALBI scores were significantly associated with failure (all $p < 0.05$). Age, sex, PDFF, and FIB-4 were not. Multivariable analysis identified BMI, liver iron deposition, and massive ascites as independent predictors. R2* demonstrated fair accuracy for predicting failure (AUC = 0.783, 95% CI: 0.694–0.872, $p < 0.001$) with an optimal threshold of ≥171 s^{-1} at 3T.
Conclusion: The technical failure rate of 3T MRE using 2D spin-echo EPI was 8%. Massive ascites, iron overload, and elevated BMI were independent predictors of unsuccessful exams. Identifying these risk factors may guide patient selection and optimize MRE performance in clinical practice.
Limitations: This single-center retrospective study using 3T 2D SE-EPI MRE is subject to design and selection bias.

Utility of slice selection gradient reversal and multi-shot echo planar imaging in rectal DWI at 3 tesla (6 min)

Nobuyuki Kawai; Gifu / Japan

Author Block: N. Kawai[1], Y. Noda[1], T. Kaga[1], Y. Ueda[2], M. Yoneyama[2], M. Asano[1], S. Ido[1], K. Kajita[1], M. Matsuo[1]; [1]Gifu/JP, [2]Tokyo/JP
Purpose: This study aimed to evaluate whether slice selection gradient reversal (SSGR) and multi-shot EPI (ms-EPI) could improve image quality compared with conventional single-shot EPI (ss-EPI) with spectral attenuated inversion recovery (SPAIR) in rectal DWI.
Methods or Background: This prospective study included 24 participants (median age, 70 years; 16 men) who underwent rectal MRI at 3T between March and August 2025. DWI was acquired using three sequences: ss-EPI with SPAIR, ss-EPI with SSGR, and ms-EPI with SSGR (two shots). Acquisition time was equalized by adjusting the number of signal averages (NSA; 8 for ss-EPI and 4 for ms-EPI). Two radiologists qualitatively assessed sharpness, distortion, artifact, lesion conspicuity, and overall image quality using a four-point Likert scale. Quantitative analysis included signal-to-noise ratio (SNR), signal intensity ratio (SIR), and apparent diffusion coefficient (ADC) value for rectal cancer.
Results or Findings: Rectal cancer was confirmed in 18 participants (75%). Sharpness, lesion conspicuity, and overall image quality were significantly better in the order of ms-EPI with SSGR, ss-EPI with SSGR, and ss-EPI with SPAIR images ($P < 0.001$ for all). Distortion and artifact were significantly reduced in ms-EPI with SSGR than in the other two images ($P < 0.001$ for both). SNR was higher in ss-EPI with SSGR than the other two images ($P < 0.001$). SIR was significantly higher in the order of ms-EPI with SSGR, ss-EPI with SSGR, and ss-EPI with SPAIR ($P < 0.001$). No significant differences were observed in ADC value ($P = 0.84$).
Conclusion: SSGR improved image quality compared with SPAIR. With equal acquisition times, ms-EPI showed lower SNR but was superior in reducing distortion and artifacts.
Limitations: Small sample size, use of a single-vendor 3T system, and adjustment of NSA to equalize scan time.
Funding for this study: No funding was received for this study.

Contrast economy without diagnostic compromise: hospital-scale savings from a simple 1.0 mL/kg, low-kVp abdominal CT protocol (6 min)

Daniel Yamada; Campinas / Brazil

Author Block: J. T. d. S. d. Castro, H. d. J. Ferreira, D. C. Novais da Silva, D. Yamada, S. San Juan Dertkigil, F. Reis; Campinas - Sao Paulo/BR
Purpose: Reducing iodine dose while maintaining diagnostic enhancement is crucial for patient safety, cost control, and environmental responsibility. The purpose was to quantify the per-patient and cohort-level contrast/iodine savings achieved after implementing a simple weight-based dosing table (1.0 mL/kg) aligned with low tube potential (80–100 kVp), compared with a conventional fixed-dose protocol.
Methods or Background: This was a single-center, real-world cohort study (pre/post implementation) analyzing 562 consecutive multiphasic abdominal CTs. Groups were: Conventional (pre-implementation, fixed dose) and three weight tiers in the post-implementation phase: G1 (≤90 kg @ 80 kVp), G2 (~91–120 kg @ 100 kVp), and G3 (≥120 kg, exploratory). A counterfactual baseline contrast volume was estimated for each post-implementation patient based on the Conventional group's median mL/kg for that weight band. Per-patient saving was calculated as baseline minus observed volume. Total cohort saving (L) and enhancement results (from Poster 1) were the primary outcomes.
Results or Findings: The new protocol delivered meaningful contrast savings across all groups: G1 (≤90 kg, n=232): Achieved the highest per-patient savings (mean 24.9 mL; median 27.2 mL). G2 (~91–120 kg, n=38): Showed modest but clear savings (mean 5.6 mL; median 6.4 mL). Total Savings: The cohort yielded a total saving of 7.40 L (G1) and 0.27 L (G2) within the dataset. Crucially, these substantial volume reductions co-occurred with higher proportions of exams meeting target portal enhancement (110–130 HU) and IRHR≥50 HU, indicating no diagnostic compromise.
Conclusion: A pragmatic 1.0 mL/kg weight-based dosing table integrated with 80–100 kVp delivers significant iodine/contrast savings at scale while successfully sustaining or improving diagnostic enhancement targets. This approach supports cost stewardship and environmental responsibility alongside demonstrable quality gains.
Limitations: Single-center, pre/post implementation cohort study, limiting the generalizability of specific savings figures to other institutions or protocols.
Funding for this study: Not applicable.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The work has been submitted to the university's Research Ethics Committee (CEP) and is currently under review for evaluation and final opinion.

Impact of monoenergetic imaging with second-generation dual-layer spectral CT on abdominal contrast enhancement and iodine dose reduction (6 min)

Asia Ciprani; Roma / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: A. Ciprani, T. Polidori, G. Tremamunno, D. De Santis, F. Virgili, F. Pacelli, M. Zerunian, D. Caruso, M. Francone; Roma/IT
Purpose: To evaluate and compare the effect on quantitative image quality of two different contrast medium (CM) injection protocols using conventional and virtual monoenergetic imaging (VMI) at 50keV.
Methods or Background: In this retrospective study, Group A (n=30) underwent abdominal CT with 700mgI/kg of CM based on lean body weight (LBW) using conventional images, while Group B (n=30) received 500mgI/kg of CM using spectral derived images at 50keV. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were measured in the liver, spleen, kidneys, pancreas, aorta, and portal vein during arterial and portal phases. Comparisons were performed with the Wilcoxon signed-rank test and Bonferroni correction, and effect sizes (Cohen's d) were calculated.
Results or Findings: Despite the lower iodine dose, Group B showed higher image quality. In the arterial phase, pancreatic SNR increased from 25.4 to 40.7 (+60%) and aortic SNR from 18.2 to 46.0 (+153%, $p<0.001$). Pancreatic CNR increased from 15.1 to 24.2 (+60%) and aortic CNR from 20.5 to 52.1 (+154%, $p<0.001$). In the portal venous phase, liver SNR increased from 28.6 to 48.0 (+68%) and portal vein SNR from 22.4 to 38.5 (+72%), with CNR showing the same trend (all $p<0.001$). Although spectral reconstructions had slightly higher noise (8.3 vs. 7.5 HU, $p<0.05$), the overall increase in SNR and CNR was substantial. Effect size analysis confirmed these differences, with Cohen's d >0.8 for most structures and >1.2 for aortic and hepatic measurements.
Conclusion: VMI at 50keV showed higher SNR and CNR than conventional reconstructions, despite lower iodine dose. Improvements were consistent in both arterial and portal phases, indicating that low-keV VMI enables iodine reduction without compromising image quality, with potential benefits for safety and diagnostic confidence.
Limitations: Single-center study with small sample size and no clinical impact assessment.
Funding for this study: None

Utility of 40 keV Virtual Monoenergetic Reconstructions in Preoperative Staging of Pancreatic Ductal Adenocarcinoma (6 min)

Nóra Éva Balogh; Budapest / Hungary

Author Block: N. É. Balogh, B. K. Budai, A. I. Vigh, E. Tóth, Á. Szücs, A. Szijártó, P. Maurovich Horvat, I. Dudás; Budapest/HU
Purpose: We aimed to evaluate whether 40 keV virtual monoenergetic image (VMI) reconstructions from photon-counting detector CT (PCD-CT) offer improved diagnostic utility over standard 70 keV in preoperative assessment of pancreatic ductal adenocarcinoma (PDAC).
Methods or Background: Three-phase contrast-enhanced PCD-CT scans (arterial, portal, and venous) were analyzed in 50 patients with histologically confirmed PDAC. Lesion diameters, image quality, and diagnostic confidence (1–5 scale) were assessed at both 40 and 70 keV. Morphologic and staging features were compared; moreover, one radiologist rated whether 40 keV reconstructions aided interpretation.
Results or Findings: Lesion diameters did not differ significantly between 40 and 70 keV, though isolated cases showed discrepancies up to 18 mm. Image quality and diagnostic confidence were significantly higher at 40 keV across all phases ($p < 0.001$). Morphologic and staging features were highly consistent, with T-stage altered in only three patients. Subjective assessment indicated that 40 keV reconstructions were helpful in 86% of cases. The portal venous phase was perceived as the most beneficial, with 40 keV aiding interpretation in 37/50 (74%) patients, followed by the venous phase in 36/50 (72%) and the arterial phase in 21/50 (42%). In 16/50 (32%) patients, the reconstructions were helpful across all three phases, and in an additional 19/50 (38%) patients, in two phases.
Conclusion: 40 keV VMI reconstructions significantly improve subjective image quality and diagnostic confidence in PDAC imaging, without compromising objective lesion measurements or staging interpretation. Occasional large differences in tumor size and consistently positive subjective feedback support the clinical utility of 40 keV, particularly in the portal venous phase, highlighting its value in preoperative staging and surgical planning.
Limitations: This was a single-center study with a retrospective study design.
Funding for this study: No funding was received for this study.

Automated CT-Based Liver Volumetry for Donor Weight Estimation: A Retrospective Study of 103 Cases (6 min)

Francesco Minonne; Turin / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: F. Minonne, A. P. Micheletti, F. Giorgino, G. De Santis, S. Tibaldi, M. Moretti, R. Aroasio, M. Gatti, R. Faletti; Turin/IT
Purpose: Accurate preoperative estimation of donor liver weight is a critical step in optimizing organ allocation and surgical planning for liver transplantation. This study evaluated the feasibility of automated computed tomography (CT)–based volumetric analysis to predict liver weight and its correlation with clinical parameters.
Methods or Background: We conducted a retrospective, single-center observational study at the Città della Salute e della Scienza di Torino, including 103 deceased donors between 2014 and 2025 (age range: 13–84 years). Each subject underwent abdominal CT close to organ procurement for orthotopic liver transplantation (OLT). Donors were stratified into two groups according to imaging protocol: non-contrast CT and contrast-enhanced CT. Each group was further split into a training cohort, used to refine weight estimation algorithms, and a validation cohort, designed to test predictive accuracy.
Results or Findings: Liver segmentation was performed using the open-source software TotalSegmentator. Mean processing time was under two minutes per scan. Across both imaging groups, predicted liver weight closely approximated actual graft weight at explant, with a mean absolute error of ±0.14 kg, corresponding to about 9% of the true value. This degree of precision was consistent between non-contrast and contrast-enhanced acquisitions.
Conclusion: These findings support the feasibility of fully automated, convolutional neural network–based approaches for liver volumetry in transplantation. The proposed workflow demonstrated speed, reproducibility, and satisfactory accuracy. By reducing the time and variability associated with manual volumetric assessments, this method could improve efficiency in clinical practice and enhance the reliability of preoperative planning in liver transplantation.

When Experts Disagree: Using AI to optimize splenic volumetry (6 min)

Ekaterina Petrash; Moscow / Russia

Author Block: E. Petrash, K. Poliakov, M. Basova, M. Dugova, R. Gareeva, A. Zakharov, V. Gombolevskiy; Moscow/RU
Purpose: Splenic volumetry is important for splenomegaly detection. The aim is to assess agreement and robustness of spleen volume estimation methods on CT. Manual linear measurements used for volume estimation may be slice- and reader-dependent, whereas AI segmentation is expected to provide reproducible, protocol-independent volumes once the software version is fixed.
Methods or Background: Experienced radiologists independently measured craniocaudal length (L), maximal diameter (D), and thickness (T) on abdominal CT and computed volumes via the formula V =30+0.58× L×D×T. The same scans were processed by a CNN-based tool Spleen-IRA which automatically extracted dimensions and volumes. Algorithm-generated masks were validated by two radiologists with more than 12 years experience, disagreements were reviewed to ensure quality. Verified AI measurements were designated as reference for splenic volume.
Results or Findings: Statistical tests demonstrated significant differences between readers and between reader-derived and AI-derived spleen volumes ($p < 10^{-7}$), underscoring the variability of manual measurements compared to the reproducibility of AI-based volumetry.
Conclusion: Manual spleen volumetry is time-consuming and inter-reader variable. Moreover, the observed expert disagreement suggests that the linear-measurement methodology itself is imperfect (landmarking and slice-selection dependent). AI segmentation delivers reader-independent spleen volumes without geometric approximations. With fixed inference settings, AI outputs are consistent on identical inputs. We therefore recommend AI segmentation as the reference method, and using the curated, quality-controlled mask dataset to audit legacy formulae and develop protocol-specific alternatives for settings where AI cannot be deployed.

Structured data extraction from non-English brain MRI reports improves with few-shot prompting of an open-weight large language model (6 min)

Kaouther Mouheb; Rotterdam / Netherlands

Author Block: K. Mouheb[1], A. Pomp[1], A. Manenti[2], H. Seelaar[1], F. Mattace-Raso[1], M. W. Vernooij[1], F. Wolters[1], S. Klein[1], E. Bron[1]; [1]Rotterdam/NL, [2]Toulouse/FR
Purpose: Automatic data extraction from free-text radiology reports enables large-scale research, but current open-weight large language models (LLMs) may underperform because they lack domain knowledge. We evaluate whether few-shot prompting with annotated examples improves extraction from non-English neuroradiology reports.
Methods or Background: We analyzed 947 Dutch free-text brain MRI reports (2016-2021) from a memory clinic. Trained medical students annotated 24 variables. We used the open-weight LLM LLaMA 3.1 to extract these variables. In zero-shot prompting, the model received only task instructions. In few-shot prompting, we provided three annotated examples selected using three strategies: random, fixed, and structural similarity-based selection. Performance was evaluated using overall accuracy, balanced accuracy for categorical, accuracy for numerical, and text similarity for free-text fields, averaged across 10 random train-test splits.
Results or Findings: The overall accuracy of LLaMA 3.1 obtained with few-shot prompting with similarity-based selection (89%, [CI: 87–90%]) was significantly higher than that obtained with zero-shot prompting (81%, [81–82%]). Similar improvements were seen with other selection strategies (random: 84%, [82–86%]; fixed: 86% [83–90%]). Notably, few-shot prompting with similarity-based selection showed significantly higher accuracies in extracting microbleed counts (92% [90-93%]) and infarct counts (81% [77-85%]) compared to zero-shot prompting (microbleeds: 80% [78-82%], infarcts: 66% [63-68%]). Visual rating scores were extracted accurately in both settings, with slight gains from similarity-based few-shot prompting (balanced accuracy: 95% [92–97%] for Fazekas score, 92% [79–100%] for MTA, and 89% [85–93%] for GCA). Performance remained lower on location-specific variables (e.g., 69% for occipital GCA with similarity-based selection).
Conclusion: LLaMA 3.1 accurately extracted 24 clinical variables from neuroradiology reports. Few-shot prompting significantly improved performance, especially with similarity-based selection.
Limitations: The limitations of the study are that it involves a single LLM, one imaging modality, and reports from one center written in Dutch.
Funding for this study: This study was co-funded by an Erasmus MC fellowship 2022. The study is part of TAP-dementia (www.tap-dementia.nl), receiving funding from ZonMw (#10510032120003) in the context of Onderzoeksprogramma Dementie, part of the Dutch National Dementia Strategy. This work was co-funded by Scan2go, a TKI-LSH funded public-private partnership (LSHM22046-H036). This work was co-funded by the European Union under Grant Agreement number 1011100633. Automated image quality assessment in shoulder MR arthrography using large language model-generated Python workflows (6 min)

Apostolos Petkoglou; Emmen / Netherlands

Author Block: A. Petkoglou[1], A. Vegter[1], T. Kwee[2], H. Stallmann[1]; [1]Stadskanaal/NL, [2]Groningen/NL
Purpose: To compare automated image sharpness measurements with manual signal and contrast to noise radio's (SNR, CNR) assessments and radiologist Likert scores in shoulder MR arthrography using saline versus gadolinium contrast.
Methods or Background: 40 patients aged 13-20 years underwent shoulder MRA between 2019-2024 on a 1.5T scanner. 20 received gadolinium (T1-weighted sequences), 20 received saline (T2-weighted sequences). Claude and Google Gemini generated Python code in Colab to convert DICOM to JPEG and perform automated sharpness measurements using variance of the Laplacian in 20 randomly placed 100×100 pixel squares centered around the joint. Manual measurements included normalized SNR/CNR from circular ROIs (1-2mm labrum, 2-5mm contrast, 10-12mm background air). Two musculoskeletal radiologists independently rated image quality using 5-point Likert scales, blinded to contrast type. Statistical analysis included Mann-Whitney U tests, Spearman correlations with FDR correction, and bootstrapped non-inferiority testing (δ=0.15).
Results or Findings: Automated sharpness showed plane-dependent differences: gadolinium sharper in axial view (whole image p=0.0006, random crops p=0.0056), saline sharper in coronal view (random crops p=0.0411). Pooled analysis showed no significant sharpness differences (p=0.1371, p=0.7765). Inter-rater agreement ranged from ICC=0.27-0.41 (single rater) to ICC=0.52-0.66 (average raters). Only supraspinatus tendon showed preference for saline by one radiologist (p=0.024). Diagnostic certainty correlated positively with normalized CNR across multiple comparisons (FDR-corrected p<0.05).
No significant differences in normalized SNR (p=0.870) or CNR (p=0.271) between contrast agents. Non-inferiority of saline confirmed via bootstrapping (95% CI within ±0.15 margin).
Conclusion: AI-generated automated workflows successfully quantified image quality metrics comparable to manual assessment. This approach enables hypothesis testing, upscaling to large datasets, and implementation in quality control and equipment procurement decisions with minimal programming expertise required.
Limitations: Single-center study with adolescent population may limit generalizability. Subjective assessments prone to inter-reader variability.
Funding for this study: We have applied for a grant from the Stichting De Cock -Hadders (research foundation).

Agentic AI framework for structured reporting (CAD-RADS) and grounding from unstructured CCTA reports (6 min)

Sinan Batman; United States

Author Block: A. G. D'Sa[1], N. Saini[1], A. Vazquez[2], S. Batman[3], G. Urrutia[3]; [1]Bengaluru/IN, [2]Frankfurt/DE, [3]Durham, NC/US
Purpose: Clinical radiology priors provide detailed patient history and imaging findings but remain unstructured (CCTA reports) and time-consuming to review. Structured reporting (CAD-RADS) standardizes and condenses reports for clarity and consistency, yet converting unstructured reports is laborious. Advances in Natural Language Processing (NLP) and Large Language Models (LLMs) enables transforming unstructured text into structured reports. However, LLMs can produce unreliable outputs (hallucinations), so detecting errors and linking structured content to the original report is crucial for accuracy and traceability.
Methods or Background: The procedure has two phases: (i) structured reporting using multiple agents, and (ii) grounding and hallucination detection (Figure 1). The document is processed by a "Study Understanding Agent" to identify the study type (e.g., plaque analysis). The "Fields Generating Agent" is invoked three times to compile a comprehensive list of fields. Next, the "Value Extraction Agent" extracts corresponding field values from the report. Empty fields are filtered out, followed by "Validation Agent" that detects incorrectly filled or unnecessary fields. On phase two, "Grounding Agent" traces values back to their sources, adding redundancy for validation. This modular approach ensures comprehensive, accurate, and validated structured reporting.
Results or Findings: Evaluated on 50 coronary CT angiography (CCTA) reports, our structured reporting framework extracted over 85% of required fields with 96% accuracy for filled values. The grounding agent achieved 88% accuracy.
Conclusion: Structured reporting accelerates clinical studies by highlighting essential fields clearly and efficiently. LLMs enable automatic generation of structured reports with high precision. Additionally, LLMs can be leveraged for traceability and validation of generated content, ensuring reliable and accurate reporting.
Limitations: Currently, evaluation is limited to CCTA reports. In future we can extend to other report types (Li-RADS, Pi-RADS) and enhance grounding accuracy using traditional NLP techniques alongside LLMs.

Initial Insights into an Institutional Secure Large Language model for MRI Examination Requests (6 min)

Yi Xian Low; Singapore / Singapore

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: J. T. P. D. Hallinan, N. W. Leow, Y. X. Low, A. Lee, W. Ong, D. Z. M. Chan, D. D-L. Loh, A. Makmur, Y. Ting; Singapore/SG
Purpose: To compare clinician MRI examination requests (MERs) with institutional secure large language model (sLLM)-augmented MERs for information quality and to evaluate protocoling accuracy of the sLLM versus board-certified radiologists across body, musculoskeletal, and neuroradiology MRI.
Methods or Background: Incomplete clinical details on MERs can lead to sub-optimal protocol selection. An institutional sLLM with access to the electronic medical record (EMR) may improve request completeness and protocol accuracy across multiple MRI subspecialties.

This retrospective study included 608 consecutive MRI examinations comprising 528 patients performed between September 2023 and July 2024. A privately hosted Anthropic Claude 3.5 model augmented each MER with EMR data and, via rule-based parsing, recommended region/coverage and contrast use. Two experienced radiologists established a consensus reference standard. Two board-certified general radiologists and the sLLM were compared with this standard. Clinical-information quality was graded using the Reason-for-Exam Imaging Reporting and Data System (RI-RADS). Inter-rater reliability was quantified with Gwet's AC1. Paired accuracies were compared with McNemar testing to determine if there was a statistically significant difference.
Results or Findings: Limited or deficient clinical information fell to 0–0.7% with sLLM augmentation versus 5.2–20.4% for clinician MERs. Overall protocol accuracy was 93.1% for the sLLM, 91.4% for Rad 3, and 92.1% for Rad 4. Region/coverage accuracy was similar (sLLM 95.2%, Rad 3 96.2%, Rad 4 94.2%). Contrast decisions were more accurate using the sLLM at 94.4% versus Rad 3 at 92.1%.
Conclusion: Across subspecialty MRI, sLLM-augmented examination requests had improved clinical context and contrast selection while matching general radiologists for region/coverage. Integrating sLLMs into vetting workflows may reduce manual workload and standardize protocoling.
Limitations: This was a single-centre, retrospective evaluation. Whether similar gains would be realised in institutions that use different order-entry systems is a future area of research.

Large Language Model-Assisted CT Protocol Selection: A Comparative Study of Finetuning vs Zero-Shot Reasoning (6 min)

Philipp Arnold; Freiburg Im Breisgau / Germany

Author Block: P. Arnold, M. Russe, E. Kotter, M. Scholz, M. Jeuck, L. Heine, T. Stein, S. Walter; Freiburg Im Breisgau/DE
Purpose: To evaluate whether large language models (LLMs) can assist radiologists in selecting the optimal CT protocol by name, correct body region, and appropriate use of intravenous contrast, we compared two strategies: supervised fine-tuning on institutional data versus zero-shot reasoning with structured prompting.
Methods or Background: CT protocol selection balances diagnostic yield against radiation and contrast risks. We retrospectively analyzed 20,000 CT exams with clinical indications, history, and standardized protocol labels covering 100 distinct protocol names, body region, and contrast use.

Fine-tuning: Qwen-2.5 models (3B–32B) were trained to map clinical text to the correct protocol name, body region, and contrast use.
Zero-shot reasoning: Qwen-3 models (4B–32B) received structured prompts with the same inputs, with or without prior imaging reports.
Benchmarking: Three resident radiologists independently selected protocols for the same test set. Accuracy was assessed for (1) protocol name, (2) body region, and (3) contrast use.
Results or Findings: Fine-tuned LLMs achieved 68–77% accuracy for protocol names across 100 labels (Top-3: 84–87%) and 90–96% accuracy for body region and contrast, with the 7B model performing best.
Zero-shot models reached 91–93% accuracy for body region and contrast, comparable to residents (87–90% / 89–94%), but lower for protocol names (53–56% vs. 58–62%). Prior imaging reports improved contrast accuracy by 1–4% across all models.
Conclusion: LLMs show potential as decision-support tools for CT protocol selection. Fine-tuned models surpassed radiologists in protocol-name matching, while zero-shot models matched human performance on individual components and leveraged prior reports to enhance contrast decisions. To improve protocol selection, inclusion of key clinical details in the provided data is essential.
Limitations: Single-institution data and protocol taxonomy may limit generalizability.

The Expertise Paradox: Who Benefits from LLM-Assisted Brain MRI Differential Diagnosis? (6 min)

Su Hwan Kim; Munich / Germany

Author Block: S. Schramm[1], B. Le Guellec[2], L. C. Adams[1], K. Bressem[1], J. S. Kirschke[1], D. M. Hedderich[1], B. Wiestler[1], S. H. Kim[1]; [1]Munich/DE, [2]Lille/FR
Purpose: To evaluate how reader experience influences the diagnostic benefit from large language model-assisted brain MRI differential diagnosis.
Methods or Background: Neuroradiologists (n = 4), radiology residents (n = 4), and neurology/neurosurgery residents (n = 4) were recruited. A dataset of complex brain MRI cases was curated from the local imaging database (n = 40). For each case, readers provided a textual description of the main imaging finding and their top three differential diagnoses ("Unassisted"). Three state-of-the-art large language models (GPT-4.1, Gemini 2.5 Pro, DeepSeek-R1) were prompted to generate top-three differentials based on the clinical case description and reader-specific findings. Readers then revised their differential diagnoses after reviewing GPT-4.1 suggestions ("Assisted"). To statistically evaluate the association between reader experience and diagnostic benefit, a cumulative link mixed model was fitted with change in diagnostic result as ordinal outcome, reader experience as a fixed effect, and random intercepts for rater and case.
Results or Findings: LLM-generated differential diagnoses achieved the highest top-3 accuracy when provided with image descriptions from neuroradiologists (top-3: 78.8-83.8%), followed by radiology residents (top-3: 71.8-77.6%), and other neurology/neurosurgery residents (top-3: 62.6-64.5%). In contrast, relative gains in top-3 accuracy from LLM assistance diminished with increasing experience, with +19.2% for neurology/neurosurgery residents (from 43.2% to 62.6%),+14.7% for radiology residents (from 59.6% to 74.4%), and +4.4% for neuroradiologists (from 83.1% to 87.5%). The cumulative link mixed model confirmed a significant negative association between reader experience and diagnostic benefit from LLM assistance (p = 0.005).
Conclusion: With increasing reader experience, absolute diagnostic LLM performance with reader-specific input improved, while relative diagnostic gains through LLM assistance paradoxically diminished. Our findings call attention to the gap between isolated LLM performance and actual clinical relevance, emphasizing the need to account for human-AI interaction.

European guideline informed RAG-based GPT-4 decision support tool in tumor board meetings for breast cancer treatment (6 min)

Javid Abbasli; Baku, Azerbaijan / Azerbaijan

Author Block: N. Abdullayev[1], V. Valiyev[2], J. Abbasli[2], S. Sanduleanu[3], J. Kottlors[1], S. Lennartz[1], H. Habibov[1], F. Yilmaz[4]; [1]Troisdorf/DE, [2]Baku, Azerbaijan/AZ, [3]Brunssum/NL, [4]Düsseldorf/DE
Purpose: To determine whether a retrieval-augmented (RAG) GPT-4 model ("MammaBoardGPT") grounded in European breast cancer guidelines improves agreement with multidisciplinary tumor board (MTB) decisions versus baseline GPT-4.
Methods or Background: Single-centre, retrospective analysis of 25 breast cancer cases discussed at a German hospital MTB. For each case, baseline GPT-4 and a RAG-enhanced GPT-4—few-shot conditioned with five MTB-labelled exemplars and guideline passages—generated management recommendations from the same structured case summary. Agreement with final MTB decisions was categorized as complete / partial / none. We additionally assessed the effect of recursive prompting using the Stuart–Maxwell test.
Results or Findings: After recursive prompting, MammaBoardGPT reached 84% complete agreement and 16% partial agreement, with 0% disagreements versus MTB decisions. Standard GPT-4 achieved 76% complete, 20% partial, and 4% complete disagreement. Agreement improved significantly for MammaBoardGPT before vs after recursive prompting (P = 0.0048), but not for standard GPT-4 (P = 0.135). Post-recursive prompting, there was no significant difference between MammaBoardGPT and GPT-4 (P = 0.37).
Conclusion: A European guideline-grounded, RAG-enhanced GPT-4 shows high concordance with MTB decisions and benefits from recursive prompting; however, the retrospective single-centre design, small cohort, restricted inputs/corpus, and lack of prospective outcome and safety assessment temper generalisability. Prospective, multi-centre, real-time studies with robust governance are required before clinical deployment.
Limitations: This single-centre retrospective study with a small sample (N=25) limits statistical power and generalisability. Inputs were structured summaries only (no imaging/EMR) with retrieval confined to selected European guidelines; few-shot/prompt design may introduce bias and potential information leakage, and outcomes relied on concordance metrics (workflow, safety, and regulatory impacts were not assessed).
Funding for this study: This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors. (Funding acquisition: not applicable.)

Large Language Model-Assisted Simplification of CT Staging Reports for Cancer Patients: A Prospective Quasi-Randomized Trial (6 min)

Felix Busch; Munich / Germany

Author Block: F. Busch, P. Prucker, K. K. Bressem, J. Peeken, A. W. Marka, S. H. Kim, S. Ziegelmayer, M. R. Makowski, L. C. Adams; Munich/DE
Purpose: To evaluate whether large language model (LLM)-assisted simplification of CT staging reports improves cancer patients' cognitive workload, text comprehension, report perception, and reading time.
Methods or Background: Prospective, controlled, open-label, quasi-randomized, pre-registered trial of 200 adult cancer patients undergoing routine CT re-staging with alternate 1:1 allocation to receive either the unmodified report or a locally generated LLM-simplified version (Llama-3.3-70B, on-premise via basebox) with mandatory radiologist review. Co-primary outcomes were reading time and three composite scores (cognitive workload, text comprehension, patient perception), each derived from three 7-point Likert items. Secondary outcomes included readability indices, word count, medical-terminology ratings, and independent radiologist assessments of factual errors, omissions, insertions, clinical usefulness, and overall quality. Logistic regression was performed to analyze patient-reported outcomes, adjusting for patient characteristics.
Results or Findings: Simplification reduced median reading time from 7 to 2 minutes (adjusted β: -3.86; 95% confidence interval (CI): -5.46, -2.26; P<.001). Patients reported lower cognitive workload (adjusted odds ratio (aOR): 0.18; 0.13, 0.25), higher text comprehension (aOR: 13.28; 9.31, 18.93), and enhanced perception of report usefulness (aOR: 5.46; 3.55, 8.38; all P<.001). Readability was significantly improved across metrics (e.g., Flesch-Kincaid Grade Level from 13.69 ± 1.13 to 8.89 ± 0.93; P<.001). Two radiologists independently identified factual errors in 6% of simplified reports (2 moderate, 4 severe), omissions in 7% (2 minor, 1 moderate, 4 severe), and unsupported insertions in 3% (1 minor, 2 moderate). The majority of simplified reports were rated clinically useful and of good or better quality.
Conclusion: LLM simplification substantially improves patient-centered outcomes and readability of CT staging reports while maintaining generally favorable clinical usefulness and quality. However, clinically relevant errors underscore the need for expert radiologist oversight before clinical implementation.
Limitations: Single-center, open-label with alternate allocation, self-reported patient outcomes.
Funding for this study: None.

Local large language models for MRI protocol selection: A privacy-preserving alternative to cloud AI (6 min)

Timotheus Josef Neumann; Bonn / Germany

Author Block: Z. Bendella, T. J. Neumann, Z. Ganji, R. Clauberg, N. Lehnen, A. Radbruch, M. Wolter, B. D. Wichtmann; Bonn/DE
Purpose: Cloud-based AI like ChatGPT has demonstrated high accuracy for MRI protocol selection. However, transmitting patient data to external servers entails privacy risks. This study evaluated whether LLaMA-3.1-8B, a compact open-source model deployable locally, can achieve comparable accuracy while maintaining complete data sovereignty.
Methods or Background: This IRB-approved, retrospective study used real-world radiology referral forms (RRFs) and corresponding MRI sequences from our institutional neuroradiology department. For model development, 8,281 consecutive MRI examinations (November 2023–January 2025) were included, with RRFs extracted from the RIS and executed sequences from the PACS, split into training (n = 6,624) and validation (n = 1,657). For testing, 1,001 consecutive RRFs (August 2023–July 2024) covering the full range of neuroradiological MRI protocols were included, with ground truth protocol selections defined by two board-certified neuroradiologists. LLaMA-3.1-8B was fine-tuned using prompt-tuning and LoRA (Low-Rank Adaptation), and compared against the pretrained model and ChatGPT-4. Accuracy was evaluated using BioBERT-based similarity scores between model outputs and expert ground truth.
Results or Findings: ChatGPT-4 achieved 99.7% accuracy on the test set. The locally deployed pretrained LLaMA-3.1-8B achieved 93.2% accuracy, improving to 94.5% with prompt-tuning and 95.4% with LoRA fine-tuning.
Conclusion: Despite being orders of magnitude smaller than ChatGPT-4, the locally deployed and fine-tuned LLaMA-3.1-8B achieved near-comparable accuracy in MRI protocol selection. This demonstrates the feasibility of privacy-preserving, institutionally controlled AI solutions to support radiologists without external data transfer, combining clinical utility with data sovereignty. These results establish a performance benchmark for local LLM deployment in radiology protocol selection.
Limitations: Fine-tuning refinements may further improve accuracy, though radiologist oversight remains essential for diagnostic safety. As this work employed a comparatively modest 8-billion-parameter model, future investigations with larger locally deployable models are expected to yield even higher performance.
Funding for this study: No funding was received for this study.

One-stop early noninvasive evaluation of renal allograft rejection and fibrosis: microstructural mapping via time-dependent diffusion MRI (6 min)
Zhouyan Liao; Wuhan / China

Author Block: C. Lyu, Z. Liao, Z. Li; Wuhan/CN
Purpose: Functional MRI offers promise for noninvasive detection of renal allograft injury, but conventional models lack biological specificity. This study aimed to evaluate the clinical utility of time-dependent diffusion MRI (td-dMRI) for detecting rejection and fibrosis in kidney transplant recipients.
Methods or Background: In this prospective observational study at a tertiary center in China, adult renal allograft recipients undergoing indication biopsies between April 2024 to June 2025 were enrolled. Microstructural maps from td-dMRI based on a Bayesian method, DWI, intravoxel incoherent motion, diffusion kurtosis imaging, stretched exponential model, fractional order calculus, and continuous-time random-walk model. The diagnostic performances of these microstructural parameters in differentiating different degrees of renal allograft fibrosis (mild, moderate and severe fibrosis) and rejection (no-rejection, acute and chronic rejection) were evaluated by areas under the receiver operating characteristic curves (AUC).
Results or Findings: A total of 100 patients (67 males, 33 females) were analyzed. Among them, 41 had acute rejection and 13 had chronic rejection; 67 had mild fibrosis, 19 moderate, and 14 severe fibrosis. td-dMRI-derived diameter significantly distinguished fibrosis grades, while cellularity identified early fibrotic changes. For rejection, diameter, fin, and fp differentiated acute rejection, and D-CTRW, fin, fp, and diameter distinguished chronic rejection. Combining td-dMRI metrics with clinical variables yielded high AUCs (0·968 for acute, 0·913 for chronic rejection).
Conclusion: This study supports td-dMRI as a biologically meaningful, one-stop contrast-free imaging approach for transplant kidney surveillance. It enables noninvasive detection of structural and cellular changes associated with rejection and fibrosis, even when conventional markers are inconclusive. Integrating td-dMRI with serum biomarkers may improve diagnostic accuracy and reduce unnecessary biopsies, promoting personalized immunosuppression and earlier intervention.
Limitations: It was a single-center study with a moderate sample size, which may limit generalizability.

Utility of Multi-Model Diffusion MRI for Stratifying High-Risk Complications in Renal Transplant Recipients (6 min)
Zhouyan Liao; Wuhan / China

Author Block: C. Lyu, Z. Liao, Z. Li; Wuhan/CN
Purpose: This study aims to develop a noninvasive comprehensive diagnostic protocol based on diffusion weighted imaging (DWI) and clinical indicators to achieve accurate and efficient identification of high-risk complications (rejection, acute kidney injury, viral infection, moderate to severe fibrosis) after renal transplantation.
Methods or Background: This prospective study enrolled 120 renal allograft recipients. Quantitative parameters of DWI, intravoxel incoherent motion (IVIM), diffusion kurtosis imaging (DKI), stretched exponential model (SEM), fractional order calculus (FROC) and continuous-time random walk (CTRW) were measured. Clinical and pathological features were also recorded. Univariate and multivariate logistic regression analyses were performed to identify independent clinical and imaging predictors of high-risk complications group. Receiver operating characteristic (ROC) curves were used to evaluate diagnostic performance. Internal validation of the combined model was performed using stratified 5-fold cross-validation and bootstrap resampling to assess model stability and generalizability.
Results or Findings: Finally, 101 patients were included. Diffusion coefficients differed significantly between superior and inferior graft function groups across models. DDC_SEM_cortex and HCO_3^- emerged as independent predictors in multivariate analysis. The AUCs for HCO3-, DDC_SEM_cortex, and their combined model in identifying patients requiring clinical management changes were 0.888, 0.898, 0.941. Internal validation confirmed strong performance (cross-validation AUC 0.938; bootstrap AUC 0.940, 95% CI 0.931–0.943)
Conclusion: DDC_SEM_cortex and serum HCO3- levels are promising noninvasive imaging biomarkers for identifying renal allograft recipients with high-risk complications. It provides a powerful noninvasive tool for clinical decision-making and is expected to guide individualized kidney transplant management.
Limitations: It was a single-center study with a moderate sample size, which may limit generalizability. MRI was acquired in free-breathing mode, making image quality susceptible to motion artifacts despite the iliac fossa location
Funding for this study: This study has received funding by the National Natural Science Foundation of China. (No. 82371942 and 82071889)

Multiparametric Renal MRI for Detecting Active Disease, Remission, and Subclinical Injury in Lupus Nephritis: A Prospective Observational Study (6 min)

Xiaoxiao Zhang; Beijing / China

Author Block: X. Zhang, H. Sun, G. Zhang, C. HUANG; Beijing/CN
Purpose: To evaluate structural and quantitative multiparametric MRI (mpMRI) features across the lupus nephritis (LN) disease continuum—active LN, clinically stable LN, and healthy controls—and to investigate correlations with clinical indices.
Methods or Background: In this prospective study, 40 patients with active LN, 40 with stable LN, and 21 matched healthy volunteers underwent renal MRI at 3.0T, including structural sequences, multi-b-value diffusion-weighted imaging (DWI/IVIM/DKI)and T1/T2 mapping. Structural abnormalities were qualitatively assessed, and quantitative parameters were compared across groups. Correlations with proteinuria, eGFR, complement levels, and disease activity scores were analyzed.
Results or Findings: Morphological abnormalities were observed in 40% of active LN and 30% of stable LN, versus none in controls. Exudative lesions were significantly more common in active LN than in stable LN (45.0% vs. 7.5%, $p < 0.001$). Quantitatively, active LN showed markedly reduced cortical ADC ($1.74 \pm 0.24 \times 10^{-3}$ mm²/s vs. 2.05 ± 0.21 in controls, $p < 0.001$) and elevated parenchymal T1 (1632 ± 123 ms vs. 1408 ± 95, $p < 0.001$). Stable LN showed partial normalization of cortical ADC ($p = 0.022$ vs. active LN) and T1 ($p = 0.007$), but parenchymal ADC and medullary ADC remained depressed ($p < 0.01$ vs. controls). Proteinuria correlated negatively with cortical diffusion ($r = –0.33$, $p = 0.038$) while eGFR correlated positively with ADC (r up to 0.48, $p = 0.002$).
Conclusion: Multiparametric renal MRI sensitively detects structural and functional changes across active LN, clinical remission, and health. Crucially, it identifies persistent microstructural injury in clinically stable patients, underscoring its potential as a noninvasive tool for monitoring treatment response and guiding long-term management.
Limitations: The lack of direct histopathological limits ability to precisely link imaging findings to specific microscopic changes

Diagnostic Value of Renal T1 and T2 Mapping in Biopsy-Proven Renal Amyloidosis: Correlation with Clinical Stage and Renal Function (6 min)

Elifnaz Şahin; Istanbul / Turkey

Author Block: E. Şahin, F. Alpaslan, T. Y. Kılıç, E. İsmailov, M. F. Kazanbaş, T. Banaz, B. Tütüncüoğlu, M. Kadıoğlu, S. Baş Özkök; Istanbul/TR
Purpose: To evaluate renal T1 and T2 mapping characteristics in patients with biopsy-proven renal amyloidosis and to explore their correlation with clinical severity and renal function indices.
Methods or Background: Renal amyloidosis is characterized by extracellular amyloid deposition that leads to progressive organ dysfunction. Non-invasive CMR-based renal mapping techniques may provide insight into disease activity and stage. Twenty-eight patients with biopsy-confirmed renal amyloidosis (mean age 53.2±12.8 years; 43% female) underwent renal T1 and T2 mapping using a 1.5 Tesla scanner. Disease severity was staged (GRADE I–V) according to clinical and histopathologic criteria. Standard renal function tests (urea, creatinine, eGFR) were obtained. Spearman's rank correlation was used to assess associations between renal mapping parameters, disease grade, and renal function. Healthy volunteers (n=20) served as controls.
Results or Findings: Median renal T1 values were significantly higher in the amyloidosis group compared with controls (1245 ms, IQR 1150–1410 vs. 1020 ms, IQR 985–1065; $p<0.01$). Similarly, median renal T2 values were elevated (82 ms, IQR 71–91 vs. 65 ms, IQR 61–70; $p<0.01$). A strong positive correlation was observed between disease grade and renal T1 ($\rho=0.62$, $p<0.001$), while renal T2 demonstrated a weaker but significant association ($\rho=0.38$, $p<0.05$). Renal T1 correlated positively with serum creatinine ($\rho=0.45$, $p<0.05$) and urea ($\rho=0.41$, $p<0.05$), and negatively with eGFR ($\rho=-0.52$, $p<0.01$). Renal T2 values showed a similar but less consistent pattern.
Conclusion: Renal T1 and T2 mapping values are elevated in renal amyloidosis and correlate with both disease severity and renal function impairment. These parameters may serve as useful non-invasive biomarkers for staging and monitoring renal involvement, complementing histopathology and laboratory measures.
Limitations: Relatively small, single-centre sample size.

MRI-Based Renal Fat Quantification as a Biomarker for Nephroprotective Therapy Monitoring in Metabolic Syndrome (6 min)

Marie I Scheuer; Düsseldorf / Germany

Author Block: M. I. Scheuer[1], C. S. Böttger[1], C. Liang[2], E. Bechler[1], A. Ljimani[1]; [1]Düsseldorf/DE, [2]Thuebingen/DE
Purpose: Metabolic syndrome is a collection of multifactorial conditions associated with combined cardiovascular pathologies and renal dysfunction. Novel therapies such as SGLT2 inhibitors show nephroprotective effects, but their clinical use is limited by the absence of noninvasive tools to monitor renal fat and treatment response. This study investigates MRI-based fat quantification as a method for assessing renal lipid accumulation.
Methods or Background: A total of 58 patients from a metabolic outpatient clinic underwent 1.5 T MRI scans (Avanto, Siemens Healthineers, Germany). Participants were divided into two groups by BMI (<30 vs. >30). Renal fat fraction (RFF) was quantified alongside visceral (VAT), subcutaneous (SAT), and abdominal muscle (AM) areas at L1–L2, as well as hepatic fat fraction (HFF). Correlations between renal and abdominal fat depots were analyzed to evaluate the potential of RFF as a biomarker.
Results or Findings: Results demonstrated significantly higher RFF in participants with BMI >30 compared to BMI <30. No significant correlations were observed between RFF and HFF, VAT, SAT, or AM.
These findings suggest that renal fat accumulation occurs independently of other fat depots. MRI-based renal fat quantification emerges as a promising noninvasive biomarker for monitoring renal lipid content in patients with metabolic syndrome. The observed group differences highlight its potential to detect renal fat burden, while the lack of correlation with hepatic or abdominal fat supports its unique role. A second MRI scan is planned after the treatment by new SGLT2 inhibitors within the study.
Conclusion: MRI-based renal fat quantification may serve as a valuable biomarker for monitoring the effectiveness of nephroprotective therapies in patients with metabolic syndrome.
Limitations: None.
Funding for this study: None.

Deep Learning-Based Kidney Volume Estimation in Polycystic Kidney Disease: Are We Ready for Clinical Practice? A Systematic Review and Meta-Analysis (6 min)

Enrique Almar Munoz; Innsbruck / Austria

Author Block: E. Almar Munoz[1], E. Colliander[2], S. Tupper[2], M. Lansner Kielberg[2], M. L. Liu[2], A. Mayr[1], R. Mirón Mombiela[2]; [1]Innsbruck/AT, [2]Herlev/DK
Purpose: n patients with autosomal dominant kidney disease (ADPKD), total kidney volume (TKV) is the gold standard biomarker for assessing the risk of progression and the need for drug therapy. However, it is a time-consuming process. In this systematic review, we evaluate the current state of deep learning (DL) algorithms for automatic kidney volume segmentation.
Methods or Background: All original research, including the search terms ADPKD, diagnostic imaging, DL, and TVK, was identified in PubMed, Embase, and Ovid MEDLINER databases from January 2000 to October 13, 2024. Articles with insufficient information to assess methodological quality were excluded. The quality was assessed using the QUADAS-2 and Checklist for Artificial Intelligence in Medical Imaging (CLAIM) tools. We focused on Dice Similarity Coefficient (DSC), bias differences, and time efficiency as outcomes.
Results or Findings: Nineteen studies were included, with an overall good quality; however, the mean adherence to the CLAIM checklist was 64%. The average DSC was 95 ± 2.89% (95% CI: 94.62–94.85) with relatively low bias for TKV in 5,622 ADPKD patients (mean age, 46.1 years; 45% male) and 9,180 scans (79% MRI). The average segmentation time was decreased by 75% compared to the ground truth. Performance differences were evident among imaging modalities, but 3D models did not outperform their 2D counterparts. No statistically significant evidence of small-study effects or publication bias was detected.
Conclusion: DL models for TKV in ADPKD patients demonstrated high precision compared to manual segmentation in a large, pooled sample with heterogeneous study designs and methods. Therefore, clinical implementation is feasible.
Limitations: Risk of data and model drift over time. High computational and environmental costs. Lack of task-specific evaluation standards (addressable by a tailored PRISMA for AI). Potential automation bias. Workflow/institutional variability. Regulatory and compliance challenges.
Funding for this study: No funding was received for this study.

Renal Transplant Ultrasound: From Normal Assessment to Early and Late Detection of Complications (6 min)

Windy Mary Fernández Rios; Albacete / Spain

Author Block: W. M. Fernández Rios, N. Lopez-Galiacho, E. Sifre Gómez, L. P. Cervera Bravo, S. Descalzo García, F. C. Mejia Galvis, M. N. Vicente de Vera, T. Vicente García, N. Carreres Creus; Alabcete/ES
Purpose: To describe the normal ultrasonographic findings of the renal graft and to review the radiological semiology of the most frequent complications through a series of cases from our department, both in the immediate postoperative period and during long-term follow-up.
Methods or Background: Renal transplantation is the most common solid-organ replacement procedure and represents the definitive treatment for chronic kidney disease. Advances in surgical technique, immunosuppression, surveillance imaging, and histopathological diagnosis of rejection have significantly improved graft survival. The increasing number of recipients and the use of higher-risk donors make thorough radiological assessment essential. The radiologist plays a pivotal role throughout the process—from baseline evaluation to the assessment of graft dysfunction and the guidance of interventional procedures.
Results or Findings: Doppler ultrasound is the first-line imaging modality in the immediate postoperative period, providing a reference examination and enabling early detection of complications. In cases of dysfunction, contrast-enhanced ultrasound or magnetic resonance imaging can provide greater diagnostic specificity. Complications are classified by timing and aetiology: immunological (rejection), vascular, urological, infectious, surgical/iatrogenic, and neoplastic. The heterotopic placement of the graft in the iliac fossa results in a characteristic spectrum of imaging findings.
Conclusion: Detailed knowledge of normal anatomy, vascular variations, surgical techniques, and donor and recipient risk factors is essential for accurate diagnosis and timely management. Ultrasound remains the cornerstone in the evaluation of renal transplantation, both in the early and late postoperative periods.
Limitations: No limitations

Diagnostic Performance and Reader Confidence of a CT-like MRI Sequence for Femoral Head Necrosis (6 min)
Felix Herr; Munich / Germany

Author Block: M. L. Schnitzer, F. Herr, N. Hohmann, C. A. Dascalescu, B. Holzapfel, J. Ricke, N. Hesse, J. Arnholdt, P. Reidler; Munich/DE
Purpose: To evaluate a novel CT-like MRI sequence for ARCO classification, reader confidence, and image quality, and compare its diagnostic performance with standard MRI and radiography.
Methods or Background: In this retrospective study, 21 patients with suspected femoral head necrosis underwent MRI (T1, T2, CT-like) and radiography. Two experienced readers independently assessed ARCO stage (I–IV), reader confidence, and image quality using a binary scale (1 = high/good, 2 = low/poor). Mean scores were calculated. Interrater reliability was assessed using intraclass correlation coefficients (ICC); intermodality agreement with weighted Cohen's Kappa. Paired comparisons used Wilcoxon signed-rank tests.
Results or Findings: CT-like MRI yielded higher ARCO scores (2.23 ± 0.78) than radiography (1.75 ± 1.01, $p = 0.001$), T1 (2.08 ± 0.73, $p = 0.010$), and T2 (2.08 ± 0.69, $p = 0.023$). Reader confidence was superior with CT-like MRI (1.11 ± 0.25) compared to T1 (1.53 ± 0.47), T2 (1.50 ± 0.46), and radiography (1.43 ± 0.37), all $p < 0.01$. Image quality ratings were highest for CT-like (1.11 ± 0.30), outperforming T1 (1.86 ± 0.51) and T2 (1.75 ± 0.51), $p < 0.001$. Agreement in ARCO staging was excellent with T1 ($\kappa = 0.904$) and T2 ($\kappa = 0.869$), and substantial with radiography ($\kappa = 0.709$). Interrater reliability was high for ARCO staging (ICC 0.82–0.93), lower for confidence (ICC < 0.40), and variable for image quality, with CT-like showing the best agreement (ICC = 0.84).
Conclusion: This CT-like MRI sequence improves diagnostic confidence and staging accuracy while avoiding ionizing radiation and reducing the need for additional imaging. It supports a more sustainable approach by minimizing exposure and streamlining diagnostics.
Limitations: Single-center design and small sample size may limit generalizability. The sequence requires specialized protocols not yet widely available.

Opportunistic comparative analysis of quantitative radiomics between zero-echo-time MRI and CT on normal hip bone during oncologic metastatic screening (6 min)
Elvis Duran-Sierra; Houston / United States

Author Block: R. F. Valenzuela, E. Duran-Sierra, M. Antony, J. Espinoza, C. M. Costelloe, W. Murphy, D. Wells, B. Amini, S. Lo; Houston, TX/US
Purpose: Zero-Echo-Time (ZTE) and Ultrashort-Echo-Time (UTE) sequences are designed to characterize short-T2 materials. By utilizing ray-sum-rendering and inverse-logarithm-rescaling, these sequences can enhance bone contrast, resembling CT. ZTE publications often rely on perception analysis to validate its use as a CT-succedaneum. We aim to quantitatively compare Ozteo (GE-ZTE) MRI and CT using radiomic analysis, first on normal bone and subsequently on sclerotic and lucent lesions.
Methods or Background: Starting July 2025, Ozteo has become part of our institutional routine MSK-pelvic-MRI across nine GE magnets (two-3T and seven-1.5T). An ongoing prospective collection included 26 patients with bone-metastases screening scanned with ZTE+CT within six months. Manual-volume-of-interest (VOI) segmentations were created from healthy right hips, using the left hip in the presence of right hip pathology or hardware. An in-house Python-based sequence-neutral software extracted 107 radiomic features, comprising 14 shape, 18 first-order, and 75 texture features. Statistical analysis compared ZTE MRI-and CT-derived radiomic features using two-tailed non-parametric Wilcoxon signed-rank paired tests.
Results or Findings: Gender: 42% male/58% female. Age-average: 50 years (range: 24-76). 22 right and four left hip VOI were segmented. The average time between ZTE-MRI and CT was two months (range: 1-day/6-months). The ZTE-MRI vs. CT statistical analysis revealed that 16-out-of-107 (15%) radiomic features were significantly similar (P>=0.05), including: glszm_largeareaemphasis (P=0.0796), glszm_zonevariance (P=0.0796), and firstorder_maximum (P=0.0559). Maximum differences (9.3%, P=2.98x10-8) included firstorder_robustmeanabsolutedeviation, firstorder_interquartilerange, firstorder_meanabsolutedeviation, firstorder_variance, glszm_graylevelvariance and firstorder_range.
Conclusion: Detached from subjective-perceptual evaluations, radiomics analysis from CT versus ZTE-MRI provided objective-quantitative evidence of maximal-similarities (15% of radiomic features) and maximal-differences (9.3%), outlining the true range of features where ZTE may be considered comparable with conventional CT. Based on preliminary data, we hypothesize that the normal bone feature range may differ from sclerotic and lytic bone lesions.
Limitations: Small sample size.

Acetabular cup version measurement in total hip arthroplasty: Comparing MRI versus CT (6 min)

Frederik Abel; Zurich / Switzerland

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: F. Abel, R. Sutter, F. Schmaranzer; Zürich/CH
Purpose: The acetabular cup version in patients with total hip arthroplasty (THA) is a key parameter influencing hip stability and functional outcomes. Although CT is the reference standard for assessing cup orientation, MRI has emerged as the first-line cross-sectional imaging modality for evaluating postoperative complications. This study compared MRI- and CT-based measurements of acetabular cup version in terms of agreement, reproducibility, and reliability.
Methods or Background: Patients who underwent THA between 2015 and 2025 and received both postoperative CT and MRI were retrospectively reviewed. MRI was performed using optimized metal-artifact reduction sequences. Acetabular cup version was measured on axial high-bandwidth T1-weighted turbo-spin echo sequences and corresponding CT scans by two musculoskeletal radiologists. Inter- and intra-reader, as well as inter-modality agreement, were assessed using intraclass correlation coefficients (ICC). Bland-Altman plots evaluated systematic bias.
Results or Findings: Thirty patients were included (median age, 69.5 years; 14 women). Mean acetabular version ranged from 31.20°–31.22° (standard deviation [SD], 9.40–10.30) and from 30.05°–30.21° (SD, 8.90–9.32) for CT and MRI for both readers, respectively.
Inter-reader reproducibility was excellent for CT (ICC, 0.96) and good for MRI (ICC, 0.76). Intra-reader reliability was excellent for both modalities (ICC, CT: 0.99; MRI: 0.94). Bland-Altman analysis showed no statistically significant differences between CT and MRI measurements with a slight positive bias for MRI (mean pooled difference, 1.05°; p = 0.06; limits of agreement, –4.66° to 6.76°) and good to excellent inter-modality agreement for both readers (ICC, 0.86–0.90).
Conclusion: MRI provides reliable measurements of acetabular cup version in THA, demonstrating good-to-excellent agreement with CT. MRI can be used for estimating cup version within clinically acceptable limits.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study.

Diagnostic Performance of Dual-Energy CT for Opportunistic Detection of Rotator Cuff Disease: A Retrospective Multireader Study (6 min)

Suwei Liu; Beijing / China

Author Block: S. Liu; Beijing/CN
Purpose: Multi-material decomposition (MMD), a key application of DECT, has shown potential in musculoskeletal research. This study aimed to compare the diagnostic performance of DECT-based MMD with standard CT and MRI in detecting rotator cuff disease.
Methods or Background: This study evaluated patients diagnosed with rotator cuff disease who underwent third-generation dual-source DECT and 3.0T MRI within a 2-week interval between December 2023 and November 2024. Shoulder arthroscopy served as the reference standard. Six readers independently assessed rotator cuff tears and determine the degree of supraspinatus tendon diseases using standard CT, DECT-based MMD and MRI. Area under the curve (AUC), sensitivity, specificity, positive/negative predictive values and accuracy were calculated for the diagnosis of rotator cuff disease. Friedman test was used to analyze the radiologists' diagnostic confidence across the three image types.
Results or Findings: In total of 103 patients (mean age: 50.0 ± 15.6 years) underwent shoulder arthroscopy. MMD demonstrated a higher average AUC for diagnosing rotator cuff tears (88% vs. 65%, P < 0.001) and supraspinatus tendon disease (86% vs. 63%, P < 0.001) compared to standard CT. Its diagnostic performance for supraspinatus tendon disease (91% vs. 90%, P = 0.35) and full-thickness tears (95% vs. 93%, P = 0.11) was comparable to that of MRI.
Conclusion: DECT-based MMD demonstrated superior diagnostic performance and reliability for detecting rotator cuff diseases compared to standard CT, with accuracy comparable to that of MRI in detecting supraspinatus tendon tears. DECT-based MMD offers a promising approach for the opportunistic detection of rotator cuff diseases.
Limitations: First, as a retrospective single-center study, the generalizability of our findings are limited. Second, its ability to identify partial-thickness tears and subtle tendon degeneration—conditions more frequently encountered in clinical practice—remains limited.
Funding for this study: This work was supported by National Key Research and Development Program of China (No.2023YFC2410703)

Ethics committee - additional information: This retrospective study was approved by the Institutional Review Board of Peking University Third Hospital (Approval Number: M2024188)

Dual-Layer Spectral CT with Electron Density in Bone Marrow Edema Diagnosis: A Valid Alternative to MRI? (6 min)

Cecilia Beltramini; Golasecca / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: C. Beltramini[1], F. Piacentino[1], F. Fontana[1], A. Coppola[1], D. Mesiano[1], C. Recaldini[1], A. M. Ierardi[2], G. Carrafiello[2], M. Venturini[1]; [1]Varese/IT, [2]Milan/IT
Purpose: Although MRI with fat-suppression sequences is the gold standard for diagnosis of bone marrow edema (BME), Dual-Layer Spectral CT (DL-SCT) with electron density (ED) provides a viable alternative, particularly in situations where an MRI is not accessible. Using MRI as the reference standard, this study analyzed how DL-SCT with ED reconstructions may be a valid alternative in the detection of BME.
Methods or Background: This retrospective study included 28 patients with a suspected diagnosis of BME via MRI conducted between March and September 2024. Patients underwent DL-SCT using ED reconstructions obtained through IntelliSpace software v. 12.1. Images were evaluated by two experienced radiologists and one young radiologist in a blinded way, giving a grade from 0 to 3 to classify BME (0 absence; 1 mild; 2 moderate; 3 severe). To reduce the recall bias effect, the order of image evaluations was set differently for each reader. p-Values were considered significant when <0.05. Fleiss' Kappa was used to assess inter-rater reliability: agreement was considered poor for k < 0; slight for k 0.01-0.20; fair for 0.21-0.40; moderate for 0.41-0.60; substantial for 0.61-0.80; and almost perfect for 0.81-1.00.
Results or Findings: All the readers detected the presence or absence of BME using DL-SCT. Inter-rater reliability for grade 0 resulted in 1 (p-value < 0.001); for grade 1: 0.21 (p-value < 0.001); for grade 2: 0.197 (p-value < 0.001); and for grade 3: 0.515 (p-value < 0.001).
Conclusion: ED reconstructions allowed the identification of BME presence or absence in all analyzed cases, thus suggesting DL-SCT as a potentially effective method for its detection.
Limitations: Heterogeneous sample that doesn't consider metabolic disorders different from osteoporosis or malignancy.
Funding for this study: None

Diagnostic value of Dual-Energy Cone Beam CT in Musculoskeletal trauma: A comparative evaluation against single-energy CBCT and MRI (6 min)

Nagore Castro; Barcelona / Spain

Author Block: N. Castro, J. Catala March; Barcelona/ES
Purpose: Dual-energy CBCT (DE-CBCT) represents a significant technological evolution in musculoskeletal imaging, offering superior tissue differentiation compared to single-energy CBCT (SE-CBCT) through material decomposition. While MRI remains the gold standard for soft tissue evaluation, DE-CBCT emerges as a promising alternative when MRI is contraindicated or unavailable.
This prospective study evaluated the diagnostic performance of DE-CBCT against SE-CBCT for bone structures and MRI for soft tissues, focusing on its clinical application in trauma and joint diseases.
Methods or Background: Thirty participants (45.57±17.93 years) with suspected or confirmed pathology and MRI inclusion criteria were enrolled. Each participant underwent DE-CBCT (80kVp; 140kVp), SE-CBCT (120kVp), and MRI (proton density and T1-weighted). Two blinded, MSK-experienced radiologists independently assessed bone detail, soft tissue contrast, and diagnostic confidence using a 5-point Likert scale.
Results or Findings: Inter-reader agreement was higher for DE-CBCT than SE-CBCT (k=0.82 vs 0.71). For soft tissues, MRI showed superior agreement over DE-CBCT (k=0.94 vs 0.76).
No significant differences in bone diagnostic accuracy emerged between DE-CBCT and SE-CBCT, although DE-CBCT received higher qualitative scores. Differences with MRI were notable for soft tissues ($p<0.05$), confirming its superior visualisation. However, DE-CBCT affirmed accurate visualisation of articular cartilage and tendons. Although not statistically significant, DE-CBCT provided greater confidence in complex fractures, such as intra-articular wrist and ankle injuries, while reducing the need for additional MRI and speeding emergency decision-making.
Conclusion: DE-CBCT is an effective tool for recent trauma, especially when MRI is unavailable. It accurately detects fractures and soft tissue changes, such as bone oedema and joint effusions, offering a comprehensive post-traumatic assessment. Clinically, DE-CBCT should be integrated into emergency departments for rapid triage of complex trauma and prioritised over SE-CBCT for bone oedema or cartilage evaluation.
Limitations: Increment of radiation exposure compared to SE-CBCT
Funding for this study: None

Diagnostic Value of Bone Marrow Edema Maps from Photon-Counting CT in Suspected Fractures (6 min)

Egle Vilkelyte; Motala / Sweden

Author Block: E. Vilkelyte, N. F. Kämmerling, E. Tesselaar; Linköping/SE
Purpose: To evaluate the diagnostic utility of bone marrow edema (BME) maps generated using dual source photon-counting CT (PCCT), compared with ultra-high-resolution (UHR) standard reconstructions, in patients with suspected fractures in different .
Methods or Background: This study included 33 patients (37 examinations; mean age 59.5 ± 22.7 years, range 13–88) with suspected fractures at various anatomical sites including spine, hip, and wrist, examined on a clinical PCCT system using a dual-source acquisition mode. Two radiologists with 9, and 10 years of experience, and a second-year radiology resident, independently reviewed anonymised datasets in two sessions: first, UHR images only; second, the same cases (in randomized order) supplemented with BME maps, and assessed fracture presence and diagnostic confidence (5-point scale). Image quality and evaluability of BME maps, and inter-rater agreement were analysed.
Results or Findings: Agreement on fracture detection improved from moderate without BME maps ($\kappa=0.514$, $p<0.001$) to substantial when BME maps were available ($\kappa=0.711$, $p<0.001$). Overall diagnostic confidence increased significantly with BME maps (median 4→5, $p=0.007$). In 7% of cases, BME maps led to newly diagnosed fractures, while 4% of suspected fractures were excluded. The change in diagnosed fractures was more frequent for the radiology resident. Interobserver agreement on the presence of an edema signal in the BME maps was low (AC1=0.197, $p=0.074$), and image quality ratings for the BME maps differed significantly between readers ($p<0.001$). BME maps were considered non-evaluable due to artifacts in 4/37 (11%) of examinations.
Conclusion: BME maps derived from PCCT improve interobserver agreement and diagnostic confidence in fracture assessment. They may aid in detection and exclusion of subtle fractures beyond UHR images alone.
Limitations: Limited sample size; heterogeneous patient cohort; absence of independent diagnostic reference standard for fractures;
Funding for this study: N.a.

Role of z effective maps for vertebral bone marrow edema assessment with dual energy ct: comparison with water calcium maps and magnetic resonance imaging (6 min)

Marco Bozzolo; Borgo San Dalmazzo / Italy

Author Block: M. Bozzolo, G. Gallarato, A. Balderi, E. Roberto, S. Amabile, D. Buccicardi; Cuneo/IT
Purpose: To explore the role of Z-effective maps as an additional tool, in combination with Water/Calcium maps, for detecting vertebral bone marrow edema (BME) in spinal fractures with dual energy ct (DECT), with MRI as reference standard.
Methods or Background: We analysed 261 vertebral bodies from 41 patients with acute spinal trauma who underwent DECT (GE Revolution CT ES 128, Rapid-Switching 80–140 kVp) and MRI. Qualitative analysis compared Z-effective and Water/Calcium maps with MRI, assessing BME presence and extent. Two independent readers evaluated all examinations blinded to MRI results. Quantitative analysis included HU, Z-effective, Water/Calcium, SNR, and spectral curves between edematous and healthy bone.
Results or Findings: Z-effective and Water/Calcium maps showed sensitivity 93.8–96.2%, specificity 98.9–99.5%, accuracy 97.3–98.5%, with inter-reader agreement (κ >0.96). Quantitative values were higher in edematous bone: HU (298 vs 53, p<0.001), Z-effective (10.36 vs 8.39, p<0.001), Water/Calcium (1071 vs 1002 mg/cm³, p<0.001), and SNR (14.4 vs 2.3, p<0.001). Z-effective strongly correlated with HU (r=0.92, p<0.001), while correlation with Water/Calcium was moderate (r=0.37, p=0.016), indicating complementary diagnostic value. Spectral curves confirmed higher attenuation in BME than healthy bone (p<0.001). ROC analysis showed excellent diagnostic performance (AUC Z-effective 0.97–0.98; Water/Calcium 0.96–0.97).
Conclusion: Z-effective maps show diagnostic accuracy comparable to Water/Calcium maps in detecting vertebral BME and provide complementary information. Their integration strengthens the role of DECT as a reliable tool for bone marrow edema assessment. In selected clinical and emergency settings, DECT may represent a practical alternative to MRI when not available or contraindicated.
Limitations: The time interval, although short, between DECT and MRI may have influenced the extent of edema.

Relatively small patient sample.

Variability of MRI scanners, potentially affecting quality and interpretation.
Funding for this study: This study received no external funding.

Deep learning-based chemical shift-artifact correction of ZTE MRI for enhanced bone assessment of the lumbar spine (6 min)

Carina Obermüller; Zurich / Switzerland

Author Block: C. Obermüller[1], U. Bach[1], F. Zecca[2], F. Heidt[1], M. Lohezic[1], R. Guggenberger[3], E. Burian[1], J. Kroschke[1], F. Ensle[1]; [1]Zürich/CH, [2]L'Aquila/IT, [3]Winterthur/CH
Purpose: To assess the impact of deep learning-based (DL) chemical shift-artifact correction (CSC) on bone assessment in zero echo time (ZTE) MRI of the lumbar spine, compared to non-DL and DL-reconstructions. ZTE is a bone-specific MRI sequence suffering from CS artifacts, particularly in the spine and at 3T.
Methods or Background: This retrospective study included 60 clinical patients with ZTE lumbar spine MRI at 3T. Raw k-space data was reconstructed offline with a prototype DLCSC algorithm (specifically designed for CS reduction), prototype DL algorithm without artifact correction and non-DL technique. Quantitative image sharpness was plotted with line profiles over vertebrae L2-4, analysed with repeated-measures ANOVA. Two radiologists assessed qualitative pathology-related criteria (pathology type, conspicuity, impact of artifacts, diagnostic confidence, n = 22) and diagnostic image quality (cortical and trabecular bone delineation, noise, artifacts, n = 38) using a 4-point scale. Ordinal data was analysed using the Friedman test and weighted Cohen's kappa.
Results or Findings: For quantitative sharpness, the mean score for DLCSC (0.388) was significantly higher than for non-DL (0.269; post-hoc p = .010) and DL (0.247; post-hoc p = .001). For the qualitative assessment, mean scores consistently improved from non-DL to DL to DLCSC, respectively: Diagnostic Image Quality (p < 0.001): means were 0.95, 1.63, and 2.37. Pathology Conspicuity (p < 0.001): means were 1.27, 1.82, and 2.18. Diagnostic Confidence (p < 0.001): means were 1.86, 2.32, and 2.59. Image Noise (p < 0.001): means were 1.18, 1.76, and 2.55. Inter-reader agreement for the qualitative assessment was moderate (k=0.45-0.6).
Conclusion: The DLCSC technique significantly enhanced bone assessment of the lumbar spine, compared to DL and non-DL reconstructions, including the evaluation of pathologies. This advancement extends the utility of ZTE for comprehensive spine imaging.
Limitations: Modest sample size
Funding for this study: No funding was received for this study (Basec-Nr 2021-02408).

Radiation safety deviation reporting of X-ray practices in Finland: analysis of the last 10 years (6 min)

Tommi Hietamies; Vantaa / Finland

Author Block: E. Hallinen, T. Hietamies, I. P. Kuurne, A. Lajunen, V. Ruonala, J. Suutari, P. Tenkanen-Rautakoski; Vantaa/FI
Purpose: This study aims to describe the characteristics, frequency, and outcomes of reported radiation safety deviations in healthcare X-ray practices in Finland, and to highlight their role in supporting continuous safety improvement.
Methods or Background: In Finland, radiation safety deviations in healthcare X-ray practices must be reported to the Radiation and Nuclear Safety Authority (STUK). Deviations are classified into significant cases, which must be reported immediately, and less significant cases, which are submitted annually. Since 2015, approximately 270 significant and 12,650 less significant deviations have been reported. The reporting system is regarded as an indicator of a strong safety culture.
Deviation reports submitted to STUK between 2015 and 2024 were analyzed. Reports were classified into predefined categories. Descriptive analyses included frequency distributions, trends over time, and typical causes. From 2025 onwards, reporting requirements will also include preventive measures taken for each deviation type.
Results or Findings: No severe radiation safety incidents have been reported since the implementation of systematic reporting. Patient exposures resulting from deviations remained below 100 mSv, occupational exposures below 1 mSv, and unintended foetal exposures below 40 mGy. The most common deviation was failed examinations due to incident, requiring repetition, typically caused by technical problems or human error. Analysis of reports and anonymized case studies have been used as educational tools in radiation safety training.
Conclusion: The systematic reporting of radiation safety deviations has proven effective in monitoring and improving safety culture in Finnish healthcare X-ray practices. The introduction of preventive action reporting from 2025 is expected to further strengthen proactive safety management.
Limitations: Not all radiation safety deviations are reported to STUK.
Funding for this study: This study is a by-product of statutory regulatory oversight, conducted and funded by STUK.

Patterns and Safety Implications of Unintended Patient Exposures in Imaging and Radiotherapy Across Multiple Countries (6 min)

Chrysa Paraskevopoulou; Athens / Greece

Author Block: C. Paraskevopoulou[1], A. Papachristodoulou[1], C. D. Filho[2], D. Baltazar[3], C. Colmo[4], A. Roncacci[1]; [1]Hague/NL, [2]Barcelona/ES, [3]Amadora/PT, [4]Padua/IT
Purpose: Unintended patient exposures in ionizing radiation procedures, including diagnostic imaging (CT, X-ray, PET-CT, Mammography, SPECT-CT) and therapeutic applications (Radiotherapy, Brachytherapy), pose risks to safety, diagnostic accuracy, and treatment precision. This study analyzed unintended exposure incidents across multiple countries to identify patterns, underlying causes, and opportunities for safety improvement.
Methods or Background: Incident data from a centralized multi-national reporting system were analyzed over a three-year period. Incidents were categorized as repeated examination, wrong patient, wrong examination, wrong site, and wrong side. Severity was classified as no physical harm, minor, medium, serious, or severe. Rates were calculated relative to 8.18 million ionizing radiation procedures performed in 376 centers across 15 countries.
Results or Findings: Across 8.18 million ionizing radiation procedures, 369 unintended patient exposures were identified (0.0011%). Repeated examinations and wrong examination events together accounted for over half of all incidents, reflecting common issues such as motion artifacts, technical failures, or request-to-procedure mismatches. Wrong patient exposures were also frequent, representing nearly one quarter of cases, while wrong site and wrong side events were less common but clinically significant (Fig.1). Most events were minor or medium in severity, yet a consistent presence of serious cases underscores the importance of systematic monitoring and targeted preventive measures.
Conclusion: Although unintended patient exposures represent a very small fraction of ionizing radiation procedures, their implications for safety and quality of care are significant. The high share of repeated and wrong examination events highlights the need for workflow optimization, request-to-procedure verification, improved patient communication, and enhanced personel training. Preventive strategies should also address wrong patient, wrong site, and wrong side incidents. Continuous monitoring are essential to guide systematic improvements and targeted preventive measures, supporting a stronger safety culture across imaging and radiotherapy services.
Limitations: N/A

Projected Impact of The U.S. Quality Measure, Excessive Radiation Dose or Inadequate Image Quality for Diagnostic CT on Radiation Dose and Projected Cancer Risks (6 min)

Rebecca Smith-Bindman; San Francisco / United States

Author Block: R. Smith-Bindman[1], G. Frija[2]; [1]San Francisco, CA/US, [2]Paris/FR
Purpose: Excessive radiation doses in CT exams are a patient safety concern. Provider-based financial incentives in the U.S.have successfully improved patient safety. UCSF, with funding from the Centers for Medicare & Medicaid Services, developed a quality measure for CT to reduce unnecessary radiation doses while maintaining diagnostic value. During the presentation, speakers will detail the measure's methodology, discuss its impact on projected cancers, and explore its potential application in Europe.
Methods or Background: The measure automates CT radiation/image noise calculations using standardized data based on scan indications. Eligible adult CT exams are assigned to categories with thresholds for allowable radiation doses and noise based on ICD-10-CM and CPT codes. Radiation dose is adjusted for patient size, and exams are flagged as "out-of-range" if they exceed thresholds supported by radiologists' estimates of diagnostic value. Testing across 7 health systems, 16 hospitals, and 606 clinicians included 48,500 CT exams, with 33% flagged as out-of-range. Data from an international CT registry showed approximately 28% of European exams were out-of-range.
Results or Findings: If dose thresholds had been applied to the 90 million CT exams conducted among 59 million adults in the U.S. in 2023, the projected number of future cancers would decrease from 93,000 to 69,000—a 26% reduction. Abdomen and pelvis CT contributed the highest cancer burden, with 31,200 projected cancers, which could be reduced by 9,556 if thresholds were implemented. Chest CT followed, with 21,500 projected cancers, 8,376 of which could be prevented. These two CT categories represent key targets for optimizing and standardizing radiation dose protocols.
Conclusion: The measure is being adopted across U.S. hospital and physician payment programs, with over 3,500 hospitals working towards reporting. Financial incentives will drive improvements in patient safety and care quality.
Limitations: None
Funding for this study: The quality measure was funded by the U.S. Centers for Medicare and Medicaid Services, and the Patient Centered Outcomes Research Institute

Organ-specific radiation doses after mispositioning or scan direction variation: Impact of single versus dual scanogram across four different CT-scanners (6 min)

Louise D'Hondt; Ghent / Belgium

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: L. D'Hondt[1], C. Haentjens[2], A. Snoeckx[3], K. Bacher[1]; [1]Ghent/BE, [2]Leuven/BE, [3]Antwerp/BE
Purpose: With the considerable number of low-dose CT examinations for lung cancer screening, participant mispositioning or scan direction variations are expected. These variations affect automatic tube current modulation (ATCM), but dose implications across CT-models remain unknown. Moreover, current screening guidelines lack scanogram specifications. This study simulated organ-specific doses when protocol deviations were preceded by either single or dual scanogram.
Methods or Background: ATCM-profiles were established using the Alderson Rando phantom on four CT-scanners (GE Revolution, Siemens SOMATOM Definition Flash, Canon Aquilion ONE, Philips Spectral CT 7500). Protocol variations included vertical and lateral mispositioning (2cm increments) and scan direction changes (craniocaudal, caudocranial), each preceded by either a single posteroanterior (PA) or dual (PA+Lateral) scanogram. Each variation was simulated with the ImpactMc Monte Carlo software for 32 patient-specific voxelmodels and organ doses were calculated (lungs, heart, thyroid, liver, breasts).
Results or Findings: GE and Siemens scanners showed considerable linear increase in organ doses (respectively 18-50% and 5-25%) with vertical/downward mispositioning using a single PA scanogram. This was eliminated by adding a lateral scanogram. Canon and Philips scanners generally displayed stable ATCM-profiles and dose levels after vertical mispositioning, regardless of scanogram type. Solely the Canon scanner showed substantial average dose increases of 37.5% and 34% after respectively a single and dual scanogram across lateral mispositioning.
The ATCM-behaviour upon changing to the craniocaudal scan direction is highly model dependent. However, combined with the dual scanogram, dose deviations are minimised for all scanners except for Siemens, where no differences are seen.
Conclusion: An additional lateral scanogram can mitigate considerable organ dose increases related to scan protocol deviations. Since ATCM-behaviour varies across CT-scanner models, scanner-specific evaluation and optimisation should involve medical physics expertise.
Limitations: The limitations of the study are the use of a phantom.
Funding for this study: Funding was provided by the FWO “Kom op tegen Kanker”-project for lung cancer screening research in Belgium. (Project number: G0B1922N).

Ethics committee - additional information:

Harmonizing Dose Monitoring and QA Reporting in Dental Cone-beam Computed Tomography (6 min)

Satu Inkinen; Helsinki / Finland

Author Block: S. Inkinen, J. H. J. Ketola, A-M. Vitikainen, M. Kortesniemi; Helsinki/FI
Purpose: We report a case emphasizing the need for harmonized external quality assurance (QA) in dental imaging, specifically regarding dose area product (DAP) monitoring. Our existing QA procedure was modified with an electronic form that radiographers complete during device QA. This form also includes externally verified DAP monitoring values, since, our dose monitoring platform cannot currently track DAP for dental cone-beam computed tomography (CBCT) units.
Methods or Background: Dental CBCT devices follow manufacturer-specific QA protocols using custom phantoms. These protocols often omit DAP monitoring, and dose monitoring systems may not receive input from dental devices via Radiation Dose Structured Reports, or only report CTDI instead of DAP that is the dose unit used for diagnostic reference levels in Finland.

QA is required at least twice a year or following service. We had a case that after a service, a dental unit’s software was reverted to factory settings (exposure settings altered) via service engineer without notifying users, leading to consistently elevated patient doses. This went unnoticed due to the lack of DAP data integration to our dose monitoring systems.
Results or Findings: We developed a multi-modality QA system using open-source libraries and a web-based interface at HUS Diagnostic Center. The system now includes dental device QA via electronic forms and monthly DAP value checks for the most common protocol (teeth). The updated system streamlines QA, eliminates parallel spreadsheet logging, and improves data consistency. It also addresses the previously reported adverse event by incorporating DAP monitoring.
Conclusion: The revised QA process is scalable across dental imaging units. The web-based form harmonizes documentation and enables dose monitoring, supporting safer and more transparent imaging practices. Manufacturers should ensure DAP values are included in baseline system checks.
Limitations: No limitations were identified.
Funding for this study: None.

Errors in hybrid nuclear medicine: overview, challenges, and prevention (6 min)

Kirill Skovorodko; Vilnius / Lithuania

Author Block: K. Skovorodko, D. Serėnaitė-Pečiulė, V. Statkus, R. Komiagienė, L. Krynke, B. Gricienė; Vilnius/LT
Purpose: Hybrid nuclear medicine methods such as PET/CT, SPECT/CT and PET/MRI have significantly improved diagnostic accuracy by combining functional and anatomical data. Despite the clinical benefits of these methods, the complexity nuclear medicine procedures and these modalities entails a wide range of potential errors, ranging from technical to human factors. The aim of this study was to analyse the reported errors in Lithuanian hospitals providing nuclear medicine services, identify the main problems associated with these errors and discuss possible ways to prevent them.
Methods or Background: An assessment of official error (unintended events and accidents) registration data for the period 2020–2025 in Lithuanian hospitals providing nuclear medicine services was conducted. An oral survey of nuclear medicine department personnel was also conducted to assess potential weaknesses that could lead to errors and identify possible measures to prevent them.
Results or Findings: Prevention strategies target both to quality assurance system and human performance should be implemented. Key measures include compressive quality assurance of the equipment, standardized training and practice, and structured reporting to reduce errors. AI and advanced software can automate checks, limit misregistration, and support interpretation. A safety-focused culture with error reporting and regular clinical audits ensures early detection and ongoing improvement.
Conclusion: In conclusion, errors in hybrid nuclear medicine are due to many factors, reflecting both technological complexity and human limitations. Some of the potential errors could be minimized by using artificial intelligence solutions in nuclear medicine. By addressing these challenges through training, protocol standardization, and technological innovation, the field can improve diagnostic reliability while ensuring patient safety and optimal clinical outcomes. Errors in hybrid nuclear medicine not only compromise diagnostic reliability but can also lead to inappropriate clinical decisions and increased radiation exposure.
Limitations: Not applicable

Replacing Error-Prone Spreadsheets with a Free and Open-Source QC Management System: A QATrack+ Pilot Study Using the Pylinac ACR MRI Large Phantom Module (6 min)

Clarissa Attard; Birkirkara / Malta

Author Block: C. Attard, D. J. M. Scicluna, K. Schembri, N. Vella, E. Pace, C. J. Caruana; Msida/MT
Purpose: Medical Physics Quality Control (MPQC) often relies on improvised, locally-developed, spreadsheet-based, software tools used to manually collect, analyse, and present results. This may lead to undetected inconsistencies and, data-entry and formula errors. A more reproducible and controlled QC process is essential. This work reviewed spreadsheet-based error in current practice and explored QATrack+ as an alternative robust centrally managed solution.
Methods or Background: A literature review was conducted using Google Scholar with the search string “error AND spreadsheet AND medical-physics” (2015–present), which retrieved n = 1,780 papers. QATrack+, a free-open-source-software (FOSS) based alternative to spreadsheets was pilot-tested on annual MRI MPQC based on ACR guidelines.
Results or Findings: No previous studies were identified that investigated, classified or quantified errors emerging from the use of spreadsheet software in MPQC, despite hundreds of ‘horror-stories’ documented by the European Spreadsheet Risks Interest Group. The fact that studies have shown that the vast majority of MPQC rely on spreadsheets which are not compliant with the Flexible, Appropriate, Structured, Transparent (FAST) Standard for spreadsheet document control, indicates that errors are likely to be present which are undetected. QATrack+ supports the following main data-integration routes: external analysis with manual or automated API data entry and internal analysis with either non-version-controlled or version-controlled custom Python code. The latter preferred method was used in this study.
Conclusion: A centrally managed, controlled system such as QATrack+ is essential particularly considering that software is legally a medical device under EU regulations. The QATrack+ based MRI pilot programme developed demonstrates that such tools are within reach of all medical physics departments.
Limitations: N/A

Reporting of MRI Incidents and Near-misses at a Multi-site Imaging Centre (6 min)

Laura-Elina Lahtela; Helsinki / Finland

Author Block: L-E. Lahtela, T. Mäkelä, T. Kaasalainen, M. Timonen; Helsinki/FI
Purpose: MRI safety relies on comprehensive staff training, well-defined duties, thorough risk awareness, access control, strict screening protocols, emergency preparedness, and management of safety incidents and concerns. Fostering an ongoing safety culture is one of the most influential strategies for sustaining and enhancing safety practices. Operating within a multi-site and multi-departmental environment introduces additional factors that must be addressed to ensure effective communication and coordination. Over the years, we have improved our incident reporting and handling protocols.
Methods or Background: Historically, MRI safety practices in Finland have largely been determined by individual imaging facilities and local established protocols. This is in contrast with ionising radiation modalities, where nationwide regulation has long promoted best clinical practices, safety monitoring, and communication.
Results or Findings: We created an online tool to report MRI incidents and near misses. Typical reported incidents include small metal objects in the scanning room and uncertainty regarding the safety of undisclosed implants or other foreign bodies. We have also identified the lack of MRI safety training of visiting non-MRI personnel as a recurring and significant risk factor. The main benefit of the tool has been lowering the barrier to report incidents. All findings are communicated in regular meetings and incorporated into staff training sessions. Significant accidents reported by other institutions worldwide are also reviewed and discussed.
Conclusion: If the safety culture does not encourage constructive feedback and open discussion, there is a risk of underreporting and an increased likelihood of preventable accidents. MRI safety can be enhanced by promoting the reporting, management, and documentation of all incidents, near-misses, and potential safety issues. The reporting system should be simple and user-friendly to encourage participation and effectiveness, and push towards continuous improvement of MRI safety.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study.

From error to excellence: seven principles for highly effective radiology learning (6 min)
Rachel Magennis; Hale / United Kingdom

Author Block: R. Magennis[1], E. K. Roditi[2]; [1]Manchester/UK, [2]Glasgow/UK
Purpose: Errors and discrepancies are an unavoidable part of radiology. The Royal College of Radiologists recommends Radiology Events and Learning Meetings (REALM) as a safe forum for discussing them. Beyond reviewing individual cases, these meetings provide powerful insights into the attitudes and behaviours that help radiologists thrive.
Methods or Background: Drawing on a year of REALM discussions and informal participant feedback, we identified seven principles that consistently supported positive learning and professional growth.

Own the Learning – contribute, seek feedback, and embrace radiology event and learning (REAL) as a tool for growth.

Start with Patient Safety – keep patient outcomes at the centre of reflection.

Collaborate to Elevate – value input from colleagues across the team.

Listen Before You Lead – understand others' reasoning when offering feedback.

Reflect, Don't React – approach discrepancies with curiosity rather than defensiveness.

Spot the Good – celebrate strong practice as well as errors.

Keep Refining – translate learning into ongoing personal and departmental improvement.
Results or Findings: By embedding these habits, REALM creates a culture of openness and continuous improvement. This strengthens individual confidence, enhances team collaboration, and, most importantly, improves patient safety.
Conclusion: These 7 simple principles help shift REALM from a retrospective review of errors into a forward-looking, supportive process that normalises error, reduces shame and seeks balance with positive cases, further boosting morale. These encourage radiologists to learn together, improve systems, and recognise good practice as well as pitfalls.
Limitations: There are no limitations
Funding for this study: No funding received

Application of Large Language Models Integrated with the BOPPPS Teaching Model in the Standardized Residency Training of Radiology (6 min)
Kai Zhao; Harbin / China

Author Block: H. Jiang, K. Zhao; Harbin/CN
Purpose: To evaluate the effectiveness and educational value of integrating a Large Language Model for Radiological Knowledge Base (LLM-RKB) with the BOPPPS teaching model in standardized radiology resident training.
Methods or Background: Fifty-six radiology residents from the Second Affiliated Hospital of Harbin Medical University were randomly assigned 1:1 to an experimental group or a control group. The experimental group received LLM-RKB combined with BOPPPS instruction, while the control group received traditional lecture-based learning. Post-training assessments included a theoretical exam, practical radiological diagnosis evaluation, and an anonymous satisfaction questionnaire. Independent-samples t-tests were used for analysis.
Results or Findings: The experimental group achieved higher scores in both theoretical knowledge and practical diagnostic skills [(87.74 ± 3.94) vs. (80.93 ± 5.94) and (85.95 ± 3.89) vs. (79.77 ± 6.46), respectively; $P < 0.05$]. Satisfaction scores were also significantly higher in the experimental group ($P < 0.05$).
Conclusion: Integrating LLM-RKB with the BOPPPS model significantly improves radiology residents' knowledge acquisition and diagnostic abilities, demonstrating its potential as an effective strategy for enhancing standardized radiology training.
Limitations: It should be noted that this study has certain limitations, such as a limited sample size and a relatively short training period, which may affect the generalizability of the results.
Funding for this study: No

Ethics committee - additional information:

Creating a safe space for learning: resident lead radiology events and learning meeting using a traffic-light addendum system (6 min)

Rachel Magennis; Hale / United Kingdom

Author Block: R. Magennis, N. Edi-Osagie, M. M. Kiandee; Manchester/UK
Purpose: Structured learning from diagnostic discrepancies is essential in radiology training, particularly in the high-stakes out-of-hours setting. This project describes the implementation of a resident-led learning meeting, tailored to on-call practice and aligned with the RCR's Radiology Events and Learning (REAL) framework.
Methods or Background: A traffic-light system was introduced to classify consultant-issued addenda to resident reports:
• Green: Consultant agrees with the provisional report.
• Amber: Minor additional finding, not impacting immediate management.
• Red: Significant change or addition requiring urgent communication with the clinical team.
Trainees' provisional reports may precede consultant review by up to 16 hours. Cases were reviewed from the amber and red categories for educational value, not just in terms of clinical diagnostic decisions but also for decision making and communication lessons or human factor related learning. The dedicated resident REAL meeting provides a safe, peer-led forum to discuss anonymised amber/red cases without the perceived inhibition of senior presence.
Results or Findings: Outcomes have included improved confidence in clinical reasoning, greater insight into diagnostic uncertainty, and a stronger culture of reflection and shared learning. Leadership skills were fostered through rotating facilitators, and participants reported feeling empowered to ask questions and openly analyse their decision-making processes.
Unforeseen benefits included early identification of recurrent error patterns and strengthened links between the trainee group and the wider department via feedback loops into the main REAL meeting.
Conclusion: This pilot demonstrates that a psychologically safe, trainee-led forum focused on local discrepancies enhances learning from error, supports professional growth, and ultimately improves patient care.
Limitations: There were no limitations
Funding for this study: No funding received

Long-term Evaluation of the Objective Structured Clinical Examination (OSCE) in Radiology Resident Training: A Multi-dimensional Assessment from Examiners' and Examinees' Perspectives (6 min)

Ning Ding; Beijing / China

Author Block: N. Ding, X. Gao, H. Sun, L. Song, X. Wang, Y. Chen, D. Zhang, H. Xue, Z. Jin; Beijing/CN
Purpose: This study aimed to evaluate the effectiveness, reliability, and validity of the Objective Structured Clinical Examination (OSCE) in radiology resident training, from the perspectives of both examiners and examinees.
Methods or Background: This retrospective observational study analyzed subjective evaluations and objective examination data collected over 6 years (2018–2021, 2023, and 2024). Subjective evaluations were gathered via questionnaires from 198 examiners and 818 examinees to assess the difficulty and satisfaction with the OSCE. Objective data, including examination scores, difficulty indices, and discrimination indices, for each OSCE station were analyzed using correlation analysis and t-tests.
Results or Findings: The OSCE demonstrated stable performance over 6 years, with consistent difficulty levels and discrimination ability across all stations. The average scores for individual stations varied; however, the overall final scores remained stable. Strong correlations between the station and final scores indicate good discrimination. Examinees rated the overall difficulty higher than examiners, but the objective indices aligned with examiner assessments. Over 6 years (198 examiners, 818 examinees), OSCE scores stabilized (85.48–88.48), with improved consistency (station range narrowed to 85.51–93.9 by 2024). Difficulty (0.12–0.15) and discrimination indices remained stable (most $p < 0.05$). Examinees rated it harder than examiners ($p < 0.001$).
Conclusion: The OSCE is a reliable, valid, and effective assessment tool in radiology. Evaluating the OSCE from both subjective and objective perspectives ensured the robustness and validity of the examination.
Limitations: This study had certain limitations. First, the retrospective design inherently limits causal inferences, though our 6-year dataset provides robust observational evidence. Second, while the 3-point Likert scale (difficult/moderate/easy) was chosen to maximize response rates during time-sensitive post-exam evaluations, future studies could adopt a 5-point scale for more nuanced feedback.
Funding for this study: This study was supported by the Peking Union Medical College, Graduate Education and Teaching Reform Project in 2024 (grant number: 2024yjsjg006)
Has your study been approved by an ethics committee? Yes

Enhancing Radiologists' Soft Skills: A Multidimensional Approach for Patient-Centered Care (6 min)

Manal El Moujahid; Agadir / Morocco

Author Block: M. El Moujahid; Agadir/MA
Purpose: -Highlight key soft skills every radiologist should develop.
-Present a multidimensional communication model for patient interactions.
-Suggest ways to integrate these skills into residency training
Methods or Background: We performed a scoping review (2010–2023) of 40 studies from PubMed, Scopus, and Embase, focusing on radiology communication and patient-centered care [1–3]. Insights were synthesized into a five-step framework: welcoming, reassuring, explaining, accompanying, and motivating patients. Training ideas—such as workshops, role-playing, and simulated patient encounters with feedback—were developed to help residents practice these skills in real-life scenarios
Results or Findings: Training in communication improves patient satisfaction (~30%) and reduces anxiety (~25%) [2].
The five-step framework gives radiologists a clear structure for interactions and can be adapted to different languages and cultures.
Simulations increase residents' communication scores by ~20% [3], building confidence and trust.
Better communication may also reduce complaints and misunderstandings.
Soft skills are not "extra"—they're essential for patient-centered care. Our framework offers a practical, adaptable approach for residency programs, helping future radiologists balance technical expertise with meaningful patient interactions. Challenges include fitting training into busy schedules.
Conclusion: A structured, multidimensional approach to communication is feasible and impactful. Integrating soft skills training into radiology education supports both professional growth and better patient experiences. Next steps include pilot testing and measuring effects on satisfaction and clinical outcomes.
Limitations: The effectiveness of our recommendations will be assessed in a subsequent study
Funding for this study: This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors

Effect of interruptions on radiologists' active reporting time (6 min)

Juho Huovinen; Kuopio / Finland

Author Block: J. Huovinen, S. Väänänen, A-P. Ronkainen, J. Hakumäki, O. M. Lahtinen; Kuopio/FI
Purpose: While previous studies have shown that interruptions are common in radiologists' workflow, they rely mostly on qualitative data. Interruptions can originate from consultations from trainees, co-workers and clinicians, IR-procedures and tele-communications. We aim to quantify how interruptions affect active reporting times.
Methods or Background: We analyzed radiological reporting between 2019-2025 at the Kuopio University Hospital, Finland. Our dataset included radiological examination and report metadata, user profiles from the reporting databases, and command-level usage logs from the PACS. Reporting times and interruptions were determined from examination opening and closing events in PACS, supplemented by “report completed” timestamps from the RIS. An interruption was defined as accession of an unrelated examination before completing the original report. We investigated the disruptiveness of interruptions by grouping them into categories (Zero, One, Two, Three-or-more interruptions) and conducted multivariable linear regression analysis.
Results or Findings: The median active reporting times of N=42772 MRI, N=92765 CT and N=241936 X-ray examinations were 13.95±18.95 min, 12.75±15.27 min and 2.13±5.28 min, respectively. The median active reporting times for interrupted cases were 16.04±19.24 min (N=9414) for MRI, 14.87±16.15 min (N=16065) for CT and 2.94±7.61 min (N=36334) for X-ray. The median duration of the interruption was 3.74±53.55 min for MRI, 3.14±47.30 min for CT and 1.38±50.10 min for X-ray. After adjusting the examination type, one interruption was associated with a 26% increase in active reporting time ($p<0.00$, $R2=0.52$), two interruptions increased the active reporting time 44% and three or more interruptions increased the active reporting time 51%.
Conclusion: Interruptions have a significant impact on radiologists’ active reporting time.
Limitations: Interruption types, subgroups and their effect on report quality will be analyzed in future studies.

Research motivation and success factors in radiology – results of a nationwide survey (6 min)

Franz Wegner; Lübeck / Germany

Author Block: F. Wegner[1], H. Heinrichs[2], K. Stahlmann[3], F. Kiessling[2], T. Bäuerle[4], P. Bannas[3]; [1]Lübeck/DE, [2]Aachen/DE, [3]Hamburg/DE, [4]Mainz/DE
Purpose: Research activities are very important for the advancement of medical disciplines. In the context of increasing workload and persistent staff shortages, both the time and willingness to engage in research are diminishing. A comprehensive understanding of determinants of scientific success is therefore essential to enable its systematic and targeted promotion. The goal of this study was to explore motivation and identify key success factors for research in radiology.
Methods or Background: A nationwide online survey (54 items, duration: 3.5 months) was conducted in Germany. The questionnaire assessed demographic, intrinsic and extrinsic success characteristics, as well as personal and organizational determinants of success, based on an available career success model. The results were reported descriptively, and associations between success factors and success characteristics were evaluated by using linear, binary-logistic, and multinomial regression models.
Results or Findings: A total of 176 individuals participated (164 with academic activity, 10 without). The majority (80%, 139/174) were employed at university hospitals, and 32% held the academic title of Privatdozent (assistant professor) or professor (56/173). The primary motivation for research was intrinsic scientific interest (55%, 89/163), followed by career advancement opportunities (25%, 41/163). Key predictors of intrinsic success included: a) support from department management ($\beta=0.26$, $p<0.001$), b) good work-life balance ($\beta=0.37$, $p<0.001$), and c) sustained engagement in research beyond career milestones ($\beta=0.16$, $p=0.016$). Extrinsic success was significantly associated with mentoring, protected research time, and active involvement in professional societies.
Conclusion: Radiology researchers in Germany are predominantly driven by intrinsic motivation. Established determinants of both intrinsic and extrinsic scientific success were confirmed in this study. Awareness of these factors enables targeted support strategies, potentially enhancing scientific achievement in radiology.
Limitations: The survey was available only in German.

Radiologists’ Quality of Life and Occupational Stress in India: A Cross-Sectional Study (6 min)

Farook Abubacker Sulaiman; Chennai / India

Author Block: F. Abubacker Sulaiman; Chennai/IN
Purpose: To evaluate the quality of life, occupational stress, and burnout prevalence among radiologists in India, and to identify key professional and interpersonal factors contributing to stress in contemporary radiology practice.
Methods or Background: A cross-sectional, questionnaire-based study was conducted among 210 practicing radiologists across India between January and June 2025. Data were collected using the WHOQOL-BREF and Perceived Stress Scale (PSS-10) along with structured questions on workload, reporting pressure, interpersonal expectations, and lifestyle habits. Responses were anonymized and analyzed using descriptive statistics and multivariate regression to determine predictors of high stress and reduced life quality.
Results or Findings: The mean age of participants was 38.4 ± 8.7 years, with a male-to-female ratio of 1.6:1. The average weekly workload was 58 ± 12 hours, and 68% reported frequent emergency or night duties. Turnaround time (TAT) pressure was identified as a major stressor by 74% of respondents, with additional strain arising from referring clinicians demanding immediate appointments and same-day reports (69%), and patients expecting instant results (63%). Overall, 54% exhibited moderate-to-high stress scores, while 39% met criteria for burnout. Long working hours, administrative load, and unrealistic reporting timelines were significantly associated with stress ($p < 0.01$). Radiologists engaged in teaching or research reported comparatively better psychological well-being.
Conclusion: Indian radiologists face significant occupational stress driven by high workload, rapid report turnaround expectations, and external pressure from referring doctors and patients. Institutional measures promoting realistic scheduling, adequate staffing, and wellness initiatives are essential to preserve mental health and professional satisfaction.
Limitations: Absence of longitudinal follow-up limit generalizability.
Funding for this study: No external funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Institutional ethical committee approval was obtained.

AI-SC 12 - Beyond detection: multimodal AI and predictive analytics in radiology

Categories: Artificial Intelligence, Imaging Informatics, Imaging Methods
ETC Level: LEVEL II+III
Date: March 6, 2026 | 08:30 - 09:30 CET
CME Credits: 1

Moderator:
Dennis M Hedderich; Munich / Germany

Chairperson's introduction (5 min)
Dennis M Hedderich; Munich / Germany

Defining multimodal AI and its future impact on radiology (20 min)
Haris Shuaib; London / United Kingdom

1. To understand the concept of multimodal AI and how it integrates imaging, clinical, genomic, and digital health data.
2. To review the benefits of real-world implementations and emerging applications in radiology.
3. To suggest ethical, legal, and regulatory frameworks guiding safe and trustworthy deployment of multimodal AI in healthcare.

A roadmap for multimodal AI in clinical and personalised care (20 min)
Benjamin D Simon; Oxford / United Kingdom

1. To explore the challenges and enablers of translating multimodal AI into daily radiology practice, including interoperability and data standards.
2. To discuss the use of stratification and prognostic models that predict disease trajectory and treatment response.
3. To envision future directions where multimodal AI supports personalised care and reshapes the role of radiologists.

Q&A: Is the radiology future multimodal and predictive? (15 min)

EFRS 12 - How to let your research gain impact

Categories: Radiographers, Research, Education

Date: March 6, 2026 | 08:30 - 09:30 CET

CME Credits: 1

This session will explore how to maximise the visibility and impact of radiography research. Topics include how to present and position research effectively within the academic writing process, highlighting its clinical impact, and strategies for communicating findings to a wider audience beyond academia. Participants will gain practical tools to ensure their research reaches the right stakeholders and drives meaningful change in both practice and public understanding.

Moderators:

Helle Precht; Middelfart / Denmark

Moreno Zanardo; Milan / Italy

Chairperson's introduction (5 min)

Helle Precht; Middelfart / Denmark

Moreno Zanardo; Milan / Italy

How to sell your research in the academic writing process (12 min)

Karen Knapp; Newton Abbot / United Kingdom

1. Examples of how to write an article that captivates readers and clearly frames the study's purpose
2. What journal to choose for the specific paper?
3. Reflect on how to make the story of the paper clear and precise

Clinical impact (12 min)

Aurelija Blaževičienė; Kaunas / Lithuania

1. Relevant research questions and best research methods to gain clinical impact
2. Ensure collaboration with clinicians and patients
3. Reflect on best practice in regard to clinical impact

How to communicate to the wider audience about your research (12 min)

Nejc Mekis; Ljubljana / Slovenia

1. What happens after an article is published?
2. How to share new knowledge with your clinical colleagues
3. Where to tell and inform about your study?

Panel Discussion (19 min)

CUBE 13 - From ablation to embolisation: modern interventional approaches in the liver

Categories: Interventional Radiology, Abdominal Viscera
ETC Level: LEVEL II+III
Date: March 6, 2026 | 09:00 - 09:30 CET
CME Credits: 0.5

Moderator:
Pascal A.T. Baltzer; Vienna / Austria

Chairperson's introduction (2 min)
Pascal A.T. Baltzer; Vienna / Austria

From ablation to embolisation: moder interventional approaches in the liver (28 min)
Peter Popovic; Ljubljana / Slovenia

1. To learn the indications and patient selection criteria for ablation and embolisation of liver lesions.
2. To appreciate the technical aspects, imaging guidance, and workflow of modern locoregional liver interventions.
3. To understand the clinical outcomes, complications, and comparative efficacy of different interventional approaches.

ST 17 - Empowering Breast Cancer Patients and Radiologists with Be Accepted

Categories: General Radiology, Professional Issues, Education, Multidisciplinary

Date: March 6, 2026 | 09:00 - 09:30 CET

This studio session focuses on how early patient education and empowerment can improve outcomes in breast cancer care while easing pressure on healthcare systems. The Be Accepted initiative as an example, highlights a patient-centered approach that combines medical expertise, emotional support, and technology, positioning women as active partners in their care. Perspectives from leadership, clinical practice, and women's health innovation show how human connection alongside diagnostic excellence strengthens prevention, communication, and treatment pathways – and how this approach can be scaled internationally to reduce disparities in breast cancer care and at the samé time relief the stain health care system.

Moderator:

Mélisande Rouger; Bilbao / Spain

Interview (30 min)

AR h13 - How to improve your head and neck cancer staging reports in practice

Categories: Oncologic Imaging, Head and Neck, Professional Issues
ETC Level: LEVEL I+II
Date: March 6, 2026 | 09:30 - 10:30 CET
CME Credits: 1

Moderator:
Ho Sang Leung; Hong Kong / Hong Kong SAR China

Introduction (3 min)
Ho Sang Leung; Hong Kong / Hong Kong SAR China

Basic principles (7 min)
Ann Dorothy King; Hong Kong / China

1. To learn how to structure head and neck cancer reports so that findings are easily extractable and clinically relevant.
2. To appreciate the importance of concise and clear language in improving communication and decision-making.
3. To understand how to tailor reports to specific head and neck cancer types, ensuring completeness without omissions.
4. To learn techniques for addressing uncertainty in imaging findings while minimising ambiguity and avoiding errors.

Cases review, interactive discussion and critiquing of reports (50 min)
Ho Sang Leung; Hong Kong / Hong Kong SAR China
Ann Dorothy King; Hong Kong / China

1. To critique reports and suggest ways of improving them.
2. To show how to make reports brief yet clinically pertinent.

BS 13 - Person-centred care in a business-oriented department

Categories: Radiographers, Management/Leadership

Date: March 6, 2026 | 09:30 - 10:30 CET

CME Credits: 1

A dynamic session highlighting the risks of standardised (non-personalised) care pathways, the challenges of prioritising person-centred care in business-driven environments, and the evolving roles of hybrid imaging and multidisciplinary education in shaping personalised radiographic practice.

Moderator:

Karen Borg Grima; Naxxar / Malta

Chairperson's introduction (5 min)

Karen Borg Grima; Naxxar / Malta

Make society aware about the risks of non-personalised pathways in radiography (10 min)

Eleni Georgiadou; Keratsini / Greece

Overcoming the challenges of person-centred care when the business comes first (10 min)

Ricardo Silva Teresa Ribeiro; Lausanne / Switzerland

Training radiography students in a multidisciplinary environment (10 min)

Martijn Kamphuis; Haarlem / Netherlands

The value of hybrid modalities for more adapted care (10 min)

Emanuele Casiraghi; Tarragona / Spain

Panel discussion: Challenges of the radiography profession in high-demand work contexts (15 min)

EFRS WS 13 - Contemporary approaches to continuing professional development: improving image quality

Categories: Radiographers, Education, Artificial Intelligence
Date: March 6, 2026 | 09:30 - 11:00 CET
CME Credits: 1.5

Moderator:
Niamh Moore; Cork / Ireland

Options for improving image evaluation education: presentation, live software demonstration (DetectedX) and Q&A (60 min)

Niamh Moore; Cork / Ireland

1. To demonstrate and apply best practices, tips and tricks for using online image review platforms to improve radiographic practice.

Objective and subjective assessment of image quality (UCC): presentation, live software demonstration and Q&A (30 min)

Mark F. Mcentee; Cork / Ireland

1. To describe best practices, tips and tricks for retrospectively evaluating image quality within medical imaging.

EIBIR 13 - Strengthening the screening of lung cancer in Europe: key achievements, lessons learned, and legacy of the SOLACE project

Categories: Oncologic Imaging, Professional Issues, Research

ETC Level: LEVEL I+II

Date: March 6, 2026 | 09:30 - 11:00 CET

CME Credits: 1.5

Strengthening the screening of lung cancer in Europe (SOLACE) is a pioneering EU4Health project under Europe's Beating Cancer Plan. SOLACE has helped implement lung cancer screening programs across Europe, removing barriers to ensure access for all social and economic groups. This session offers attendees the chance to engage with experts from the SOLACE project, discussing key achievements, lessons learned, and innovative approaches in lung cancer screening across Europe.

Moderator:
Anna Kerpel-Fronius; Budapest / Hungary

Chairperson's introduction (3 min)
Anna Kerpel-Fronius; Budapest / Hungary

Key achievements and lessons learned of SOLACE (7 min)
Joanna Chorostowska-Wynimko; Warsaw / Poland

Lung cancer screening pilots across Europe: data collection and preliminary results (10 min)
Emily Nischwitz; Heidelberg / Germany

Chest LDCT acquisition and reporting: insights from SOLACE (10 min)
Roberta Eufrasia Ledda; Parma / Italy

Improving female participation in LCS: key insights from SOLACE (10 min)
Marie-Pierre Revel; Paris / France

Reaching the unreached: strategies for recruiting hard-to-reach individuals in LCS (10 min)
Ildiko Horvath; Budapest / Hungary

Targeting higher-risk populations: insights from SOLACE (10 min)
Eva Kocova; Hradec Kralove / Czechia

Ensuring long-term impact: evaluation, sustainability, and training in LCS (10 min)
Helmut Prosch; Vienna / Austria

Panel discussion (20 min)

E³ 1318 - Abdomen: pancreas and colon

Categories: Oncologic Imaging, GI Tract, Abdominal Viscera, President's Choice

ETC Level: LEVEL II+III

Date: March 6, 2026 | 09:30 - 11:00 CET

CME Credits: 1.5

The aim of the session is to understand the importance of radiologic-pathologic correlation in solid tumours of the pancreas and to be aware of the importance of radiologic-pathologic correlation in colorectal cancer.

Moderator:

Sofia Gourtsoyianni; Athens / Greece

Chairperson's introduction (5 min)

E³ 1319 - Ovarian-adnexal reporting and data system (O-RADS): what you need to know for clinical practice

Categories: Oncologic Imaging, Genitourinary
ETC Level: LEVEL I+II
Date: March 6, 2026 | 09:30 - 11:00 CET
CME Credits: 1.5

Moderator:
Shabnam Bhandari Grover; Greater Noida, NCR-Delhi. / India

Chairperson's introduction (5 min)
Shabnam Bhandari Grover; Greater Noida, NCR-Delhi. / India

US ovarian-adnexal reporting and data system (O-RADS) (20 min)
Tanya Punita Chawla; Toronto / Canada

1. To learn about the key elements of classifying pelvic masses with US O-RADS.
2. To learn about key technical considerations for US O-RADS.
3. To appreciate the strengths and weaknesses of US O-RADS.

MRI ovarian-adnexal reporting and data system (O-RADS) (20 min)
Theresa Mokry; Heidelberg / Germany

1. To learn about the key elements of classifying pelvic masses with MRI O-RADS.
2. To learn about key technical considerations for MRI O-RADS.
3. To appreciate the strengths and weaknesses of MRI O-RADS.

Ovarian-adnexal reporting and data system (O-RADS): lessons learnt and the reality of practice (20 min)
Priyanka Jha; San Francisco / United States

1. To appreciate the key clinical considerations in the workup of women with a pelvic mass.
2. To learn how to combine US and MRI O-RADS in clinical practice.
3. To appreciate the challenges of using O-RADS in clinical practice.

Case-based panel discussion: learning from challenging cases (25 min)
Isabelle Thomassin-Naggara; Paris / France

E³ 1321 - Post-mortem imaging: focus on undetected tumours

Categories: Oncologic Imaging, Medico-legal, Forensic Imaging
ETC Level: LEVEL III
Date: March 6, 2026 | 09:30 - 11:00 CET
CME Credits: 1.5

Thoracic lesions (45 min)
Nicolò Gennaro; Chicago / United States

1. To assess undetected tumours or additional predictive features in the thoracic area.

Abdominal lesions (45 min)
Virginie Magnin; Lausanne / Switzerland

1. To assess undetected tumours or additional predictive features in the abdominal area.

E³ 1323 - Paediatric

Categories: Neuro, Paediatric, Chest, GI Tract, Abdominal Viscera

Moderator:
Claudia Sa Dos Reis; Lausanne / Switzerland

Chairperson's introduction (5 min)
Claudia Sa Dos Reis; Lausanne / Switzerland

Clinical outlook: emerging trends in breast imaging (12 min)
Antonio Portaluri; Amsterdam / Netherlands

1. To identify key technological advancements shaping the future of breast imaging (e.g., contrast-enhanced mammography, AI integration, ultra-fast MRI and tomosynthesis).
2. To understand how emerging imaging techniques are improving early detection, diagnosis, and personalised care in breast health.
3. To learn the interventional imaging evolutions that are available to improve patient outcomes.

The mammographer's perspective about personalised breast screening (12 min)
Patsy Whelehan; Swindon / United Kingdom

1. To understand the principles and benefits of personalised breast screening approaches.
2. To explore how mammographers adapt imaging techniques to individual patient risk profiles.
3. To recognise the challenges and opportunities of implementing personalised screening in clinical practice.

Cutting-edge techniques in advanced breast imaging modalities (12 min)
Solveig Hofvind; Oslo / Norway

1. To identify the latest advancements in breast imaging technologies, including in the nuclear medicine domain.
2. To understand how these advanced modalities improve diagnostic accuracy and patient outcomes.
3. To explore the evolving role of radiographers in implementing and optimising cutting-edge imaging techniques.

Open forum discussion (19 min)

PC 13a - Implementing the European Cardiovascular Health (ECVH) Plan

Categories: Cardiac, Imaging Methods, Management/Leadership, Multidisciplinary, President's Choice, Professional Issues

Rodrigo Salgado; Antwerp / Belgium

Chairpersons' introduction (5 min)
Rodrigo Salgado; Antwerp / Belgium
Carlo Catalano; Rome / Italy

The EU Cardiovascular Health Plan: a roadmap to reduce preventable and premature deaths (10 min)
Romana Jerković; Brussels / Belgium

1. To outline the European Commission's Cardiovascular Health Plan, explain its main objectives and policy context, as well as to highlight the role of the European Parliament's upcoming cardiovascular health report in providing political guidance, scrutiny and support for effective implementation.
2. To recognise the central importance of prevention, early detection and equity in reducing the cardiovascular disease burden, with particular attention to the influence of social, environmental and commercial determinants of health on cardiovascular risk and outcomes.
3. To identify how EU-level action can support member states in strengthening cardiovascular health policies, improving coordination across sectors and levels of governance, and reducing persistent inequalities in cardiovascular outcomes across the European Union.

Understanding the EU policy framework on a national and international level (15 min)
Piotr Szymański; Warsaw / Poland

1. To learn how EU-level policy frameworks can be leveraged to promote cardiovascular disease prevention, structured early-diagnosis pathways, and truly patient-centred models of care.
2. To appreciate the synergies between cardiovascular strategies and broader European health initiatives and how these programmes can be mutually reinforcing.
3. To understand the key policy levers and implementation mechanisms that national health systems can adopt to translate EU strategic objectives into measurable improvements in cardiovascular outcomes.

Integration of radiology in the CVH plan: benefits and challenges (15 min)
Rodrigo Salgado; Antwerp / Belgium

1. To learn how radiology can contribute to the different aspects of the CVH plan.
2. To understand the different challenges for practical implementation.
3. To outline different possible solutions integrated in the current vision of ESR-ESCR for future collaboration.

Potential of imaging in prevention and early detection (15 min)
Rozemarijn Vliegenthart; Groningen / Netherlands

1. To understand the current practice and challenges in the prevention of CVD.
2. To learn about the potential value of imaging in the early detection of CVD.
3. To appreciate the gaps in knowledge regarding the implementation of imaging in this area.

Panel discussion: A multidisciplinary approach to tackling European Cardiovascular Health: how to proceed? (30 min)

PC 13b - The changing art of reporting chest radiographs, the beginning of the end?

Categories: Chest, Radiographers, Professional Issues, Artificial Intelligence, President's Choice
ETC Level: LEVEL II+III
Date: March 6, 2026 | 09:30 - 11:00 CET
CME Credits: 1.5

Moderator:
Nigel Howarth; Carouge / Switzerland

Chairperson's introduction (5 min)
Nigel Howarth; Carouge / Switzerland

Who reports chest radiographs across Europe? (20 min)
Thomas Frauenfelder; Zürich / Switzerland

1. To learn how many chest radiographs are performed across Europe
2. To understand who reports chest radiographs.
3. To find out if any chest radiographs are unreported in Europe.

Who will be the expert teacher if radiologists are no longer the experts? (20 min)
Annemiek Snoeckx; Zandhoven / Belgium

1. To learn how radiologists, pulmonologists, and radiographers learn to read chest radiographs.
2. To learn how one can test and how audits can help quality.
3. To understand what one should expect from an "expert".

Chest radiograph reporting using AI by non-radiologists/radiographers (20 min)
Fergus Gleeson; Oxford / United Kingdom

1. To learn how AI affects the reporting of chest radiographs.
2. To learn how AI can improve our reporting.
3. To understand AI's pitfalls and how we can recognise them.

Panel discussion: How can we teach the younger generations to be confident in diagnosing of chest radiographs? (25 min)

RC 1311 - Pick up the phone in the neuroradiology reading room

Categories: Emergency Imaging, Neuro, Head and Neck, Vascular, President's Choice

Neuro-opthalmological emergencies (12 min)
Augustin Lecler; Paris / France

1. To identify important imaging signs that help detect serious neuro-ophthalmologic problems needing urgent treatment.
2. To know how to spot critical conditions like optic nerve damage, orbital apex issues, or space-occupying lesions.
3. To learn to tell the difference between real emergencies and look-alike findings that are not dangerous, to avoid unnecessary alarms and delays in care.

Brain cases with urgent findings in stroke and trauma (12 min)
Valentina Elisabetta Lolli; Lille / France

1. To learn to catch the subtle signs of stroke or trauma on imaging, those small but important clues that can easily be missed in a busy emergency setting.
2. To learn how to look at brain images step by step to avoid mistakes in trauma and vascular cases.
3. To learn to identify urgent findings that need to be reported immediately because they can change treatment.

Don't miss lessons: infectious and inflammatory emergencies (12 min)
Vanesa Carlota Andreu Arasa; Boston / United States

1. To learn to spot key imaging findings in brain infections and inflammation—think abscesses, encephalitis, and autoimmune flare-ups.
2. To differentiate imaging patterns of acute infectious and inflammatory diseases from neoplastic or ischemic processes in the emergency setting.
3. To recognise when something is on the scan means you need to call the clinical team immediately.

Radiological findings that can be omitted from the report to avoid confusion (12 min)
Zoran Rumboldt; Rovinj-Rovigno / Croatia

1. To identify imaging findings that are incidental or non-contributory in the emergency setting and may be omitted from the radiology report.
2. To learn how to apply criteria to distinguish clinically relevant abnormalities from anatomical variants and benign conditions.
3. To make your reports clear and helpful: Focus on what changes patient care, so your report helps the team make the right decisions quickly.

Panel discussion: Integrating neuroradiology into clinical decision-making in emergencies (10 min)

RPS 1301 - AI in liver and pancreatic oncology

A Multimodal Deep Learning Model for Prediction of Early Progression in Patients with Advanced Hepatocellular carcinoma Treated with Atezolizumab-Bevacizumab (6 min)
Gaia Crescimanno; Palermo / Italy

Author Block: G. Crescimanno, R. Cannella, C. Celsa, S. Contino, L. Cruciata, G. Cirrincione, R. Pirrone, G. Brancatelli, C. Cammà; Palermo/IT
Purpose: Atezolizumab-Bevacizumab is recommended as first-line treatment for advanced/unresectable hepatocellular carcinoma (HCC). However, validated clinical or radiological systems able to predict early treatment response or identify non-responsive patients at risk of early therapeutic failure are currently lacking. This study developed a multimodal AI model to predict 6-month progression-free survival (PFS).
Methods or Background: 51 patients (mean age 78.2±9.2 years, 78.4% male) with advanced/unresectable HCC treated with Atezolizumab-Bevacizumab as first-line systemic treatment between 2021 and 2024 were retrospectively included at a single tertiary referral centre. We designed a multimodal neural architecture using late fusion strategy: (1) convolutional neural network (CNN) for feature extraction from pre-treatment contrast-enhanced CT images using the arterial phase, and (2) multilayer perceptron (MLP) for conventional clinical-laboratory data. Feature vectors were concatenated and fed into a final classifier. Primary outcome was 6-month PFS. Performance metrics included accuracy, precision, recall, F1-score, and area under the curve (AUC).
Results or Findings: During median follow-up of 14.5 months, median overall survival was 23.6 months (95%CI:15.1-38.0) and median PFS was 14 months (95%CI:9.9-23.6), with 19.6% of patients experiencing radiological progression or death within 6 months. There were no Traditional statistical analysis failed to identify significant predictors of 6-month PFS by using conventional statistical analysis. The multimodal AI model demonstrated excellent performance for 6-month PFS prediction, with accuracy of 96.25%, precision 97.82%, recall 70.66%, F1-score 82.05%, and AUC 0.95.
Conclusion: Multimodal AI framework can successfully address the critical gap in early prediction of treatment failure for HCC patients on Atezolizumab-Bevacizumab. The high precision could make it a reliable clinical decision-support tool for identifying patients at risk of early therapeutic failure, improving personalized treatment.
Limitations: Single-center study with a small number of patients.

Ensemble Deep Learning Models on Multi-Sequence MRI for Enhanced Prediction of Microvascular Invasion in Hepatocellular Carcinoma (6 min)
Yifan Pan; Fuzhou / China

Author Block: Y. Pan; Fuzhou/CN
Purpose: To evaluate and compare three ensemble strategies—soft voting, hard voting, and stacking—in deep learning models integrating multi-sequence MRI data for predicting microvascular invasion (MVI) in hepatocellular carcinoma (HCC).
Methods or Background: Retrospective study included 299 postoperatively pathologically confirmed HCC patients from two centers. Six MRI sequences (T2WI, T1WI, arterial/portal venous/delayed/hepatobiliary phases) were manually annotated with bounding boxes to fully cover tumors. Six 3D ResNet-18 single-sequence models were built, with 5-fold cross-validation to ensure training robustness. The three ensemble strategies integrated model output probabilities; stacking used a support vector machine (SVM) as the meta-model for further training. Performance was assessed via receiver operating characteristic (ROC) curves.
Results or Findings: In the validation set, five-fold cross-validation showed the following average AUCs for single-sequence models: T2WI (0.685), T1WI (0.690), AP (0.689), PVP (0.712), DP (0.694), and HBP (0.666). For fusion strategies: soft voting aggregated MVI risk scores to reach AUC 0.775 and accuracy 0.721; hard voting yielded AUC 0.733 and accuracy 0.738. Among the three, stacking performed best (AUC 0.791, accuracy 0.740), outperforming the other two in integrating multi-sequence MRI for more accurate MVI prediction.
Conclusion: Multi-sequence MRI models consistently outperform single-sequence counterparts in HCC MVI prediction, as they integrate complementary info (e.g., T2WI's soft-tissue contrast, enhanced phases' vascular patterns) single-sequence models miss. Among ensembles, stacking excels by using an SVM meta-model to refine cross-sequence feature fusion—avoiding voting methods' flaws—and delivers the highest performance. This supports more reliable MVI stratification, aiding clinicians in optimizing surgical plans and postoperative follow-up for precise HCC management.
Limitations: The sample size needs expansion, and further multi-center studies are required to improve the generalizability of the findings.

Deep Learning on Gd-EOB-DTPA-Enhanced MRI for Predicting Early Recurrence and Prognosis Stratification in Hepatocellular Carcinoma (6 min)

Feng Che; Chengdu / China

Author Block: F. Che, Y. Wei, B. Song; Chengdu/CN
Purpose: This study aimed to develop and validate a Gd-EOB-DTPA-enhanced MRI–based deep multiple instance learning (D-MIL) model with knowledge distillation to predict early recurrence (ER) in HCC.
Methods or Background: We retrospectively enrolled 709 patients who underwent Gd-EOB-DTPA-enhanced MRI before resection from two centers. Patients from Center A (n=542) were divided into a training (n=434) and internal test set (n=108), while Center B (n=167) served as an external test set. A deep learning model was built on a multiple instance learning (MIL) framework using HBP images. The model applied a knowledge distillation strategy combining supervised learning from the TransMIL backbone, prediction alignment with an attention-based MIL model, and attention consistency constraints. Qualitative imaging features were assessed. Univariate and multivariate logistic regression identified independent predictors. RFS and OS were analyzed using Kaplan–Meier curves.
Results or Findings: The proposed D-MIL model showed robust predictive performance for ER, with an AUC of 0.80 in training, 0.76 in internal testing, and 0.73 in external testing. Multivariate logistic regression identified serum alpha-fetoprotein, tumor size, and HBP peritumoral hypointensity as independent predictors, used to construct the clinical-radiological model. The D-MIL model significantly outperformed both the clinical-radiological model (AUC 0.68) and the BCLC system (AUC 0.64) in the internal test set ($p < 0.05$). No significant difference was observed between the D-MIL model and the hybrid model combining clinical-radiological features. Kaplan–Meier analysis showed high-risk patients by the D-MIL model had significantly shorter RFS and OS than low-risk patients (both $p < 0.05$).
Conclusion: The proposed D-MIL model shows potential as a decision-support tool for predicting postoperative ER in HCC, enabling effective risk stratification of RFS and OS and supporting personalized therapy.
Limitations: The retrospective nature of the study may lead to selection biases.
Funding for this study: Not applicable.

Interpretable Hepatocellular Carcinoma Risk Stratification Model in Cirrhotic Patients: Integrating MRI-based Radiomics Deep Learning and Body Composition (6 min)

Yanjin Qin; Guangzhou / China

Author Block: Y. Qin, D. Xu, X. Zhou, S-T. Feng; Guangzhou/CN
Purpose: Purpose: Hepatocellular carcinoma (HCC) poses a significant global health challenge, underscoring the critical importance of accurate risk stratification in cirrhosis, which currently remains limited. This study aims to develop and validate an interpretable risk stratification prediction (called IRSP) model that integrates MRI-based radiomics, deep learning, body composition, and clinical features to enhance early HCC prediction in cirrhotic patients.
Methods or Background: Methods: This analysis included 479 cirrhotic patients from three primary cohorts who had undergone gadoxetic acid-enhanced MRI between January 2015 and December 2020. Radiomic and deep learning features were extracted from liver regions of interest at multi-MRI sequences (unenhanced, late arterial, and hepatobiliary phase). Unenhanced MRI-quantified body composition was measured. Using features mentioned above, the IRSP model was developed in the discovery cohort (n = 302), and then validated in an internal validation cohort (n = 73), and an external validation cohort from 2 external centers (n = 104).
Results or Findings: Results: The IRSP model effectively predicted short-term HCC development in cirrhotic patients with an area under the curve (AUC) of 0.924 (95% confidence interval 0.876-0.9721) in the discovery cohort, 0.895 (0.835-0.955) in the internal validation cohort, and 0.915 (0.882-0.948) in the external validation cohort. By applying optimal thresholds of 0.31 and 0.67, the high-risk (n = 121, 16.0%) and medium-risk (n = 233, 30.7%) groups, which covered 92.6% (88/95) of the patients who developed HCC, had significantly higher rates of HCC occurrence compared to the low-risk group (n = 404, 53.3%) (17.3% vs 4.8% vs 0.31%, $P < 0.001$).
Conclusion: Conclusion: The novel IRSP model provides reliable estimates of HCC development for cirrhotic patients and may have the potential to improve the precision in clinical decision-making and early initiation of HCC treatments.
Limitations: Not applicable.

A CT radiomic-integrated model to predict the risk of Hepatocellular Carcinoma in Cirrhotic patients (6 min)

Silvia Schirò; Parma / Italy

Author Block: S. Schirò[1], L. Leo[1], G. Besutti[2], C. Marrocchio[1], M. V. Bazzocchi[1], D. Stefanelli[1], E. Gjataj[2], G. Missale[1], N. Sverzellati[1]; [1]Parma/IT, [2]Modena/IT
Purpose: To develop and externally validate a clinico-radiomic model for predicting the risk of hepatocellular carcinoma (HCC) progress in cirrhotic patients employing non-contrast-enhanced CT scans
Methods or Background: In this retrospective bicentric study 141 cirrhotic patients were included and divided into a discovery cohort (n=98) and an independent test cohort (n=43). All subjects underwent at least one non-contrast abdominal CT prior to HCC onset (HCC cohort) or during follow-up (non-HCC cohort). The whole liver parenchyma was manually segmented from non-contrast CTs. Comprehensively 851 radiomic features were extracted and filtered for reproducibility and redundancy. A radiomics-only model (RAD) and a clinico-radiomic model (INT) integrating radiomics with clinical variables (alpha-fetoprotein, FIB-4 index, Child-Pugh score) were trained on the discovery cohort and validated on the test set.
Results or Findings: The RAD model, made of three selected features and a decision tree classifier, achieved an AUC of 0.696 in the external test set, with 0.905 sensitivity and 0.500 specificity. The INT model, incorporating RAD-score and clinical parameters via stochastic gradient descent, improved specificity to 0.681 while maintaining good sensitivity (0.809), yielding an AUC of 0.703. Decision curve analysis showed a higher net clinical benefit of both models compared to default strategies across a range of decision thresholds.
Conclusion: Radiomic features extracted from whole liver on non-contrast CT, especially when integrated with routine clinical data, can stratify the risk of HCC progress in cirrhotic patients
Limitations: Firstly, the retrospective study design may have introduced bias on subjects' selection. Secondly, the size of the study population was small, although this was partly compensated by using an external validation cohort to test model performance. Further validation on larger and prospective cohorts is required to address these limitations and confirm the clinical utility of our model.
Funding for this study: No funding was received for this study
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective bicentric study has been approved by the ethics committee (protocol number 930/2022/OSS/UNIPR)

Deep learning-accelerated Dixon MRI enables rapid and reliable liver fat quantification (6 min)

Stephan Rau; Freiburg Im Breisgau / Germany

Author Block: S. Rau[1], A. Fink[1], R. Strecker[2], D. Nickel[2], L. Michel[1], D. I. Klemm[1], F. Bamberg[1], J. Weiß[1], M. Russe[1]; [1]Freiburg Im Breisgau/DE, [2]Erlangen/DE
Purpose: To assess the accuracy and clinical feasibility of deep learning–accelerated T1-weighted VIBE Dixon sequences for whole-liver fat-signal fraction (FSF) quantification compared with standard protocols.
Methods or Background: In this prospective single-centre study, 60 patients (mean age 64 years, 55% female) underwent abdominal MRI at 1.5 T, including a standard VIBE Dixon sequence and two accelerated protocols ("fast" and "ultra-fast") reconstructed with deep learning. Acquisition times were 15, 10 and 6 seconds, respectively. Whole-liver FSF was calculated using a validated automated convolutional neural network–based segmentation. Agreement between accelerated and standard sequences was evaluated using mean absolute error (MAE) and Spearman's correlation.
Results or Findings: Liver volumes obtained from accelerated protocols showed excellent correlation with the standard sequence ($\rho = 0.975–0.988$, $p < 0.001$). Median liver fat fractions were 2.25% (standard), 2.61% (fast), and 2.35% (ultra-fast). The MAE from the standard was 0.57% for fast and 0.52% for ultra-fast. Correlations for FSF remained high ($\rho = 0.923–0.936$, $p < 0.001$), with no systematic bias across protocols.
Conclusion: Deep learning–accelerated Dixon MRI allows reliable and fully automated liver fat quantification with substantial reduction of breath-hold duration, supporting its use as an interchangeable alternative to standard protocols.
Limitations: The limitations of the study are its single-vendor setting and use of a two-point Dixon reference rather than a multi-echo or histological gold standard.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes

Radiomics of Hepatocellular Carcinoma: Identifying Predictors of Microvascular Invasion Using Multi-Phase CT (6 min)

Caterina Vitale; Verona / Italy

Author Block: F. Spoto, N. Cardobi, C. Vitale, B. Mascarin, L. Ordofendi, F. Apolloni, R. De Robertis Lombardi, M. D'Onofrio; Verona/IT
Purpose: To explore radiomic texture features from multi-phase contrast-enhanced CT as potential predictors of microvascular invasion (MVI) in hepatocellular carcinoma (HCC).
Methods or Background: This exploratory single-center study retrospectively analyzed 49 patients (54 HCC lesions) who underwent liver resection between 2018-2022. Radiomic analysis extracted 642 features across arterial, venous, and delayed phases using original and 5mm-expanded tumor margins.
Results or Findings: The 20-50mm lesion subgroup (n=37) provided the most reliable results, with arterial phase texture homogeneity features achieving AUC 0.772. Features from lesions <20mm (n=14, 4 MVI+) showed clear evidence of overfitting and were excluded from primary analyses. Delayed phase features showed preliminary associations (AUC 0.8) in a small LR-3/4 subset (n=20).
Conclusion: Multi-phase CT radiomic analysis shows potential for MVI prediction in intermediate-sized HCC lesions, though external validation in larger cohorts is essential before clinical application.
Limitations: This hypothesis-generating study has significant limitations including small sample size, single-center design, and lack of correction for multiple comparisons.
Funding for this study: None
Has your study been approved by an ethics committee? Not applicable
Ethics committee - additional information:

Reducing Breath-Hold Time in Liver MRI: Clinical Performance of Deep Learning-Accelerated Post-Contrast T1 VIBE (6 min)

Stephan Rau; Freiburg Im Breisgau / Germany

Author Block: S. Rau[1], A. Fink[1], V. Sacalean[1], K. Kästingschäfer[1], R. Strecker[2], D. Nickel[2], F. Bamberg[1], J. Weiß[1], M. Russe[1]; [1]Freiburg Im Breisgau/DE, [2]Erlangen/DE
Purpose: To assess whether deep learning-accelerated post-contrast liver MRI can shorten breath-holds while maintaining diagnostic image quality.
Methods or Background: In this prospective study, ninety-nine patients (mean age 61.0 ± 15.4 years; 49.5% female) underwent three T1-weighted two-point Dixon gradient-echo sequences on a 1.5 T system: a standard protocol (18 seconds) and two deep learning-accelerated protocols (10 and 6 seconds). Three blinded radiologists rated overall image quality, motion artefacts, other artefacts, anatomical differentiability, and lesion conspicuity on five-point Likert scales. Per-patient consensus was the median across readers. Global differences were tested with the Friedman test followed by Holm-adjusted Wilcoxon signed-rank tests. Non-inferiority of diagnostic acceptability (Likert score at least 3) for accelerated versus standard sequences was tested with a non-inferiority margin of minus five percentage points.
Results or Findings: The standard sequence yielded higher ratings for anatomical differentiability (median 5 vs 4 and 4) and lesion conspicuity (5 vs 4 and 4; both p<0.001) and slightly higher overall image quality (4 vs 4 and 4; p<0.001). Motion-artefact ratings did not differ across sequences. Diagnostic acceptability met non-inferiority for both accelerated sequences across all items.
Conclusion: Deep learning reconstruction enabled substantial acceleration of post-contrast liver MRI, reducing breath-holds by 44% (10 seconds) and 67% (6 seconds) without loss of diagnostic acceptability. Faster, motion-robust acquisitions may benefit patients with limited breath-hold capacity.
Limitations: Single-centre study with minor image-quality trade-offs relative to the standard sequence.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes

Novel methods using dynamic-gadoxetate enhanced MRI to identify inhibitors of drug metabolism by the liver (6 min)

Sam Jenkins; Leeds / Austria

Author Block: S. Jenkins, O. Spear, E. Checkley, S. Sourbron, B. Rea; Sheffield/UK
Purpose: To demonstrate that dynamic gadoxetate enhanced MRI (DGE-MRI) can distinguish inhibitors from non-inhibitors of liver transporter function by measuring the effect of ciclosporin (known inhibitor) and metformin (no evidence of inhibition) on hepatocellular gadoxetate uptake and excretion.
Methods or Background: The identification of drugs at risk of drug-drug interactions (DDI) early in the drug development life cycle is key to avoid late stage drug development failures. DGE-MRI can potentially detect liver-mediated DDI's by assessing drug effects on liver transporter function, but it is currently unclear whether it is sufficiently sensitive to distinguish levels of inhibition.

This prospective study recruited 12 healthy volunteers, split evenly between ciclosporin and metformin groups. Each participant underwent two visits and at each visit underwent two contrast-enhanced (1/4 dose of gadoxetate) MRI liver scans one-hour apart. The second scan ensured biliary excretion could be accurately evaluated. At Visit B, a one-off clinical dose of metformin or ciclosporin was administered prior to imaging. Liver uptake and excretion rates were derived by MRI signal modelling.
Results or Findings: Ciclopsorin reduced hepatocellular uptake by 67% (p<0.001, 95%CI 61-72) and biliary excretion rate by 50% (p=0.027), although more variable (95%CI 21-80). Metformin did not affect hepatocellular uptake rate (average -7.3%, p=0.25, 95%CI -2.3-17) and or biliary excretion of gadoxetate (average 11%, p=0.35, 95%CI -8.2-31).
Conclusion: DGE can distinguish weak from strong inhibition of uptake and excretion. In future, the method may be of use in drug safety assessment to help predict DDI risk.
Limitations: Further assessment is required to develop DGE-MRI as a biomarker, including administration of drugs specific to individual transporters and testing in patients with impaired liver function.
Funding for this study: The research leading to these results received funding from the Innovative Medicines Initiatives 2 Joint Undertaking under grant agreement No 116106. This Joint Undertaking receives support from the European Union's Horizon 2020 research and innovation programme and EFPIA.

MRI-Based Deep Learning Quantification of Liver 3D-PDFF and Upper Abdominal Composition for Prognostic Prediction in HCC Treated with TACE plus Systemic Therapy (6 min)

Shuwei Zhou; Nanjing / China

Author Block: S. Zhou[1], Y-C. Wang[1], Y. Song[2]; [1]Nanjing/CN, [2]Shanghai/CN
Purpose: To investigate the prognostic value of MRI-derived three-dimensional proton density fat fraction (3D-PDFF) and upper abdominal composition parameters for survival prediction in hepatocellular carcinoma (HCC) patients receiving transarterial chemoembolization (TACE) combined with systemic therapy.
Methods or Background: This retrospective single-center study (December 2022–December 2024) included consecutive BCLC stage B-C HCC patients who underwent TACE plus systemic therapy with pre-treatment contrast-enhanced MRI. Fully automated deep learning-based volumetric analysis quantified liver 3D-PDFF, spleen and liver volumes, and skeletal muscle, visceral adipose tissue (VAT), and subcutaneous adipose tissue areas at L1-L2 vertebral levels. Continuous variables were Z-score normalized for hazard ratio comparability. Cox regression analysis identified independent overall survival predictors.
Results or Findings: A total of 125 patients (median age, 62 years; 107 men) were analyzed. Univariate analysis showed that high 3D-PDFF (> 5%), increased spleen volume, and reduced skeletal muscle and adipose tissue areas at L1 and L2 were significantly associated with shorter OS (all $P < 0.1$). In multivariate analysis, 3D-PDFF (HR: 2.23; 95% CI: 1.19–4.18), spleen volume (HR: 1.32; 95% CI: 1.03–1.70), and VAT area at L1 (HR: 0.66; 95% CI: 0.50–0.89) remained independent prognostic factors.
Conclusion: MRI-derived 3D-PDFF, spleen volume, and L1 VAT area are independent imaging biomarkers for predicting survival in HCC patients treated with TACE plus systemic therapy. The use of fully automated, AI-based analysis further highlights the potential for integration of these imaging metrics into clinical workflows.
Limitations: This study utilized L1-L2 level measurements instead of conventional L3-based body composition analysis, as standard upper abdominal MRI protocols typically do not include L3 levels. While this limits direct comparison with L3-based literature, our approach enhances clinical practicality and real-world applicability for routine implementation.

Next generation spectral AI-based reconstruction for abdominal spectral detector dual energy CT: superior quality for liver imaging (6 min)

Lukas Fortmann; Cologne / Germany

Author Block: L. Fortmann[1], J. Lueckel[1], L. Hieronymi[1], S. Skornitzke[2], D. Maintz[1], N. Große Hokamp[1]; [1]Cologne/DE, [2]Hamburg/DE
Purpose: Spectral detector DECT (sdDECT) offers advantages in liver imaging, like virtual monoenergetic images. A new prototype deep learning–based spectral reconstruction algorithm (SAI, Philips) was evaluated for conventional reconstructions (SAI) and virtual monoenergetic images (SAI-VMI) to optimize reconstruction settings for abdominal image quality compared to existing fully-iterative reconstruction (FI-R) and hybrid-iterative reconstruction (HI-R/HI-VMI).
Methods or Background: For 20 patients undergoing abdominal sdDECT, conventional images were reconstructed with FI-R, HI-R, and five SAI settings: SAI-Sharper, SAI-Sharp, SAI-Standard, SAI-Smooth, and SAI-Smother. For 55keV-VMI, we compared HI-VMI with the five SAI-VMI settings. Quantitative analysis with eight liver ROIs included signal-to-noise (SNR) and contrast-to-noise ratio (CNR). Image quality was assessed by two radiologists using a two-alternative forced-choice design.
Results or Findings: For conventional images, mean attenuation was comparable between FI-R, HI-R, and SAI (103.31HU±18.93HU;$p>.05$). Noise was lowest for FI-R and SAI-Smoother (4.12HU±0.85HU and 5.05HU±1.11HU;$p\leq.05$ vs. remaining; HI-R:15.08HU±3.91HU). FI-R achieved highest SNR (25.72±6.64;$p\leq.05$) and CNR (51.91±7.59;$p\leq.05$) followed by SAI-Smoother (SNR: 21.13±5.79, CNR: 43.82±8.19; both $p\leq.05$ vs. remaining; HI-R SNR:7.23±2.33 and CNR:15.29±3.31). Regarding subjective quality, radiologists showed a significant preference for SAI-Smoother (81.67%±9.60%) and SAI-Smooth (75.83%±7.60%) compared to FI-R (65.00%±13.13%), HI-R (19.58%±8.67%), and other reconstructions ($p\leq.05$). For 55keV-VMI, there was no significant difference in mean attenuation between HI-VMI and SAI-VMI (146.94HU±28.14HU). Noise was significantly lower with SAI-VMI-Smoother (4.97HU±2.68HU, HI-VMI:12.68HU±3.27HU;$p\leq.05$), resulting in significantly higher SNR (30.40±7.04, HI-VMI:12.10±3.88;$p\leq.05$) and CNR (55.16±10.43, HI-VMI:23.35±4.92;$p\leq.05$). Radiologists significantly preferred SAI-VMI-Smooth (81.50%±7.45%) and SAI-VMI-Smoother (81.00%±15.53%) compared to HI-VMI (38.50%±7.45%) and other reconstructions ($p\leq.05$).
Conclusion: For conventional sdDECT, novel SAI-Smooth and SAI-Smoother are preferred by radiologists, despite having lower quantitative SNR and CNR than FI-R. Additionally, SAI-VMI-Smooth and SAI-VMI-Smoother also yield better quantitative and qualitative results than HI-VMI.
Limitations: The study is limited by its retrospective design.
Funding for this study: This work was funded by Philips Healthcare. The funding source had no involvement in study design, collection or interpretation of data.

CECT-Based Deep Learning for Pancreatic Lesion Diagnosis and Three-Tier Management: Multicenter Development, External Validation, and Reader Study (6 min)

Yueyi Zhang; Shanghai / China

Author Block: C. Ma, Y. Zhang, L. Lin, K. Zhang, N. Zhang, K. Cao; Shanghai/CN
Purpose: To develop and validate a contrast-enhanced CT (CECT)–based deep learning model for accurate differential diagnosis and three-tier clinical management of pancreatic lesions.
Methods or Background: Retrospective cross-sectional study of 7,748 cases across 10 categories from a tertiary center (2015-2023). Ten categories included: pancreatic ductal adenocarcinoma, pancreatic neuroendocrine tumors, solid pseudopapillary neoplasms, intraductal papillary mucinous neoplasms(IPMN), mucinous cystic neoplasms(MCN), serous cystadenomas, periampullary carcinomas(PAC), chronic pancreatitis, acute pancreatitis, and normal pancreas (confirmed by two-year follow-up). Model training used 6343 cases, with 1405 internal and 2361 external tests. A hybrid CNN–Transformer addressed performed 10-class diagnosis, dysplasia grading in IPMN/MCN, and three-tier management (discharge/surveillance/intervention). Performance was evaluated using AUC, Top-1 accuracy, and balanced accuracy (BA). A 12-radiologist reader study assessed assistive value.
Results or Findings: Internal test set (ten-class model): sensitivity 97.5% (95% CI, 96.4–98.3), specificity 99.6% (95% CI, 98.5–100), AUC 99.8% (95% CI, 99.7–99.9), Top-1 accuracy 88.8% (95% CI, 87.0–90.3), and BA 83.0% (95% CI, 79.7–86.1). The model improved mean diagnostic accuracy versus original radiology reports by 7.42% (79.9% vs 72.4%; 95% CI, 1.5–13.7; p=0.004). Dysplasia grading: AUC 84.8% (95% CI, 78.5–90.4), BA 76.8% (95% CI, 70.6–83.1). Clinical management: BA 84.3% (95% CI, 77.2–88.6). External test set: BA 72.4% (95% CI, 69.5–75.2) for diagnosis, 66.6% (95% CI, 60.2–72.9) for dysplasia grading, and 80.0% (95% CI, 77.1–82.7) for clinical management. In the reader study, AI assistance increased specificity by 9.8% (94.4% vs 84.7%; p=0.0003), diagnostic BA by 10.8% (75.1% vs 64.4%; p<0.001), and clinical management BA by 6.9% (70.2% vs 63.2%; p<0.001).
Conclusion: A CECT-based deep learning model achieves high diagnostic performance and significantly enhances clinical management decisions for pancreatic lesions, including in multi-center evaluation and reader-assisted settings.
Limitations: No prospective validation, some benign lesions excluded, PAC not subtyped.

Deep Learning-based segmentation of pancreatic neuroendocrine neoplasms: development and validation of a hierarchical model (6 min)

Francesco Prato; Milan / Italy

Author Block: A. Belardo, M. Fois, E. Guccinelli, F. Prato, L. Tonelli, D. Palumbo, M. G. Ubeira-Gabellini, C. Fiorino, F. De Cobelli; Milan/IT
Purpose: This study aims to train and validate a neural network for pancreatic neuroendocrine neoplasms (PanNENs) segmentation. The enrolled patients belong to a retrospective cohort used in a previous study where baseline radiomic analyses were performed [https://doi.org/10.1007/s00330-022-09351-9].
Methods or Background: The training dataset consisted of 107 patients' CTs of patients who underwent surgery for PanNENs between January 2015 and December 2021. For each patient, the previously segmented ROI was transferred onto the arterial phase images. The volume's median value was 5.71cc (IQR=[1.63, 17.55]cc). First, the segmentation of the pancreas was performed using TotalSegmentator. All propagated segmentations were reviewed and verified by an experienced radiologist. Model training was then performed using a nnUNet region class order strategy, in which the network learns to segment anatomical structures following a hierarchical order to improve consistency across labels, restricting the search to the segmented pancreas. The test phase was conducted on 30 additional PanNEN patients who underwent surgery between February 2017 and March 2025. The volume's median value on this cohort was 5.29cc (IQR=[3.87, 8.56]cc).
Results or Findings: For 10 out of 107 patients, no prediction was obtained due to failure of the model in finding reasonable contours. For the remaining 97 patients, the model achieved an average Dice value of 0.85 (IQR=[0.84, 0.92]). On the test population, the average Dice score was 0.60 (IQR=[0.54, 0.78]). Given the prevalently small volumes, results indicate good segmentation accuracy, although the significantly worse performance in the test cohort needs further investigation.
Conclusion: AI-based segmentation of PanNEN is feasible with performances consistent with inter-observer variability of manual segmentation [https://doi.org/10.1016/j.ejmp.2018.12.005].
Limitations: In cases of unclear contours (about 10% of cases), position at the pancreas borders or poor enhancement, the model fails in recognizing PanNEN presence or position.
Funding for this study: Not available now.

Ritse Mann; Nijmegen / Netherlands

T2 Hyperintensity in Breast MRI: a Useful Marker in Lesion Characterization? (6 min)
Eliana Rubino; Rome / Italy

Author Block: E. Rubino[1], C. M. L. Trombadori[1], C. Boldrini[1], A. Marra[1], A. D'Angelo[1], P. Belli[1], P. Clauser[2]; [1]Rome/IT, [2]Vienna/AT
Purpose: In breast magnetic resonance imaging (MRI), T2-weighted (T2w) hyperintensity is typically observed in benign lesions but can also occur in some malignant tumors. The aim of our study was to retrospectively evaluate the association between T2 hyperintensity and histopathological and molecular features of breast lesions.
Methods or Background: We retrospectively analyzed 1387 breast MRIs performed between 2022 and 2024. For each lesion, a breast radiologist assessed signal intensity on T2w images using non-fat suppressed T2-TSE sequences, enhancement pattern, histology, molecular subtype (Luminal A, Luminal B, HER2+, triple-negative), and Ki67 proliferation index. Associations among these variables were analyzed using Pearson's chi-squared test, Fisher's exact test, Mann-Whitney U test, and Spearman's correlation.
Results or Findings: Out of 1387 patients, 779 lesions were hyperintense on T2w images. No statistically significant association was found between T2 hyperintensity and lesion benignity or malignancy, with similar proportions of hyperintensity in both groups. Analysis of malignant histological subtypes revealed that tumors with an in situ component (DCIS and DCIS + IDC) were more frequent among non-hyperintense lesions, while rare tumor subtypes - such as mucinous, papillary, and metaplastic carcinomas - were significantly more frequent among T2-hyperintense lesions ($p<0.001$). Molecular subtype analysis showed that Luminal A tumors were underrepresented among T2-hyperintense lesions, whereas Luminal B and triple-negative tumors were more common ($p<0.05$). Spearman's correlation indicated that higher T2 signal intensity was associated with higher Ki67 levels ($p<0.001$).
Conclusion: In our cohort, T2 hyperintensity showed significant associations with rare tumor subtypes (mucinous, papillary, and metaplastic carcinomas), Luminal B and triple-negative molecular subtypes, and high proliferative activity. These preliminary findings suggest that T2w signal characteristics may contribute to refining lesion interpretation in breast MRI and highlight their potential role in lesion characterization.
Limitations: Retrospective single-study center, single reader

MRI-based differentiation of breast lesions using high b-value DWI: role of quantitative and qualitative ADC assessment (6 min)
Alessia Angelino; Rome / Italy

Author Block: A. Angelino[1], F. Ferrara[1], V. Longo[1], E. Farina[1], A. Carcagnì[1], C. M. L. Trombadori[1], P. Belli[1], A. D'Angelo[1], P. Clauser[2]; [1]Rome/IT, [2]Vienna/AT
Purpose: To explore the role of high b-value 1400 DWI in breast lesion characterization comparing a quantitative assessment of the apparent diffusion coefficient (ADC) map with a qualitative visual analysis.
Methods or Background: This retrospective, IRB-approved, single-center study included women with at least one breast lesion classified as BI-RADS 2–6 at consecutive MRIs performed from January 2022 to February 2024. The reference standard was histology from image-guided biopsy or ≥2 years follow-up for non-suspicious lesions. MRI was performed on 1.5T scanners according to international guidelines, including DWI with b=0,1400 s/mm². ADC maps were generated using mono-exponential fitting. One of six breast radiologists (≥3 years' experience), blinded to clinical data, evaluated lesions quantitatively (ADC measured with a ROI in the darkest area) and qualitatively (5-point visual scale: hyperintense/non-suspicious to markedly hypointense/highly suspicious). ROC analysis determined sensitivity and specificity; the highest Youden index on the ROC curve defined the optimal ADC threshold.
Results or Findings: A total of 773 lesions in 760 women (mean age 51.2 years) were analyzed: 597 malignant (77.2%) and 176 benign (22.8%). Malignant lesions had lower ADC values (0.85×10^{-3} mm²/s, SD 0.21) than benign lesions (1.23×10^{-3} mm²/s, SD 0.34; p<0.001). Quantitative analysis achieved an AUC of 0.81 (95% CI: 0.78–0.87). ADC threshold for distinguishing malignant from benign lesions was of 1.03×10^{-3} mm²/s (85% sensitivity, 72% specificity). Visual assessment showed an AUC of 0.73 (95% CI: 0.68–0.78), with high sensitivity (89%) but low specificity (49%).
Conclusion: Quantitative and qualitative ADC map assessment effectively differentiated benign from malignant breast lesions but remained less accurate than CE-MRI (p=0.001 and p=0.027). Visual ADC analysis achieved good sensitivity yet low specificity.
Limitations: Retrospective, single-center study; high cancer prevalence, inter-reader variability, subjective scoring.
Funding for this study: No funding was received for this study.

Accelerated Multiparametric Breast MRI: Tumor Grade Differentiation with Diffusion and Perfusion (6 min)

Konstantin Kenigsberg; Haifa / Israel

Author Block: K. Kenigsberg, I. Eisenberg, C. Ben, G. Badarni, N. Goldberg; Haifa/IL
Purpose: To evaluate an 11-minute multiparametric breast MRI protocol and assess correlations of diffusion and perfusion parameters with tumor grade.
Methods or Background: Forty patients with biopsy-proven breast cancer underwent MRI, including Deep-Resolve STIR, DWIBS, and GRASP-VIBE dynamic contrast-enhanced perfusion. GRASP-VIBE provided high temporal resolution and motion-compensated reconstruction. Semi-quantitative parameters included arrival time (AT), time to peak (TTP), peak enhancement index (PEI), wash-in slope (W_in), wash-out slope (W_out), and iAUC_60. Quantitative Tofts modeling provided K^trans, k_ep, v_e, and iAUC. Diffusion metrics included ADC_min, ADC_mean, and ADC_max. The tumor grades were 1 (n=11), 2 (n=17), and 3 (n=12). Statistical analysis used Kruskal–Wallis with Bonferroni correction, Mann–Whitney U, and Kendall's τ-b. Additionally, a delayed high-resolution VIBE was acquired. All examinations were independently evaluated by two radiologists with 14 and 11 years of expertise in oncologic and breast imaging.
Results or Findings: Between tumor grades 1 and 2, significant differences were observed for the diffusion parameter ADC_min (p = 0.009). In contrast, among perfusion metrics, PEI and VE demonstrated significant differences between grade 2 and grade 3 (p=0.011 and p=0.005, respectively). It can be concluded that at higher malignancy grades, the discriminative properties are exhibited by the MRI parameters PEI and VE, whereas at lower grades, only the DWI indicator ADC_min demonstrates discriminative potential. Adding delayed high-resolution VIBE did not provide incremental diagnostic information compared with GRASP-VIBE.
Conclusion: The proposed 11-minute multiparametric breast MRI protocol provides reliable tumor grading by combining DWI and high-temporal-resolution perfusion imaging. It ensures comprehensive lesion characterization within a clinically practical timeframe, supporting the integration of breast MRI into routine practice.
Limitations: This was a single-center study with a limited sample size and potential ROI-based variability; larger multicenter validation is warranted.
Funding for this study: This study received no external funding.

Phase-Dependent Transformation in NME: From Clumped to Clustered Ring on Breast MRI (6 min)

Eda Nur Korkmaz; Ankara / Turkey

Author Block: E. N. Korkmaz, H. Aydin, M. Kamışlık; Ankara/TR
Purpose: In breast MRI of non-mass enhancement (NME), BI-RADS internal enhancement patterns—clumped and clustered ring (CRE)—have not been reported to transform across dynamic phases. We observed that lesions appearing clumped on early dynamics often demonstrated CRE on later or high-resolution images, suggesting that limited spatial resolution may obscure early CRE. This study evaluated the malignancy association of this phase-dependent transformation and its added diagnostic value combined with ADC.
Methods or Background: This single-centre retrospective study (2022–2025) included 80 patients with histopathology-proven NME. MRI was performed at 1.5 T with a dedicated breast coil. Early and late post-contrast DCE-MRI, a high-resolution sagittal sequence, and diffusion-weighted imaging were obtained. Enhancement patterns were assessed by two blinded radiologists. Statistical analysis included χ^2/Fisher's tests, Mann–Whitney U for age, ROC analysis, and logistic regression.
Results or Findings: Among 80 lesions, 47 were benign and 33 malignant. Malignant cases were significantly older ($p = 0.015$). Late-phase and high-resolution images showed a stronger association of CRE with malignancy. Phase-dependent transformation occurred in 43.8% of lesions and was associated with increased malignancy risk. Washout kinetic curves were more frequent in malignant lesions. ADC showed moderate diagnostic performance, and logistic regression identified CRE and wider distribution as independent predictors.
Conclusion: Phase-dependent transformation from clumped to CRE is a frequent and diagnostically valuable feature of NME. Incorporating late-phase, high-resolution imaging and diffusion assessment into breast MRI protocols may improve specificity and guide biopsy decisions.
Limitations: This study has several limitations. Its retrospective, single-centre design may limit generalisability. Not all benign lesions had histological confirmation or complete follow-up, possibly underestimating malignancy. Interobserver variability remains a factor despite consensus reading, and ultrafast MRI was not directly evaluated.
Funding for this study: This study received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors

Evaluating Tumor-Infiltrating Lymphocytes in Breast Cancer: The importance of Clinicopathological and MRI Features (6 min)

Jiejie Zhou; Wenzhou / China

Author Block: J. Zhou, M. Du, M. Wang; Wenzhou/CN
Purpose: Tumor-infiltration lymphocytes (TILs) is a key prognostic factor for breast cancer. It is a crucial component of the tumor microenvironment associated with the metabolism of tumor cells and the local immune response. The study aimed to evaluate the clinicopathological parameters associated with TILs, and MRI features corresponding to TILs expression.
Methods or Background: A total of 785 patients were retrospectively investigated in this study, with 676 as training dataset and 109 as testing dataset. The percentage of TILs in the stroma adjacent to the tumor cells was assessed on H&E-stained slides, and they were separated into low (<10%) and high (≥10%) groups. MRI features were reviewed by two radiologists by consensus using BI-RADS lexicon descriptors. Clinicopathological and MRI features were compared between low and high TILs groups, and parameters with $P<0.05$ were used to build logistic regression model. The analysis of disease-free survival (DFS) was performed to assess the model's performance.
Results or Findings: Of 676 patients, 43 (6.4%) underwent recurrence with the DFS 54.1±17.4 (mean±SD) months, compared to non-recurrence group with DFS 29.0±20.4 months. Histological grade, ER, PR, HER2 over-expression, low-HER2, Ki-67≥20%, molecular subtype and the presence of peri-tumor edema showed significant difference between low and high TILs groups. Nomogram was build with above parameters and the AUC was 0.727 in training and 0.710 in testing dataset. Kaplan-Meier survival analysis showed patients with high TILs level had better DFS than who with low TILs, but without showing significant difference ($P=0.052$, HR=1.80).
Conclusion: Certain important pathological parameters and edema presence on MRI are associated with high TILs expression, which may help identify patients who may be candidate for immunotherapy and have better response to neoadjuvant therapy and better survival.
Limitations: The cutoff of TILs level hasn't been standardized.
Funding for this study: This study was supported by National Natural Science Foundation of China (No. 82572172).

Application of Quantitative MTR Combined with Ultra-Fast DCE in Breast Malignant Tumor Evaluation (6 min)

Shiwei Lai; Guiyang / China

Author Block: S. Lai; Guiyang/CN
Purpose: To explore the value of magnetization transfer ratio (MTR) obtained via single gradient echo (GRE) sequence scan combined with VITA ultra-fast dynamic contrast-enhanced (DCE) MRI (temporal resolution: 5s) in the diagnosis and efficacy evaluation of breast malignant tumors.
Methods or Background: • 100 prospectively enrolled patients (50 malignant/50 benign; age 48±11 years) underwent 3.0T MRI.
• MTR: Measured via single GRE (T1, MT-weighted, MTR maps).
• Ultra-fast DCE: VITA (1mm³ spatial resolution) for early dynamic parameters (max slope, time to peak).
• Analysis: Independent samples t-test, Logistic regression, ROC, ICC (SPSS 26.0, α=0.05).
Results or Findings: • Malignant group: Lower MTR (23.7±3.8‰ vs 38.9±4.2‰, P<0.001), higher early slope (6.8±1.2%/s vs 4.8±1.0%/s, P=0.002).
• Combined AUC=0.97 (sensitivity 96%, specificity 92%) > single parameters.
• Post-neoadjuvant chemotherapy: MTR elevation correlated with pathology (r=0.78), slope drop >35% predicted efficacy (OR=9.4).
• ICC=0.94 (excellent consistency).
Conclusion: Quantitative MTR combined with ultra-fast DCE early dynamic parameters can reflect malignant tumor collagen matrix degradation via reduced MTR values (23.7±3.8‰), and the early slope (6.8±1.2%/s) captured with 5s temporal resolution indicates abnormal angiogenesis. With a combined diagnostic AUC of 0.97, it provides a new paradigm for non-invasive breast cancer diagnosis. MTR elevation and slope decrease during treatment constitute dual biomarkers for efficacy monitoring.
Limitations: 1. Small sample size (n=100) limits generalizability.
2. Lack of multi-center validation weakens conclusion robustness.
3. Applicability to lower-field MRI (not 3.0T) is unproven.
4. No long-term follow-up for method durability.
Funding for this study: Not applicable
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study has been approved by the Ethics Committee of Guiqian International Hospital.

Increased Breast Density-Breast Cancer Relationship: Volumetric Assessment with MRI (6 min)

Seyma Kılıçarslan Özdemir; Izmir / Turkey

Author Block: S. Kılıçarslan Özdemir, G. Sezgin, M. F. Tumer, M. Yağtu, K. A. Sinci, B. GENÇER; Izmir/TR
Purpose: Although many studies have reported an association between breast density and breast cancer, this relationship remains debated. Dense parenchyma is typically defined by visual mammographic assessment. This study aimed to quantitatively evaluate the relationship between breast density and breast cancer using three-dimensional volumetric MR images.
Methods or Background: This retrospective study reviewed MR exams from January to December 2022. Of 411 examinations, cases with bilateral malignancy (n=32), breast implants (n=59), prior contralateral mammoplasty (n=74), asymmetric parenchyma (n=3), or pure DCIS (n=2) were excluded. The final cohort included 121 patients with unilateral breast cancer and 121 controls without malignancy; none in the control Group developed cancer during two-year follow-up. MR scans were obtained using a 3T Lumina system with an 18-channel breast coil.Breast density was measured semi-automatically on non–fat-suppressed 3D T1-weighted images. The thoracic region was cropped along the pectoral muscle, and total breast and fat volumes segmented using a bright fat thresholding technique. Parenchymal volume was calculated by subtraction. Two observers performed the measurements. Based on BI-RADS 4th edition, densities ≥50% were classified as “dense.”
Results or Findings: Among malignant cases, 83 were invasive ductal, 28 invasive lobular, and 10 other types. The mean age was 52.8 years in the malignant group and 45.2 in controls. Dense parenchyma was found in 15.7% of malignant and 3.3% of controls. Breast density was significantly higher in the malignant group (p=0.000). Logistic regression indicated malignancy risk increased with fat content and age.
Conclusion: Quantitative MR analysis confirmed a strong association between increased breast density and breast cancer. Three-dimensional MR provides reliable volumetric assessment, though semi-automatic segmentation is time-consuming.
Limitations: Single-center design, limited sample size, and interobserver variability. Future multicenter studies using automated deep learning and radiomics methods may improve reproducibility.

Diagnostic performance of Kaiser Score in the evaluation of breast cancer using MRI: a systematic review and meta-analysis (6 min)

Saeed Mohammadzadeh; Tehran / Iran

Author Block: S. Mohammadzadeh; Tehran/IR
Purpose: To evaluate the performance of Kaiser score (KS) in detecting breast cancer on magnetic resonance imaging (MRI).
Methods or Background: The protocol was pre-registered at (https://osf.io/83c6j/). Until 30 October 2024, we performed a comprehensive search in PubMed, Embase, Cochrane Library, and Web of Science for studies that used KS for detection of breast cancer on MRI. Quality Assessment of Diagnostic Accuracy Studies 2 (QUADAS-2). was used to assess the risk of bias in the included studies. Diagnostic values were calculated using a random-effects bivariate model. Meta-regression and subgroup analysis were performed to explore the source of heterogeneity when I2 was ≥ 50%.
Results or Findings: A total of 29 studies with 7918 patients and 8451 breast lesions were included. The pooled sensitivity, specificity, and AUC of KS for detecting malignant breast lesions on MRI were 95% (95% CI = 94% to 96%), 70% (95% CI = 64% to 75%), and 0.94 (95% CI = 0.91 to 0.96), while for Breast Imaging Reporting and Data System (BI-RADS), they were 97% (95% CI = 92% to 99%), 46% (95% CI = 30% to 62%), and 0.89 (95% CI = 0.86 to 0.91). Sensitivity difference was not statistically significant (p-value = 0.803), but specificity difference was significant (p-value = 0.001). Also, KS demonstrated slightly better diagnostic accuracy for mass lesions with an AUC of 0.96 (95% CI = 0.94 to 0.97) compared to non-mass lesions with an AUC of 0.91 (95% CI = 0.88 to 0.94). KS showed better performance in larger lesions.
Conclusion: The KS's superior diagnostic performance compared to BI-RADS, particularly its ability to avoid unnecessary biopsies, makes it valuable for diagnostic and clinical decision-making.
Limitations: All included studies except one were retrospective in their design.
Funding for this study: None

Role of the Kaiser Score in breast MRI to reduce unnecessary second-look ultrasounds and biopsies in patients undergoing neoadjuvant chemotherapy: a two-year retrospective study (6 min)

Eliana Tallamona; Gela / Italy

Author Block: E. Tallamona[1], P. Francesco[2]; [1]Gela/IT, [2]Misterbianco/IT
Purpose: To evaluate the role of the Kaiser Score (KS) applied to pre-treatment breast MRI in reducing unnecessary second-look ultrasound examinations and biopsies in patients scheduled for neoadjuvant chemotherapy (NACT).
Methods or Background: This retrospective single-center study included consecutive patients with biopsy-proven breast cancer evaluated for NACT between January 2023 and December 2024. All patients underwent baseline breast MRI. For each MRI-detected lesion, the KS was calculated based on morphology, dynamic enhancement, and additional diagnostic features. Lesions with KS ≥5 were considered suspicious, while those with KS ≤4 were considered likely benign. Second-look ultrasound was performed for lesions without sonographic correlates or not already biopsied, and biopsies were conducted according to institutional protocols. Final histopathological results were used as the reference standard. The primary endpoints were the number of second-look ultrasounds and biopsies that could be avoided by applying the KS. Diagnostic performance metrics, including sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV), were calculated.
Results or Findings: We included in the study 56 patients. Only the "second-look" lesions evaluated as suspicious and biopsied by a team of at least 5 year experienced breast radiologists were included in the study. Histological results were collected and classified according the Easton Ellis classification from B1 to B5 and then compared to the given imaging score. By adopting a KS threshold of 5 both second-look ultrasounds and biopsies could have been safely avoided with a low grade of missing "B3" and malignant lesion.
Conclusion: The KS is a reliable tool to stratify MRI-detected lesions in patients undergoing NACT. Its systematic use before second-look ultrasound could substantially reduce unnecessary imaging and biopsies, streamlining pre-treatment workup and minimizing patient burden.
Limitations: This study is limited by its retrospective, single-center design,
Funding for this study: No funding needed

An interpretable model for differentiating early-stage breast cancer and benign lesions, automatically generating structured reports (6 min)

Su Lui; Chengdu / China

Author Block: J. Qu, Y. Liu, S. Lui; Cheng Du/CN
Purpose: To develop and evaluate an interpretable model for distinguishing early breast cancer (BC) from benign lesions and generating structured reports.
Methods or Background: Preoperative MRI scans and corresponding radiological reports from patients with breast lesions were retrospectively collected across five institutions. Lesion descriptors extracted from MRI reports were translated into standardized BI-RADS lexicon terms (hereafter termed "concepts") by radiologists. These concepts, alongside multiparametric MRI sequences, were input into a Concept Bottleneck Model (CBM) designed to differentiate BC from benign lesions and to generate structured reports. Classification performance of the CBM was compared against a black-box model. CBM-derived concept accuracy was also assessed. Additionally, a two-phase multi-reader study was conducted to evaluate the clinical utility of the CBM.
Results or Findings: A total of 1,695 pathology-confirmed breast lesions (857 malignant and 838 benign) from 1,634 patients were included. In the test set, the CBM achieved an AUC of 0.92 (95%CI 0.90-0.93), comparable to the benchmark black-box model (AUC: 0.93 [95%CI 0.92-0.94]). The accuracy of CBM-generated concepts ranged from 0.62 to 1.00. In the multi-reader study, the CBM yielded an accuracy of 0.89, performing on par with one radiologist and outperforming the other seven (all $P < 0.05$). With CBM assistance, radiologists correctly downgraded 22.1% of the lesions to benign. Diagnostic accuracy improved for three radiologists, increasing from 0.71-0.72 to 0.82-0.91 (all $P < 0.05$). Furthermore, CBM support enhanced inter-reader agreement in both concept recognition and BI-RADS classification, with Gwet's AC1 increasing from 0.27-1.00 to 0.55-1.00.
Conclusion: The CBM enhances intrinsic interpretability through image-concept alignment, effectively discriminates early BC from benign lesions, potentially reduces unnecessary benign breast lesion biopsies, and improves reporting consistency among radiologists.
Limitations: The limited size of the dataset warrants further validation in larger, preferably prospective cohorts.

Automatic Segmentation of Breast Ductal Carcinoma in Situ on MRI with Active learning based Deep-learning: A Multicenter Study (6 min)

Sungwon Ham; Ansan-si / Korea, Republic of

Author Block: S. Ham[1], B. K. Seo[1], S. Wang[2], J. Y. Lee[1], M. S. Bae[1], K. R. Cho[3], O. Woo[3], S. E. Song[3], S-Y. Kim[3]; [1]Ansan/KR, [2]Cambridge/UK, [3]Seoul/KR
Purpose: Ductal carcinoma in situ (DCIS) often presents on MRI as nonmass enhancement with variable enhancement than invasive cancer. We aimed to develop and validate a deep learning–based automatic segmentation algorithm for biopsy-proven DCIS on preoperative MRI, achieving robust performance across lesion types, background parenchymal enhancement (BPE), and invasive cancer upgrade.
Methods or Background: This retrospective multicenter study included 842 DCIS lesions (Institution A, 342; Institution B, 500) collected over 11 years from nine 3T scanners (five vendors). SAM 2.1-L was initially trained on 292 cases from Institution A, with 50 held out for testing. Active learning was applied to Institution B in three iterations (250, 150, and 50 cases), using expert corrections for retraining. Final evaluation was performed on an independent test set of 100 lesions (50 per institution). Subgroup analyses included lesion type, size, BPE, and invasive upgrade. Segmentation performance was assessed with the dice similarity coefficient (DSC) and compared with training from scratch. Annotation times were compared between manual and active learning–assisted labeling.
Results or Findings: Overall DSC improved from 0.68 in the initial model to 0.73 after multiple iterations ($p<0.05$). DSC did not differ by lesion type (mass, 0.72 vs. nonmass enhancement, 0.73) or invasive upgrade (pure DCIS, 0.77 vs. invasive upgrade, 0.71; both $p>0.05$), but was significantly higher in tumors >30 mm and with lower BPE (minimal or mild) (all $p<0.05$). Annotation time decreased from 453 to 35 seconds per lesion ($p<0.05$).
Conclusion: Active learning with SAM 2.1-L enabled robust DCIS segmentation on MRI regardless of lesion type or invasive upgrade, while dramatically reducing annotation time. Gains in accuracy and efficiency support its potential for clinical integration in breast MRI analysis.
Limitations: External multicenter datasets is needed to confirm generalizability.
Funding for this study: This research was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (RS-2024-00347290).

Simultaneous Multiparametric 18F-Fluorodeoxyglucose (18F-FDG)-PET/MR-imaging Biomarkers for Overall Survival Prediction in Breast Cancer: Conventional Parameters Remain Strongest (6 min)

Thomas Spiegel; Vienna / Austria

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: T. Spiegel[1], V. Romeo[2], D. A. Resch[1], O. Lafci[1], S. Rasul[1], A. Stiglbauer-Tscholakoff[1], P. Clauser[1], K. Pinker-Domenig[3], T. H. Helbich[1]; [1]Vienna/AT, [2]Naples/IT, [3]New York, NY/US
Purpose: To evaluate whether multiparametric 18F-Fluorodeoxyglucose (18F-FDG)-PET/MR-imaging biomarkers provide prognostic value for predicting overall survival (OS) in breast cancer (BC) patients.
Methods or Background: This retrospective analysis of a prospectively performed single-center study includes 202 BC patients (median age 52 years, range 25-82 years), who underwent simultaneous 18F-FDG-PET/MRI of the breast and whole body using a Biograph mMR system (Siemens, Germany) for staging purposes. Follow-up was available for up to 103 months (median 69 months). Imaging parameters of the index lesion included tumor size, SUVmax, ADC and perfusion parameters (Plasma Flow, Volume Distribution, Mean Transit Time). Histopathological and clinical variables included lymph node (LN) status, presence of distant metastases, and molecular subtype. Kaplan-Meier survival curves with log-rank tests, univariate and multivariate Cox regression analyses using hierarchical modeling to assess incremental prognostic value, were performed; $p<0.05$ was considered significant.
Results or Findings: During follow-up, 28 (13.9%) patients passed away. Tumor size predicted poorer OS (HR 1.224 (95% CI 1.044-1.435), p=0.013). Presence of distant metastases was strongly predictive for OS (HR 3.609 (95%CI 1.632-7.982), p=0.002). OS differed significantly among molecular subtypes (log rank $p<0.001$). LN status showed only a trend (HR 2.330 (95%CI 0.990-5.482), p=0.053). SUVmax, ADC, and perfusion parameters were not significant in predicting OS. Adding distant metastasis to tumor size improved the model (p=0.013). Further inclusion of LN information (p=0.191), molecular subtype (p=0.084) and imaging parameters ($p>0.225$) contributed minimally.
Conclusion: Among several histopathologic and clinical variables tumor size and distant metastases remain the strongest predictors for OS in BC patients. Several 18F-FDG-PET/MR-imaging biomarkers did not improve prognostic models significantly. This indicates that FDG-PET/MR-imaging parameters do not yet surpass conventional assessments of tumor size and metastases in predicting OS.
Limitations: Single-center design, limited number of events, and heterogeneous follow-up duration.
Funding for this study: This study is supported by the WWTF (Vienna Science and Technology Fund), grant number LS20-065.

T-Stage Accuracy of Invasive Breast Carcinoma (IBC) with CEM and MRI (6 min)

Greta Chiffi; Rome / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: G. Chiffi[1], Ö. Lafci[2], A. Santonocito[3], N. Pirringer-Pötsch[2], A. Stiglbauer-Tscholakoff[2], M. Costantini[1], T. H. Helbich[2], P. A. Baltzer[2], P. Clauser[2]; [1]Rome/IT, [2]Vienna/AT, [3]Turin/IT
Purpose: To evaluate the accuracy of tumor size and T-stage estimation in IBC by Contrast-Enhanced Mammography (CEM) and Magnetic Resonance Imaging (MRI), compared with pathology.
Methods or Background: This retrospective single-centre study included 100 patients (mean age 57 years) with biopsy-proven IBC who underwent pre-surgical CEM and MRI, each showing at least a component of mass enhancement. Two radiologists independently measured the maximum invasive mass component. CEM lesions were measured on low-energy and recombined images, MRI measurements on early post-contrast dynamic series (MRI-dyn) and Maximum Intensity Projection reconstructions (MRI-MIP). Pathology was the reference standard. Agreement was evaluated with intraclass correlation coefficients (ICC), Bland–Altman analysis using a ±2.5 mm margin. Impact on T-stage classification was assessed.
Results or Findings: A total of 112 invasive lesions were analysed (mean pathological size 13.8 mm). All modalities showed good correlation with pathology (ICC 0.825–0.876, $p < 0.001$). Mean lesion sizes were close to pathology, but case-wise agreement varied. Bland–Altman analysis showed for CEM mean differences ranged from –0.9 to +0.2 mm across reader, with limits of agreement (LOA) –11.4 to +9.6 mm; for MRI-dyn, –1.1 to 0.0 mm, LOA –11.5 to +9.3 mm. MRI-MIP showed differences –1.6 to +0.5 mm with wider LOA (–12.2 to +11.2 mm). Discrepancies increased with tumor size, trending toward underestimation. T-stage accuracy was highest with MRI-dyn (84%), followed by CEM (80%), while MRI-MIP consistently overstaged. Small but consistent inter-reader shifts were observed.
Conclusion: CEM and MRI-dyn showed good correlation with pathology, but accuracy declined for larger tumors. For preoperative size and T-stage assessment, MRI-dyn should be preferred, CEM as an alternative. Standardized measurement rules may reduce inter-reader variability.
Limitations: Single-centre retrospective design, modest sample size, exclusion of non-mass enhancement, which-though likely irrelevant for T stage-may influence surgical planning.
Funding for this study: Not applicable
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was approved by the Institutional Review Board (IRB), which ruled that written informed consent is unnecessary. Data were collected within a prospective study comparing the diagnostic value of CEM to MRI in a problem-solving setting (Ethics Review Board number 2282/2019).

Preoperative Detection of Pure Ductal Carcinoma In Situ (pDCIS) of the Breast: A Two-Center Comparison Between CEM and MRI (6 min)

Javier Azcona Sáenz; Barcelona / Spain

Author Block: J. Azcona Sáenz[1], J. Molero-Calafell[1], U. Lalji[2], T. Wegman[2], P. Santiago Díaz[1], J. M. Maiques Llacer[1], R. Alcantara Souza[1], M. d. M. Vernet Tomás[1], T. Van Nijnatten[2]; [1]Barcelona/ES, [2]Maastricht/NL

Purpose: To compare contrast-enhanced mammography (CEM) and MRI in the preoperative diagnosis of pure ductal carcinoma in situ (pDCIS), and to evaluate their performance in detecting additional lesions (ALs).
Methods or Background: In this international two-center retrospective study, 46 pDCIS lesions at Hospital del Mar and 18 lesions at Maastricht UMC+, all of whom underwent preoperative CEM and MRI, were reviewed. The sensitivity, morphology, and extent of pDCIS on each modality, as well as their ability to detect ALs, were assessed.
Results or Findings: CEM and MRI combined with low-energy images (LEI) showed the highest sensitivity for pDCIS detection at both centers (100.0%), followed by MRI (97.5% at Hospital del Mar; 93.3% at Maastricht UMC+), recombined images (RCI) (90.0% and 86.7%), and LEI (80.0% and 86.7%) of CEM. Calcifications were the most frequent LEI descriptor (~60%). On RCI and MRI, pDCIS predominantly presented as non-mass enhancement (60.0–75.0). LEI tended to underestimate tumor size, particularly at Maastricht UMC+, whereas MRI provided the most accurate estimations, closely followed by RCI. MRI detected more ALs than CEM; however, most corresponded to false positives (Hospital del Mar: 21 vs. 12 [MRI vs. CEM]; Maastricht UMC+: 15 vs. 11). CEM failed to identify one additional malignant lesion.
Conclusion: CEM and MRI + LEI showed slightly higher sensitivity than MRI for detecting pDCIS. MRI provided the most accurate preoperative size assessment, closely followed by RCI, with both modalities overestimating size. MRI was superior to CEM in detecting additional malignant lesions.
Limitations: -Small sample size in both cohorts.
-Retrospective design.
-Lesion size assessment may have been biased in cases where VAB were performed.
-Diagnostic specificity and disease prevalence could not be evaluated.
-Not all patients underwent bilateral mastectomies. Therefore, assessment of true false-negative rates was precluded.
Funding for this study: No
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective study was approved by the Institutional Ethics Committees of both centers, with a waiver of informed consent.

Deciphering Lung Function Changes: Phase-Resolved Functional Lung MRI Findings in Dilated Cardiomyopathy (6 min)
Wenliang Fan; Wuhan / China

Author Block: W. Fan, F. Yang; Wuhan/CN
Purpose: Dilated cardiomyopathy (DCM) involves systemic pathophysiological changes, yet the specific alterations in lung ventilation and perfusion remain unclear. This study aims to comprehensively evaluate lung ventilation and perfusion changes in DCM patients using phase-resolved functional lung (PREFUL) MRI, to uncover the cardiopulmonary interplay in DCM.
Methods or Background: Eighty-five DCM patients and 124 age- and sex-matched healthy controls (HC) were prospectively enrolled. All participants underwent cardiovascular MRI and PREFUL MRI. Cardiac parameters including Left Ventricular Mass Index (LVMI), Cardiac Index (CI), Stroke Volume Index (SVI), End-Systolic Volume Index (ESVI), and Ejection Fraction (EF) were calculated from cardiovascular MRI data. PREFUL MRI data were used to quantify regional flow volume loop (RFVL)-based ventilated volume (VV), perfused volume (Q), and ventilation-perfusion (V/Q) matching. Two-sample t-tests compared lung parameters between groups, and Pearson correlation analysis explored cardiac-lung parameter relationships.
Results or Findings: Homogeneous ventilation and perfusion time-to-peak (TTP) maps were obtained for all subjects. DCM patients had significantly lower mean lung perfusion and ventilation, higher perfusion (QDP) and ventilation (VDP) defect percentages, and smaller fractional ventilation flow-volume loops than HCs. CI positively correlated with mean perfusion and negatively with QDP; SVI positively correlated with mean perfusion; ESVI negatively correlated with QDP.
Conclusion: PREFUL MRI can quantitatively assess regional lung perfusion and ventilation in DCM patients. The study reveals reduced lung perfusion and ventilation in DCM, with ventilation dynamics and regional heterogeneity correlated to disease stages, offering potential non-invasive biomarkers for DCM assessment.This study's findings can facilitate early DCM detection, guide personalized treatment, predict prognosis, and drive further research into cardiopulmonary mechanisms, ultimately improving patient care and outcomes.
Limitations: Not applicable.

The potential role of MRI in predicting worsening of CTD-ILD (6 min)
Nicolò Davide Igor Colomba; Castellammare Del Golfo / Italy

Author Block: N. D. I. Colomba, P. Bica, F. Corrao, C. Zichichi, M. Molino; Trapani/IT
Purpose: Interstitial lung disease (ILD) is a common complication in patients with connective tissue disease (CTD). The ILD is generally quantified with HRCT. The purpose of the study is to identify a qualitative evaluation of the CTD-ILD and eventually a biomarker of worsening with the MRI.
Methods or Background: We optimized an MRI thorax protocol with a T2W fat sat breath-gated sequences which enhance the fluids. The study started in January 2025 and we selected so far twelve patients with mild to advanced stage CTD-ILD. Only patient with serological or sistemic simphtoms worsening has been enrolled. All patients took a first MRI scan followed by a second scan six months later.
Results or Findings: We found a similar pattern in almost all patient with hyperintensity in the subpleural regions of the inferior lobes usually in the context of honey combing areas. Since only water has a high signal in the sequence we used those alterations found in our patiens are very likely to be oedema. We found the amount of oedema was not strictly related to the stage of the ILD. In our group six patients with moderate to severe oedema alterations were basically stable at the six months follow-up. Three patients had a slight remission of the oedema while tree had a subtle worsening. Among the three of the last group two had a real worsening of the stage of the ILD in the following HRCT scans.
Conclusion: Our preliminary results suggest that the presence and the evolution of oedema in the MRI scan could relate the potential likelihood of worsening of ILD. We definitely need more patients and a longer follow-up. The study is still in progress.
Limitations: No limitations were identified.
Funding for this study: No funding was provided for this study.

Magnetic resonance imaging detects dilated bronchial arteries in patients with primary ciliary dyskinesia (6 min)

Defne Cetiner; Heidelberg / Germany

Author Block: D. Cetiner[1], P. Leutz-Schmidt[1], M. Stahl[2], O. Sommerburg[1], C. P. Heußel[1], H-U. Kauczor[1], M. A. Mall[2], M. O. Wielpütz[3], L. Wucherpfennig[1]; [1]Heidelberg/DE, [2]Berlin/DE, [3]Greifswald/DE

Purpose: Bronchial arterial dilatation (BAD) is known to be associated with pulmonary hemorrhage and is highly prevalent in patients with chronic muco-obstructive lung diseases such as cystic fibrosis. However, studies on the prevalence of BAD in patients with primary ciliary dyskinesia (PCD) and their association with lung disease severity are lacking. Thus, the aim of our study is to evaluate BAD onset and its association with disease severity in patients from two different centers with PCD by magnetic resonance imaging (MRI).

Methods or Background: 68 patients with PCD (mean age at baseline 17.3±14.4 yr) performed annual standardized MRI including dynamic contrast-enhanced (DCE) MRI or angiography, contributing to a total of 155 examinations. The presence of BAD was assessed visually by two readers in consensus. Disease severity was assessed using the validated chest MRI score and spirometry (percent predicted forced expiratory volume in 1s [ppFEV1]).

Results or Findings: At baseline, at least one BAD was present in 30 patients (44.1%), with most patients having one or two BAD (53.3% and 26.6%, respectively). The number of BAD correlated strongly with patient age ($r=0.641$, $p<0.001$). The mean MRI global score was significantly higher in patients with BAD at baseline compared to patients without BAD (26.3±6.7 vs. 19±8.1, $p=0.002$), while ppFEV1 did not show differences (76.2±20.8% vs. 73.1±18.5%, $p=0.57$). During follow-up, four patients developed a BAD for the first time (5.8%) and three patients (4.4%) developed an additional BAD. BAD development was neither associated with changes in the MRI score, nor in ppFEV1 ($p>0.99$ and $p=0.87$).

Conclusion: Our study demonstrates a high prevalence of BAD in children and adults with PCD and an association between prevalence of BAD markers of greater disease severity.

Limitations: Not all patients received angiography additional to DCE-MRI.

Funding for this study: This study was supported by grants from the German Federal Ministry of Education and Research (BMBF) (82DZL004A1, 82DZL009C1 and 01GL2401A) and the German Research Foundation (CRC 1449 – project 431232613). MS is participant of the BIH-Charité Clinician Scientist Program funded by the Charité – Universitätsmedizin Berlin and the BIH. Multimodality imaging insights in atypical thoracic hydatidosis (6 min)

Manish Kumar; Raipur, Chhatisgarh / India

Author Block: M. Kumar[1], K. K. RATRE[2], A. Rai[2], A. Agrawal[2]; [1]Raipur, Chhatisgarh/IN, [2]Raipur/IN
Purpose: To identify characteristic imaging features of atypical thoracic hydatid disease on multimodality imaging
To emphasize the importance of imaging in guiding clinical management and surgical planning in complicated hydatid disease.
Methods or Background: 6 patients with confirmed thoracic hydatid disease were retrospectively evaluated using CXR, ultrasound, CECT and MRI. Findings were correlated with clinical and surgical outcomes.
Results or Findings: 1.Extrapleural hydatid

CXR demonstrated homogeneous radiodense lesion in the left upper zone which on CT appeared solid non-enhancing. MRI revealed a multilocular cystic lesion with internal T2 hypointense membranes located outside the pleural cavity with cervical extension and compressing the left brachial plexus.

2.Endobronchial and pleural rupture of pulmonary hydatid cyst with air and fluid in pleural space.

3.Pleural hydatidosis secondary to ruptured pulmonary hydatid

CECT revealed multiple cystic lesions in the lung parenchyma bilaterally with left sided effusion & one of them showing rupture into the left pleural space. Multilocular lesion was seen in the left pleural cavity with pleural thickening, internal membranes and hydatid sand.

4.Primary pleural hydatid

Chest CT reveals presence of moderate sized pleural effusion and a large lesion inseparable from the collapsed right lower lobe. Ultrasound showed a multilocular cystic lesion outside the lung.

5.Calcification within pulmonary hydatid cysts.

CECT revealed solitary/ multiple lesions with calcification in the wall or membranes.
Conclusion: Pleural hydatid cysts may be primary or secondary to rupture of pulmonary cysts.
Ultrasound is superior to CT in characterisation of pleural lesions/disease.
Extrapleural hydatid disease can mimic chest wall or pleural tumors.
Calcification represents chronicity.
MRI is reserved for unusual cases like extrapleural or mediastinal lesions.
Identifying pleural rupture is paramount as it needs emergency chest tube placement or planned surgical decortication in refractory cases.
Limitations: Less number of cases
Funding for this study: None recived.

Diagnostic performance of single breath-hold lung MRI scan with AI-powered compressed sensing for Nodule Detection in comparison toPhoton Counting Detector-CT (6 min)

Giulia Piccinni; Milano / Italy

Author Block: G. Piccinni, A. Palmisano, D. Serra, E. Bruno, A. Esposito; Milano/IT
Purpose: Evaluate the performance of a single breath-hold accelerated 3D-T1-FFE 3T MRI sequence for the screening of lung nodules using Photon-Counting Detector CT as the reference standard.
Methods or Background: This single-center prospective study enrolled 97 healthy adults who underwent Photon-Counting Detector CT scans after pulmonary nodules were detected by 3T whole-body magnetic resonance imaging (3D-T1-FFE with AI and breath-hold) between June 2024 and June 2025. All nodules were evaluated in terms of size and composition and sensitivity of MRI in comparision to PCD-CT in nodule detection capability was calculated. Intermodality agreement was assessed with the Prevalence-Adjusted Bias-Adjusted Kappa and Lin's Concordance Correlation Coefficient.
Results or Findings: Using CT as the reference standard, MRI achieved a specificity of 97.0% (95% CI: 84.7–99.5) and a positive predictive value of 98.7% (95% CI: 93.1–99.8), indicating that nearly all nodules detected by MRI were true positives. Stratifying lesions by size (<4 mm vs. ≥4 mm), MRI showed a sensitivity of 60.8% (95% CI: 49.7–70.8), specificity of 89.7% (95% CI: 76.4–95.9), PPV of 92.3% (95% CI: 81.8–97.0), NPV of 53.0% (95% CI: 41.2–64.6), and an overall accuracy of 70.3% (95% CI: 61.6–77.8) compared with CT . Stratifying by composition, MRI demonstrated excellent ability to identify solid nodules with a sensitivity of 86.3% (95% CI: 76.6–92.4), specificity of 100% (95% CI: 92.1–100), PPV of 100% (95% CI: 94.3–100), NPV of 81.8% (95% CI: 69.7–89.8), and an accuracy of 91.5% (95% CI: 85.1–95.3), indicating that MRI has an excellent accuracy for detection of solid nodule, whereas false negatives occur in calcific lesions.
Conclusion: A single breath-hold accelerated 3D-T1-FFE MRI scan is a fast valuable tool for solid lung nodule screening with an excellent agreement with CT.
Limitations: Small patient sample.
Funding for this study: No.

Ethics committee - additional information: The study was approved by the local Ethic Commitee (AIMOMICS-BANK CET 233-2024), and written informed consent was obtained.

The value of CT Lymphangiography and MR Lymphangiography in the diagnosis and classification of lymphatic plastic bronchitis (6 min)

Hao Qi; Beijing / China

Author Block: H. Qi; Beijing/CN
Purpose: To investigate the diagnostic value of CT lymphangiography (CTL) and MR Lymphangiography (MRL) in lymphatic plastic bronchitis.
Methods or Background: The clinical and imaging data of 27 patients diagnosed lymphatic plastic bronchitis were analyzed. All patients were examined by CTL and MRL. According to the extent of the abnormal lymphatic vessels in the neck and chest, MRL was divided into four types: Type I shows small abnormal lymphatic vessels in the supraclavicular region and mediastinum, type II shows increase of abnormal lymphatic vessels in the supraclavicular region but did not extend to the mediastinum. Type III shows increase of abnormal lymphatic vessels in the supraclavicular region, extending into the mediastinum; Type IV shows lymphatic abnormalities in the supraclavicular region extending into the mediastinum, lung parenchyma, and interstitium. Type I and II patients were classified as mild, and type III and IV patients as severe. CTL imaging findings of each group were recorded respectively and statistically analyzed.
Results or Findings: The 27 patients were divided into a mild group of 10 cases and a severe group of 17 cases.There was statistical difference in lymphatic malformation,patchy ground glass opacity, large mesh shadow and bronchial vascular bundle thickening between the two groups were statistically significant ($P < 0.05$), The abnormal deposition of contrast agents around pericardium, subcarina, pulmonary hilum and bronchial vascular bundle was statistically significant between the two groups ($P < 0.05$).
Conclusion: CTL and MRL are of great significance in the diagnosis and classification of lymphatic PB, providing important imaging evidence for the treatment and management of lymphatic PB.
Limitations: (1) Since lymphatic-originated PB is a rare disease, the sample size is relatively small; (2) There is a lack of a control group for the study of lymphatic abnormalities.

Impact of Zonally Magnified Oblique Multi-slice Technique (Zoom DWI) Versus Conventional DWI on Image Quality and ADC Measurements in Mediastinal Lesions (6 min)

Yoshiyuki Ozawa; Toyoake / Japan

Author Block: Y. Ozawa, T. Ueda, M. Nomura, T. Yoshikawa, D. Takenaka, Y. Ohno; Toyoake/JP
Purpose: Zonally magnified oblique multi-slice DWI (Zoom DWI) enables a smaller field of view than conventional DWI (cDWI), reducing aliasing and echo planar imaging distortion. However, Zoom DWI's impact on image quality and apparent diffusion coefficient (ADC) measurements in mediastinal lesions remains unexplored. This study compared Zoom DWI with cDWI in terms of image quality and ADC assessment.
Methods or Background: Thirty patients with mediastinal lesions underwent STIR, Zoom DWI, and cDWI on a 3T MR system. Tumor long- and short-axis diameters (LA and SA) were measured on STIR and each DWI for distortion evaluation. ADC values and signal-to-noise ratios (SNR) of tumor and muscle were obtained from ROI analyses. Two radiologists assessed image quality, artifacts, and diagnostic confidence. Spearman's correlation and Bland-Altman analysis evaluated diameter agreement, while paired t-tests or Wilcoxon tests compared quantitative and qualitative indices.
Results or Findings: On correlation between STIR and each DWI, Zoom DWI (LA and SA: $r=0.99$, $p<0.0001$) showed significant and better correlations than cDWI (LA: $r=0.98$, $p<0.0001$; SA: $r=0.97$, $p<0.0001$). The limits of agreement (mean, SD) of Zoom DWI (LA: -0.8, 3.4 mm, SA: -0.3, 1.6 mm) were smaller than those of cDWI (LA: -4.1, 4.4 mm, SA: -2.6, 2.2 mm). ADC values of tumor on Zoom DWI was significantly higher than that of cDWI ($p< 0.01$). Zoom DWI showed significantly better qualitative image quality indices than cDWI ($p<0.01$).
Conclusion: Zoom DWI has the potential to reduce image distortion and enhance image quality, as well as influence tumor ADC measurements, compared with conventional DWI.
Limitations: First, relatively small number of the cases. Second, explore of further clinical Utility for diagnosis of mediastinal lesions is needed.
Funding for this study: No funding was provided for this study.

Early Prediction of Progression-Free Survival in Advanced NSCLC Using Spectral CT Histogram Features (6 min)

Wen Yang; Nanjing / China

Author Block: W. Yang, Q. Feng, X. Chen, X. Xin; Nanjing/CN
Purpose: This study aimed to evaluate the predictive value of spectral CT-derived histogram features for progression-free survival (PFS) in patients with advanced NSCLC undergoing immunotherapy.
Methods or Background: This retrospective study included 43 patients who underwent baseline spectral contrast-enhanced CT prior to immunotherapy and a first follow-up scan at three months, with progression-free survival (PFS) recorded. Spectral image series-including conventional images, 40/70 keV virtual monoenergetic images (VMI), iodine density, effective atomic number, electron density, and water/iodine-based maps-were reconstructed in arterial and venous phases. Lesions were segmented on VMI-40 keV images for extraction of histogram features. Significant predictors were selected using univariate and variance inflation factor analyses, followed by Cox proportional hazards regression. Patients were stratified into high- and low-risk groups based on Cox-derived risk scores (median cutoff). Kaplan–Meier (KM) analysis compared PFS between groups, and model performance was evaluated by concordance index (C-index).
Results or Findings: At follow-up, 12 patients (26.1%) remained progression-free, while 34 (73.9%) progressed (PFS range: 1.7–25 months, mean 9.05 ± 5.61). Three baseline features yielded a Cox model with a C-index of 0.72. Ten follow-up features achieved the same C-index. KM analysis showed significant PFS differences between high- and low-risk groups (log-rank $p < 0.01$). Median 12-month survival was markedly shorter in high-risk groups compared with low-risk groups.
Conclusion: Histogram features derived from spectral CT at baseline or early follow-up are significant predictors of immunotherapy response and PFS in advanced NSCLC, offering potential for early risk stratification.
Limitations: Sample size is small.

Oxygen-Enhanced ZTE-MRI for Pulmonary Nodule Assessment: A Comparative Study with CT (6 min)

Tian-cai Yan; Harbin / China

Author Block: T-c. Yan, T. Zhang; Harbin/CN
Purpose: This study aimed to evaluate the feasibility of oxygen-enhanced (OE) ZTE-MRI at varying oxygen concentrations (21% and 100%) for both the subjective and objective assessment of pulmonary nodules. It further explored the potential of OE-ZTE-MRI in detecting nodules, its diagnostic utility in Lung-RADS classification, and its role in evaluating malignant potential.
Methods or Background: Frequent computed tomography scans for pulmonary nodule monitoring lead to increased radiation exposure and a potential risk of malignancy. Although lung magnetic resonance imaging (MRI) is gradually approaching CT in terms of performance, the effectiveness of zero-echo-time (ZTE) sequences remains to be fully optimized, particularly in terms of diagnostic accuracy under the Lung-RADS.
Results or Findings: The nodule detection rate for OE-ZTE-MRI was 87.5%, with a diagnostic performance comparable to that of CT for assessing nodule diameter. OE-ZTE-MRI showed a high agreement with CT in nodule characterization (kappa = 0.789) and Lung-RADS (kappa = 0.756). Additionally, OE-ZTE-MRI exhibited strong inter-observer consistency in nodule size measurements.
Conclusion: OE-ZTE-MRI, which incorporates oxygen concentration adjustments, outperformed conventional ZTE-MRI in both subjective and objective evaluations. It achieves diagnostic performance comparable to that of CT in terms of nodule size. According to the Lung-RADS classification, OE-ZTE-MRI is gradually approaching the same diagnostic accuracy as CT.
Limitations: First, the single-center design and limited sample size may have introduced selection bias, restricting the generalizability of our findings. Second, although this study evaluated SNR and CNR changes following oxygen modulation, it did not compare nodule composition or pathological characteristics between OE-ZTE-MRI and ZTE-MRI. Third, nodule selection was not restricted based by type or number, and we did not assess additional pulmonary pathologies, such as emphysema or cystic nodules. As highlighted by the Fleischner Society, nodules should be assessed from 4 mm onwards.
Funding for this study: This study was supported by the National Natural Science Foundation of China (Grant No. 62376078)
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This single-center, prospective study was approved by the Institutional Review Board of the Committee of the Fourth Affiliated Hospital of Harbin Medical University and conducted according to the principles outlined in the Declaration of Helsinki.

Non-invasive assessment of pulmonary ventilation across breathing patterns in healthy volunteers: a phase-resolved functional lung MRI study (6 min)

Meng Qin; Chengdu / China

Author Block: M. Qin, C. Xia; Chengdu/CN
Purpose: To investigate the feasibility of phase-resolved functional lung (PREFUL) MRI in non-invasive assessment of pulmonary ventilation across different breathing patterns in healthy volunteers and its correlation with pulmonary function tests (PFTs).
Methods or Background: Accurate evaluation of pulmonary function is essential for respiratory disease management, but conventional PFTs lack regional information. In this prospective study, thirty healthy adults with normal lung function were recruited between September 2024 and March 2025. PREFUL-MRI scans were performed under both free and deep breathing using a 3.0T system with an 18-channel body coil. Ventilation parameters included regional ventilation (RV), flow-volume loop correlation (FVLc), ventilation defect percentage (VDP), and flow-volume loop defect percentage (FVL-DP). MRI-derived parameters and PFT indices (FEV1%, FVC%, FEV1/FVC) were compared using correlation analysis. The consistency and agreement of PREFUL-MRI parameters between free and deep breathing were additionally assessed.
Results or Findings: RV was significantly lower during free breathing compared with deep breathing ($t = -10.378$, $P < 0.001$). FVLc, VDP, and FVL-DP showed no significant differences between breathing modes ($P > 0.05$) but demonstrated strong correlations (FVLc: $r = 0.699$, $P < 0.001$; VDP: $r = 0.510$, $P < 0.01$; FVL-DP: $r = 0.687$, $P < 0.001$) and good agreement in Bland-Altman analysis. Under free breathing, RV correlated positively with FVC% ($r = 0.402$, $P < 0.05$) and negatively with FEV1/FVC ($r = -0.442$, $P < 0.05$), while no significant correlations were observed for other parameters. No significant correlations were found under deep breathing.
Conclusion: PREFUL-MRI provides a non-invasive, radiation-free approach for regional ventilation assessment. Its consistency across breathing patterns suggests that complex respiratory maneuvers are unnecessary, thereby enhancing clinical feasibility.
Limitations: The sample size was limited, and only healthy volunteers were included.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the Medical Ethics Committee of West China Hospital, Sichuan University, and written informed consent was obtained from all volunteers.

Compared to Perfusion Assessment Capabilities among ECG- and PPG-Gated PREFUL and Dynamic CE-Perfusion MRIs (6 min)

Yoshiharu Ohno; Toyoake / Japan

Author Block: Y. Ozawa[1], T. Ueda[1], M. Nomura[1], T. Yoshikawa[1], D. Takenaka[1], M. Endo[2], Y. Ohno[1]; [1]Toyoake/JP, [2]Shizuoka/JP
Purpose: To directly compare the quantitative capabilities of regional perfusion and pulmonary functional change assessment among electrocardiogram (ECG-) and photoplethysmography (PPG-) phase-resolved functional lung (PREFUL) MRIs and dynamic contrast-enhanced (CE-) perfusion MRI in thoracic oncologic patients.
Methods or Background: 17 thoracic oncologic patients prospectively underwent ECG- and PPG-gated PREFUL MRI, dynamic CE-perfusion MRI and pulmonary function test. Then, quantitatively assessed ECG- and PPG-gated perfusion-weighted (PW-) MRI and perfusion map from dynamic CE-perfusion MRI were generated. On each method, regional perfusions were determined by ROI measurements, and overall perfusion was determined as average value of ROI measurements. Then, Pearson's correlations were performed to determine relationship among all regional perfusions. On comparison of regional perfusion among ECG- and PPG-gated PW-MRI and quantitative perfusion maps, Tukey's HSD test was performed. To assess pulmonary functional loss on each MRI method, each overall perfusion was correlated with %VC and %FEV1 by Pearson's correlation.
Results or Findings: Correlation of regional perfusion between ECG- and PPG-gated PW-MRIs was determined as significant and good ($r=0.79$, $p<0.0001$). However, correlations between ECG- or PPG-gated PW-MRIs and quantitative perfusion map were assessed as significant and fair (ECG: $r=0.4$, $p<0.0001$; PPG: $r=0.36$, $p<0.0001$). ECG- and PPG-gated PW-MRI demonstrated significantly higher perfusion than quantitative perfusion map ($p<0.0001$). Moreover, ECG-and PPG-gated PW-MRIs and quantitative perfusion map had significant and moderate correlations with them (%VC: $0.59<r<0.64$, $p<0.05$; %FEV1: $0.51<r<0.7$, $p<0.05$).
Conclusion: When compared to others, PPG-gated PREFUL MRI had almost similar potential for quantitatively assessed regional perfusion and pulmonary functional change assessments in thoracic oncologic patients.
Limitations: Limited study population

Robustness of Radiomics in Dual-Layer Spectral CT: A Phantom Study on the Impact of Acquisition and Reconstruction Parameters (6 min)

Jinyi Jiang; Hangzhou City, Zhejiang Province / China

Author Block: J. Jiang[1], L. Shi[1], M. Lin[1], C. Huang[1], Y. Wang[2], T. OuYang[1], Q. Zhou[1], J. Hu[1], Y. Zhou[1]; [1]Hangzhou/CN, [2]Shanghai/CN
Purpose: To assess the impact of acquisition and reconstruction factors on the robustness of radiomics within Dual-Layer Spectral CT.
Methods or Background: A chest phantom consisting of 12 pulmonary nodules was scanned with different acquisition and reconstruction factors, including tube voltage (120 kV vs 100 kV), tube current (10–90mAs vs 100mAs), slice thickness(0.67 mm, 3 mm, 5 mm vs 1 mm), iterative reconstruction levels(idose0–idose7 vs idose4), reconstruction kernels(smooth [A], standard [B], sharp [C], lung [E], y-Sharp [YA] vs y-Detail [YB]), collimation, (16 × 0.625, 32 × 0.625, 64 × 0.625 vs 128 × 0.625) and pitch(0.66, 1.473 vs 1). A total of 31 different scanning sets of 40–100keV virtual monochromatic images and conventional images were reconstructed. Regions of interest were segmented using a semi-automated approach, and 108 radiomics features were extracted. Reproducibility was quantified by the intraclass correlation coefficient (ICC)and concordance correlation coefficient (CCC), while variability was measured using coefficient of variation (CV) and quartile coefficient of dispersion (QCD).
Results or Findings: Across all virtual monochromatic and conventional images, the percentages of features were high for both ICC > 0.90 (median: 77.78%; interquartile range [IQR]: 72.22%-80.56%) and CCC > 0.90 (median: 75.93%; IQR: 69.44%-78.70%) when pitch, collimation, tube voltage, or iterative reconstruction level were modified, as well as under higher tube current (≥70 mAs) conditions. Reproducibility was low (median: 30.56%.; IQR: 24.77%-39.12% for ICC; median: 27.78%; IQR: 23.15%-36.57% for CCC) under conditions of altered reconstruction kernel or slice thickness. The inter-protocol variability suggested that 30.56% and 51.85% of features had a CV < 10% and QCD < 10%, respectively.
Conclusion: Dual-Layer Spectral CT radiomics was robust to tube voltage, collimation, pitch, iterative reconstruction level, and tube current, but remained sensitive to slice thickness and reconstruction kernel.
Limitations: Phantom study.

Radiomics Feature Reproducibility Across Virtual Monoenergetic and VNC Reconstructions Using Native Phase as Reference (6 min)

Andrey Ustalov; Moscow / Russia

Author Block: A. Ustalov, S. A. Shmeleva, E. V. Kondratyev, S. Tamaeva, V. Aznaurov, D. Bogomolov, V. Gurina, V. Shirokov, I. Gruzdev; Moscow/RU
Purpose: To evaluate the reproducibility of radiomics features extracted from virtual monoenergetic (MonoE) and virtual non-contrast (VNC) reconstructions of the liver parenchyma compared with native phase imaging, using a standardized 3D region of interest (ROI).
Methods or Background: Fifty patients who underwent abdominal CT were included. A spherical 3D ROI (15 mm diameter) was placed in a homogeneous, vessel-free area of the liver parenchyma. Segmentation was initially performed on one phase and propagated across other reconstructions. Radiomics features were extracted from: native phase (reference standard), VNC from arterial phase, VNC from portal venous phase, MonoE at 200 keV (portal).
All features were z-score normalized prior to analysis. Reproducibility was assessed using intra-class correlation coefficient (ICC 2,1), concordance correlation coefficient (CCC), within-subject coefficient of variation (wCV), mean absolute percentage error (MAPE), and paired t-tests with Benjamini–Hochberg FDR correction. A composite instability score was used to identify the least reproducible features.
Results or Findings: VNC-portal demonstrated the highest agreement with native phase, with mean CCC >0.90 for shape and first-order features and the largest proportion of “core-like” reproducible features (≈45%). VNC-arterial showed slightly lower reproducibility, particularly for texture classes (GLCM, GLRLM). MonoE200 exhibited significantly reduced reproducibility, with numerous features showing CCC <0.70, MAPE >25%, and systematic bias ($q<0.05$). The least reproducible features were predominantly wavelet- and LoG-based texture metrics from MonoE200. Shape and first-order features remained robust across all reconstructions.
Conclusion: VNC-portal reconstructions provide radiomics features most comparable to native images and may serve as a reliable surrogate when native acquisitions are unavailable. MonoE200 reconstructions introduce substantial variability, particularly in high-frequency texture features, and should be used with caution in radiomics studies.
Limitations: Retrospective single-center design, limited sample size
Funding for this study: No external funding.

Augmented Intelligence for Crohn's Disease: Boosting Prognostic Accuracy by Integrating CT Radiomics with LLM-Processed Electronic Health Records Data (6 min)

Zhoulei Li; Guangzhou / China

Author Block: Z. Li[1], Y. Yi[2], S. Li[1], Y. Wang[1], J. Lin[1], S-T. Feng[1], X. Li[2]; [1]Guangzhou/CN, [2]Macau/CD
Purpose: Accurate early prediction of adverse outcomes in Crohn's disease (CD) is paramount for personalized therapy. Current approaches often operate in silos: quantitative CT radiomics models or qualitative clinical narrative assessments. We hypothesize that integrating structured imaging biomarkers with unstructured, context-rich data from Electronic Health Records (EHRs) via Large Language Models (LLMs) will create a superior, holistic predictive framework.
Methods or Background: In this multicenter study, we enrolled 212 CD patients from six hospitals. We developed a multimodal fusion model that synergistically combines: 1) A CT Radiomics Model (VAT-RM), extracting 850 features (texture, first-order, wavelet) from baseline CT using pyradiomics and employing a Support Vector Machine (SVM) classifier; and 2) An LLM-based Clinical Narrative Analyzer, processing unstructured EHR data (symptom history, medication usage, endoscopic reports) using Gemini-2.5 to generate quantitative clinical embeddings. The outputs of both models were integrated using a logistic regression meta-learner to generate the final prognostic prediction.
Results or Findings: The integrated multimodal model demonstrated exceptional performance, achieving an AUC of 0.920 (95% CI 0.871–0.956) in the external test cohort. This significantly outperformed both the standalone VAT-RM (AUC=0.882, P=0.039) and the best-performing standalone LLM (Gemini-2.5 AUC=0.791, P<0.001). The fusion model also showed superior calibration and reclassification metrics, indicating its enhanced clinical utility. The LLM component provided unique value in interpreting complex clinical narratives, such as subtle symptom progression and medication adherence patterns, complementing the robust imaging biomarkers.
Conclusion: Fusing CT radiomics with LLM-derived clinical insights creates a powerful synergistic model that surpasses either modality alone. This integrated approach offers a comprehensive and superior strategy for risk stratification in CD, paving the way for more precise and data-driven clinical decision support.
Limitations: Not applicable.
Funding for this study: None.

Robustness of radiomics features between poly-energetic images and virtual mono-energetic images: synchronizing kiloelectron-volt level for better radiomics reproducibility (6 min)

Jingyu Zhong; Shanghai / China

Author Block: J. Zhong, Y. Song, Z. Xu, H. Zhang, W. Yao; Shanghai/CN
Purpose: To find the kiloelectron-volt (keV) level of virtual mono-energetic images (VMIs) matching to the poly-energetic images (PEIs) that provide better radiomics reproducibility for subsequent clinical analysis.
Methods or Background: A phantom of twenty diverse texture materials was scanned using single-source mode at tube voltages of 70, 80, 90, 100, 110, 120, 130, 140, and 150 kVp, and dual-source mode at tube voltage combinations of 70/150Sn, 80/140, 80/150Sn, 90/150Sn, and 100/150Sn kVp, respectively, all with a radiation dose of 5 mGy. Nine sets of PEIs were reconstructed as reference. Thirty-one sets of VMIs at 40 to 190 keV with a stepwise of 5 keV were reconstructed for five dual-source scans, resulting 155 sets of VMIs. Ninety-three radiomics features were extracted from each material per PyRadiomics. The reproducibility of features between PEIs and VMIs was evaluated using intraclass correlation coefficient (ICC) and concordance correlation coefficient (CCC).
Results or Findings: According to ICC and CCC values, the keV levels of VMIs for highest radiomics reproducibility were 55, 60, 65, 65, 65, 70, 75, 75, and 75 keV for PEIs at 70, 80, 90, 100, 110, 120, 130, 140, and 150 kVp, respectively. The radiomics features showed highest percentage of 82.2% and 79.6% with ICC>0.90 and CCC>0.90 at 70 keV VMI for 120 kVp PEIs.
Conclusion: The ideal keV levels of VMIs that provide appropriate radiomics reproducibility increased with the tube voltages for PEIs. Synchronizing keV levels can provide better radiomics reproducibility between VMIs and PEIs. The keV levels are important for generalizability radiomics models across conventional and spectrum CT platforms.
Limitations: The limitations of the study are: (1) phantom study; (2) the exact best keV level VMI for PEI at each kVp not confirmed; (3) impact on diagnostic performance not investigated.
Funding for this study: Funding was provided by National Natural Science Foundation of China (82302183, 82471935, 82271934), Research Found of Health Commission of Shanghai Municipality (20244Y0214), Research Found of Health Commission of Changing District, Shanghai Municipality (2023QN01), Laboratory Open Fund of Key Technology and Materials in Minimally Invasive Spine Surgery (2024JZWC-ZDA04, 2024JZWC-YBA07), and Research Fund of Tongren Hospital, Shanghai Jiao Tong University School of Medicine (TRKYRC-XX202204, TRYJ2021JC06).

Machine Learning Survival Prediction in Esophageal Cancer Using Radiomics and Body Composition from Pretreatment and Follow-Up T12-Level CT (6 min)

MingCheng Liu; Taichung / Taiwan, Chinese Taipei

Author Block: M. Liu, S-C. Lin, C-H. Liao, W-H. Chen, Y-J. Liu; Taichung/TW
Purpose: This study aimed to develop prognostic models for esophageal cancer by integrating body composition indices and radiomic features of skeletal muscle and adipose tissue at the T12 level from both pretreatment and follow-up CT scans, along with clinical and demographic data.
Methods or Background: This retrospective study included 212 esophageal cancer patients who underwent concurrent chemoradiotherapy, with both pretreatment and follow-up chest CT scans available. Body composition analysis (BOA) and radiomic features were extracted from skeletal muscle and adipose tissue at the T12 level using automated tools. Four feature subsets (no-radiomics, pretreatment only, follow-up only, and combined inputs) were developed using logistic regression with LASSO for feature selection, followed by Cox regression. Prognostic models—including nomogram, support vector classifier, logistic regression, and extra trees classifier—were constructed to predict 1-, 2-, and 3-year overall survival.
Results or Findings: The model integrating both BOA and radiomics from pretreatment and follow-up CT, combined with clinical data, achieved the highest AUC (0.91), sensitivity (0.81), and specificity (0.88) using the logistic regression model. The most predictive features included both clinical variables, body composition indices, and radiomic features, particularly from follow-up VAT. Follow-up imaging contributed significantly to model performance, reinforcing its value in treatment response evaluation.
Conclusion: This is the first study to demonstrate that BOA indices and their corresponding radiomics at the T12-level from both pretreatment and follow-up CT scans—combined with clinical data—can provide accurate prognostic information for esophageal cancer. This approach offers a practical alternative when L3-level imaging is unavailable and supports the clinical integration of automated T12-based imaging biomarkers. The integration of these imaging features with clinical parameters enhances the prediction of survival outcomes.
Limitations: Conducted retrospectively at a single center, with relatively small and heterogeneous patient cohort.
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective study was approved by the IRB of Taichung Veterans General Hospital.

AI-Assisted CT Diagnosis of Appendicits: Synergistic Gains Across Radiologist Experience Levels (6 min)

Stefan Reischl; Munich / Germany

Author Block: S. Reischl, J. D. B. Brandt, F. Reischl, S. Ziegelmayer, A. Sauter, F. Lohöfer, M. R. Makowski, D. Rueckert, R. Braren; Munich/DE
Purpose: To evaluate the diagnostic performance of a deep learning system for appendicitis in CT and its synergistic effect when used as decision support across radiologists with varying experience levels.
Methods or Background: We developed AIppendix, an end-to-end deep learning pipeline combining a 3D Retina-UNet for detection and a 3D ResNet18 for classification of appendicitis and co-pathologies. Training was performed on 580 annotated CT scans with 116 cases reserved for validation and 162 independent cases for external testing. The system was assessed in a reader study including 12 participants: medical students (n=4), residents with >3 years of experience (n=3), and board-certified radiologists (n=5, including 2 gastrointestinal subspecialists). Readers classified if appendicitis was present on abdominal CT scans of patients with abdominal discomfort first unaided, then with AI support.
Results or Findings: The AI system achieved an accuracy 0.93 (sensitivity 0.96, specificity 0.90) on internal data and 0.88/0.87 AUC on external testing, matching senior radiologists and surpassing residents in specificity. Without AI support, accuracy increased with experience (students 0.72, residents 0.91, senior radiologists 0.93). With AI assistance, performance improved in all groups. Students benefited most (accuracy 0.72→0.87; sensitivity 0.78→0.87; specificity 0.67→0.88). Residents improved from 0.91→0.97, mainly through specificity gains (0.83→0.96), while senior radiologists showed only marginal benefit (0.93→0.95). The AI thus compensated for inexperience, reduced false positives among residents, and acted as a safeguard for experts.
Conclusion: The model achieves radiologist-level performance in diagnosing appendicitis and demonstrates the strongest impact when combined with less experienced readers, harmonizing diagnostic quality across experience levels.
Limitations: Retrospective single-center study with moderate dataset size; end-to-end performance remains limited by detection accuracy.
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the ethical review board of the Technical University of Munich. Informed consent was waived according to the regulations of the university for retrospective analyses.

The clinical and radiomics study of predicting the pathological grade of pancreatic neuroendocrine neoplasm based on spectral CT imaging (6 min)

Jiajia Shi; CHINA Henan Zhengzhou / China

Author Block: J. Shi; CHINA Henan Zhengzhou/CN
Purpose: To explore the clinical value of dual-layer spectral detector CT(DLCT) imaging combined with conventional CT and radiomics features in the differential diagnosis of pancreatic neuroendocrine tumor (PNET) and pancreatic neuroendocrine carcinoma (PNEC).
Methods or Background: A total of 128 patients who underwent DLCT scans with pathologically confirmed pancreatic neuroendocrine neoplasm (PNEN) were included in this study. All patients were divided into PNET group (n=86) and PNEC group (n=42) and randomly divided into training (n=89) and validation (n=39) according to 7:3. The general clinical data, conventional CT features and spectral CT parameters of the patients were collected, and radiomics features were extracted based on 40keV virtual monoenergetic images (VMI) in venous phase. Logistic regression analysis was used to screen for independent predictors discriminating between PNET and PNEC, and conventional CT model, spectral CT model, radiomics models based on 40keV VMI, conventional-DLCT model, DLCT-radiomics model and the combined model were constructed. The areas under the curve (AUCs) of each model was compared by Delong test, and the nomogram was plotted based on the optimal model.
Results or Findings: The analysis showed that the combined model had the best prediction performance. The AUC of conventional CT model, DECT model, 40keV radiomics model, conventional-DLCT model, DLCT-radiomics model and the combined model were 0.794, 0.835, 0.871, 0.884, 0.932 and 0.956 in the training cohort, and 0.787, 0.805, 0.811, 0.864, 0.896 and 0.905 in the validation cohort, respectively. The clinical decision curve (DCA) and calibration curve showed that the combined model had good clinical practicability and calibration.
Conclusion: The combined model had exceptional performance in the identification of PNET and PNEC, which is conducive to clinical decision-making analysis.
Limitations: Not application.
Funding for this study: No fundings was provided for this study.

CT-based radiomics for HCC recurrence prediction after liver transplantation: which choices really matter? Insights on segmentation margins, bin width, and contrast phase (6 min)

Virginia Piva; Milano / Italy

Author Block: V. Piva, G. Zorzi, F. Rizzetto, G. Bruschi, C. De Mattia, A. Vanzulli, P. E. Colombo; Milano/IT
Purpose: Aim of this study was to evaluate the impact of CT contrast phase, segmentation margins and radiomic features extraction bin width on the performance of a machine learning model for predicting post-transplant HCC recurrence.
Methods or Background: We retrospectively included 54 histologically confirmed HCC patients who underwent pre-transplant liver CT imaging between 2010 and 2019 at a single institution, yielding a total of 116 lesions. A single radiologist segmented the lesions with four different peritumoral expansions (PT 0, 5,10 and 15 mm) on arterial, venous and delayed phases. Radiomic features were extracted using PyRadiomics with varying bin widths (3,5,10,20,25) and isotropic resampling. Principal Component Analysis (PCA) was used to select relevant features for each combination. A multilayer perceptron (MLP) model was trained with stratified 10-fold cross-validation and hyperparameters optimized via GridSearchCV. Model performance was evaluated across different combinations of segmentation margin, contrast phase, and bin width to compare their effect.
Results or Findings: The MLP achieved its best performance on the arterial phase with no peritumoral expansion and a medium bin width of 10 (AUC 0.82, accuracy 0.80, specificity 0.87). With PT0–PT5, the arterial phase outperformed the delayed phase, achieving higher values for AUC (0.72–0.82 vs. 0.62–0.75), accuracy (0.78–0.80 vs. 0.77–0.79), and comparable specificity (0.87–0.88 vs. 0.88–0.89). Larger expansions (PT10–PT15) decreased performance across phases. The portal phase did not achieve predictive value (AUC<0.60). Model performance also declined with very small or very large bin widths (AUC<0.78).
Conclusion: CT-based radiomics can support prediction of post-transplant HCC recurrence; however, model performance is highly dependent on contrast phase, segmentation strategy, and feature extraction settings. Careful optimization of these factors is essential to achieve reliable predictions.
Limitations: The small patient cohort and its retrospective nature.
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Institutional Review Board approved the retrospective data collection in anonymous form.

The impact of deep learning image reconstruction on image quality and diagnostic confidence of liver tumors in 40 kev virtual monochromatic imaging (6 min)

Caijun Huang; Guiyang / China

Author Block: C. Huang, C. He; Guiyang/CN
Purpose: To investigate the effect of deep learning image reconstruction (DLIR) on the synchronous visualization of liver tumors in 40 keV virtual monochromatic images (VMIs).
Methods or Background: This prospective study enrolled 50 patients who underwent abdominal contrast-enhanced dual energy CT (DECT) imaging, 40 keV VMIs were obtained during the venous phase. Images were reconstructed with different algorithms: filtered back projection (FBP), adaptive statistical iterative reconstruction V (ASIR-V 60%), DLIR-M, and DLIR-H. Measurements included liver SD, lesion-background contrast-to-noise ratio (CNR). Two radiologists independently scored image quality, lesion conspicuity and diagnostic confidence using a 5-point Likert scale. Lesions were categorized as hypervascular or hypovascular based on blood supply for subgroup analysis. Noise equivalent dose (NED) and image quality index (IQF) were calculated considering image noise and radiation dose.
Results or Findings: The smallest SDs of liver was observed in the DLIR-H group, there was no significant difference between ASIR-V 60% and DLIR-M, though both were lower than FBP. For liver lesion CNR, DLIR-H significantly outperformed ASIR-V 60% and FBP, while no significant difference was found between DLIR-M and ASIR-V 60%. In lesion conspicuity and diagnostic confidence assessments—for both hypovascular and hypervascular tumors—DLIR-H yielded superior scores compared to ASIR-V 60%. The NED was lowest in the DLIR-H group, comparable between ASIR-V 60% and DLIR-M, both lower than FBP; conversely, the IQF showed an opposite trend.
Conclusion: 40 keV VMIs with DLIR-H markedly enhances the visualization and diagnostic confidence of liver tumors, demonstrating the highest dose-to-image quality efficiency.
Limitations: First, single-center study, the distribution of lesion types is uneven, and it is difficult to avoid bias. Second, the number of cases is small, and diagnostic control studies cannot be conducted. Third, no images of other energies are explored.
Funding for this study: No funding was received for this study.

CT-based Radiomics in Colorectal Liver Metastases: Redefining Pre-operative Survival Prediction (6 min)

Angela Ammirabile; Milan / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: A. Ammirabile[1], G. Matteucci[1], F. Fiz[2], E. Lanza[1], L. Cavinato[1], A. Laghi[1], G. Torzilli[1], F. Ieva[1], L. Viganò[1]; [1]Milan/IT, [2]Genoa/IT
Purpose: Surgery with perioperative chemotherapy is potentially curative for colorectal liver metastases (CRLM). Selection of candidates should rely on survival prediction; however, available prognostic factors have limited reliability, and most biomarkers are assessed on surgical specimens. This study evaluated preoperative CT-based radiomics for overall survival (OS) prediction, focusing on the impact of CT–surgery interval and peritumoral tissue analysis and comparison with clinical scores.
Methods or Background: All consecutive patients undergoing CRLM resection (2010-2020) with contrast-enhanced CT performed ≤60 days before surgery and at least one CRLM ≥10 mm were considered. Manual tumor segmentation (Tumor-VOI) and automatic 5-mm peritumoral expansion (Margin-VOI) were performed on portal phase images. From each VOI, 110 IBSI-compliant radiomic features were extracted. Three prediction models were developed: Clinical, Clinical+Tumor-radiomics, Clinical+Tumor/Margin-radiomics. Features selection used Boruta algorithm, followed by Random Forest classification with 10-fold cross-validation. Models were evaluated in the whole cohort and in patients with CT-surgery interval ≤30 days. Inter-tumour heterogeneity was assessed with Tree-Edit Distance and Hierarchical Clustering to stratify patients, and resulting clusters were integrated into survival models.
Results or Findings: 306 patients were included (mean age 63 years; 187 men). Five-year survival was 40.9% (mean follow-up 34 months). At validation, the clinical model achieved C-index=0.629. Radiomics provided modest improvement in the entire cohort, with greater impact in the 212 patients with a CT-surgery interval ≤30 days: the Clinical+Tumor-radiomics model reached C-index=0.691, increasing to 0.717 with Margin-VOI features. Clinical–radiomic models outperformed established scores (Fong, GAME, m-CS; C-indices=0.553–0.613). Inter-tumor heterogeneity did not improve prediction.
Conclusion: Radiomic features of CRLM and peritumoral tissue improve preoperative survival prediction beyond clinical scores, with better performance at shorter CT-surgery intervals. Combined models may refine CRLM treatment strategies, acting as a preoperative filter.
Limitations: Retrospective single-center design; Manual segmentation; OS-only analysis.

Multiple Instance Learning with Radiomics Features Enables Peritoneal Carcinomatosis Detection from CT Images: preliminary results (6 min)

Konstantinos Vrettos; Heraklion / Greece

Author Block: K. Vrettos[1], B. Huang[2], I. Moberg[2], I. Rouvelas[2], M. Klontzas[1], A. Tzortzakakis[2]; [1]Heraklion/GR, [2]Stockholm/SE
Purpose: Peritoneal carcinomatosis (PC) correlates with advanced cancer and its identification can significantly impact treatment planning and patient outcomes. Current detection methods such as CT and circulating protein biomarkers have limitations in terms of accuracy and efficiency. Radiomics, an AI-driven approach that extracts quantitative features from medical images, holds promise for improving PC detection. The aim of this work is to develop an open-access radiomics model that assists radiologists in identifying PC from CT scans, while maintaining human accountability and ethical oversight, through a human-in-the-loop approach.
Methods or Background: The model architecture is an attention-based Multiple Instance Learning(MIL) network, which utilizes an instance feature extractor, an attention mechanism and a final classifier operating on aggregated features. The dataset consists of 141 patients with gastric tumors who underwent laparoscopy and biopsy to detect PC. Radiomics features were extracted from CT images for 12 biopsy spots(the tumor was not included) corresponding to the conventional laparoscopic based Peritoneal Cancer index score . Boruta feature selection and interpretability analysis were performed . The model's performance was evaluated using AUC,Accuracy,F1-score,Sensitivity and Specificity on a held-out test set. CLAIM guidelines were followed.
Results or Findings: The radiomics model achieves an AUC of 0.7,Accuracy of 0.81 and Specificity of 0.94. The model's performance was non-inferior to expert radiologists' predictions of PC from CT scans. The human-in-the-loop approach yielded comparable results with an increased sensitivity of 0.8, when radiologist performance was combined with model performance. Analysis of existing literature, revealed that the proposed model outperforms current PC detection approaches, including CA125 blood test.
Conclusion: This study highlights the potential of radiomics-based models to assist radiologists in detecting PC on CT scans. It further shows that radiologist-AI collaboration can improve detection performance while ensuring transparency.
Limitations: Dataset size

Dual-energy CT Radiomics combined with Body Composition to Predict Urate Crystals in Gouty Arthritis (6 min)

Baoyue Zhang; Kunming□Yunnan / China

Author Block: B. Zhang; Kunming□Yunnan/CN
Purpose: To develop and validate a prediction model based on Dual-energy CT radiomics combined with body compositions and clinical factors for predicting monosodium urate□MSU□crystal deposition in gouty arthritis.
Methods or Background: A retrospective analysis was conducted on the clinical data of 185 patients with MSU crystal deposition confirmed by dual-energy CT and 108 patients with non-MSU crystal deposition.The dataset was randomly divided into a training set □n=205□and a validation set□n=88□at a ratio of 7:3 to construct predictive models.The LIFEx software was used to extract the radiomic features of subcutaneous adipose tissue,skeletal muscle,visceral adipose tissue,and vertebral bodyarea of each patient based on the L3 vertebral level in abdominal CT scan.10 machine models were used to build radiomics model based on the selected features.The diagnostic performance of the models was evaluated in terms of receiver operating characteristics area under the curve □AUC□in the validation set,and we constructed a radiomics score.Univariable and Multivariate logistic regression analysis was used to screen for independent risk factors associated with MSU crystal deposition.A nomogram model was then constructed by integrating radiomic rescore and risk factors.
Results or Findings: The AUC of the subcutaneous adipose tissue,skeletal muscle,visceral adipose tissue,and vertebral body in the validation set is 0.751,0.646,0.765 and 0.663 respectively.Therefore,VAT demonstrated high diagnostic performance.Multivariate logistic regression analysis showed that gender,fatty liver,diabetes mellitus,hyper uric acid were independent risk factors for MSU crystal deposition.The AUCs of the nomogram model to predict MSU crystal deposition in the training and validation sets were 0.946 and 0.960,respectively.
Conclusion: The nomogram model was constructed based on radiomics score and risk factors had a good predictive performance for MSU crystal deposition.
Limitations: This was a retrospective study conducted in a single institution with insufficient samples.

Effectiveness of Deep-Learning Based Denoising on the Image Quality and Diagnostic Performance of Low-Dose Abdominal CT for Acute Appendicitis (6 min)

CHUNGHWAN SHIN; Iksan / Korea, Republic of

Author Block: C. SHIN, Y. H. Lee; Iksan/KR
Purpose: The aim of this study is to evaluate the effectiveness of deep-learning based denoising images using low-dose abdominal CT in terms of image quality and diagnostic performance for evaluating acute appendicitis.
Methods or Background: We retrospectively analysed 53 patients underwent low-dose abdominal CT for suspected acute appendicitis. Images were reconstructed using filtered-back-projection (FBP) and iterative reconstruction (IR), then processed using deep-learning-based denoising software (ClariCT.AI, Claripi), resulting in four image sets per patient. For quantitative analysis, image noise and signal-to-noise ratio were measured. Two radiologists independently scored for qualitative analysis (noise, sharpness, artifacts, overall) on a 4-point Likert scale and assessed the presence of acute appendicitis. Statistical analyses included repeated measures ANOVA, Friedman test, Wilcoxon signed-rank test, and McNemar's test.
Results or Findings: Four image sets demonstrated significant differences in both noise and SNR ($p<0.001$). The noise progressively decreased in the order of FBP(25.53±1.98), IR(17.07±1.27), denoised FBP(11.45±0.86), and denoised IR(8.36±0.63). SNR was highest in denoised IR (23.11±2.84), followed by denoised FBP(16.92±2.04), IR(11.37±1.36), and FBP(7.65±0.93). Denoised FBP achieved higher overall quality than FBP, IR, and denoised IR in both readers ($p<0.01$), providing superior sharpness and fewer artifacts, while denoised IR images achieved lower image noise. All image sets showed 100% sensitivity for acute appendicitis. In reader 1, denoised images showed higher specificity (95.35% each) than undenoised FBP and IR(90.70% each). In reader 2, FBP showed lower specificity (88.38%) than other image sets (95.35% each). No statistically significant difference was observed for specificity in either readers.
Conclusion: Deep-learning-based denoising markedly improves noise reduction in low-dose abdominal CT. Reconstructed images with denoising provided superior image quality and higher diagnostic accuracy than undenoised FBP or IR images for evaluating acute appendicitis.
Limitations: Quantitative assessment was performed in regions unrelated to the appendix.
Funding for this study: This study received no specific funding.

Deep-learning-based liver age estimation predicts major health outcomes (6 min)

Robin Tibor Schirrmeister; Freiburg Im Breisgau / Germany

Author Block: R. T. Schirrmeister, M. Jung, M. Reisert, F. Bamberg, J. Weiß; Freiburg Im Breisgau/DE
Purpose: Various studies have shown that AI can estimate biological age from medical imaging and predict outcomes beyond traditional risk factors. In this study we developed a deep learning model (MR-LiverAge) that estimates liver age from MR imaging and investigated its association with different health outcomes.
Methods or Background: MR-LiverAge was developed in a two-step approach using 30025 subjects from the German National Cohort (NAKO): Model 1) segmentation of the liver from T1-weighted abdominal MRI; Model 2) takes the segmented pancreas mask of Model 1 as the only input and outputs a liver age estimate in years.Independent validation was performed in 40151 subjects of the UK Biobank (UKB). To account for potential confounders such as BMI, sex or liver fat, generalized additive models were fitted to predict the AI-estimated MR-LiverAge from those confounders. The remaining difference between MR-LiverAge and confounder-estimated age was used to group individuals into decelerated, normal and accelerated aging groups. Cox proportional hazards regression assessed the association between age groups and incident diabetes, liver disease, cardiovascular events and mortality.
Results or Findings: MR-LiverAge had a Pearson-R correlation of 80.4% in the NAKO and 50.9% in the UKB with chronological age. Individuals with accelerated MR-LiverAge in the UKB had a higher risk of incident diabetes (HR=1.66, 95% CI=1.37–2.01, $p < 0.001$), liver disease (HR=1.52, 95% CI=1.19–1.96, p=0.001), cardiovascular events (HR=1.38, 95% CI=1.1–1.73, p=0.005) and mortality risk (HR=1.45, 95% CI=1.16–1.81, p=0001) independent of traditional risk factors.
Conclusion: MR-LiverAge has potential as a novel opportunistic imaging biomarker to estimate risk of major health outcomes.
Limitations: Results have only been obtained from MRI on the UKB dataset and would need to be further validated on other datasets and other modalities.
Funding for this study: We acknowledge support by the Deutsche Forschungsgemeinschaft (DFG, German Research Foundation), grant number 525002713.

Transdiagnostic compression of connectome gradient in major depression, bipolar disorder, and schizophrenia: A large-scale multicenter resting-state fMRI study (6 min)
Qinger Guo; Hangzhou / China

Author Block: Q. Guo, H. Yang; Hangzhou/CN
Purpose: To examine connectome gradient dysfunction associated with major depressive disorder (MDD), bipolar disorder (BD), and schizophrenia (SCZ), and to identify transdiagnostic variation patterns.
Methods or Background: Using a large cohort of resting-state fMRI data from 3266 participants recruited at 23 sites, including 1275 healthy controls (HC), 1531 MDD, 187 BD and 273 SCZ patients, we applied diffusion map embedding to estimate connectome gradient. Statistical analyses were conducted on range, variance, and gradient values of principal gradient, and correlations were examined with clinical scales.
Results or Findings: The principal gradient extends from primary visual (VIS) and somatosensory/motor networks (SMN) to default mode network (DMN). MDD showed less variance than HC. BD and SCZ exhibited narrower range and less variance than HC and MDD. Regionally, gradient values in DMN regions exhibited a pattern of SCZ < BD < MDD < HC. MDD, BD, and SCZ groups had lower gradient scores in VIS regions and higher in SMN compared to HC, indicating opposite changes within primary systems. The mean gradient value in SMN regions of MDD showed significant positive correlations with anxious mood and tension scores (FDR-corrected). MDD and SCZ in VIS exhibited positive correlation trends with scores on several items of their respective scales ($p < 0.05$ before FDR correction).
Conclusion: This study demonstrated that principal gradient compression was both shared and spectrally distributed across MDD, BD, and SCZ. The non-uniform compression was characterized by heterogeneous alterations within primary systems. These findings not only provide a unified neurobiological account for sensory-cognitive integration deficits in these disorders but also propose a new perspective: mental disorder patients may maintain a relatively stable baseline of sensory reality through VIS's protective compensation.
Limitations: The sample sizes for BD and SCZ groups are relatively small.
Funding for this study: No funding was received for this study.

Brain connectivity during listening to different styles of classical music: a prospective fMRI study (6 min)
Clément Dalmasso; Tours / France

Author Block: C. Dalmasso, F. Andersson, I. Maldonado, M. A. Siragusa, V. Lefevre, C. Destrieux, W. El-Hage, T. Desmidt, J-P. Cottier; Tours/FR
Purpose: While numerous studies have examined the effects of musical styles on pleasure and fear, few have investigated the overall brain activity underlying these emotional responses, particularly across different styles and periods of classical music.
The present study aimed to use fMRI to explore functional connectivity during listening to four excerpts from different periods of Classical music, and to identify musical parameters associated with the engagement of clinically relevant networks.
Methods or Background: This prospective, single-centre study included 25 healthy subjects with musician status and psychometric assessment using validated scales. A 3T MRI scanner acquired BOLD fMRI data during a task involving watching emotionally neutral images and listening to four 1-minute excerpts presented in random order (Rossini Guillaume Tell, Minkus La Bayadère, Satie Gymnopédie No. 1, Stravinsky The Rite of Spring). Data were processed using the Conn Toolbox and MatLab®, highlighting significant co-activations for each stimulus (atlas MNI AAL3).
Results or Findings: Each contrast (opposing stimuli) revealed significant co-activations (t-tests, $p < 0.05$) between distinct brain areas, recruiting different network profiles: audio–visuo–fronto-linguistic coupling with orbitofrontal involvement (valence/reward) for Rossini; limbic–cerebellar and occipital circuits (contextual encoding, motor imagery) for Minkus; salience/interoception pole (insula) and thalamic-striatal-cerebellar loops compatible with calm attentional state for Satie; orbitofrontal axis–temporal poles (structural complexity, semantic combinatorics, emotional coloring) for Stravinsky. Slow tempi and regular meters favored insula–thalamus/limbic and cerebellar networks, whereas fast tempi and/or irregular meters engaged orbitofrontal and temporal poles.
Conclusion: Our results highlight a diversity of cerebral co-activation during listening to different classical styles. Tempo and metrical regularity appeared as modulators of network architecture. This network-centered mapping may pave the way for personalized "musical prescriptions" in music therapy (interoceptive calming, language/rhythm training, cognitive flexibility...).
Limitations: Not applicable

Hypoxic–Ischaemic Brain Alterations and Their Association with Neurodevelopmental Disorders: Focus on Autism Spectrum Disorder and Speech Delay (6 min)

Nataly Dichko; Kyiv / Ukraine

Author Block: N. Dichko; Kyiv/UA
Purpose: Hypoxic–ischaemic (HI) events during early brain development can lead to structural and functional alterations that may predispose children to neurodevelopmental disorders (NDDs).
Methods or Background: Perinatal and early childhood HI events can disrupt the maturation of neural networks. Increasing evidence suggests that such early-life brain insults may contribute to the development of neurodevelopmental disorders (NDDs). Despite emerging interest in the link between HI injury and NDDs, there is still limited large-scale clinical research exploring this association across diverse pediatric age groups.
This study aims to fill this gap by evaluating structural brain alterations following HI injury and examining their potential association with subsequent diagnoses of ASD and/or speech delay in a well-characterized pediatric cohort.

This retrospective observational study included 331 pediatric patients, inclusion criteria required evidence of hypoxic–ischaemic brain injury confirmed through neuroimaging (MRI) and availability of clinical neurodevelopmental assessments.
Patients with genetic syndromes or major congenital brain malformations unrelated to HI injury were excluded.
Results or Findings: Hypoxic–ischaemic brain alterations were predominantly observed in the periventricular white matter (63%), basal ganglia and thalami (41%), temporal lobes (38%), and frontal lobes (26%). Diffuse white matter abnormalities and cortical atrophy were more common in patients diagnosed with ASD or combined ASD and speech delay.
• Periventricular leukomalacia (PVL), basal ganglia and thalamic involvement, temporal lobe abnormalities and diffuse cortical atrophy showed a strong correlation of combined ASD and speech delay.
Conclusion: Our findings support the growing evidence that early-life HI injury disrupts critical neural pathways involved in language acquisition, social communication, and cognitive functioning. Early neuroimaging, particularly MRI, plays a vital role in identifying at-risk children and may provide predictive value for long-term neurodevelopmental outcomes.
Limitations: Retrospective design, heterogeneity of age and timing of injury, imaging modalities and quality.
Funding for this study: This study did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.Future research expansion and longitudinal follow-up will require external funding support.

Assessing Glymphatic System Alterations in Autism Spectrum Disorder using DTI-ALPS index (6 min)

Shravan Reddy Kankara; Bengaluru / India

Author Block: S. Reddy Kankara, D. Jayanna, S. R. Kankara, U. Nayak, A. Josephine, V. M. Tellis; Bangalore/IN
Purpose: To assess glymphatic system alterations in children with autism spectrum disorder (ASD) using diffusion tensor imaging along the perivascular space (DTI-ALPS) and to compare findings with age- and sex-matched healthy controls.
Methods or Background: The glymphatic system facilitates metabolic waste clearance via perivascular pathways, and dysfunction may contribute to neurodevelopmental disorders. In this retrospective case–control study, 30 children with DSM-5–confirmed ASD (mean age 7.4 ± 2.0 years; 22 males) and 30 matched controls (7.1 ± 2.3 years; 21 males) were included. Eligibility required age 3–12 years and diagnostic-quality 3T MRI with DTI; exclusions were prior CNS infection/trauma, structural brain abnormalities, or motion-degraded scans. ALPS indices were derived at the lateral ventricular body using standardized ROIs in projection and association fibers, placed independently by two blinded raters. Group comparisons were performed with independent-samples t-tests, and age–ALPS relationships were assessed with Pearson correlation.
Results or Findings: Children with ASD showed significantly lower ALPS indices than controls (Left: 1.10 ± 0.13 vs 1.32 ± 0.16, $p < 0.001$; Right: 1.12 ± 0.14 vs 1.30 ± 0.15, $p = 0.002$), remaining significant after bilateral correction. Age correlated positively with ALPS in both ASD ($r = 0.38$, $p = 0.04$) and controls ($r = 0.31$, $p = 0.04$), indicating maturational improvement; however, values in ASD remained consistently lower across the age spectrum.
Conclusion: Pediatric ASD is associated with reduced DTI-ALPS indices, consistent with impaired glymphatic function. Despite age-related gains, glymphatic activity remains attenuated in ASD. DTI-ALPS provides a feasible, non-contrast imaging biomarker of neurofluid dynamics, with potential relevance for studying neurodevelopmental disorders.
Limitations: The study is limited by its retrospective, single-center nature, small cohort, and reliance on manual ROI selection. Future work could include longitudinal evaluations and explore associations with clinical severity.
Funding for this study: Not applicable

Cortical Excitability and Molecular Profiling Reveal Distinct Neurobiological Subtypes of Schizophrenia (6 min)

Sixuan Guo; Chengdu / China

Author Block: S. Guo, Q. Gong, Y. Zhao, S. Lui, L. Li, R. Xie, X. Zhang; Chengdu/CN
Purpose: Dysregulation of excitation–inhibition balance in specific neural circuits is believed to underlie the diverse positive and negative symptoms of schizophrenia (SCZ). This study aimed to identify neurobiological subtypes of drug-naïve first-episode SCZ (FES) using cortical excitability (CE) mapping to advance precision-medicine approaches for SCZ.
Methods or Background: Resting-state fMRI data from 77 drug-naïve FES patients and 76 matched healthy controls were analyzed using a novel CE-mapping approach. After deriving individual CE profiles, support vector machines (SVM) assessed diagnostic accuracy, and hierarchical clustering delineated neurobiological subtypes. Twelve-month follow-up data evaluated treatment-related changes. Molecular analyses integrated transcriptomic data via partial least squares regression with functional enrichment and JuSpace-based neuroreceptor mapping to identify subtype-specific molecular correlates.
Results or Findings: FES patients exhibited significantly reduced CE compared with controls, predominantly in the bilateral frontal lobes, sensorimotor cortex, and right cuneus. SVM achieved 86.7% diagnostic accuracy. Hierarchical clustering identified two subtypes: FES1, showing widespread CE reductions with more severe depressive, negative, and cognitive symptoms; and FES2, showing milder alterations. Longitudinal analysis revealed partial CE recovery in FES1 but persistent reductions in FES2. Molecular profiling suggested that FES1 was characterized by synaptic dysfunction and neurodevelopmental disruption, whereas FES2 reflected multisystem impairments accompanied by compensatory processes.
Conclusion: This study delineates two neurobiological subtypes of FES with distinct CE profiles and molecular underpinnings. CE-based subtyping offers a promising framework for linking clinical heterogeneity with underlying neurobiology and may inform precision treatment strategies in SCZ.
Limitations: The modest sample size and one-year follow-up may limit generalizability, and clinical assessments were restricted, constraining exploration of CE–FES heterogeneity. Transcriptomic analyses were confined to the left hemisphere, precluding bilateral evaluation of gene–CE associations.
Funding for this study: This study was supported by grants from the National Key R&D Program of China (2022YFC2009900), National Natural Science Foundation of China (82027808), and National Natural Science Foundation of China (82302167).

Functional MRI evidence of altered emotional attention network in adolescents with bipolar disorder (6 min)

Xiaoping Yi; Chongqing / China

Author Block: X. Yi[1], B. T. Chen[2]; [1]Chongqing/CN, [2]Duarte, CA/US
Purpose: Adolescents with bipolar disorder (BD) exhibit heightened emotional reactivity and deficits in cognitive control, yet the neural mechanism underlying attentional control under emotional interference remains poorly understood.
Methods or Background: Using brain functional magnetic resonance imaging (fMRI), we examined brain activation during an emotional Go/No-Go task in 43 adolescents with BD and 18 age- and gender-matched healthy control (HC) participants. Emotional (happy/sad) versus neutral facial expressions were contrasted to isolate emotion-specific neural responses. Behavioral performance data, clinical symptoms, and cognitive functions were also assessed.
Results or Findings: Compared to the HC participants, the adolescents with BD exhibited significantly increased activation in the cognitive control network, particularly in the inferior frontal gyrus, caudate nucleus and cingulate cortex, during emotional versus neutral conditions. Aberrant activation in the right inferior frontal gyrus was significantly correlated with response inhibition errors, executive function scores on the Stroop Color and Word Test, and depressive symptom severity.
Conclusion: The adolescents with BD showed increased activation in the brain regions for attentional and inhibitory control, which may reflect compensatory mechanism to allocate more resource to maintain cognitive control when processing emotional stimuli. These findings implicated dysfunctional emotion-attention interactions in adolescents with BD and suggested potential neural targets for early intervention.
Limitations: The sample size was relatively small, and this was a cross-sectional study.

Connectivity Patterns across Bipolar Disorder Stages: a Tractography-based Graph Analysis (6 min)

Simonetta Gerevini; Cremona / Italy

Author Block: S. Capelli[1], A. Arrigoni[1], S. Saluzzi[2], P. Patani[2], S. Martinelli[2], A. Caroli[1], A. Di Giorgio[2], S. Gerevini[2]; [1]Ranica/IT, [2]Bergamo/IT
Purpose: Diffusion-weighted MRI (DW-MRI) tractography enables non-invasive mapping of brain connectivity and may reveal biomarkers of structural network alterations in psychiatric disorders. This study investigated connectome changes across clinical stages of Bipolar Disorder (BD), including individuals at familial risk, using advanced DW-MRI processing and graph analysis.
Methods or Background: Forty-five participants were recruited from two Italian centers and classified according to the Kupka–Hillegers staging model: Stage 0–1 (n = 13, familial risk and subthreshold symptoms), Stage 2 (n = 8, first hypo/manic episode), Stage 3 (n = 13, recurrent episodes), and Stage 4 (n = 11, chronic non-remissive course). DW-MRI data were acquired using a 3T scanner and processed with a custom pipeline integrating single-shell 3-tissue constrained spherical deconvolution (SS3T-CSD), anatomically constrained probabilistic tractography (iFOD2-ACT), and graph-based connectome analysis. Tractograms were optimized with the COMMIT2 method, and connectivity metrics were derived using Python's bctpy package. T1-weighted imaging was coregistered to the DW-MRI scan using ANT and parcellated with FreeSurfer. Group differences were assessed with Kruskal-Wallis tests and Wilcoxon pairwise comparisons ($p < 0.05$), with Bonferroni correction applied.
Results or Findings: Mean nodal strength showed a significant group effect ($p = 0.024$), with post hoc analysis indicating reduced strength in Stage 4 compared to Stage 2 ($p = 0.002$) and a trend compared to Stage 3 ($p = 0.072$). Among node-wise metrics, the betweenness of the left posterior cingulate cortex (PCC) had the most significant effect ($p < 0.001$), which remained significant after Bonferroni correction.
Conclusion: Findings indicate progressive disruption of structural connectivity with advancing BD stage, particularly affecting PCC centrality. DW-MRI tractography and connectome metrics hold promise as biomarkers for disease progression and stratification in BD.
Limitations: Single-center image acquisition, modest sample size, and lack of external validation.

Integrative brain neural activity and molecular analyses of interaction between chronic nicotine addiction and alcohol dependence (6 min)

Bohui Mei; Zhengzhou / China

Author Block: L. Ma, M. Zhang, B. Mei, Y. Wei, S. Han, Y. Zhang; Zhengzhou/CN
Purpose: Previous studies have demonstrated that nicotine addiction and alcohol dependence are frequently comorbid. However, the underlying neurobiological mechanisms remain unclear. Therefore, we will investigate the impacts of two factors on spontaneous neural activity and specific neurotransmitter system.
Methods or Background: This study used a two-way factorial design, including the following four groups: 1) Alcohol dependence smokers (n = 32); 2) Non-alcohol dependence smokers (n = 30); 3) Alcohol dependence non-smokers (n = 21); 4) Healthy control (n = 27). Functional magnetic resonance imaging (fMRI) was used to compare the differences in fractional amplitude of low-frequency fluctuation (fALFF) among the four groups to detect the interaction effect of nicotine addiction and alcohol dependence on spontaneous neural activity. Furthermore, correlations between fALFF values and PET- and SPECT-driven maps to examine specific neurotransmitter system alternations underlying two factors.
Results or Findings: Our study revealed a significant antagonistic interaction between two factors in the right cerebellum. The main effect of nicotine addiction is in the bilateral occipital lobes. The main effects of alcohol dependence are in the bilateral precentral gyrus. Cross-modal correlations revealed alternations in spontaneous neural activity in interactive brain regions associated with the serotonin system (5-HT1b).
Conclusion: This study identified an antagonistic interaction of the cerebellum between nicotine addiction and alcohol dependence. Besides, our study further correlates the serotonin system with the intrinsic neural activity associated with this comorbidity. This may be a potential neurobiological mechanism of smoking and alcohol, offering new directions for the treatment of this comorbidity.
Limitations: The Juspace toolbox achieves indirect coupling of functional imaging with neurotransmitter systems. However, these neurotransmitters are limited in types and information. Future studies should use PET and MRI to provide more direct evidence.

Artificial intelligence–assisted voxel-based morphometry for imaging biomarkers of alcohol-related brain atrophy (6 min)

Shreyash Subhash Bhoyar; Pune / India

Author Block: S. S. Bhoyar, P. Shah, P. NAIK, A. G. Sasane; Pune/IN
Purpose: Alcohol dependence is associated with selective brain atrophy, yet conventional magnetic resonance imaging remains largely qualitative and observer-dependent. Artificial intelligence–assisted voxel-based morphometry enables automated, reproducible volumetric quantification. This study evaluated its ability to objectively identify region-specific atrophy in alcohol dependence and explored its potential role as a clinically translatable imaging biomarker.
Methods or Background: Sixty consecutive adult patients diagnosed with alcohol dependence syndrome (ICD-10 criteria) were prospectively enrolled over 18 months. Magnetic resonance imaging was performed on a 1.5T system using a three-dimensional T1-weighted spoiled gradient recalled acquisition sequence. Automated segmentation and volumetric analysis were conducted using a validated artificial intelligence–based morphometry pipeline, normalised to intracranial volume. Quantitative volumes of cortical and subcortical regions were compared with established normative references.
Results or Findings: Frontal lobe atrophy was universal (100 per cent), with high prevalence also observed in the temporal lobes (93 per cent), cerebellum (90 per cent), basal ganglia (putamen 90 per cent, caudate 88 per cent), and hippocampus (81.7 per cent). The amygdala (68 per cent) and thalamus (65 per cent) were variably affected, while the occipital lobes (40 per cent) and brainstem (23 per cent) were relatively preserved. This pattern highlights selective vulnerability of fronto-limbic and cerebellar circuits, correlating with executive dysfunction, impaired memory, and motor incoordination. The artificial intelligence–assisted pipeline consistently generated robust, reproducible volumetric outputs with reduced observer bias and faster processing compared with conventional approaches.
Conclusion: Artificial intelligence–assisted voxel-based morphometry provides objective, reproducible imaging biomarkers of alcohol-related brain atrophy. It paves the way for early diagnosis, personalised risk stratification, and treatment monitoring, positioning artificial intelligence as a transformative tool in neuropsychiatric care.
Limitations: Absence of a matched control group and lack of direct neuropsychological correlation.

How sleep disorder affect glymphatic circulation and network efficiency in internet gaming disorder: Insights from a DTI-ALPS (6 min)

Bohui Mei; Zhengzhou / China

Author Block: L. Ma, M. Zhang, B. Mei, Y. Wei, S. Han, Y. Zhang; Zhengzhou/CN
Purpose: Sleep disorders can impair the glymphatic system and may exacerbate cognitive deficits in internet gaming disorder (IGD). Therefore, this study aimed to investigate whether the glymphatic system and the human brain network are impaired in IGD patients with sleep disorder (IGDSD) compared to IGD patients without sleep disorders (IGDNSD), which is crucial for elucidating the neuropathological mechanisms of IGD.
Methods or Background: This study recruited 36 IGDSD, 30 IGDNSD, and 30 healthy controls, who performed magnetic resonance imaging (MRI) scanning and clinical symptom assessment. The glymphatic function and network efficiency were calculated based on diffusion images along the perivascular space (DTI-ALPS) index and resting-state functional MRI, respectively. Differences between groups, neural/clinical correlations, mediation analyses, and diagnostic performance were further explored.
Results or Findings: Compared to IGDNSD, IGDSD had a significantly lower ALPS index. The correlation analysis showed that the ALPS index in IGDSD was significantly correlated with the local brain efficiency and the sleep quality. The mediation analysis showed that sleep quality partially mediated the effect of local brain efficiency on glymphatic system function. In addition, the area under the ROC curve of ALPS in distinguishing IGDSD from IGDNSD was 0.93, with a cut-off value of 1.32.
Conclusion: These results indicated the severely impaired glymphatic function and network efficiency in IGDSD. And this study also adds important evidence that the brain network efficiency disrupts the glymphatic system function by affecting sleep quality, which may reveal the neuropathological mechanisms of IGDSD.
Limitations: The DTI-ALPS method is a deductive measure of glymphatic system function. The ALPS index does not comprehensively reflect the clearance function of the glymphatic system.
Funding for this study: This study was supported by the Natural Science Foundation of China [grant numbers 81601467, 81871327, and 62106229] and the Funding for Scientific Research and Innovation Team of The First Affiliated Hospital of Zhengzhou University [grant numbers QNCXTD2023007].

Functional Gradient Alteration and Structural Remodeling in the Postpartum Women (6 min)

Bochao Cheng; Chengdu / China

Author Block: B. Cheng; Chengdu/CN
Purpose: Postpartum women (PW) undergo profound brain functional and structural reorganization to support maternal adaptation. However, the specific neural adaptation mechanisms keep unclear. This study used multimodal MRI and clinical assessments to investigate brain changes in PW. We analyzed functional gradients, network topology, and brain volumes using advanced computational tools. The study aimed to: identify postpartum-specific brain changes; test if GMV mediates functional gradient shifts via network integration/segregation; link neural measures to clinical symptoms; and track longitudinal recovery of brain, hormonal, and clinical changes.
Methods or Background: The current study employed a multimodal MRI approach integrating functional gradient analysis, graph-theoretical network metrics, and morphometry to explore the brain connectome reorganization across the postpartum period and its clinical correlates in 206 participants (134 PW and 72 healthy nulliparous women (HNW)).
Results or Findings: Compared to HNW, PW exhibited a significant contraction of the first two principal functional gradients, reduced network modularity and local efficiency, and widespread gray matter volume (GMV) reductions. Mediation analysis revealed that GMV alterations modulate functional gradient reorganization by influencing network integration and segregation. These neural changes were closely linked to clinical symptoms including sleep disturbance, stress, and grit. Longitudinal modeling captured dynamic trajectories of brain plasticity, prolactin levels, and clinical symptom recovery.
Conclusion: Our findings unveil a transient, disorder-like network reconfiguration supporting maternal behavior, simultaneously elucidating neurobiological mechanisms of adaptive plasticity and vulnerability to postpartum mood disorders.
Limitations: First, while our study examined neuroplastic changes in PW, it did not address the distinct neural signatures associated with postpartum depression or anxiety. Future research should investigate disorder-specific neuropathological profiles to better understand their underlying mechanisms. Second, while we demonstrate macroscale hierarchical network alterations, their underlying biological mechanisms require further validation.

EFRS 13 - Advance Practice in Nuclear Medicine – what do these roles look like and why are they important?

Categories: Radiographers, Professional Issues, Molecular Imaging, Nuclear Medicine, Cardiac

Date: March 6, 2026 | 10:00 - 11:00 CET

CME Credits: 1

This session will provide attendees with an opportunity to learn more about advance practice in Nuclear Medicine. There will be three short presentations, focusing on advance practice in cardiac stress testing for myocardial perfusion scintigraphy, DEXA reporting and molecular therapy /theranostics delivery. This session will also aim to explore the academic, professional and legislative requirements for establishing advance practice roles.

Moderators:

Ana Geão; Montijo / Portugal

Angelo Rafael Felgosa Cardoso; Münchenbuchsee / Switzerland

Chairperson's introduction (5 min)

Ana Geão; Montijo / Portugal

Angelo Rafael Felgosa Cardoso; Münchenbuchsee / Switzerland

Advancing Practice in Cardiac Nuclear Medicine (12 min)

Tristan Barnden; Maidstone / United Kingdom

1. To present advance practice on cardiac stress testing for myocardial perfusion scintigraphy.
2. To explore the academic, professional and legislative requirements.
3. To examine the importance of being an accredited advanced clinical practitioner in nuclear medicine

The Role of Radiographers in DEXA Reporting (12 min)

Marisa da Cruz; London / United Kingdom

1. To present advance practice in DEXA reporting.
2. To explore local departmental pathways for establishing a radiographer DEXA reporting service.
3. To appreciate the impact of radiographers/technologists reporting DEXA scans, on the clinical reporting backlog.

Delivering Molecular Therapies and Theranostics: Professional Roles, Partnerships, and Person-Centred Care (12 min)

Luisa Pereira; Maidstone / United Kingdom

1. To present advance practice in molecular therapy /theranostics delivery.
2. To examine the professional collaborations required within this setting.
3. To understand and appreciate the importance of integrating person-centred care when delivering molecular therapies /theranostics.

Panel discussion (19 min)

OF 13Y - Game on: navigating the EDiR CORE case resolution, win a spot for an EDiR simulation and webinar (part 2)

Categories: Professional Issues, Students, Education
ETC Level: LEVEL II
Date: March 6, 2026 | 10:00 - 10:30 CET
CME Credits: 0.5

Moderators:
Laura Oleaga Zufiria; Barcelona / Spain
Hatice Tuba Sanal; Ankara / Turkey

Chairpersons' introduction (5 min)
Laura Oleaga Zufiria; Barcelona / Spain
Hatice Tuba Sanal; Ankara / Turkey

Let the games begin (20 min)
Hatice Tuba Sanal; Ankara / Turkey

1. To scan and interpret two cases of musculoskeletal radiology and possible outcomes based on the attendees' decisions.
2. To get to know and team up with peers from all over the world to help as many patients as possible.
3. To solve the quiz to win an EDiR Simulation and Webinar. Please note that there can only be one winner per session.

Pooling of conclusions and perceptions (5 min)

ESR Sustainability 13 - Carbon footprint in the hospital lifecycle

Categories: Professional Issues, Management/Leadership, Sustainability, President's Choice

ETC Level: ALL LEVELS

Date: March 6, 2026 | 10:15 - 11:15 CET

CME Credits: 1

In this session, the carbon footprint related to the radiology department will be presented from three different perspectives. An industry representative will outline the areas of concern and action being taken by our industry partners; a radiologist will provide a perspective on measuring and implementing practical actions in day to day practice and a radiology department manager will discuss the actions that can be taken at the management level, including actions to support change, as well as a focus on procurement.

Moderator:

Sarah Lucy Sheard; London / United Kingdom

Chairperson's introduction (5 min)

Sarah Lucy Sheard; London / United Kingdom

Sustainable procurement (10 min)

Hannah Hoehn; Brussels / Belgium

Radiologist's perspective. ESR green imaging department scheme: starting from nothing? (10 min)

Lucien Widmer; Fribourg / Switzerland

Radiology manager's perspective on sustainable transformation (10 min)

Bruno Tonello; London / United Kingdom

Panel discussion: How can we work together to accelerate the carbon footprint of radiology? (25 min)

CUBE 14 - Breast interventions: a case-based walkthrough

Categories: Breast, Interventional Radiology
ETC Level: LEVEL II+III
Date: March 6, 2026 | 10:30 - 11:00 CET
CME Credits: 0.5

Moderator:
Peter Popovic; Ljubljana / Slovenia

Chairperson's introduction (2 min)
Peter Popovic; Ljubljana / Slovenia

Breast interventions: a case-based walkthrough (28 min)
Pascal A.T. Baltzer; Vienna / Austria

1. To learn how to approach and manage common and challenging breast intervention scenarios.
2. To appreciate the spectrum of technique selection, imaging guidance, and complication avoidance in breast procedures.
3. To understand the workflow, decision algorithms, and interdisciplinary considerations that guide successful breast interventions.

MD 13b - Rectal cancer: new developments in organ preservation - updated recommendations for clinical practice and directions for the future

Categories: Oncologic Imaging, GI Tract, Research, Abdominal Viscera, Multidisciplinary
ETC Level: ALL LEVELS
Date: March 6, 2026 | 11:15 - 12:15 CET
CME Credits: 1

Moderator:
Regina G.H. Beets-Tan; Amsterdam / Netherlands

Chairperson's introduction (2 min)
Regina G.H. Beets-Tan; Amsterdam / Netherlands

1. To highlight new developments in the organ-preserving treatment of rectal cancer.
2. To critically review recent evidence in imaging and put this in perspective with the new treatment developments.
3. To provide recommendations for clinical practice and directions for the future.

The radiation oncologist's perspective (8 min)
Vincenzo Valentini; Rome / Italy

The surgeon's perspective (8 min)
Geerard L. Beets; Maastricht / Netherlands

The radiologist's perspective (8 min)
Regina G.H. Beets-Tan; Amsterdam / Netherlands

Expert panel discussion (34 min)

PL 2 - Whole Brain Living: The Anatomy of Choice and the Four Characters That Drive Our Life

Categories: Neuro, President's Choice
Date: March 6, 2026 | 11:15 - 12:00 CET
CME Credits: 0.5

Introduction (2 min)
Minerva Becker; Geneva / Switzerland

Whole Brain Living: The Anatomy of Choice and the Four Characters That Drive Our Life (43 min)
Jill Bolte Taylor; Bloomington, IN / United States

CUBE 15 - Percutaneous cryoablation: advances in renal tumour therapy

Categories: Interventional Radiology, Genitourinary
ETC Level: LEVEL II+III
Date: March 6, 2026 | 12:00 - 12:30 CET
CME Credits: 0.5

Moderator:
Pascal A.T. Baltzer; Vienna / Austria

Chairperson's introduction (2 min)
Pascal A.T. Baltzer; Vienna / Austria

Percutaneous cryoablation: advances in renal tumour therapy (28 min)
Peter Popovic; Ljubljana / Slovenia

1. To learn the indications and patient selection criteria for percutaneous cryoablation of renal masses.
2. To appreciate the technical aspects, procedural workflow, and imaging guidance used during renal cryoablation.
3. To understand the clinical outcomes, complication rates, and long-term efficacy compared with alternative treatment options.

EFRS WS 14 - Contemporary approaches to continuing professional development: improving practice through simulation

Categories: Radiographers, Education, Artificial Intelligence
Date: March 6, 2026 | 12:00 - 13:30 CET
CME Credits: 1.5

Moderator:
Chiara Martini; Parma / Italy

How to effectively implement computer simulation (CT) into CPD to benefit patients: presentation, live software demonstration and Q&A (45 min)

How to effectively implement computer simulation (MR) into CPD to benefit patients: presentation, live software demonstration and Q&A (45 min)
Carmen Cionca; Cluj-Napoca / Romania

HW PC 14 - Managing errors: communicating mistakes to colleagues and patients

Categories: Professional Issues, Education, President's Choice
ETC Level: LEVEL II+III
Date: March 6, 2026 | 12:00 - 13:30 CET
CME Credits: 1.5

Moderators:
Caterina Giannitto; Milan / Italy
Elaine C Curtis Meyer; Boston, MA / United States

Introduction and warm-up (15 min)
Caterina Giannitto; Milan / Italy
Elaine C Curtis Meyer; Boston, MA / United States

Brainstorming session (10 min)
Elaine C Curtis Meyer; Boston, MA / United States

Mini lecture (10 min)
Giulia Lamiani; Milan / Italy

1. To learn the difference between adverse events and medical errors.
2. To learn some protocols on how to communicate medical errors to patients and families.
3. To appreciate the role of transparency, respect, accountability and kindness in communicating medical errors.
4. To appreciate the role of self-compassion, repairment and forgiveness in case of medical error.

Simulation and debrief (45 min)
Lisa Vampa; Milan / Italy
Nicolò Turri; Jerago con Orago / Italy
Sebastiano Pindilli; Milan / Italy

Lessons learned (10 min)
Lisa Vampa; Milan / Italy
Elaine C Curtis Meyer; Boston, MA / United States

HW Uh 14 - Head and neck practical ultrasound

Categories: Head and Neck
ETC Level: ALL LEVELS
Date: March 6, 2026 | 12:00 - 13:30 CET
CME Credits: 1.5

Moderators:
Timothy Beale; London / United Kingdom
Simon Morley; London / United Kingdom

Introduction: ultrasound of the neck in 7 sweeps (30 min)
Timothy Beale; London / United Kingdom
Andrew Sinclair McQueen; Newcastle Upon Tyne / United Kingdom

1. To gain a logical and systematic approach to neck ultrasound examination.
2. To understand the relevant anatomy.
3. To learn techniques to better visualise this region and how to avoid the pitfalls.

Hands-on demonstration (60 min)

Demonstrators
Pim De Graaf; Amsterdam / Netherlands
Mariana Horta; Lisbon / Portugal
Marcella Pucci; Geneva / Switzerland
Elene Gotsiridze; Tbilisi / Georgia
Edith Vassallo; Msida / Malta

AI-SC 14 - AI in the context of the European Health Data Space (EHDS)

Categories: Professional Issues, Management/Leadership, Imaging Informatics, Artificial Intelligence

ETC Level: LEVEL II+III

Date: March 6, 2026 | 12:15 - 13:15 CET

CME Credits: 1

SESSION RECOMMENDED BY EIBIR | EUROPEAN INSTITUTE FOR BIOMEDICAL IMAGING RESEARCH

Moderators:

Luis Marti-Bonmati; Valencia / Spain

Adrian Brady; Cork / Ireland

Chairpersons' introduction (2 min)

Luis Marti-Bonmati; Valencia / Spain

Adrian Brady; Cork / Ireland

EHDS basics (12 min)

Carla Meeuwis; Arnhem / Netherlands

1. To learn how the European Health Data Space (EHDS) aims to streamline the use of health data across borders, with a focus on radiological data and imaging technologies.
2. To appreciate the potential of EHDS to enhance clinical decision-making, diagnostic accuracy, and research by facilitating access to standardized and interoperable radiological data.
3. To understand the implications of EHDS for data governance, patient privacy, and the integration of radiology workflows within the broader European healthcare system.

Xt-HER eplained (12 min)

Esther Peelen; The Hague / Netherlands

1. To learn how the Xt-EHR project supports the realisation of the European Health Data Space Regulation. The EHDS envisions to strengthen Europe’s digital future by empowering EU citizens, EHR-systems market and health professionals alike.
2. To appreciate that eHealth experts from all Member States collaborate to develop European harmonised specifications for sharing medical imaging studies and reports across Europe.
3. To understand the contents of the Xt-HER Medical imaging studies and reports: implementation guide on EEHRxF, functional and technical requirements for EHR systems and how this impacts your current way of working.

EU Imaging Report and it's embedding in IHE (12 min)

Marc Kämmerer; Bochum / Germany

1. To learn how medical imaging will be integrated into the EHDS.
2. To appreciate that this integration has only been possible due to the joint effort from all stakeholders resulting in an interoperable solution which has the potential to be used in practice.
3. To understand how the EU Imaging Report can enforce the usage of structured information in medicine and the role STOs like HL7 and IHE will play for achieving this.

Opportunities of EHDS for research (12 min)

Luis Marti-Bonmati; Valencia / Spain

1. To learn how the new EHDS and the secondary use of data help radiologists to perform research.
2. To appreciate the comprehensive contractual and governance structure of data sharing within the EHDS.
3. To understand the role of the European Cancer Imaging initiative (EUCAIM) within the EHDS.

Panel discussion: EHDS: Opportunity or money pit? (10 min)

EFRS 14 - Innovative Pedagogy in Radiography Education

Categories: Radiographers, Professional Issues, Education

Date: March 6, 2026 | 12:15 - 13:15 CET

CME Credits: 1

This session will explore innovative approaches to strengthening radiography education through technology and pedagogy. Presentations will highlight the pedagogical potential of serious games, practical strategies on how to implement artificial intelligence in radiography education, and the benefits of simulation as a tool to enhance learning outcomes. Together, these talks will showcase how educational innovation can equip future radiographers with the skills, confidence, and adaptability required in modern healthcare.

Moderator:

Martijn Kamphuis; Haarlem / Netherlands

Chairperson's introduction (5 min)

Martijn Kamphuis; Haarlem / Netherlands

The Pedagogical Potential of Serious Games for Radiography Education (12 min)

Celine Gaignot; Geneve / Switzerland

1. Explore how serious gaming has been applied in radiography education worldwide and what lessons we can take into our own teaching.
2. Compare different serious gaming approaches and discuss which best support learning outcomes in your context.
3. Explore how serious gaming can be implemented in your curriculum and assessments.

How to implement Artificial Intelligence in Radiography Education (12 min)

Sonyia Lorraine Mcfadden; Belfast / United Kingdom

1. Understand the role of AI in shaping the future of radiographer education and practice
2. Critically examine current gaps and challenges in AI education for radiographers
3. Develop strategies to integrate AI education into radiography curricula and continuing professional development

Improving Radiography Education with Simulation (12 min)

Mona Vestbøstad; Bergen / Norway

1. Explore how simulation has been applied in radiography education worldwide and what lessons we can take into our own teaching.
2. Compare different simulation approaches and discuss which best support learning outcomes in your context.
3. Consider how evidence from simulation research can inform curriculum design, assessment, and strategies for teaching patient safety and collaboration.

Panel Discussion (19 min)

AR 14 - How to improve your emergency neuroradiology reports

Categories: Neuro, Professional Issues
ETC Level: LEVEL I+II
Date: March 6, 2026 | 12:30 - 13:30 CET
CME Credits: 1

Moderator:
Franca Wagner; Aarau / Switzerland

Introduction (10 min)
Franca Wagner; Aarau / Switzerland

Structured reporting in emergency neuroradiology (50 min)
Franca Wagner; Aarau / Switzerland

1. To learn how to craft clear, concise, and structured reports that address key findings in urgent neuroradiological cases.
2. To appreciate how phrasing and clarity in reports influence clinical outcomes and decision-making.
3. To understand essential language strategies that enhance communication and reduce ambiguity in time-critical scenarios.

ESR/UEMS - Harmonia: the power of collaboration

Categories: Professional Issues, Management/Leadership, Education

Putting your interest first: the ESR approach (8 min)
Andrea Grace Rockall; London / United Kingdom

1. To learn about the mission and the vision of the ESR.
2. To understand the structure of the ESR.
3. To understand the importance of political involvement in EU affairs.
4. To understand the importance of advocacy at the EU level.
5. To understand the influence of EU directives on national legislation and daily practice.

Putting your interest first: the UEMS approach (8 min)
Paolo Ricci; Roma / Italy

1. To learn about the mission and the vision of the UEMS.
2. To understand the structure of the UEMS.
3. To understand the importance of political involvement in EU affairs.
4. To understand the importance of advocacy at the EU level.
5. To understand the influence of EU directives on national legislation and daily practice.

The Accreditation Council in Imaging: introduction, provider's and reviewer's perspective (12 min)
Miraude Adriaensen; Heerlen / Netherlands
Anagha P. Parkar; Bergen / Norway
Mitja Rupreht; Maribor / Slovenia

1. To learn about the Accreditation Council in Imaging.
2. To know about the EACCME criteria 3.0.
3. To understand how to gain ECMECs.

The European Diploma in Radiology: introduction, examiner's and Educational Grant Winner 2025's perspective (12 min)
Laura Oleaga Zufiria; Barcelona / Spain
Rosana De Oliveira Pinto Gonçalves Dos Santos; Lisbon / Portugal
Barbora Horehledova; Heerlen / Netherlands

1. To learn about the EDiR.
2. To know about the different types of exam questions.
3. To understand the various ways to prepare yourself for the EDiR.

The European Training Assessment Programme: introduction, assessor's and certified centre's perspective (12 min)
Jeannette Kraft; Leeds / United Kingdom
Colin Stephanie Cantwell; Donnybrook / Ireland
Jens Bremerich; Basel / Switzerland

1. To learn about the ETAP 2.0 programme.
2. To know how to become certified in only six steps.
3. To understand the benefits of being an ETAP-certified centre.

Questions and answers (4 min)

E³ 20D - Open book on pulmonary nodules!

Categories: Chest, President's Choice

ETC Level: LEVEL I+II

Date: March 6, 2026 | 12:30 - 13:30 CET

CME Credits: 1

This case-based session will review the signs that allow nodules to be classified as benign: the presence of fat, criteria for intrapulmonary lymph nodes, and slow doubling time. It will also highlight pitfalls such as pseudotumoural forms of lipid pneumonia. For subsolid nodules, morphological signs suggesting an invasive nature will be presented.

Moderator:

Lena Wucherpfennig; Heidelberg / Germany

Chairperson's introduction (3 min)

Lena Wucherpfennig; Heidelberg / Germany

Malignant lung nodules (24 min)

Anna Kerpel-Fronius; Budapest / Hungary

Benign lung nodules and carcinoid tumours: CT characteristics (24 min)

Guillaume Chassagnon; Paris / France

Panel discussion: What is the optimal approach to lung nodule characterisation? (9 min)

How 14 - How we report diagnostic and follow-up MRI scans in multiple sclerosis (MS)

Categories: Neuro, Multidisciplinary, President's Choice
ETC Level: ALL LEVELS
Date: March 6, 2026 | 12:30 - 13:30 CET
CME Credits: 1

Moderator:
Zsigmond Tamas Kincses; Szeged / Hungary

Chairperson's introduction (5 min)
Zsigmond Tamas Kincses; Szeged / Hungary

Clinical context and diagnostic criteria (15 min)
Tomáš Uher; Prague / Czechia

1. To explain the clinical presentation and differential diagnosis of multiple sclerosis and related disorders.
2. To review the role of paraclinical tools (CSF, visual and somatosensory evoked potentials, etc.) and how they integrate with imaging in the diagnostic workflow.
3. To learn how to apply the 2024 McDonald criteria with special attention to dissemination in space and time, RIS/CIS cases.

MRI in the diagnosis of MS: imaging criteria and diagnostic guidelines (15 min)
Silvia Messina; Oxford / United Kingdom

1. To explain the MRI features characteristic of MS lesions in the brain and spinal cord, including dissemination in space and time.
2. To review international new diagnostic imaging guidelines and their application in clinical practice.
3. To learn how to apply standardised reporting frameworks for MS, including lesion descriptors, anatomical localisation, terminology, and structured report templates.

MRI protocols and advanced imaging: towards quantitative evaluation and follow-up (10 min)
Zsigmond Tamas Kincses; Szeged / Hungary

1. To explain the recommended MRI acquisition protocols for MS diagnosis and follow-up, covering sequence selection, resolution, anatomical coverage, and harmonisation.
2. To review advanced imaging techniques (e.g. volumetry, DTI, MTR, fMRI) and their potential role in monitoring disease progression and treatment response.
3. To learn how to report diagnostic and follow-up MRI scans in MS using consistent language, longitudinal comparisons, and standardised criteria for new/enlarging lesions and atrophy.

Open forum discussion (15 min)

OF 14R - Radiographer person-centred care for special patients

Categories: Paediatric, Radiographers, Professional Issues
Date: March 6, 2026 | 12:30 - 13:30 CET
CME Credits: 1

Moderator:
Mark F. Mcentee; Cork / Ireland

Chairperson's introduction (5 min)
Mark F. Mcentee; Cork / Ireland

Beyond the image: tackling stigma and supporting patients with high BMI (10 min)
Laura Ninić; Ljubljana / Slovenia

1. To recognise and challenge weight-related stigma in radiographic practice.
2. To adapt communication and care approaches to support patients with high BMI.
3. To implement inclusive strategies to improve patient comfort and dignity during imaging.

Working with patients with dementia during medical imaging procedures (10 min)
Elin Kjelle; Borre / Norway

1. To learn how to recognise the challenges that dementia presents during imaging procedures.
2. To use person-centred communication to reduce anxiety and increase cooperation.
3. To adapt imaging environments and workflows to support patients with cognitive impairment.

Radiographers and paediatric patients: managing emotions a providing compassionate care (10 min)
Vladimir Bahun; Doha / Qatar

1. To learn how to manage radiographers' emotions during suspected child abuse procedures.
2. To understand the emotional needs of paediatric patients during imaging procedures.
3. To apply age-appropriate communication to reduce fear and build trust.

Involving caregivers of special patients as co-constructors of special approaches (10 min)
Christina Malamateniou; London / United Kingdom

1. To highlight the value of caregiver insight.
2. To promote collaborative technique development.
3. To encourage a culture of inclusive practice.

Open forum discussion (15 min)

OF 14Y - Career paths in radiology: shaping your future, weighing the options

Categories: Students, Research, Management/Leadership, Education

ETC Level: ALL LEVELS

Date: March 6, 2026 | 12:30 - 13:30 CET

CME Credits: 1

Radiology offers a wealth of career choices - but how do you find your path? This session brings together experienced professionals from across Europe to discuss the wide spectrum of career options: public vs private, general vs subspecialised, academic vs industry, and teleradiology vs interventional. With honest insights into what it takes to succeed and where the hidden challenges lie, this is a must-attend for anyone planning their future in radiology.

Moderators:

Annemiek Snoeckx; Zandhoven / Belgium

Lisa C. Adams; Munich / Germany

Radiology Subspeciality Training: A Global Perspective (10 min)

Salman Qureshi; Abu Dhabi / United Arab Emirates

Plugged in: teleradiology as a career, not a side gig (10 min)

Nora Navina Sommer; München / Germany

Beyond the hospital: radiologists in industry (10 min)

Mathias Goyen; Essen / Germany

Life in academia: is the university hospital worth it? (10 min)

Michael N. Patlas; Burlington / Canada

Open forum discussion: Where do you see yourself in 10 years? (15 min)

RC 1410 - Imaging of the shoulder

Categories: Musculoskeletal, Imaging Methods
ETC Level: LEVEL I+II
Date: March 6, 2026 | 12:30 - 13:30 CET
CME Credits: 1

Moderator:
Paul Max Martin; Bremen / Germany

Chairperson's introduction (5 min)
Paul Max Martin; Bremen / Germany

Shoulder instability (15 min)
Üstün Aydingöz; Ankara / Turkey

1. To name and identify the stabilising structures of the shoulder.
2. To discuss different categories of shoulder instability.
3. To describe "the glenoid track" concept and how it relates to treatment planning in anterior shoulder instability.

Rotator cuff pathology (15 min)
Philip Robinson; Leeds / United Kingdom

1. To describe the anatomy and function of the rotator cuff tendons.
2. To explain the development of common rotator cuff pathologies and their imaging appearances.
3. To compare the sensitivity and specificity of imaging techniques available to assess rotator cuff pathology.

Other causes of shoulder pain (15 min)
Marco Zanetti; Baden / Switzerland

1. To name and identify the anatomic structures and pathologic conditions in the rotator cuff interval.
2. To recognise and classify acromioclavicular (AC) joint injuries.
3. To know the differential diagnoses of shoulder muscle abnormalities unrelated to rotator cuff tendon tears.

Panel discussion: Diagnostic challenges in patients with shoulder pain (10 min)

RC 1413 - Innovative educational approaches: boosting safety in interventional radiology and cardiology with AI, virtual and augmented reality, and computational techniques

Categories: Radiographers, Physics in Medical Imaging, EuroSafe Imaging/Radiation Protection, Interventional Radiology, Vascular, Artificial Intelligence

ETC Level: LEVEL II

Date: March 6, 2026 | 12:30 - 13:30 CET

CME Credits: 1

SESSION RECOMMENDED BY ESR EUROSAFE IMAGING

Moderators:

Olivera CIRAJ BJELAC; Vienna / Austria

Efi Koutsouveli; Athens / Greece

Chairpersons' introduction (5 min)

Olivera CIRAJ BJELAC; Vienna / Austria

Efi Koutsouveli; Athens / Greece

Using augmented reality to enhance medical practice and to boost radiation protection in vascular surgery (15 min)

Stefano Bonvini; Trento / Italy

1. To learn about the development of AR-based scenarios to simulate realistic environments for medical professionals.
2. To understand the principles and applications of augmented reality (AR) to boost radiation protection during endovascular procedures.
3. To evaluate the effectiveness of the integration of augmented reality (AR) in a clinical setting.

Virtual reality for advanced training in interventional rooms (15 min)

Katharina Stella Winter; Oberschleißheim / Germany

1. To understand the principles and applications of virtual reality (VR) in radiation protection.
2. To explore the development and features of a VR-based training environment, including the awareness and proper use of protective devices.
3. To discuss practical, low-cost implementation solutions of VR technology for enhancing education and training events.

The use of computational and AI-based occupational dosimetry for ALARA and teaching purposes in medical ionising radiation applications (15 min)

Filip Vanhavere; Mol / Belgium

1. To understand the principles and methodologies of computational and AI-based occupational dosimetry.
2. To explore the development and validation of real-time personal dosimetry systems, such as the PODIUM project, for employing motion tracking and Monte Carlo simulations.
3. To evaluate the effectiveness of computational dosimetry in optimising radiation protection and enhancing the application of the ALARA principle in interventional radiology and cardiology.

Panel discussion: How virtual augmented reality and AI technology will transform education on radiation safety in the coming decades? (10 min)

RC 1416 - Oligometastatic disease: a need for standardisation

Categories: Hybrid Imaging, Oncologic Imaging, GI Tract, Breast, Interventional Oncologic Radiology, Multidisciplinary, President's Choice

ETC Level: LEVEL II+III

Date: March 6, 2026 | 12:30 - 13:30 CET

The EORTC-ESTRO classification of oligometastatic disease (16 min)

Matthias Guckenberger; Zurich / Switzerland

1. To understand the clinical background and history of oligometastatic disease.
2. To learn about the EORTC-ESTRO classification of oligometastatic disease.
3. To know how structured classifications improve communication in tumour boards.

The impact of imaging modality and definition of oligometastatic disease (16 min)

Clarisse Dromain; Lausanne / Switzerland

1. To understand how imaging accuracy affects the definition of oligometastasis.
2. To learn about tumour-specific imaging approaches for suspected oligometastasis.
3. To know how modern diagnostic imaging exams may lead to stage migration.

Current evidence of benefit in metastasis-directed radiotherapy (16 min)

Joost JC Verhoeff; Utrecht / Netherlands

1. To understand how radiation therapy is used to treat oligometastatic cancers.
2. To learn about challenges for and limitations of metastasis-directed radiotherapy.
3. To know how radiology can contribute to radiation treatment planning.

Panel discussion: Is it time for modified definitions of oligometastaticdisease for specific cancer entities? (9 min)

RC 1417 - Near misses and overcalls in non-trauma emergency imaging

Categories: Emergency Imaging, Neuro, Paediatric, Chest, GI Tract, President's Choice
ETC Level: LEVEL II+III

Head and neck: subtle signs versus mimickers of acute infections (12 min)
Idil Güneş Tatar; Leuven / Belgium

1. To recognise the subtle imaging signs of acute infections in the head and neck.
2. To differentiate between acute infections and mimicking conditions, such as neoplasms, vascular malformations, and inflammatory diseases, based on imaging features.
3. To understand the diagnostic workup and clinical decision-making process for distinguishing acute infections from other neurological and non-neurological mimickers in the emergency setting.

Chest: from normal to abnormal. Features of anatomic variants versus minor emergencies (12 min)
Jonas Anužis; Vilnius / Lithuania

1. To identify common anatomic variants in thoracic imaging, including pulmonary, vascular, and skeletal anomalies, and understand their normal variants versus pathologic findings.
2. To distinguish between benign findings and minor thoracic emergencies.
3. To evaluate imaging findings that may suggest the need for further investigation or intervention, especially in patients presenting with minor thoracic symptoms that could be easily misinterpreted.

Abdomen: subtle signs of small and large bowel ischaemia (12 min)
Mariano Scaglione; Naples / Italy

1. To recognise the early and subtle imaging signs of small and large bowel ischaemia.
2. To differentiate between the imaging features of ischaemia and other conditions that may mimic bowel ischaemia.
3. To understand the role of advanced imaging modalities in diagnosing and assessing the severity of mesenteric ischaemia and guiding clinicians.

Paediatrics: subtle signs of MSK infections in the paediatric patient (12 min)
Laura S Kox; Leiden / Netherlands

1. To recognise the subtle imaging signs of musculoskeletal infections in paediatric patients.
2. To differentiate between musculoskeletal infections and other conditions in children that may present with similar symptoms.
3. To understand the role of imaging in the staging and management of paediatric musculoskeletal infections.

Panel discussion: When subtle signs indicate non-subtle pathologies (10 min)

RPS 1402 - Hot Topic: personalised imaging

Breast density and the value of integrated imaging: evidence from the P.I.N.K. study (6 min)
Ludovica Anna Incardona; Florence / Italy

Author Block: L. A. Incardona[1], S. Molinaro[2], S. Pieroni[2], B. Di Nubila[3], G. M. Giuseppetti[4], P. Belli[5], E. Montrucchio[1], M. Franchini[2]; [1]La Spezia/IT, [2]Pisa/IT, [3]Milan/IT, [4]Ancona/IT, [5]Rome/IT
Purpose: Breast density is a major limitation of mammographic screening, reducing sensitivity and delaying cancer diagnosis. The P.I.N.K. Study was designed to evaluate the contribution of multimodality imaging in breast cancer diagnosis. This sub-analysis quantified mammography (MX) performance according to density and assessed the additional detection (AD) provided by ultrasound (US), digital breast tomosynthesis (DBT), and magnetic resonance imaging (MRI).
Methods or Background: The P.I.N.K. database included 29,360 women who underwent 60,270 integrated diagnostic exams between 2017 and 2025. A total of 1,246 breast cancers were surgically confirmed. MX sensitivity and the AD of US, DBT, and MRI were calculated across density categories (A–D).
Results or Findings: Of 1,246 cancers, 422 occurred in fatty breasts (A–B) and 824 in dense breasts (C–D). In A–B breasts, MX detected 389 of 422 cancers (92.2%), with 33 additional cancers (7.8%) identified by other modalities. In C–D breasts, MX detected 575 of 824 cancers (69.8%), while integrated imaging identified 249 additional cancers (30.2%), increasing detection by up to 25%. The benefit was greatest in younger women and in those with extremely dense tissue.
Conclusion: Integrated imaging adds little in fatty breasts but significantly improves detection in dense breasts. On a large multicentre scale, P.I.N.K. demonstrates that tailoring imaging strategies to breast density enhances early diagnosis while avoiding unnecessary procedures in low-density women, supporting more effective and resource-efficient screening pathways.
Limitations: This was a retrospective analysis of clinical data.

Correlation between Background Parenchymal Enhancement in Contrast Enhanced Mammography and breast cancer risk: towards personalised screening (6 min)
Elisa D'Ascoli; Rome / Italy

Author Block: E. D'Ascoli, C. Depretto, G. Rossini, C. De Berardinis, G. Irmici, G. Della Pepa, L. Corradini, G. P. Scaperrotta, F. Sardanelli; Milan/IT
Purpose: To evaluate the correlation between background parenchymal enhancement (BPE) on contrast-enhanced mammography (CEM) and breast cancer (BC) risk, in order to identify a useful indicator for risk stratification and the adoption of personalised screening strategies.
Methods or Background: We retrospectivly evaluated CEMs performed at our Institution between 2021 and 2022, including patients diagnosed with BC and patients who underwent CEM for problem solving, with at least 2-year negative follow-up. For each examination, breast density (BD) and BPE (none/minimal = 1, mild = 2, moderate = 3, severe = 4) were assessed according to the BI-RADS lexicon by two independent readers with at least 3 years of CEM experience. For BC cases, BD and BPE were assessed by evaluating the contralateral breast. For each BD class, BPE scores were compared between patients with BC and healthy controls in order to assess the association between BPE and increased cancer risk.
Results or Findings: We performed a preliminary analysis on 179 patients. For each BD category, 25 patients with BC and 25 healthy controls were included, with the exception of category A, for which only 4 healthy subjects were identified. In all BD categories, the average BPE was higher in patients with BC than in controls. Specifically, in category A, the average BPE was 1.36 in cancer patients and 1.25 in healthy subjects (increase of 8.8%); in category B, 1.68 vs 1.56 (+7.7%); in category C, 2.20 vs. 1.64 (+34.1%); in category D, 2.92 vs. 2.32 (+25.9%).
Conclusion: The analysis showed an association between high BPE and BC, regardless of density; BPE could therefore be integrated into risk assessment models and represent a useful indicator for population stratification, promoting personalised screening.
Limitations: Retrospective monocentric study with limited number of patients.

Deep Learning with Transfer Learning on Digital Breast Tomosynthesis: A Radiomics-Based Model for Predicting Breast Cancer Risk (6 min)

Gloria Barcaroli; Rome / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: G. Barcaroli, F. Galati, R. Maroncelli, C. De Nardo, V. Rizzo, G. Moffa, F. Pediconi; Rome/IT
Purpose: Digital breast tomosynthesis (DBT) is a valuable imaging modality for breast cancer detection; however, its interpretation remains time-consuming and subject to inter- reader variability. This study aimed to develop and evaluate two deep learning (DL) models based on transfer learning for the binary classification of breast lesions (benign vs.malignant) using DBT images to support clinical decision-making and risk stratification.
Methods or Background: In this retrospective monocentric study, 184 patients with histologically or clinically confirmed benign (107 cases, 41.8%) or malignant (77 cases, 58.2%) breast lesions were included. Each case underwent DBT with a single lesion manually segmented for radiomic analysis. Two convolutional neural network (CNN) architectures—ResNet50 and DenseNet201—were trained using transfer learning from ImageNet weights. A 10-fold cross-validation strategy with ensemble voting was applied. Model performance was evaluated through ROC–AUC, accuracy, sensitivity, specificity, PPV, and NPV.
Results or Findings: The ResNet50 model outperformed DenseNet201 across most metrics. On the internal testing set, ResNet50 achieved a ROC–AUC of 63%, accuracy of 60%, sensitivity of 39%, and speci- ficity of 75%. The DenseNet201 model yielded a lower ROC–AUC of 55%, accuracy of 55%, and sensitivity of 24%. Both models demonstrated relatively high specificity, indicating potential utility in ruling out malignancy, though sensitivity remained suboptimal.
Conclusion: This study demonstrates the feasibility of using transfer learning-based DL models for lesion classification on DBT. While the overall performance was moderate, the results highlight both the potential and current limitations of AI in breast imaging. Further studies and approaches are warranted to enhance model robustness and clinical applicability.
Limitations: Retrospective and monocentric study, small cohort
Funding for this study: None

AI-assisted double reading in mammography screening: exam risk score patterns and early cancer risk prediction (6 min)

Claudia Maria Weiss; Villorba / Italy

Author Block: C. M. Weiss, E. Di Gaetano, E. Cattarin, R. Cerniato, I. Vinci, G. Soppelsa, G. Morana; Treviso/IT
Purpose: Recent studies show that AI-algorithms for breast cancer (BC) diagnosis have potential applications in risk-assessment, specifically in utilizing exam risk scores (EXRS) to predict the likelihood of developing the disease. We examined whether ExRS on baseline negative screening mammograms (SM) could predict BC detected in the subsequent round in an AI-supported-screening (AISS) using human-double-reading, and evaluated if these results were consistent across different BI-RADS breast-density categories (BD).
Methods or Background: A retrospective analysis was conducted on 135,372 SMs from two consecutive AISS rounds, examining 67,686 women between November 2021 and July 2025, with an average interval of 777 days between rounds. AI assigned an ExRS (0–100) to each SM. ExRS values were compared between women who developed BC (451/67,686) and those who did not (67,235/67,686), with subgroup analyses by BD. Statistical tests included chi-square or z-tests, t-test or Mann–Whitney U-test, and McNemar's test.
Results or Findings: Among 451 BC cases, mean ExRS rose from 15.4 at baseline to 73.9 in the subsequent round (median 6.8vs83.0;p<0.001). Women negative at both rounds (n=67,235) had little change: means were 6.7 and 6.4 (medians 2.1 and 2.3;p<0.001). ExRS was significantly higher in BC cases than negatives at both baseline (15.4vs6.7;p<0.001) and subsequent (73.9vs6.4;p<0.001). Baseline ExRS were higher in dense (C–D) than non-dense (A–B) breasts. For BC cases, mean ExRS increased from 13.8 to 73.7 (A–B) and 17.6 to 74.1 (C–D). In negatives, ExRS stayed low: 6.0 to 5.5 (A–B) and 7.6 to 7.9 (C–D).
Conclusion: The AI-derived ExRS is able to differentiate between women with varying levels of risk for developing BC at baseline, and this ability was consistent across all BD categories. The results show that ExRS can be also used for risk-based stratification in screening
Limitations: No limitations
Funding for this study: No fundings

External Validation of Four Breast Cancer Risk Models With and Without Breast Density in a prospective Dutch Screening Cohort (6 min)

Jim Peters; Nijmegen / Netherlands

Author Block: J. Peters[1], D. Van Der Waal[1], M. Schmidt[2], C. Van Gils[3], M. Broeders[1]; [1]Nijmegen/NL, [2]Amsterdam/NL, [3]Utrecht/NL
Purpose: Tailoring breast cancer screening to individual risk can improve its harm–benefit ratio versus a 'one-size-fits-all' approach. We externally validated four widely used risk models—Gail, BCSC, BOADICEA, and IBIS—in a large Dutch screening cohort. Recent model updates include breast density using different approaches (categorical or continuous), so we evaluated performance with and without density.
Methods or Background: The PRISMA study is a prospective cohort (2014–2019) embedded in the Dutch biennial breast cancer screening program, which invites women aged 50-75 years. Breast cancer risk was predicted for 38,767 participants using four models (Gail, BCSC, BOADICEA, IBIS) based on questionnaire data (personal, lifestyle, hormonal, family history) and breast density. Gail does not include density; BCSC uses density categories; BOADICEA and IBIS allow categories, a continuous measure, or no density. Volumetric percent density and Volpara Density Grades (Volpara version 1.5.0) were measured on raw mammograms. Breast cancers were ascertained via linkage with the Netherlands Cancer Registry until October 2023. Model performance for 5-year risk was evaluated using the concordance index (C-index), observed–expected (O/E) ratio, and calibration slope.
Results or Findings: During a median 4.3 years follow-up, 609 breast cancers occurred. Discrimination was poor for Gail (C-index 0.56) and modest for BCSC, BOADICEA and IBIS (C-indices 0.60-0.61). Calibration was good for BCSC (O/E 1.03, slope 0.81) and BOADICEA (O/E 0.96, slope 0.78), but IBIS (O/E 0.71, slope 0.66) and Gail (O/E 0.79, slope 0.59) overpredicted risk. Adding continuous breast density improved discrimination (ΔC-index +0.02–0.04) and calibration most.
Conclusion: Traditional breast cancer risk models show at most moderate performance; despite small improvements from continuous breast density, overall accuracy remains limited for personalized screening.
Limitations: The limitations of the study are incomplete family history and genetic data, which may particularly underestimate BOADICEA and IBIS performance.
Funding for this study: Dutch Cancer Society (KWF7626) and Dutch Research Society (ZonMw 200500004)

Epidemiological and deep learning breast cancer risk models compared for an increased-risk population (6 min)

Machteld Keupers; Leuven / Belgium

Author Block: M. Keupers, W. Sarkol, S. Nijssen, Y-K. Wang, L. Cockmartin, H. Bosmans, C. Van Ongeval; Leuven/BE
Purpose: For women with clinically elevated breast cancer risk due to personal risk factors, family history or breast density, screening guidelines remain ambiguous. Epidemiological risk-models like CanRisk and IBIS, are currently used to guide supplemental screening. Recent studies demonstrated that deep learning models might be superior. This study compares risk assessment of two epidemiological models with two deep learning models.
Methods or Background: In this single-center cohort 401 women with clinically elevated breast cancer risk were included (2014) with ten-year follow-up info. CanRisk v2.4.2. and IBIS v8.0b assessed lifetime and short-term risk based on patient files. Deep learning models i.e. MIRAI and Transpara were used to predict short-term risk. Model performance was evaluated using receiver operating characteristic (ROC) analysis; areas under the curve (AUCs) were calculated and compared using paired DeLong's test.
Results or Findings: Of the 401 women (mean age=49 ±7) 25 developed breast cancer after a ten-year period; 11 cancers were detected after five years. The AUCs for risk assessment within five and ten years for CanRisk were 0.58 (95% confidence interval (CI) [0.37; 0.79]) and 0.61 (95% CI [0.49; 0.73]) resp, and for IBIS lifetime risk it was 0.61 (95% CI [0.49; 0.72]). Deep learning models were evaluated to predict breast cancer risk after five years. Transpara (0.73 (95% CI [0.52; 0.95]) showed superior performance over Mirai (0.57 (95% CI [0.38; 0.77]) (p=0.042).
Conclusion: In this single-center cohort with elevated breast cancer risk, one deep learning model outperformed the epidemiological models for short term risk prediction. Generalizability of deep learning models for increased-risk populations should be tested. Further evaluation in larger cohorts is needed.
Limitations: Number of patients in this single-center, increased-risk cohort.
Still some missing data despite thorough review of electronic patient files.
Funding for this study: No funding was received for this study.

Impact of scan parameters on the reliability of automatic coronary artery calcium quantification and density measurement in low-dose chest CT (6 min)
Won-Seok Yoo; Seoul / Korea, Republic of

Author Block: W-S. Yoo[1], S. Hong[1], Y. J. Suh[1], C. Kim[2]; [1]Seoul/KR, [2]Ansan/KR
Purpose: To evaluate the reliability of AI-based automatic coronary artery calcium (CAC) quantification and density measurement on non-ECG-gated low-dose chest CT (LDCT) compared with manual measurements on calcium scoring CT (CSCT), and to investigate the influence of scan parameters.
Methods or Background: This retrospective study included 417 patients from four academic hospitals who underwent both CSCT and LDCT within six months, with CAC scores >0. CT scans were obtained on scanners from four different vendors. CSCT was reconstructed at 3-mm with standard kernel; LDCT was reconstructed in 1-mm and 3-mm pairs with various kernels (identical within each pair). Patients were grouped as high- and low-noise by LDCT noise level. Agatston score, peak density attenuation, and density score (Agatston score divided by total calcium area) were measured manually on CSCT by cardiac radiologists and obtained automatically on LDCT using commercial software. Reliability of each variable between manual CSCT and automatic LDCT (LDCTauto) was evaluated using the concordance correlation coefficient with 95% CIs.
Results or Findings: In the low-noise group (n=337), 1-mm LDCTauto demonstrated higher reliability than 3-mm LDCTauto across all variables: Agatston score (0.943 [0.932–0.952] vs. 0.922 [0.908–0.934]), peak density attenuation (0.812 [0.773–0.846] vs. 0.710 [0.664–0.750]), and density score (0.565 [0.496–0.627] vs. 0.556 [0.490–0.615]). However, in the high-noise group (n=80), 1-mm LDCTauto showed lower reliability than 3-mm LDCTauto for Agatston score (0.710 [0.604–0.791] vs. 0.838 [0.763–0.890]) and peak density attenuation (0.157 [0.087–0.226] vs. 0.690 [0.567–0.782]), but slightly higher reliability for density score (0.442 [0.270–0.587] vs. 0.411 [0.219–0.572]).
Conclusion: The reliability of automatic CAC measurements on LDCT is influenced by slice thickness and noise level. With lower-noise kernels, 1-mm LDCT may provide more reliable automatic CAC quantification and density measurement than 3-mm LDCT.
Limitations: Further validation using different software is required.
Funding for this study: None.

Spectral Photon-counting CT at reduced tube potential enables high quality coronary imaging at ultra-low-radiation dose: A comparative study to standard dose protocols (6 min)
Sinan Barus; Freiburg im Breisgau / Germany

Author Block: S. Barus[1], M. T. Hagar[2], M. Soschynski[1], F. Bamberg[1], C. L. Schlett[1], T. Krauß[1], C. Schuppert[1]; [1]Freiburg im Breisgau/DE, [2]Charleston, SC/US
Purpose: Photon-counting detector coronary CT angiography (PCD-CCTA) is typically performed at 120/140 kVp (standard dose, SD) to enable full spectral applications, including material decomposition and virtual monoenergetic imaging (VMI). Low-dose (LD) acquisitions at 90/70 kVp are limited to VMI but may suffice to rule out coronary artery disease.
Methods or Background: In this single-center post-hoc study, consecutive low-risk-profile patients (age <60 years, BMI <30, Agatston score <200) underwent clinically indicated CCTA using a dual-source PCD-CT system. Scans were randomly acquired in either full (SD) or reduced spectral mode (LD), using high-pitch or prospective sequence acquisition. Images were reconstructed as 55 keV VMIs using a vascular kernel (Bv48, 0.4 mm). Quantitative image quality included signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR) averaged across the ascending aorta, proximal and distal coronaries; CNR of ≥10.0 was defined as diagnostic. Radiation dose was evaluated using the dose-length product (DLP), and multivariate analysis was used to assess indicators of radiation dose.
Results or Findings: A total of 192 patients were included (115 LD, 48.1 ± 8.3 years; 77 SD, 53.0 ± 7.1 years). LD reduced radiation dose by 52.6% (91 [58–179] vs. 192 [137–475] mGy·cm, p<0.01), with slightly lower SNR (15.5 [13.1–17.6] vs. 19.2 [15.5–23.3], p<0.001) and CNR (13.0 [11.1–14.9] vs. 16.2 [13.2–20.6], p<0.001), although both exceeded diagnostic thresholds. In multivariate analysis, LD and high-pitch acquisition predicted lower dose (β = -138.8 and -215.6, p<0.001), while higher BMI and male sex increased dose (β = 7.8 and 47.2, p=0.016 and 0.018).
Conclusion: PCD-CCTA acquired at low tube potentials enables substantial radiation dose reduction while maintaining diagnostic image quality. Our results indicate that in low-risk patients, patient-protective measures should be favored over full spectral capacity.
Limitations: Post-hoc, single-center study.
Funding for this study: No funding was provided for this study.

Harmonizing T1 Mapping Across Sequences and Diseases: Insights from a Real-World Dual-Sequence CMR Study (6 min)

Huaying Zhang; Peking / China

Author Block: H. Zhang, M. Lu; Peking/CN
Purpose: The clinical translation of cardiovascular magnetic resonance (CMR) T1 mapping is limited by inconsistent acquisition protocols and reference ranges. We aims to establish the ranges of native T1 and extracellular volume (ECV) in healthy Chinese adults and across various cardiovascular diseases, and to evaluate their diagnostic performance.
Methods or Background: This prospective study included 1,237 human subjects with 15 cardiovascular conditions and 12 swine for histopathologic validation. T1 mapping were acquired using Modified Look-Locker Inversion Recovery (MOLLI) and Shortened MOLLI (ShMOLLI) sequences on a 3 Tesla Siemens scanner. Histological collagen volume fraction (CVF) in swine myocardium was quantified and correlated with T1 mapping. Global native T1 and ECV were compared between myocardial disease groups and healthy controls. The differences between MOLLI and ShMOLLI measurements were analyzed using Bland-Altman analysis.
Results or Findings: Histological validation in swine confirmed strong correlations between T1 mapping parameters and CVF. In clinic, the references ranges derived from healthy controls were 1179±29 ms (MOLLI) and 1147±33 ms (ShMOLLI) for native T1, and 25.1±2.1% (MOLLI) and 25.5±1.9% (ShMOLLI) for ECV. Gender stratification revealed higher native T1 in females compared to males within healthy population. MOLLI yielded systematically higher native T1 values compared to ShMOLLI across the entire cohort and in all conditions. ECV showed inter-sequence consistency. Across the spectrum of cardiovascular diseases, significant deviations in native T1 and ECV were observed. T1 mapping had exceptional diagnostic performance for cardiac amyloidosis and Fabry disease, and strong diagnostic capabilities for most primary cardiomyopathies, ischemic heart disease, and myocarditis.
Conclusion: This large-scale study established comprehensive reference ranges for native T1 and ECV using MOLLI and ShMOLLI at 3 Tesla, highlighting their diagnostic utility across diverse cardiovascular conditions.
Limitations: Patients were enrolled based on a single primary cardiovascular diagnosis

Non-invasive estimation of blood oxygen saturation with Standard T1/T2 CMR mapping: enhanced accuracy through flow-based adjustment (6 min)

Aurelio Secinaro; Roma / Italy

Author Block: A. Perazzolo[1], T. C. Chao[2], D. Curione[1], M. Rebonato[1], M. Pilari[1], G. Butera[1], L. Natale[1], T. Leiner[2], A. Secinaro[1]; [1]Rome/IT, [2]Rochester, MN/US
Purpose: Blood oxygen saturation is a key physiological marker of cardiopulmonary function. Differences in magnetic susceptibility of oxygenated versus deoxygenated hemoglobin affect MRI relaxation times. Models such as the Luz–Meiboom (LM) equation link T2 to oxygen saturation, while synthetic hematocrit (HCT) can be inferred from native T1. Nonetheless, flow-related artifacts remain a limitation to quantification. We evaluated the feasibility of non-invasive CMR-based oxygen saturation assessment, validated against simultaneous sampling during MRI-guided catheterization in pediatric patients, and tested a physiological flow-based correction.
Methods or Background: Synthetic HCT was calculated from native T1 (MOLLI), and T2 maps were obtained from a T2-prep bSSFP sequence (echo times 0 and 55 ms). These inputs were applied to the LM model to generate saturation maps. Right ventricular blood-pool ROIs provided image-based values, compared with catheter samples from pulmonary arteries under matched conditions. Additional morpho-functional indices (ventricular volumes, ejection fraction, main pulmonary artery [MPA] flow) were extracted to assess their influences on image-based SbO_2. A linear correction model was derived associating peak velocity of MPA (VmaxMPA) and ΔSbO_2 (difference between catheter and image-based measurement) verified by leave-one-out cross validation.
Results or Findings: Thirteen pediatric patients were retrospectively included (9 restrictive cardiomyopathies, 1 dilated cardiomyopathy, 1 Uhl's anomaly, 1 congenitally-corrected transposition, 1 idiopathic right atrial dilatation). MPA peak velocity (Vmax) correlated with ΔSbO_2 (R^2=0.93). Leave-one-out cross validation demonstrated that applying VmaxMPA correction reduced root mean square error from 15.92% to 2.77%, mitigating flow-related artifacts.
Conclusion: Non-invasive blood oxygen saturation estimation from standard T1/T2 mapping is feasible when synthetic HCT and the LM equation are combined with a physiological correction for MPA flow. Validation against invasive sampling supports the robustness and clinical applicability of this approach for artifact-resistant quantification.
Limitations: Small sample size and absent external validation.

Retrospective Evaluation of Short Protocols in Cardiac MRI: Role of Mapping and Left Ventricular Function as Decision Making Parameters for Possible Intravenous Contrast Administration (6 min)

Eleonora Cantalamessa; Sassuolo (Mo) / Italy

Author Block: E. Cantalamessa[1], F. Fiocchi[1], G. Battinelli[1], R. Cuoghi Costantini[1], G. Ligabue[2]; [1]Modena/IT, [2]Sassuolo/IT
Purpose: The use of shortened non-contrast Cardiac Magnetic Resonance (CMR) protocols may reduce examination time and still maintain diagnostic accuracy. This study aimed to assess the effectiveness of such an approach for detecting left ventricular myocardial disease, using mapping and ventricular function as decision-making criteria.
Methods or Background: This single-center retrospective study included 337 patients referred for CMR with heterogeneous clinical indications. Each examination was blindly evaluated using a short protocol including cine sequences, edema-sensitive sequences and T1/T2 mapping. For each one of them, functional parameters (LVEDV, LVEDV/BSA, LVEF, LVSV) and mapping values (T1 MAX, T2 MAX) were collected. T1 MAX and T2 MAX were defined as the highest mean values assigned to a myocardial segment in native T1 and T2 mapping, respectively. The diagnosis obtained with the standard contrast-enhanced protocol served as the reference standard. ROC analysis was used to assess the performance of individual parameters and combined models (logistic regression, decision tree) in predicting LGE positivity.
Results or Findings: T1 Max demonstrated an AUC of 0.716 (sensitivity 67.2%; specificity 66.8%), which improved with the addition of LVEDV/BSA (AUC 0.721). The decision tree achieved an AUC of 0.751. A T1 Max cut-off >1113 ms identified a high-risk subgroup (positivity 70%), whereas T1 Max <1025 ms defined a low-risk subgroup (positivity 13%). In intermediate cases, adding LVEDV/BSA >93 ml/m² improved discriminatory capacity.
Conclusion: In a heterogeneous population, a short non-contrast CMR protocol based on T1 mapping thresholds and left ventricular function may identify patients at higher risk of myocardial injury. Implementing a shortened protocol could significantly reduce acquisition times, supporting more efficient and personalized diagnostic pathways in everyday clinical practice.
Limitations: Limitations include retrospective single-center nature of the study, heterogeneous patient population, and the need for experienced radiologist presence.
Funding for this study: No funding was received for this study.

Ethics committee - additional information: The study is retrospective

Prognostic value of CMR parametric mapping in cardiac amyloidosis: An updated systematic review and meta-analysis (6 min)

Giulia Francese; Rouen / France

Author Block: S. Forouzannia[1], S. R. Rafiei Alavi[1], S. M. Forouzannia[2], M. Umair[3], G. Francese[4]; [1]Tehran/IR, [2]San Francisco, CA/US, [3]New York, NY/US, [4]Genoa/IT
Purpose: Cardiac amyloidosis (CA) is the leading cause of mortality in systemic amyloidosis, highlighting the need for accurate risk assessment to guide patient management. While the diagnostic value of cardiac MR (CMR) parametric mapping is well established, its prognostic utility remains inconsistent across studies. To perform a systematic review and meta-analysis to evaluate the prognostic value of CMR parametric mapping in patients with CA.
Methods or Background: An extensive search was conducted in Medline, Scopus, Embase and Web of Science databases. Eligible studies were observational studies that reported HRs for predicting adverse outcomes in patients with CA using CMR parametric mapping.
Results or Findings: 22 studies with 3398 patients were included in this systematic review. Higher extracellular volume (ECV) values were associated with increased mortality, both as a dichotomous (HR: 2.90; 95% CI: 1.68 to 5.01) and continuous variable (HR for 1% increase: 1.08; 95% CI: 1.06 to 1.10; HR for 3% increase: 1.17; 95% CI: 1.11 to 1.22 and HR for 10% increase: 2.11; 95% CI: 1.70 to 2.62). Higher native T1 mapping values were associated with mortality as a dichotomous variable (HR: 1.33; 95% CI: 0.79 to 2.24). Native T2 mapping showed inconsistent associations with prognosis across studies.
Conclusion: Higher ECV and native T1 values are associated with worse prognosis in CA, supporting their role in risk stratification. Further studies with standardised CMR protocols are needed to enhance the prognostic utility of parametric mapping in clinical practice.
Limitations: The heterogeneity in ECV and T1 cut-off values across studies presents a challenge to standardisation, thereby limiting direct comparisons. Another limitation is the insufficient data available on native T2 mapping due to the limited number of studies investigating its values in the setting of CA.
Funding for this study: No funding was received for this study.

Myocardial Extracellular Volume difference according to sex, fibrosis and left ventricular hypertrophy in Fabry Disease: A Retrospective Cardiac MRI Study (6 min)

Clément Filliol; Lyon / France

Author Block: C. Filliol[1], C. De Bourguignon[2], A. Ghaouar[1], M. Bourmaaz[1], A. Braillon[1], A. Deliniere[1], A. Jobbe-Duval[1], A. Fouilhoux[2], S. A. Si-Mohamed[1]; [1]Bron/FR, [2]Lyon/FR
Purpose: To analyze differences in myocardial extracellular volume (ECV) according to sex, left ventricular hypertrophy (LVH) and fibrosis in Fabry disease.
Methods or Background: Between February 2017 and August 2023, 64 patients with Fabry disease (36 women [56%], mean age 45 ± 15 years) from our reference center who underwent baseline cardiac magnetic resonance imaging (CMR) on a 1.5 Tesla MRI system (Philips XXX) were retrospectively included. ECV was calculated using the hematocrit level obtained on the same day after semi-automatic segmentation on short-axis T1 mapping images, using a clinical workstation (ISPortal, CM Suite, Philips). The presence of fibrosis and left ventricular hypertrophy (LVH) was assessed in consensus by 2 experienced observers. Following data were registered: age, sex, alpha-galactosidase A levels, troponin levels, left ventricular ejection fraction (LVEF). Mann-Whitney and t- test were used according to their normality.
Results or Findings: Age, troponine and LVEF were not significantly different according to sex, Alpha-galactosidase level was significantly lower in men (0.46±0.15 vs 3.07±1.8, p<0.001). LVH status was significantly higher in men (11(44%) vs 5(12.8%), p<0.001) and fibrosis status was significantly higher in men (9(36%) vs 11(28.2%), p<0.001). 13(20%) patients presented both LVH and fibrosis (4 women, 9 men). 46(72%) patients were indemn of LVH and fibrosis (29 women, 17 men). In men, global ECV was significantly higher in presence of LVH (27.7%±3.9 vs 24.4%±2.4, p=0.02), as well as in presence of fibrosis (28.2%±4.2 vs 24.6%±2.3, p=0.04). No statistical difference was found in women.
Conclusion: Myocardial ECV is significantly elevated in men with LVH and fibrosis, highlighting sex-specific differences in cardiac tissue alterations. These findings suggest that assessing ECV, particularly in male patients, may offer valuable insights into myocardial involvement and disease progression in Fabry disease
Limitations: Retrospective and monocentric study.

Automatic volumetric evaluation of extracellular volume from CT: prognostic value in pre-TAVI risk stratification (6 min)

Alberto Colombo; Milan / Italy

Author Block: A. Colombo, C. Gnasso, D. Vignale, M. Liberotti, A. Palmisano, A. Esposito; Milan/IT
Purpose: To develop an automatic software for myocardial extracellular volume (ECV) analysis and to evaluate its association with a composite outcome of death and heart failure at 12 months after transcatheter aortic valve implantation (TAVI) in patients with aortic stenosis (AS).
Methods or Background: In this retrospective single-centre study, we considered patients who underwent pre-TAVI CT (10/2020-12/2023) and employed a fully automated pipeline for volumetric quantification of ECV and fibrotic burden (FB), a.k.a. percentage of left ventricular voxels with ECV values above a set threshold. The pipeline consisted of four steps: 1-segmentation of cardiac structures and 2-their post-processing, 3-co-registration of late post-contrast and pre-contrast scans, 4-actual ECV quantification. Agreement between automated (ECVauto) and manual (ECVmanu) measurements by two radiologists was assessed with Bland-Altman analysis, while prognostic value was evaluated using Kaplan-Meier curves with log-rank cutoffs and multivariable Cox models adjusted for clinical and echocardiographic variables. Analyses were performed in Python (v3.9.13), with p=0.05 significance.
Results or Findings: Among the 438 included patients (median age 82 years, F221/M217), median EuroSCORE was 5.2, mean gradient 44 mmHg, and ejection fraction 59%. The 12 months composite outcome occurred in 74 patients (16.9%), including 57 deaths (10.7%). The pipeline processed all CTs in ~4.5min/patient. Bias and limits of agreement between ECVauto and ECVmanu were 0.82% (-11.9%/13.6%). ECVauto and ECVmanu were higher in patients with events (32.5vs29.3%, p=0.001; 30.1vs28.0%, p=0.020, respectively). Elevated ECVauto independently predicted worse outcomes (cutoff 32.9%, p<0.001; HR 1.04 per 1%, p=0.028), as did high FB (cutoff 48.5%, p<0.001; HR 1.02, p=0.031).
Conclusion: The pipeline enabled rapid, automated ECV mapping, independently predicting 12-month outcomes. Results further support CT-based fibrosis assessment.
Limitations: Limitations include retrospective, single-center design, improving the segmentation step to exclude artifacts, and possible inclusion of undiagnosed amyloidosis.

The study is a retrospective analysis of prospectively collected data and was conducted according to the Declaration of Helsinki. Written informed consent was obtained for all participants.

Synergistic role of CT-derived Extracellular Volume Fraction (ECV) and Flow-Gradient Patterns in Risk Stratification of Patients with Severe Aortic Stenosis Undergoing TAVI (6 min)

Chiara Gnasso; Milan / Italy

Author Block: C. Gnasso, D. Vignale, A. Palmisano, D. Serra, D. Margonato, A. Esposito; Milan/IT
Purpose: Previous studies have demonstrated that CT for transcatheter aortic valve implantation (TAVI) planning can quantify interstitial fibrosis as extracellular volume fraction (ECV), associated with a worse prognosis. Also the echocardiographic flow-gradient pattern (high-gradient [HG]; paradoxical low-flow [LF] low-gradient [LG], and classical LFLG AS) is associated with prognosis, with classical LFLG having the worst. Thus, we aimed to investigate the incremental prognostic value of ECV over flow-gradient pattern.
Methods or Background: Single-center prospective observational study. Consecutive patients undergoing TAVI (October 2020-November 2023) were enrolled and categorized as HG, paradoxical or classical LFLG AS. ECV was calculated from a 5-minute delayed scan. After a follow-up of at least 1 year, a composite endpoint of death or heart failure hospitalization was collected.
Results or Findings: In the final population of 460 patients (82 [77-85] years), 83% had HG AS, 8.0% paradoxical, and 8.9% classical LFLG AS. After a median follow-up of 468 days, patients with classical LFLG had a higher rate of events (39.0%) than paradoxical LFLG (29.7%), and HG (15.6%) (p=0.004) and a higher ECV (32.0% [27.3-34.9] vs 28.0% [25.2-31.2] vs 28.0% [26.2-33.0], respectively; p=0.001). On Kaplan-Meier analysis, the combination of flow-gradient pattern and ECV distinguished distinct risk profiles: patients with classical LG-LF AS and a high ECV had the worst prognosis (p<0.001). The improved risk stratification capability of ECV was confirmed with the likelihood ratio test (p=0.019) and the net reclassification index (0.3).
Conclusion: ECV derived from pre-procedural TAVI planning has an incremental prognostic value over echocardiographic flow-gradient pattern.
Limitations: Relatively small sample size; ECV assessed with a single manual ROI with a single-energy CT method; absence of a standard of reference to detect cardiac amyloidosis (to reduce this bias, we excluded patients with an ECV >40%).
Funding for this study: This study was partially granted by: European Union - Next Generation EU, Mission 4 Component 1, CUP D53D23021100001", Bando PRIN PNRR 2022 (P2022JBKN2), Italian Ministry of University and Research (MUR).

Dynamic MR Sialography with Lemon Juice Stimulation: A Non-Invasive Functional Imaging Biomarker for Sjögren's Syndrome (6 min)
Ashraf Ahmed Basheer Ahmed; Melmaruvathur / India

Author Block: A. A. Basheer Ahmed[1], F. Abubacker Sulaiman[2], R. Praveenkumar[2], D. Velan[2], J. Lydia[2], P. K. Anbazhagan[2]; [1]Melmaruvathur/IN, [2]Chennai/IN
Purpose: To evaluate the diagnostic potential of dynamic MR sialography following lemon juice stimulation as a non-invasive, functional biomarker for detecting early salivary gland involvement in Sjögren's syndrome.

The objective was to assess both morphological and secretory changes of major salivary glands and to correlate these imaging findings with serological and clinical parameters.
Methods or Background: A prospective observational study was conducted on 40 participants—20 with clinically confirmed Sjögren's syndrome (based on ACR/EULAR criteria) and 20 healthy controls. Imaging was performed using 3T MRI with high-resolution, heavily T2-weighted 3D MR sialography sequences (SPACE/DRIVE technique). Each subject received 5 mL of freshly squeezed lemon juice orally to stimulate salivary flow. Sequential scans were acquired at baseline, 3 minutes, and 10 minutes post-stimulation.

Quantitative evaluation included ductal visualization grading, glandular parenchymal signal intensity, and dynamic excretory flow assessment. All results were correlated with Schirmer's test, unstimulated salivary flow rate, and anti-Ro/La antibody positivity.
Results or Findings: Healthy subjects showed a prompt increase in ductal visualization and salivary excretion following stimulation, while Sjögren's patients exhibited reduced or delayed flow, ductal beading, and glandular atrophy. Combined dynamic and structural parameters achieved superior diagnostic accuracy (AUC = 0.93) compared to conventional morphological imaging alone.

The technique demonstrated high interobserver reproducibility and excellent gland-to-duct contrast resolution.
Conclusion: Lemon juice–stimulated MR sialography represents a promising, radiation-free, and functionally dynamic imaging modality for early detection and grading of Sjögren's syndrome, offering a potential alternative to invasive diagnostic techniques such as parotid sialography or labial gland biopsy.
Limitations: The study was limited by a relatively small cohort size, absence of histopathological validation in all cases, and interindividual variability in lemon-induced stimulation response. Larger multicenter studies with standardized stimulation protocols are warranted to establish reproducibility and optimize diagnostic thresholds.

Radiological features of recurrent adenoid cystic carcinoma (ACC) of the head and neck following carbon ion radiotherapy (6 min)
Lorena Levante; Squinzano / Italy

Author Block: L. Levante[1], C. Fichera[2], G. Fontana[1], V. Dolcetti[1], J. Fragomene[1], B. Vischioni[1], E. Orlandi[1], L. Preda[1], S. Imparato[1]; [1]Pavia/IT, [2]Lodi/IT
Purpose: To identify early radiological features of recurrent adenoid cystic carcinoma (ACC) of the head and neck after carbon ion radiotherapy (CIRT).
Methods or Background: Radiological features (shape, margins, mass effect, contrast enhancement, DWI, mean ADC on ROI, necrosis, side relative to treated area, location relative to initial tumor volume, growth trend, T2 and T1 signal) were retrospectively analyzed in 51 patients with recurrent ACC treated with CIRT between 2013 and 2022 at CNAO. The same variables were assessed in 51 patients without recurrence (control group). In recurrent cases, imaging was evaluated at three time points (t.p.): 6 months after treatment (t.p.0), 6 months before recurrence (t.p.1), and at recurrence (t.p.2). For controls, t.p.2 corresponded to the mean recurrence time of the other group (34 months). ΔADC values across time points were also calculated in both groups.
Results or Findings: Compared with controls, recurrent ACC exhibited significantly more frequent features ($p<0.001$), including rounded or lobulated shape, mass effect, homogeneous enhancement, mean ADC of 1098 mm^2/s, ΔADC of –460 mm^2/s, progressive growth, peripheral localization, and intermediate T2 signal. At t.p.1, these characteristics were already comparable to those observed at t.p.2, except for mean ADC, which showed a progressive reduction, and ΔADC, which had already increased compared with t.p.0 (1306 and –250 mm^2/s, respectively). A reproducible radiological pattern of recurrent ACC after CIRT was identified, with some features being objectively quantifiable, particularly ΔADC, a parameter scarcely investigated to date.
Conclusion: This preliminary study outlines the main radiological features of ACC recurrence after CIRT and provides a basis for developing response criteria related to salivary gland tumors of the head and neck treated with particle therapy.
Limitations: This is a single-center study

Elastography and Doppler ultrasound synergy in the diagnosis of major salivary gland lesions (6 min)

Noha Mohamed Ali Attia; Mansfield / United Kingdom

Author Block: N. M. A. Attia, R. R. Ayoub, S. A. E-A. Sayed; Assiut/EG
Purpose: To investigate the accuracy of combining Doppler ultrasound and elastography in the differentiation between benign and malignant salivary gland lesions.
Methods or Background: A prospective study which included 34 patients who attended the outpatient clinics with suspected parotid or submandibular gland lesions. Doppler Ultrasound and elastography features were recorded. Fine needle aspiration cytology or core biopsies were taken. Doppler ultrasound was used to assess lesion vascularity. On elastography, the mean shear moduli, elasticity score and the strain ratio were measured.
Results or Findings: Out of 34 studied cases; seven cases (20.6%) were histologically proven to be malignant and 27 (79.4%) were benign. On Doppler ultrasound, benign lesions showed mild-to-moderate internal vascularity while malignant lesions showed no or mild vascularity with P-value= 0.026. The mean shear moduli were significantly higher in malignant lesions compared to benign lesions [median (range) was 140 kPa (115 – 178) vs. 54 kPa (5.4 – 188.0), P=0.001] respectively. At a cut-off value of ≥ 115 kPa, the sensitivity was 94.0%, specificity 85.2%, and accuracy 88.2% with area under the ROC curve 89.9% (95%CI: 0.794 – 1.0, P=0.001). The elasticity score was three and four in malignant lesions and below three in benign lesions ($P<0.001$). The strain ratio was significantly higher in malignant lesions compared to benign lesion [median (range) was 2.9 (0.8 – 3.9) vs. 0.4 (0.1 – 3.6), $P<0.001$] respectively. At a cut-off value of ≥ 2.1; the sensitivity was 85.7%, specificity 92.6%, and accuracy 91.2% with area under the ROC curve 92.1% (95%CI: 0.816 – 1.0, P=0.001).
Conclusion: Utilizing shear wave elastography, elasticity score and strain ratio in combination with Doppler ultrasound increases the accuracy in diagnosing major salivary gland lesions.
Limitations: The sample size was relatively small.

Diagnostic Value of Shear Wave Elastography and Multiparametric MRI in The Diagnosis of Parotid Tumors (6 min)

Chiara Zito; Palermo / Italy

Author Block: C. Zito, R. Cannella, V. Pampalone, F. A. Cordaro, F. Pandolfo, A. Lo Casto; Palermo/IT
Purpose: This study aims to evaluate the diagnostic accuracy of shear wave elastography (SWE) and multiparametric MRI in differentiating benign from malignant parotid gland lesions, based on quantitative assessment of tissue stiffness and perfusion parameters.
Methods or Background: From October 2022 to September 2025, 47 patients (24 females, 23 males; age range 15–85 years) presenting with 53 parotid lesions (size range 8–60 mm) were prospectively evaluated at our Department of Radiological Sciences. Each patient underwent ultrasound with SWE using a 5–14 MHz linear probe. Regions of interest (ROI) were sampled multiple times per lesion (10 measurements each). Additionally, all patients underwent 3-Tesla MRI with dynamic contrast-enhanced sequences. MRI curve patterns were classified based on parameters including peak signal intensity, time to peak (T-peak), wash-in, and wash-out rates. Surgical excision and histopathological analysis were performed for definitive diagnosis.
Results or Findings: A total of 35 parotid lesions underwent histopathological analysis, of which 26 were benign (including 10 cystadenolymphomas and 9 pleomorphic adenomas) and 9 were malignant. Malignant lesions were significantly larger than benign ones (median size: 31 mm vs. 20 mm; p = 0.013). The median SWE values were 40.6 kPa in malignant lesions and 37.5 kPa in benign lesions, with no significant difference (p=0.437). On dynamic contrast-enhanced MRI, the brevity of enhancement showed a tendency toward statistical significance (median values: 88.3 in malignant vs. 49.2 in benign lesions; p = 0.078).
Conclusion: Parotid tumors demonstrated overlapping stiffness values on SWE. However, dynamic contrast-enhanced MRI revealed a trend toward significant differences, suggesting potential value in differentiating malignant from benign lesions.
Limitations: Single-center study. Small number of included patients.

Quantitative and Histogram-Based MRI Metrics of Salivary Glands in Sjögren's Syndrome (6 min)

Zeynep Nazli Doghramachi; Ankara / Turkey

Author Block: Z. N. Doghramachi, T. Cankurtaran, M. ALIYEV, T. Yıldırım, A. Isik, G. Kahraman, C. S. Oygur, D. KALEMCİ, O. Kayık, A. Beheshtırooy; Ankara/TR
Purpose: To investigate structural and diffusion-related heterogeneity in salivary glands of Sjögren patients using quantitative MRI and histogram-derived parameters.
Methods or Background: Fifty-six participants (26 with Sjögren's syndrome, 30 controls; mean age 47 years) underwent MRI of parotid and submandibular glands. Volumetric measurements, inter-rater agreement for Kojima and Makula grading, and quantitative metrics (T1 mapping, ADC, fat fraction, R2*) were assessed. Histogram analyses were performed with dedicated software and included mean, standard deviation, interquartile range (IQR), robust mean absolute deviation (rMAD), root mean square (RMS), entropy, skewness, and kurtosis. Group comparisons were performed.
Results or Findings: Salivary gland volumes were reduced in Sjögren patients ($p<0.05$). Inter-rater reliability was high for Kojima grading and moderate for Makula. In parotid glands, mean T1 values tended to be higher without significance ($p=0.085$), while entropy, IQR, rMAD, and SD were significantly elevated (all $p<0.05$); skewness and kurtosis showed no differences. Parotid glands ADC metrics (mean, RMS, rMAD, SD) were also higher in Sjögren (all $p<0.05$), whereas submandibular glands showed no significant differences. Fat fraction and R2* values were comparable between groups.
Conclusion: Sjögren's syndrome is associated with increased parotid gland heterogeneity in both T1 and ADC histogram metrics, while fat and R2* values remain unchanged. Histogram-derived MRI metrics may provide non-invasive biomarkers for salivary gland involvement.
Limitations: Single-center cohort with a moderate sample size; voxel-based or whole-gland segmentation was not performed.
Funding for this study: Funding was provided by Siemens Healthineers, Erlangen, Germany.

Ethics committee - additional information: The study was approved by Baskent University Institutional Review Board and Ethics Committee. (reference number KA22/180).

Diffusion MRI Assessment of Salivary Glands Following Vitamin C Administration in Healthy Subjects (6 min)

Atakan Isik; Ankara / Turkey

Author Block: A. Isik, T. Cankurtaran, D. KALEMCİ, C. S. Oygur, M. ALIYEV; Ankara/TR
Purpose: To investigate the effect of vitamin C on salivary glands using diffusion-weighted MRI with the IVIM technique.
Methods or Background: Thirty healthy control participants (mean age: 48 years) were evaluated using diffusion-weighted MRI with multiple b-values for IVIM analysis of the submandibular and parotid glands. A custom-built graphical user interface, developed by Atakan Işık (Başkent University, Department of Biomedical Engineering), was employed for IVIM parameter calculation and participant assessment. IVIM images were acquired once before vitamin C administration and three times afterwards. Four different fitting approaches were implemented in the application: free fitting, segmented fitting, Bayesian fitting, and tri-exponential fitting. The null hypothesis assumed that measurements across all time points would not show significant changes.
Results or Findings: For the parotid gland, the perfusion fraction of the fast compartment measured with segmented and Bayesian fitting methods rejected the null hypothesis. In addition, the fast compartment perfusion fraction obtained with tri-exponential fitting also rejected the null hypothesis. However, all other parameters showed no evidence of significant changes ($p < 0.005$). For the submandibular gland, only the fast compartment of tri-exponential diffusion and the pseudo-diffusion coefficient derived from Bayesian inference rejected the null hypothesis ($p < 0.005$).
Conclusion: Although the sample size should be increased, our findings demonstrate that IVIM can reveal measurable effects of vitamin C on both salivary gland regions. However, the lack of significant changes in other parameters suggests that further studies with larger cohorts are warranted to confirm these observations.
Limitations: Low number of cohort. High noise due to nature of IVIM images that makes selection of glands harder than usual,voxel-wise measurement not performed
Funding for this study: Funding was provided by Siemens Healthineers, Erlangen, Germany.

Magnetic Resonance Radiomics Analysis for Differentiating Parotid Neoplasms: A Two-Center Study (6 min)

Weiwei Deng; Shanghai / China

Author Block: B. Wen[1], Z. Zhang[1], Y. Zhang[1], D. Zheng[2], H. Cui[3]; [1]Zhengzhou/CN, [2]Beijing/CN, [3]Hangzhou/CN
Purpose: To establish and validate MR-based radiomics models for differentiating benign from malignant parotid tumors (BT vs MT), and pleomorphic adenomas (PA) from Warthin tumors (WT).
Methods or Background: This two-center study included 200 patients (BT=133 [PA=87, WT=46], MT=67). Radiomics features were extracted from T1WI, fs-T2WI, and fs-CE-T1WI, reduced with Pearson correlation, and used to build machine learning models. A clinical model was developed from demographics and MR features. Fused models combining radiomics and clinical variables were evaluated by ROC and decision curve analysis.
Results or Findings: Radiomics and fused models showed robust diagnostic performance. For BT vs MT, AUCs reached 88.3% (validation) and 86.5% (external test). For PA vs WT, AUCs reached 98.7% and 91.4%, respectively. Clinical models showed lower accuracy. Fused models provided greater clinical benefit than radiomics or clinical models alone.
Conclusion: Fused models integrating radiomics and clinical features achieved high accuracy in differentiating BT from MT and PA from WT, and may support preoperative decision-making.
Limitations: Limited external validation; larger multicenter studies are warranted.

MRI findings affecting the time to return to play (RTP) and re-injury rate with the potential role of artificial intelligence (AI) in most common thigh muscle injuries in professional football players (6 min)
Sherif Mohyeldin Elhennawy; Cairo / Egypt

Author Block: S. M. Elhennawy, Y. A. A. E. F. Hassan; Cairo/EG
Purpose: Evaluate predictive value of MRI-based BAMIC & MLG-R classification systems for RTP time and re-injury risk with thigh muscle injuries in professional football players with the potential enhancement of AI integration.
Methods or Background: Retrospective study on 48 professional football players with recent thigh muscle injuries in biceps femoris, adductor longus and rectus femoris muscles between 2018 and 2024. Two professional MSK radiologists independently classified injuries.. Statistical analysis included Pearson correlation, ROC analysis, inter-rater reliability (κ), and others. AI model was trained to predict time to RTP and re-injury rate
Results or Findings: BAMIC showed strong correlation with RTP time (r = 0.72) and good predictive accuracy (AUC = 0.81,). MLG-R also demonstrated high correlation (r = 0.66) with AUC = 0.77. Anatomical location significantly impacted outcomes: biceps femoris distal myotendinous T-junction injuries showed longest RTP time and highest re-injury rate (37.5%). Length of injury and intermuscular fluid also showed prolonged RTP. Combined classification model improved correlation to r = 0.76 with AUC = 0.84. AI based model achieved cross-validation accuracy of 79.2% with improved correlation (r = 0.79, AUC = 0.87).
Conclusion: BAMIC and MLG-R classification systems demonstrate good-to-strong predictive value for RTP timing in professional football thigh muscle injuries. Specific anatomical injury locations significantly influence recovery outcomes. Other MRI parameters including cranio-caudal length and intermuscular fluid volume provide additional prognostic value. AI-enhanced models incorporating anatomical and quantitative factors achieve superior predictive accuracy
Limitations: Retrospective design with inherent selection bias. Limited sample size (n=48) may affect statistical power and generalizability. Study limited to Egyptian and Gulf region professional football players, potentially affecting generalizability to other sports. Machine learning model requires external validation in larger independent cohorts. Rehabilitation protocols varied between clubs, introducing potential confounding variables
Funding for this study: Saudi German Hospital and Paxera-health

MRI-based predictive modelling for estimating anterior cruciate ligament injury timing (6 min)
Alessio Piacentini; Milan / Italy

Author Block: A. Piacentini, K. Abdelmaguid, S. Gitto, S. Fusco, C. Messina, F. Ambrogi, A. Vanzulli, L. M. Sconfienza, D. Albano; Milan/IT
Purpose: Accurate estimation of anterior cruciate ligament (ACL) tear timing is essential for clinical and medico-legal purposes. We aimed to identify MRI parameters linked to lesion chronological age and develop a logistic-regression model to distinguish acute (≤12 weeks) from chronic (>12 weeks) injuries.
Methods or Background: This retrospective study included 426 patients with clinically and MRI-confirmed ACL tears (2014–2024). MRI (1.5/3 T) assessed 11 direct and indirect signs including bone oedema, effusion, tear morphology, ACL atrophy, ACL thinning, "wavy" morphology, anterior tibial translation, angulated posterior cruciate ligament and uncovered lateral meniscus. Firth-penalized logistic regression predicted injury timing; discrimination was assessed by AUC with bootstrap validation (n=200) and a simplified rule-based score was developed for clinical use.
Results or Findings: Among the 426 patients (mean age 35±14 years; 71% male), 261 had acute tears, 73 sub-acute, and 92 chronic. The regression model achieved excellent discrimination between recent and chronic tears with AUC 0.97 (bias-corrected 0.96); at the optimal Youden-index threshold (0.56) it yielded 96% sensitivity, 96% specificity, 96% accuracy, and PPV 0.99. Key discriminators of chronicity were ACL atrophy, thinning, and inhomogeneous thickening. The simplified algorithm–requiring either all major (atrophic ACL, thinned ACL, inhomogeneous thickening of the ACL) or ≥5 minor criteria (bone edema, effusion, uncovered lateral meniscus, full thickness tear with fibers edema, absent wavy ligament, absent anterior tibial translation)–retained high performance (sensitivity 94–96%, specificity 95–96%), closely mirroring the full model.
Conclusion: MRI-based multifeatured analysis accurately distinguishes acute from chronic ACL tears. The simplified rule-based model retains high diagnostic performance and it is practical for routine imaging and medico-legal timing of ACL injuries.
Limitations: Single-center retrospective design; exclusion of clinical variables (age, mechanism of injury) may limit generalizability; the model yields probability estimates rather than a definitive diagnosis.
Funding for this study: No funding received.

Evaluating the Clinical Impact of Radiologist Reporting in AI-Positive Skeletal Radiographs: A Retrospective Single-Site Quality Study (6 min)

Ramprabananth Sivanandan; Asker / Norway

Author Block: R. Sivanandan[1], L. Tveiten[2], A. J. Fagerlund[3], K. Malm-Nicolaisen[3], B. A. Graff[2]; [1]Asker/NO, [2]Drammen/NO, [3]OSLO/NO
Purpose: To evaluate the therapeutic impact and clinical relevance of radiologist reporting on AI-positive fracture detections in trauma patients, within a workflow where orthopedists often initiate treatment prior to radiologist review.
Methods or Background: This retrospective, single-center study was conducted over two months following the implementation of an AI algorithm for fracture detection in trauma care. Of 2,394 consecutive skeletal radiographs reviewed, 1,127 (47%) AI-positive cases were included and detailed analysis on fracture cases performed. Data collected include patient demographics, fracure type, AI-report, radiologist's-report, musculoskeletal-radiologists (MSKr) report and orthopedist's-report . Discordant cases between AI alone and AI+radiologist interpretations were analyzed for therapeutic impact with orthopedists and MSKr as ground truth.
Results or Findings: In AI-positive cases, concordance between AI and radiologist reports for fractures was high (97%) and discordance was noticed in 3% (20 cases). Of the 20 discordant cases, the MSK radiologists agreed with AI in 3 cases (15%) and disagreed in 17 (85%). The orthopedists with AI in 6 cases (30%), disagreed in 12 (60%), and was uncertain in 2 cases (10%). Ground truth was defined by the orthopedist's assessment, with the MSKr used to resolve the 2 uncertain cases. False-positive AI results led to 1 over-treatment, 1 under-treatment while others received adequate necessary treatment (Fig-4).
Conclusion: In an AI-supported workflow for fracture detection, therapeutic decisions were primarily driven by orthopedists integrating AI with their clinical judgment. Our findings suggest that adding radiologist input to AI may not significantly improve accuracy in discordant cases, whereas an AI+orthopedits approach appears more clinically relevant and efficient—allowing radiologists to focus on complex, high-impact tasks.
Limitations: This is a single-site retrospective study and may be feasible when orthopedists assess the radiographs with AI as part of routine clinical care.

Ankle Injuries with Deltoid Complex Involvement: MRI findings and Association with Fascial Sleeve and Retinaculum Tears (6 min)

Stefano Fusco; Milan / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: S. Fusco[1], L. Cerezal Pesquera[2], A. M. Perez[3], F. Idoate[4], L. M. Sconfienza[1], E. Llopis San Juan[5]; [1]Milan/IT, [2]Santander/ES, [3]Terrassa/ES, [4]Pamplona/ES, [5]Alzira/ES
Purpose: To describe MRI findings associated with ankle injuries involving the deltoid complex, with focus on fascial sleeve avulsion of the medial malleolus and periosteal stripping of the flexor retinaculum, and to assess their relationship with injury timing.
Methods or Background: Two musculoskeletal radiologists retrospectively evaluated 165 ankle MRIs with deltoid complex injury. Each study was reviewed for: superficial and deep deltoid tears, fascial sleeve avulsion, flexor retinaculum stripping, lateral ligaments and syndesmotic tears, osteochondral lesions(OCLs), soft tissue impingement, pathology of the posterior tibial tendon(PTT), and peroneal tendons. Injuries were classified as acute, chronic, or acute-on-chronic. Descriptive statistics and chi-square tests were used.
Results or Findings: Deep deltoid tears were present in 160/165 cases. Superficial deltoid proximal tear was seen in 84/165(50.9%). Fascial sleeve avulsion occurred in 74/165(44.8%), and flexor retinaculum stripping in 66/165(40.0%); both coexisted as “complete fascial sleeve” in 55/165(33.3%). These lesions were associated with superficial deltoid proximal tears (fascial sleeve in 88.1% vs 0%; retinaculum stripping in 66.7% vs 12.3%; complete fascial sleeve in 65.5% vs 0%; $p<0.0001$). The prevalence of complete fascial sleeve increased with chronicity, being less common in acute (25.4%) and more frequent in chronic (45.2%) and acute-on-chronic injuries (64.1%) ($p<0.001$). Isolated deltoid injuries were rare: >95% also had lateral ligament tears. Additional findings included syndesmotic injuries (9%), OCLs (15%), soft tissue impingement (24%), PTT abnormalities (27%), and peroneal pathology (28%).
Conclusion: Deltoid complex injuries are rarely isolated and usually coexist with lateral ligament tears. Fascial sleeve avulsion and retinacular stripping—especially in combination—are closely associated with proximal superficial deltoid tears, likely functioning as a biomechanical unit. These findings are more common in chronic injuries, reflecting their link to chronic lateral ankle instability.
Limitations: Retrospective; lack of surgical correlation; lack of long-term outcomes

Virtual arthroscopic imaging: validation of a low-field rotating MRI harnessing the magic angle effect in the investigation of suspected anterior cruciate ligament rupture (6 min)

Dimitri Amiras; London / United Kingdom

Author Block: D. Amiras, K. Chappell, C. Tsitsifylla, H. Lanz, Y. Joshi, J. Mcginley, C. Gupte, M. Ristic; London/UK
Purpose: A novel rotating low-field MRI can harness the magic angle effect to identify collagen fibre alignment and orientation in vivo. Typically, imaging collagen fibres relies on negative contrast, caused by adjacent water or haemorrhage, to depict injuries, as collagen produces inherently low signal on most MR techniques. In this study, we utilise magic angle directional imaging (MADI) to image the anterior cruciate ligament (ACL) in patients being investigated for ACL tears and correlate the findings with surgical outcomes.
Methods or Background: A novel 0.15T rotating transverse magnet allowed reorientation of the main B0 field. Seven to eight 3D T1 FLASH isotropic volumes at different B0 orientations, relative to the projected orientation of the ACL, were acquired. In post-processing, co-registration of these volumes was performed, and collagen fibre vectors were calculated for regions of interest corresponding to the ACL. These vectors were then visualised as tractograms superimposed on the previously acquired volume. Conventional MRI and magic angle MR images (MAMRI) were compared to arthroscopic findings.
Results or Findings: Five cases from four patients were compared with arthroscopic findings. Three cases had complete ACL tears, whereas one case had a 'cyclops' lesion post-ACL reconstruction, and the same patient had an old partial ACL tear on their contralateral knee. MAMRI performed at least as well as conventional MRI and, in one case, correctly predicted a complete tear when conventional MRI suggested a partial-thickness tear.
Conclusion: This is the first report demonstrating the clinical applicability of low-field magic angle MRI in the assessment of ACL tears in an injured population. Whilst only five cases had surgical correlation, the images obtained were promising and revealed detail not previously visible on conventional MRI.
Limitations: Limited sample size; Arthroscopic subjectivity; Limited data on MAMRI interpretation

Frequent musculoskeletal MRI findings in pre-signing medical assessments of professional soccer players (6 min)

Elena Höhne; Frankfurt / Germany

Author Block: E. Höhne, S. Mahmoudi, T. Vogl, K. Eichler, C. Booz, I. Yel; Frankfurt/DE
Purpose: Prior to player transfers professional soccer clubs conduct comprehensive musculoskeletal assessments in healthy athletes to evaluate their current condition and injury risk. Magnetic resonance imaging (MRI) plays a central role in this process by detecting musculoskeletal abnormalities even in the absence of symptoms. This study presents common MRI findings in a cohort of professional soccer players and aims to improve understanding of the physical condition of elite athletes.
Methods or Background: In this retrospective analysis, 3T MRI examinations performed between August 2019 and March 2025 during pre-signing assessments were reviewed. Clinical data were extracted from medical records and supplemented with functional information. Non-age-typical structural alterations were systematically categorized, and prevalence patterns were analyzed by playing position.
Results or Findings: Fifty professional players (mean age 25.4 ± 4.7 years) were included. Secondary cleft signs (42%) and lumbar disc bulging (40%) were the most frequent abnormalities. Additional common findings comprised knee chondropathy (34%), acetabular labral degeneration (26%), femoroacetabular impingement (22%), and various soft tissue or bone-related changes. While most abnormalities were evenly distributed across positions, the prevalence of secondary clefts differed significantly ($\chi^2 = 8.07$, $p = 0.045$), with strikers showing the highest proportion (69%).
Conclusion: MRI screening in professional soccer players most frequently revealed structural musculoskeletal abnormalities, many of which were also present in asymptomatic individuals. This underscores the ability of MRI to detect subclinical alterations that may later develop into clinically relevant conditions. Overall, the findings support routine use of MRI in pre-signing assessments to guide individualized prevention, rehabilitation, and long-term player management.
Limitations: The relatively small sample size, absence of a control group, and uneven distribution of playing positions and limb dominance may limit the generalizability of these findings.

Exercise-related signal abnormalities (ERSA) in Lower Limb MRI of Athletes: Prevalence, Patterns, and Symptom Correlation (6 min)

Stefano Fusco; Milan / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: S. Fusco[1], F. Idoate[2], L. Cerezal Pesquera[3], A. M. Perez[4], L. M. Sconfienza[1], E. Llopis San Juan[5]; [1]Milan/IT, [2]Pamplona/ES, [3]Santander/ES, [4]Terrassa/ES, [5]Alzira/ES
Purpose: To describe the prevalence, distribution, and clinical associations of exercise-related signal abnormalities (ERSA) in lower limb MRI of athletes, and to assess their relationship with symptoms and concomitant muscle injuries.
Methods or Background: One musculoskeletal radiologist reviewed lower limb MRI of professional and non-professional athletes performed for suspected muscle injury or follow-up, to identify ERSA lesions (ovoid peritendinous and/or ring-shaped perifascial edema).
For each MRI, the following parameters were assessed: ERSA type (A/B/C), muscle(s) involved, longitudinal distribution, laterality, relationship to the clinically targeted compartment (site of suspected/ongoing injury).
Correlation with reported pain and with acute, subacute, or chronic lesions/scar was assessed. Descriptive statistics and Fisher's exact/Chi-square tests were used.
Results or Findings: ERSA lesions were found in 30 athletes (mean age 26.7 years; 27 male; 21 soccer players), involving a single muscle in 19/30 (63.3%), two in 8/30 (26.7%), and ≥3 in 3/30 (10.0%). Subtypes included type B in 15(50.0%), type C in 13(43.3%), and type A in 2(6.7%). The rectus femoris was most frequently affected(n=12), followed by soleus, vastus lateralis, and adductor major (n=4). Pain in the ERSA compartment was present in 20/30(66.7%). In 12, pain was explained by concomitant acute/subacute injuries, while in 8 it occurred with isolated ERSA. Conversely, 10/30 showed ERSA in non-target compartments without pain.
No significant association was found between pain and ERSA subtype(p=0.099).
Conclusion: ERSA are a relatively frequent MRI finding in athletes investigated for suspected muscle injury. Our data suggest a mixed picture: ERSA may explain pain in the absence of associated muscle injuries but are also frequently found in asymptomatic compartments. Prospective studies are needed to clarify their clinical relevance or determine whether they represent overload-related changes.
Limitations: Retrospective design; relatively small sample size; lack of prospective symptom monitoring

Comparative Analysis of Deep Learning-Based Reconstruction and Hybrid Iterative Reconstruction in Ultra-Low-Dose Ankle and Foot CT Imaging (6 min)

Chuluunbaatar Otgonbaatar; Seoul / Korea, Republic of

Author Block: C. Otgonbaatar[1], S. Cha[2], S. H. Jeon[2], H. Shim[1], S. M. Ko[2], H. Kim[2]; [1]Seoul/KR, [2]Wonju-si/KR
Purpose: This study aimed to evaluate the quantitative and qualitative image analysis of ultra-low-dose CT with deep learning image reconstruction (DLR) compared with hybrid iterative reconstruction (IR) in patients with ankle and foot fractures.
Methods or Background: This retrospective study included 32 patients who underwent ultra-low-dose CT of the ankle and foot (effective dose ~0.86 µSv). Images were reconstructed with DLR and hybrid IR. Objective analysis included image noise, SNR, CNR, and sharpness (assessed with a no-reference perceptual sharpness metric). Subjective quality was rated by two board-certified radiologists on a 5-point scale.
Results or Findings: DLR demonstrated clear advantages over hybrid IR, with substantially lower image noise (47.33 ± 6.60 HU vs. 87.65 ± 12.48 HU) and significantly higher SNR (31.42 ± 5.81 vs. 19.15 ± 4.48) and CNR (50.59 ± 7.62 vs. 24.08 ± 3.81) (all $p < 0.001$). Image sharpness was also enhanced (0.76 ± 0.09 for DLR vs. 0.59 ± 0.09 for hybrid IR, $p < 0.001$). Subjective evaluations confirmed the superiority of DLR, with improved ratings for overall image quality, trabecular architecture, cortical bone delineation, and fracture depiction (all $p = 0.001$).
Conclusion: Ultra-low-dose CT reconstructed with DLR improves image quality while maintaining minimal radiation exposure in the assessment of ankle and foot fractures.
Limitations: Not applicable

ChatGPT as a diagnostic support tool in the preoperative MRI evaluation of ACL tears: a semi-quantitative and surgical validation study (6 min)

Abdullah Şükün; Antalya / Turkey

Author Block: A. Şükün[1], C. Özenbaş[2], B. Sargın[1], K. Gökkuş[1], M. Ş. Sahin[1]; [1]Antalya/TR, [2]Izmir/TR
Purpose: To assess the diagnostic accuracy of a semi-quantitative signal scoring system for anterior cruciate ligament (ACL) tears on preoperative 1.5T knee MRI, and to compare the performance of conventional radiology reports with ChatGPT-based scoring, using arthroscopic findings as the reference standard.
Methods or Background: This retrospective single-center study received institutional review board approval (KA25/133, March 26, 2025). Between 2012 and 2024, 185 patients undergoing arthroscopic ACL surgery were screened. Exclusion criteria were the absence of preoperative MRI, poor image quality, or missing PACS data. After applying the criteria, 100 patients with surgically confirmed ACL rupture were included. Sagittal T1- and PD-weighted sequences were anonymized and exported in JPEG format (300 dpi, 1350×1200 pixels). Three PD and three T1 sagittal slices best depicting the ACL were selected. Semi-quantitative scoring was applied exclusively to PD images by freehand ROI placement, classifying ACLs as intact (<2), partial (2–3.5), or complete (>3.5) on a four-point scale. T1 images were used for anatomical correlation. Scoring was performed independently by ChatGPT, with surgery as the gold standard.
Results or Findings: A total of 100 patients (86 males [86%], 14 females [14%]; mean age, 31.99 ± 9.25 years) underwent preoperative knee MRI and arthroscopic ACL surgery. All had surgically confirmed complete ACL tears. ChatGPT achieved 64% diagnostic accuracy, compared to 45% for radiology reports. The semi-quantitative scoring system with ChatGPT improved accuracy by ~20% versus conventional reporting.
Conclusion: ChatGPT-assisted semi-quantitative scoring significantly enhanced the accuracy of preoperative MRI in diagnosing ACL tears compared to routine radiology reporting, suggesting its potential as a supportive decision-making tool in clinical practice.
Limitations: The retrospective design, single-center cohort, and restriction to surgically confirmed complete tears limit generalizability. External validation with larger, multi-center, and prospective datasets is warranted.

Ultra-High Resolution Photon-Counting CTA for Follow-up Assessment of Intracranial Aneurysms after Flow Diverter: Initial Experience (6 min)
Naying He; Shanghai / China

Author Block: R. Li[1], N. He[1], Y. Cui[2], Z. Xu[1], H. Jiang[3], F. Yan[1], S. Haller[4]; [1]Shanghai/CN, [2]Nanjing/CN, [3]Shagnhai/CN, [4]Geneve/CH
Purpose: To evaluate the preliminary diagnostic performance and utility of UHR-PCCTA and standard resolution (SR) PCCTA compared to immediate post-deployment DSA following FD treatment, with emphasis on comprehensive characterization of post-FD follow-up.
Methods or Background: This prospective study consecutively enrolled 47 participants treated with FD and subsequently underwent PCCTA with UHR and SR reconstructions between August 2023 and August 2024. Two readers independently analyzed images blindly, including aneurysm size, occlusion status, neck coverage, wall apposition, stent deformation, branch vessel with Likert-scale (1-5). The inter-rater reliability for both UHR and SR-PCCTA was assessed using the intraclass correlation coefficient (ICC) and weighted Cohen's kappa. The diagnostic performance of PCCTA within 1 month after FD was compared with that of immediate post-deployment DSA using a confusion matrix.
Results or Findings: The study included 47 participants with 57 intracranial aneurysms treated with 51 FD stents. UHR-PCCTA exhibited higher diagnostic confidence (median=5, IQRs=5-5) compared to SR-PCCTA (median=4, IQRs=4-5, P<0.05). UHR-PCCTA demonstrated a trend toward higher inter-rater agreement (κ range:0.814-1.0; ICC range:0.902-0.960) relative to SR-PCCTA (κ range:0.668-1.0; ICC range:0.873-0.966) among both aneurysm size and stent morphology. Compared with immediate post-deployment DSA, UHR-PCCTA showed excellent diagnostic accuracy for aneurysm neck coverage (93.3%), wall apposition (100.0%), stent deformation (93.8%), and branch vessel inclusion (93.3%), along with very-good accuracy for aneurysm occlusion (88.2%).
Conclusion: UHR-PCCTA demonstrates high reliability and diagnostic accuracy in the assessment of intracranial aneurysms following FD treatment. Its comprehensive imaging evaluation capability has the potential to inform clinical decision-making.
Limitations: (1) relatively small sample size owing to the preliminary clinical nature; (2) potential changes during the ≤1-month interval between PCCTA and DSA, may affect accuracy assessments; (3) Whether the sub-stent hypodensity detected by UHR-PCCTA suggested neointima requires histopathological confirmation.
Funding for this study: No
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This prospective single-center study was approved by the local review board (KY2023-186) and written informed consent was obtained from all participants.

Quality improvements in ultra-high resolution photon counting detector CT-angiography of the cerebral vasculature with image acquisition at lower kVp and application of sharper reconstruction kernels (6 min)
Florentina Maria Egidius Pinckaers; Maastricht / Netherlands

Author Block: F. M. E. Pinckaers, T. Flohr, B. A. J. M. Wagemans, I. Huijberts, J. E. Wildberger, A. Postma; Maastricht/NL
Purpose: To assess quality improvements in ultra-high resolution (UHR) photon counting detector (PCD) CT angiography (CTA) of the cerebral vasculature when moving to image acquisition at lower kVp and image reconstruction with sharper kernels.
Methods or Background: Over a period of 25 months, all cerebral CTA imaging on PCD-CT was evaluated. Records were excluded in case of protocol deviations, severe motion artifacts or cerebral circulatory arrest. Using UHR resolution (0.2 mm), three protocols were evaluated: (1) 140 kVp/medium sharp kernel (Hv40); (2) 90 kVp/Hv40; (3) 90 kVp/very sharp kernel (Hv72). Vessel attenuation, signal-to-noise ratios (SNR) and contrast-to-noise ratios (CNR) were derived at four locations in the anterior circulation. Vessel sharpness was quantified using the edge rise distance and edge rise slope. Subjective assessments of image noise, vessel attenuation and vessel sharpness were performed by two experienced readers on a 5-point Likert scale.
Results or Findings: Out of 154 consecutive records, 141 (92%) were included. Vessel attenuation, SNR and CNR improved with image acquisition at 90 kVp compared to 140 kVp in the protocols using a medium sharp reconstruction kernel. SNR and CNR decreased when applying (very) sharp reconstruction kernels at 90 kVp due to an increase in noise. However, while an evident decrease in SNR and CNR was observed in smaller calibre vessels when using a medium sharp kernel at 90 kVp, these parameters remained relatively stable when using (very) sharp kernels. Vessel sharpness was markedly improved in the 90 kVp/(very) sharp kernel protocol. Subjective assessments of image quality also favoured the 90 kVp/(very) sharp kernel protocol.
Conclusion: Image quality of UHR PCD-CTA of the cerebral vasculature is improved with image acquisition at 90 kVp and image reconstruction with (very) sharp kernels.
Limitations: Single-centre, retrospective study.

Differentiation of Carotid Atherosclerotic Plaque Components Using Dual-Layer Spectral CTA (6 min)

Yu Wang; Shanghai / China

Author Block: F. Xu, Y. Wang, D. Mu; Shanghai/CN
Purpose: Carotid plaque composition is a major determinant of plaque vulnerability and thromboembolic stroke. This study investigated the performance of dual-layer spectral CT angiography (DLCTA) parameters to characterize carotid atherosclerotic plaques components, with high-resolution MRI (HR-MRI) or histopathology of postoperative specimens as reference standard.
Methods or Background: Fifteen patients with moderate-to-severe carotid bifurcation stenosis were prospectively enrolled. All patients underwent both DLCTA and HR-MRI, with findings correlated with histopathology in surgical cases. Plaque components including intraplaque hemorrhage (IPH), lipid-rich necrotic core (LRNC), fibrous tissue, and calcifications were identified on MRI or histopathology, and mapped to CTA using slice-to-slice coregistration. Quantitative parameters recorded included conventional CT (con-CT) values, virtual monoenergetic images (VMI, 40-140keV, 10-keV intervals), effective atomic number (Z-eff), and electron density (ED) . Diagnostic performance was evaluated by ROC analysis.
Results or Findings: A total of 42 slices and 164 ROIs were analyzed. Calcifications were clearly distinguished by conventional CT values, while non-calcified components (LRNC, IPH, and fibrous tissue) showed significant differences on VMI40keV and Z-eff (LRNC: 25.5 ± 16.1 HU, 7.19 ± 0.08; IPH: 122.3 ± 40.5 HU, 7.66 ± 0.43; fibrous tissue: 66.4 ± 20.8 HU, 7.40 ± 0.09; all $p < 0.001$). VMI40keV and Z-eff demonstrated the highest accuracy for differentiating LRNC from other non-calcified components (AUC 0.99, 95% CI 0.97–1.00 and 0.96, 0.83–1.00, respectively). For distinguishing IPH from fibrous tissue, AUC was 0.82 for VMI40keV.
Conclusion: DLCTA, particularly VMI40keV and Z-eff, enables noninvasive differentiation of carotid plaque components and may offer a practical alternative to contrast-enhanced MRI for identifying vulnerable carotid plaques, with potential implications for stroke risk stratification
Limitations: Study limited by small sample size and limited histopathologic confirmation.

Ultra-High-Resolution Photon-Counting CTA With Black Blood Technique for Carotid Plaque Characterization (6 min)

Zhonghui Li; Beijing / China

Author Block: Z. Li[1], X. Fan[1], M. Lyu[2], F. Feng[1]; [1]Beijing/CN, [2]Shanghai/CN
Purpose: To evaluate the feasibility and performance of photon-counting CT (PCCT) with black-blood technique for carotid plaque characterization, by comparing with vessel wall MRI (VW-MRI) and biphasic CT angiography (CTA).
Methods or Background: From January 2024 to May 2025, a total of twenty-five patients scheduled for carotid revascularization underwent CTA with arterial and delayed-phase using PCCT and eight patients voluntarily received vessel wall MRI (VW-MRI) within 2 weeks. Black-blood CT (BBCT) images was generated for each CTA phases. Totally 50 bilateral vessels were included for qualitative analysis between BBCT and biphasic CTA. And thirteen plaques were evaluated for quantitative analysis and plaque type classification. Qualitative scores (including calcified/non-calcified plaque visibility, diagnostic confidence, overall image quality) were independently assessed by two radiologists blindly using a 5-point scale between biphasic CTA and BBCT. Quantitative parameters (stenosis rate, plaque area, calcium area, non-calcium area) were compared between BBCT and VW-MRI using intraclass correlation coefficients (ICCs). Carotid Plaque-RADS evaluation was further applied in BBCT, biphasic CTA and VW-MRI.
Results or Findings: Compared with arterial and delayed images, BBCT achieved significantly higher scores in non-calcified plaque visibility, diagnostic confidence, and overall image quality (all $p < 0.001$). BBCT showed excellent agreement with VW-MRI, especially for non-calcified area (ICC = 0.96). Confusion matrix analysis illustrated that BBCT identified more high-risk plaques compared to biphasic CTA (such as intraplaque hemorrhage), and it exhibited strong concordance with VW-MRI.
Conclusion: BBCT enabled accurate carotid plaque quantification with excellent agreement to VW-MRI and outperforms biphasic CTA in image quality, diagnostic confidence, and high-risk plaque detection, suggesting its potential utility in stroke risk stratification when combined with Carotid Plaque-RADS.
Limitations: The number of carotid plaques with matched VW-MRI is small due to only single-center inclusion.
Funding for this study: None.

Normalization Strategies for Perfused Blood Volume Quantification in Photon-Counting CT of the Lung (6 min)

Anna M. Hunkemöller; Hannover / Germany

Author Block: A. M. Hunkemöller, K. Höffler, K. Katsirntaki, F. Wacker, B. Wiegmann, H-O. Shin; Hannover/DE
Purpose: Photon-counting CT (PCCT) inherently provides spectral data, enabling reconstruction of virtual non-contrast (VNC) and perfused blood volume (PBV) images. However, quantitative PBV assessment remains challenging due to variability in lung inflation and iodine concentration. This study systematically evaluated normalization strategies to improve PBV reproducibility across different inflation states, contrast concentrations, and acquisition conditions in an ex-vivo lung model.
Methods or Background: Five explanted porcine lungs were perfused and ventilated on the Organ Care System (OCS™) Lung platform under three standardized inflation states (inspiration, mid-inspiration, expiration) and two contrast concentrations. PCCT datasets were reconstructed into VNC and PBV images. After manual segmentation, three normalization approaches were applied: (1) normalization to an intravascular reference region (PBV_rel), (2) further normalization to total lung volume (PBV_lung), and (3) adjustment for lung tissue fraction derived from VNC attenuation (PBV_VNC). The dependence of PBV on inflation state was analyzed using repeated-measures ANOVA.
Results or Findings: Unnormalized PBV demonstrated significant dependence on lung inflation ($p = 0.0143$; SD = 5.00 HU). Normalization to an intravascular reference (PBV_rel) effectively mitigated this effect ($p = 0.9388$; SD = 0.13). PBV_lung retained minor residual variation ($p = 0.0292$; SD = 0.11), while PBV_VNC yielded the most consistent results across inflation states ($p = 0.0825$; SD = 0.08), indicating superior robustness and reduced variability.
Conclusion: PBV quantification in PCCT is strongly affected by lung inflation and iodine concentration. Normalization substantially enhances measurement stability, with VNC-based tissue fraction adjustment (PBV_VNC) providing the most reliable and inflation-independent standardization for quantitative pulmonary perfusion assessment.
Limitations: This ex-vivo study employed a small sample size and controlled ventilation conditions, which may limit direct translation to in-vivo applications.
Funding for this study: No funding.

Direct Comparison of Photon counting-CT and Conventional CT in Evaluation of Coronary Stents: a Systematic Review and Meta-Analysis of Anthropomorphic Studies (6 min)

Saeed Mohammadzadeh; Tehran / Iran

Author Block: S. Mohammadzadeh, I. Kiani, H. Ghorani, M. Saeed, I. Razeghian; Tehran/IR
Purpose: To evaluate and compare coronary stent imaging parameters using photon-counting computed tomography (PC-CT) and conventional energy-integrating detector computed tomography (EID-CT).
Methods or Background: Protocol pre-registration was performed a priori at PROSPERO (CRD42025642922). We searched PubMed, Web of Science, Embase, and Cochrane Library for studies until December, 2024. Risk of bias was assessed using Quality Assessment of Diagnostic Accuracy Studies-Comparison (QUADAS-C). The imaging modalities were compared with Likert scores of image quality, image noise, and stent diameter using random effects pooling method.
Results or Findings: A total of 10 studies were included with 110 coronary stents. The PC-CT had a significantly higher pooled Likert score of 1.29 (95% CI = 0.41 to 2.17, p-value = 0.004) than EID-CT, indicating its higher image quality. Also, it demonstrated a pooled 18.5% (95% CI = 3.5% to 36.6%, p-value = 0.015), reduction in image noise in comparison to EID–CT. As for stent diameter assessment, the PC-CT revealed a pooled 17.4% (95% CI = 1.9% to 32.8%, p-value = 0.027) lower diameter length than real stent diameter evaluated by calipers. On the other hand, EID-CT revealed a greater discrepancy with 25.8% (95% CI = 16.1% to 35.5%, p-value <0.001) lower diameter length in comparison to real stent diameter indicating higher inaccuracy of the EID-CT in measuring stent sizes relative to PC-CT.
Conclusion: PC-CT is an emerging method for the coronary stents imaging, providing better image quality. PC-CT showed lower image noise and high stent diameter measurement accuracy compared to conventional EID-CT. Our findings support the incorporation of PC-CT into future clinical research to further exploration on its diagnostic efficacy.
Limitations: The primary problem arises from the varied methodologies and acquisition parameters marked by diverse scanner types, reconstruction parameters, phantom designs, and stent characteristics.

Diagnostic Study on Differentiating Portal Vein Thrombosis from Tumour Thrombus using Photon-Counting CT (6 min)

Yuhan Zhou; Zhengzhou / China

Author Block: Y. Zhou, Y. Guo, Z. Wang, L. Lei, X. Guo; Zhengzhou/CN
Purpose: This study aims to evaluate the diagnostic value of contrast-enhanced photon-counting CT (PCCT) in differentiating between bland thrombus and tumour thrombus in the portal venous system, with the goal of improving clinical diagnostic accuracy.
Methods or Background: This prospective study enrolled 100 patients with portal venous system thrombosis who underwent spectral contrast-enhanced CT using PCCT. 50 patients were confirmed with bland portal vein thrombosis and 50 with tumour thrombus. ROIs were drawn at the thrombus sites, and spectral post-processing (SPP) datasets were reconstructed to obtain conventional mixed-energy images (CI), virtual monoenergetic images (VMI, 40-150 keV), iodine density maps (ID), and spectral curves. A multiparametric spectral model combining iodine density and VMI (ID-VMI40-150 keV) was established. For each ROI, conventional CT values (CIHU), iodine density values (ID value), and the slope of the spectral curve (λHU) were measured. Univariate logistic regression was performed to assess the predictive value of the spectral parameters in distinguishing between bland thrombus and tumour thrombus. ROC curves were generated, and the AUC and cutoff values were calculated to compare the diagnostic performance of each spectral parameter.
Results or Findings: Compared with unenhanced CT values (AUC: 0.767), arterial phase CT values (AUC: 0.899), venous phase CT values (AUC: 0.960;), arterial iodine density (AUC: 0.891), and virtual monoenergetic images at 40 keV (AUC: 0.909), 50 keV (AUC: 0.909; cutoff: 0.744), and 60 keV (AUC: 0.913), the spectral model ID-VMI60 keV demonstrated the highest diagnostic performance for differentiating between bland thrombus and tumour thrombus in the portal vein (AUC: 0.983).
Conclusion: The spectral model offers superior diagnostic accuracy compared to conventional CT values and individual spectral parameters in distinguishing between bland thrombus and tumour thrombus in the portal venous system.
Limitations: Not Applicable.

Added Value of Extremity-Specific Isotropic Voxel Spacing in Below-Knee Spectral Ultrahigh-Resolution Photon-Counting CT (6 min)

Sardi Hyska; Munich / Germany

Author Block: M. T. Hagar[1], S. Hyska[2], M. Vecsey-Nagy[3], J. I. Griggers[1], J. Osoria-Velasquez[4], T. S. Emrich[5], A. Varga-Szemes[4]; [1]Freiburg Im Breisgau/DE, [2]Munich/DE, [3]Budapest/HU, [4]Charleston, SC/US, [5]Mainz/DE
Purpose: Below-knee CT angiography (CTA) is limited by artifacts from calcified plaques in peripheral artery disease (PAD). Combined spectral ultrahigh-resolution (UHR) photon-counting CT (PCD-CT) may improve performance, but optimal conditions remain unclear.
Methods or Background: In this IRB-approved post-hoc study, consecutive patients with PAD undergoing clinically indicated PCD-CTA were included. Scans were performed on a dual-source PCD system in combined spectral and UHR mode (collimation 120 × 0.2 mm, 120 kVp). Axial images were reconstructed as down-sampled (DS, 0.8 mm, Bv40), virtual monoenergetic images (VMIs, 45–90 keV, 0.4 mm, Bv60), iodine maps (IM, 0.4 mm, Bv60), and UHR (0.2 mm, Bv60). Additional extremity-specific reconstructions with isotropic voxel spacing were generated (FOV 205 × 205 mm; UHRfocused: 0.2 mm, spectral: 0.4 mm). For small-caliber vessels (2.0 mm) with calcified plaques, perpendicular line profiles were analyzed to derive lumen and plaque widths using full-width-at-half-maximum (FWHM_lumen and FWHM_plaque). Digital subtraction angiography (DSA) served as reference, and diagnostic performance was assessed.
Results or Findings: A total of 59 patients (mean age 64.6 ± 13.5 years; 40 men, 68%) with 111 lower extremities were analyzed. Both UHR_focused and iodine map (IM_focused) reconstructions offered superior lumen visualization (FWHM_lumen: UHR 1.68 ± 0.76; IM 1.70 ± 0.76) and minimized blooming (FWHMplaque: UHR 1.01 ± 0.28; IM 0.98 ± 0.27; all $p<0.01$). In contrast, DS reconstructions were limited by blooming artifacts (FWHMlumen: 0.60 ± 0.78; FWHMplaque: 2.11 ± 0.60). UHR_focused and IM_focsued achieved highest sensitivity (93% (95% CI: 77–99%)), with UHRfocused additionally reaching the highest per-segment accuracy of 94% (95% CI: 83–99%, n=50).
Conclusion: UHR PCD-CT with per-extremity reconstruction using isotropic voxel spacing enhances image quality, improves lumen and plaque delineation, and yields highest diagnostic accuracy in below-knee CTA.
Limitations: The limited sample size requires confirmatory research.

AI Triage in Emergency Radiology: Enhancing Detection or Adding Noise? (6 min)
Guillaume Herpe; Poitiers / France

Author Block: T. Clement[1], L. Mabit[1], G. Davy[1], G. D'Assignies[2], R. Guillevin[1], G. Herpe[1]; [1]Poitiers/FR, [2]Nantes/FR
Purpose: AI-driven triage tools are increasingly used in emergency radiology to help detect and prioritize urgent conditions such as brain injuries, pneumothorax, and incidental pulmonary embolism. This study assesses the real-world impact of deploying multiple AI alerting systems.
Methods or Background: This retrospective multi-centric study was conducted over two months in three ER department. AI algorithms were applied to detect intracranial hemorrhage on CT, pneumothorax on chest X-ray, and incidental pulmonary embolism on contrast-enhanced CT across 2,336 CT and 119 Chest X-rays. Discrepancies between AI outputs and radiology reports were first reviewed by a radiologist and then resolved by an emergency radiologist. Performance was evaluated using diagnostic metrics.
Results or Findings: ICH detection : Among 682 head CT scans, AI flagged 133 positives(19.5%,133/682), including 46 false positives (6.7%,46/682) and 11 false negatives(1.6%,11/682). AI detected 2 additional true positives(1.5%,2/133) missed by radiologists.
Pneumothorax Detection: Out of 119 chest X-rays, AI identified 3 positive cases(2.5%,3/119), including 1 missed by the radiologist (0.8%,1/119), with no false positives.
Incidental Pulmonary Embolism Detection : In 1654 contrast-enhanced CT scans, AI flagged 70 positives(4.2%,70/1654), with 22 true positives(31.4%,22/70) and 9 missed by radiologists(41%,9/22). AI increased the detected prevalence from 0.8%(14/1654) to 1.3%(22/1654), but the false-positive rate was 68.6%(48/70).
Overall, at the cost of about 1.5 false alerts per day, AI helped uncover one life-threatening condition every five days.
Conclusion: AI triage tools in emergency radiology enhance detection of missed critical findings and remain valuable if false positives are carefully managed to avoid alert fatigue.
Limitations: This retrospective, short-duration study limits generalizability, especially given the small sample size for some modalities. The reference standard relied solely on radiologist re-reads without follow-up confirmation. Finally, AI real impact on workflow, alert fatigue, and patient outcomes was not assessed.

A Machine Learning Model for Predicting Abnormal Head CT Findings in Non-Traumatic Pediatric Emergency Patients: A Multi-center Derivation and Validation Study (6 min)
Jianman WU; Fuzhou / China

Author Block: J. WU[1], Y. Li[2], P. Zhang[1], H. Huang[1], J. Hu[1]; [1]Fuzhou/CN, [2]Zhangzhou/CN
Purpose: To identify clinical predictors and develop a prediction model to identify non-traumatic pediatric patients at risk of abnormal head CT findings in emergency department(ED).
Methods or Background: Emergency pediatric patients (≤14 years old) were identified from four tertiary general hospitals. Age; Gender; Medical history; Fever;Crying; Seizure; Headache; Dizziness; Syncope; Vomiting; Abnormal Physical examination; Impaired Consciousness, etc., were used as candidate clinical factors. Multivariate logistic regression analysis were used to identify the independent clinical predictors of abnormal head CT findings. Datasets from two hospitals were used for model training and the other two for external validation. We developed models using logistic regression and machine learning (KNN, NNet, Random Forest, XGBoost, Naive Bayes).The best-performing model was identified, assessed with Decision Curve Analysis (DCA), and its feature contributions were explained via SHAP values.
Results or Findings: 127 of 2,272 (5.6%) cases with abnormal head CT findings. Younger age (OR=0.89), medical history (OR=40.43), non fever(OR=0.35), crying(OR=11.13), vomiting (OR=4.75), headache(OR=2.18), physical examination abnormalities (OR=23.17), and consciousness disorders (OR=21.69) were clinical independent predictors. XGBoost was the top-performing model, with validation AUCs of 0.84 (Test1) and 0.88 (Test2). It showed a balanced sensitivity and specificity(Test1: 67.9% sensitivity, 91.0% specificity; Test2: 81.2% sensitivity, 81.6% specificity) at the Youden threshold and provided the highest net benefit on DCA in the clinically relevant range (0.20-0.30), reducing interventions by 57.8–90.6 per 100 patients. SHAP analysis showed impaired consciousness, age, fever, abnormal physical examination, and seizure were the top predictors of abnormal head CT findings.
Conclusion: The validated XGBoost model enables more selective uses of head CT for emergency pediatric patients, potentially reducing unnecessary scans without a loss in sensitivity.
Limitations: The relatively small number of abnormal CTs may affect the stability of the estimates for some predictor variables.

Real-World Evaluation of an AI-Powered Intracranial Hemorrhage Detection System in Emergency Head CT: A Clinical Validation Study (6 min)

EMINE ESRA AKTUFAN; Antalya / Turkey

Author Block: E. E. AKTUFAN; Antalya/TR
Purpose: To evaluate the real-world performance of an AI-powered intracranial hemorrhage (ICH) detection system in emergency head CT. After the session, participants will understand the diagnostic strengths and limitations of AI, recognize common causes of false results, and appreciate its implications for clinical workflows.
Methods or Background: Deep learning algorithms show high accuracy in ICH detection, but real-world validations are limited. This retrospective study included all emergency non-contrast head CTs performed over three months at a tertiary hospital. Cases with motion and metallic artifacts were retained to reflect real practice. The ground truth was defined by board-certified radiologist reports, which were retrospectively compared with AI outputs (hStroke V1, Hevi AI, Istanbul). The model employs a CNN-RNN architecture with attention for ICH subtype classification.
Results or Findings: In 1,421 CTs from 1,379 patients (mean age: 50.6 years; 57% male), 73 were hemorrhage-positive (5.8%). The AI achieved 97.5% accuracy, 95.9% sensitivity, 97.6% specificity, and 68.6% precision. Common subtypes were IPH (n=35), SAH (n=37), and SDH (n=39). Multiple subtypes occurred in 37 cases, most often IPH+SAH+SDH. Three hemorrhages were missed, while 24 false positives mainly arose from artifacts, masses, and calcifications.
Conclusion: The AI tool demonstrated high accuracy and sensitivity for ICH detection in a real-world emergency setting. False positives remain a concern, emphasizing radiologist oversight and improved artifact handling.
Limitations: This single-center retrospective study relied on board-certified radiologist reports as ground truth, without interobserver analysis. Subtype-specific stratification was limited by sample size. Only axial CTs were analyzed, excluding multiplanar reconstructions that may improve detection in anatomically complex regions.
Funding for this study: This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study protocol was approved by the institutional ethics committee (Protocol No: 2024-122, Decision No: 11/28; Approval Date: August 8, 2024). Informed consent requirements were waived due to the retrospective nature of the study and the anonymization of all datasets

AI Assistance Improves Radiology Resident Reader Performance in CT Diagnosis of Intracranial Hemorrhage (6 min)

Philipp Reschke; Frankfurt / Germany

Author Block: P. Reschke, K. Eichler, T. Vogl, C. Booz; Frankfurt/DE
Purpose: Accurate detection of intracranial hemorrhage (ICH) on non-contrast CT is critical in emergency settings, where missed diagnoses may delay treatment and worsen outcomes. While artificial intelligence (AI) models demonstrate high standalone performance, their additive value as a second reader for radiology residents is not well established.
Methods or Background: This retrospective study included 1,337 non-contrast head CT scans from 2015–2019 (670 ICH-positive, 667 ICH-negative). A previously validated AI model was used for ICH detection. Two radiology residents reviewed all scans in consensus, first without and later with AI support after a 30-day washout. Ground truth was established by expert consensus. Diagnostic performance metrics were calculated.
Results or Findings: AI assistance significantly improved radiology residents' diagnostic performance. Sensitivity increased from 0.85 to 0.94 and specificity from 0.87 to 0.97 (both $p < 0.01$). ROC-AUC rose from 0.86 to 0.95, and PR-AUC from 0.83 to 0.95 ($p < 0.0001$). The number of false negatives dropped from 101 to 41 with AI support. The greatest benefit was observed in subdural hematomas (SDH), where misses declined from 32 to 9 (20.3% to 5.7%; $p < 0.001$), corresponding to a 72% relative risk reduction. Misses also decreased for intraparenchymal hemorrhages (IPH: 37 to 20; RRR 46%) and subarachnoid hemorrhages (SAH: 30 to 11; RRR 63%). AI support reduced common error sources: small hemorrhage volume (48 to 21), atypical locations (30 to 12), and image-degrading artifacts (23 to 8). False positives fell from 87 to 21.
Conclusion: By reducing diagnostic errors and supporting learning, AI serves as a valuable second reader for radiology residents—enhancing both patient safety and resident training in ICH detection.
Limitations: This study did not evaluate radiologists' trust in or interaction with the system.
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Ethical approval was granted by the institutional review board of the University of Frankfurt and written informed consent was waived due to the retrospective nature of the study (approval number: 19-236).

Artificial Intelligence Software versus Expert Radiologists in Traumatic Ankle and Foot Fracture Detection (6 min)

Paul Botti; Genève / Switzerland

Author Block: D. Ferreira Branco, P. Botti, A. Platon, P-A. A. Poletti, S. Boudabbous; Geneva/CH
Purpose: To evaluate a commercial AI fracture detection tool on foot/ankle radiographs, with emphasis on midfoot fractures (Chopart/Lisfranc), compared with board-certified musculoskeletal radiologists using a composite reference standard (CBCT and/or clinical follow-up).
Methods or Background: This retrospective single-center study included all emergency radiographs for adult patients with foot/ankle trauma over six months. Radiographs were first interpreted in routine workflow by radiologists, then independently (stand alone) by the AI tool (BoneView™, Gleamer), each blinded to the other. Descriptive analyses summarized fracture prevalence and distribution (overall, Chopart, Lisfranc). Diagnostic performance of AI and radiologists was assessed, with inter-reader agreement (Cohen's κ). Paired comparisons used McNemar's test.
Results or Findings: In total, 701 studies were analyzed; 319 fractures (45.5%) were found: 24 Chopart (7.6%), 22 Lisfranc (6.8%), and 273 (85.6%) other bony structures. AI achieved overall sensitivity 74.3%, specificity 83.0%, accuracy 79.0%. Radiologists achieved sensitivity 84.0%, specificity 95.5%, accuracy 90.3% ($p=0.145$); $\kappa=0.65$.
For Chopart fractures, AI sensitivity was 62.1%, specificity 99.6%, accuracy 98.0%; radiologists achieved sensitivity 82.8%, specificity 99.7%, accuracy 99.0% ($p=0.180$); $\kappa=0.80$. For Lisfranc fractures, AI sensitivity was 65.4%, specificity 99.9%, accuracy 98.6%; radiologists achieved sensitivity 80.8%, specificity 100.0%, accuracy 99.3% ($p=0.453$); $\kappa=0.82$
Conclusion: AI and radiologists achieved comparable overall performance for detecting foot/ankle fractures on radiographs, with substantial agreement. Radiologists showed a better performance in detecting Lisfranc/Chopart fractures than AI. Our findings support the AI use as complementary help for radiologists in a busy workflow, with targeted attention to midfoot injuries where detection remains challenging.
Limitations: Given the low prevalence of Chopart and Lisfranc fractures, the study period was relatively short.
Funding for this study: No funding was received for this study.

Making the small things easy: Hand unfolding in polytrauma whole-body photon-counting CT (6 min)

Hanns-Leonhard Kaatsch; Koblenz / Germany

Author Block: H-L. Kaatsch[1], D. Dillinger[1], C. Bauer[1], D. Friedmann[2], B. Schmidt[2], S. Waldeck[1], D. Overhoff[1]; [1]Koblenz/DE, [2]Forchheim/DE
Purpose: This study aims to assess a prototype hand unfolding reformation algorithm in polytrauma whole-body photon-counting CT (WB-PCCT) regarding time saving and image quality compared to a conventional bone reconstruction algorithm.
Methods or Background: We retrospectively analyzed 20 polytraumatized patients with bone injuries of the hand, who underwent polytrauma WB-PCCT, and reconstructed a total of 68 hands (matching 34 unfolded and 34 conventional (Br60 kernel) reconstructions). The hand unfolding reformation algorithm uses AI to automatically locate the hands in the WB-PCCT. After a deep learning-based detection of the course of the finger bones, the algorithm maps the original image to a predefined template using a deformation algorithm. This effectively unfolds each hand and enables visualization in the standard anatomical position. Quantitative image analysis was performed based on the calculation of the contrast-to-noise ratio (CNR). Two readers randomly assessed hand reconstructions with regard to reading time, subjective image quality (overall image quality, image noise perception, fracture delineation, fracture/joint dislocation) and diagnostic confidence using a 5-point Likert scale.
Results or Findings: Unfolded hand reformations significantly reduced ($p<0.001$) reading time for sufficient evaluation compared to conventional hand reconstructions by 57% (mean: 59 seconds versus 138 seconds). The novel reformation algorithm significantly improved CNR (28.18 versus 20.93; $p <0.001$). Subjective evaluation revealed comparably higher ratings for overall image quality, image noise perception, fracture and joint dislocation, and diagnostic confidence for unfolded hand reformations with equal ratings for fracture delineation.
Conclusion: The novel hand unfolding reformation algorithm for polytrauma WB-PCCT applied in this study led to 57% reduction in time required for hand assessment in time-critical polytrauma setting and improves both objective as well as subjective image quality compared to conventional bone reconstruction.
Limitations: Small sample size (n=20).
Retrospective design.
Funding for this study: No funding.

Artificial Intelligence (AI) may not increase the sensitivity of chest radiographs in the emergency setting (6 min)

Eleftheria Chara Stamoulaki; Heraklion / Greece

Author Block: E. C. Stamoulaki, E. Detorakis, N. Christodoulides, D. Grigoropoulou, M. Klontzas, M. Raissaki; Heraklion/GR
Purpose: To assess performance of chest radiography without and with AI assistance compared to CT for abnormality detection in the emergency setting.
Methods or Background: 150 patients (males 63,33%), aged 17-92 years (mean 72,5) underwent frontal PA or AP and lateral radiographs and CT within 10 days (mean 1 day). A junior radiologist assessed radiographs for lung, mediastinal and pleural/rib abnormalities, initially without AI assistance (reading 1), and following a three-week weaning interval with AI assistance (reading 2). CT findings were subsequently recorded by another junior and a senior radiologist, formulating ground truth. Lesions were marked as 0=not present, 1=present. Statistical analysis was performed using R programming language (v4.2.2 in RStudio for MacOS). Agreement between CT and each reading was assessed with weighted kappa statistics. Confusion matrices were used to calculate sensitivity, specificity, balanced accuracy, positive and negative predictive value. $P<0.05$ was statistically significant.
Results or Findings: Agreement between radiography and CT for presence of abnormalities ranged from slight to moderate (weighted k-values 0.18-0.67). The addition of AI did not increase the sensitivity of radiographs for any of the assessed abnormalities. The weighted kappa ranged from slight for mediastinal masses (k=0.17 without vs 0.17 with AI) to substantial for pleural effusion (k=0.67 without vs 0.69 with AI) ($P<0.001$). Both readings showed excellent specificity (range 87.2%-100%). Both readings had similar sensitivity which was low for lung and mediastinal masses, nodules and rib fractures (13.3%-33.9%), moderate for consolidation (46.7% without AI vs 54.8% with AI) and high for pleural effusion (80% for both readings).
Conclusion: In our small cohort, the addition of AI did not result in a statistically significant improvement of agreement between radiographic findings and CT.
Limitations: Small sample size.
Funding for this study: No funding was provided for this study.
Has your study been approved by an ethics committee? Yes

Can AI train radiologists to better assess chest radiographs in the emergency setting? (6 min)

Dimitra Grigoropoulou; Herakleion / Greece

Author Block: D. Grigoropoulou, E. C. Stamoulaki, E. Detorakis, N. Christodoulides, M. Klontzas, M. Raissaki; Herakleion/GR
Purpose: To investigate the educational effect of artificial intelligence on junior radiologists who report chest radiographs.
Methods or Background: Two sets of 75 patients who presented in the emergency department underwent PA or AP chest radiography and lateral chest radiography on the same day and chest CT within 0-10 days. The first set were assessed by one junior resident radiologist (reader) for lung, mediastinal and pleural/rib abnormalities separately without and with AI assistance. The second set was subsequently assessed by the same reader, blinded to CT-findings, which were recorded by two additional radiologists in consensus. Lesions were marked as 0=absent, 1=potentially/definitely present.
Statistical analysis was performed using R programming language (v4.2.2 in RStudio for MacOS). Agreement between CT and each reading was assessed with weighted kappa statistics. Confusion matrices were used to calculate sensitivity, specificity, balanced accuracy, positive and negative predictive value, which were compared between two sets. $P<0.05$ was statistically significant.
Results or Findings: Assessment of 1st set of radiographs without AI yielded a low to moderate agreement with CT, with a weighted kappa ranging between 0.108 (detection of mediastinal masses) and 0.529 (detection of pleural effusion). This agreement did not change with the assistance of AI, except for pleural effusion detection where agreement increased from 0.529 to 0.689. Assessment of the 2nd set without AI exhibited increased agreement with CT for nodules (0.131 before vs 0.478 after), lung (0.251 before vs 0.681 after) and mediastinal masses (0.108 before vs 0.520 after). Regarding sensitivity of radiographs for nodules, lung and mediastinal masses, it increased by 24-33%. Specificity was similar before and after the use of AI.
Conclusion: The addition of AI in chest radiography may increase sensitivity and may accelerate education of junior radiologists.
Limitations: Small sample size.

MD 14 - Cystic pancreatic tumours: new developments in imaging and treatment - recommendations for clinical practice and directions for the future

Categories: Oncologic Imaging, GI Tract, Research, Abdominal Viscera, Multidisciplinary, President's Choice
ETC Level: ALL LEVELS
Date: March 6, 2026 | 12:45 - 13:45 CET
CME Credits: 1

Moderator:
Riccardo Manfredi; Rome / Italy

Chairperson's introduction (2 min)
Riccardo Manfredi; Rome / Italy

1. To highlight new developments in the treatment of cystic pancreatic tumours.
2. To critically review recent developments in imaging and put this in perspective with the treatment developments.
3. To provide recommendations for clinical practice and directions for future research.

The surgeon's perspective (8 min)
Roberto Salvia; Verona / Italy

The pathologist's perspective (8 min)
Claudio Luchini; Verona / Italy

The radiologist's perspective (8 min)
Riccardo Manfredi; Rome / Italy

Expert panel discussion (34 min)

CUBE 16 - Innovative fusion imaging in neurointervention: tips and tricks

Categories: Radiographers, Education
Date: March 6, 2026 | 13:00 - 13:30 CET
CME Credits: 0.5

Moderator:
Shane J Foley; Dublin / Ireland

Chairperson's introduction (2 min)
Shane J Foley; Dublin / Ireland

How can radiographers support innovative fusion imaging in interventional neuroradiology? (28 min)
Andrea Roletto; Milan / Italy

1. To learn about the role of fusion imaging in neurointerventional radiology.
2. To appreciate the requirements for supporting the provision of high-quality fusion imaging.
3. To understand the technical challenges for producing fusion images.

EIBIR 15 - Advancements in medical imaging technologies: photonics research

Categories: Neuro, Research, Physics in Medical Imaging
ETC Level: LEVEL III
Date: March 6, 2026 | 13:45 - 14:45 CET
CME Credits: 1

Moderator:
Regina G.H. Beets-Tan; Amsterdam / Netherlands

Chairperson's introduction (5 min)
Regina G.H. Beets-Tan; Amsterdam / Netherlands

Using hyperspectral imaging to provide real-time information to neurosurgeons during surgery (20 min)
Pietro Ricci; Florence / Italy

1. To learn about HyperProbe's hyperspectral imaging technology and how it advances neurosurgical imaging and precision.
2. To appreciate the potential of hyperspectral imaging for non-invasive diagnosis and improved neuronavigation in clinical settings.
3. To understand the importance of collaboration among researchers, radiologists, and medical professionals in supporting the adoption and application of HyperProbe technology.

Evaluating micro-electromechanical systems-based multi-element optical probes for medical ultrasound (20 min)
Michiel Oderwald; Delft / Netherlands

1. To appreciate the transition from traditional electrical piezoelectric transducers to optical MEMS-based chips.
2. To learn an overview of integrated photonics ultrasound transducer fundamentals and key considerations in design and development, limited to the information we are comfortable sharing.
3. To understand the current results.

Discussion (15 min)

BS 15 - Imaging of benign hepatic and biliary tree pathology: from common to rare entities

Categories: Abdominal Viscera
ETC Level: LEVEL II
Date: March 6, 2026 | 14:00 - 15:00 CET
CME Credits: 1

Moderator:
Ioana Gabriela Lupescu; Bucharest / Romania

Chairperson's introduction (5 min)
Ioana Gabriela Lupescu; Bucharest / Romania

Benign biliary tree pathology (15 min)
Adrian Dijmarescu; Bucharest / Romania

1. To review current imaging techniques used to evaluate the biliary tree.
2. To discuss and illustrate the main benign conditions that may affect the biliary tree.
3. To underline possible pitfalls and errors in BT interpretation.

Focal benign liver lesions (15 min)
Alain Luciani; Paris / France

1. To become familiar with the main benign liver lesions and their clinical importance.
2. To be able to recognise key imaging features of the most common benign liver tumours.
3. To know how to avoid errors and discrepancies in interpreting focal benign liver lesions.

Diffuse benign liver lesions (15 min)
Raffaella Basilico; Chieti / Italy

1. To learn key points for an optimised imaging to detect diffuse benign liver lesions.
2. To review key diagnostic features of the most current diffuse benign liver diseases.
3. To review the main differential diagnoses of diffuse benign liver lesions.

Panel discussion: Importance of imaging protocols, findings, and structured report (10 min)

CUBE 17 - Foreign body removal

Categories: Interventional Radiology
ETC Level: ALL LEVELS
Date: March 6, 2026 | 14:00 - 14:30 CET
CME Credits: 0.5
The session aims to provide information on the tools one should have on hand for foreign body removal and how to use them.

Moderator:
Tobias F Jakobs; München / Germany

Chairperson's introduction (2 min)

Opportunistic Detection of Vertebral Fragility Fractures using AI on Routine Chest X-Rays in a Cancer Patients: A Retrospective Cohort Study (8 min)
Sarah Marie Simpson; Manchester / United Kingdom

Author Block: H. Rogerson-Bevan, S. M. Simpson, C. Higham, F. Frost, L. Berger, F. J. Wong, C. Barker; Manchester/UK
Purpose: Vertebral fragility fractures (VFFs), indicative of underlying osteoporosis, are common in cancer patients, attributed to the aetiology of the disease and treatment regimes. Frequently mis- and under-diagnosed, VFFs are linked to higher mortality, morbidity, and increased hip fracture risk. We assessed the prevalence and clinical context of VFF detected opportunistically on chest X-rays (CXRs) performed for unrelated indications in cancer patients.
Methods or Background: A retrospective review was conducted of adult cancer patients who underwent CXR within a large, tertiary cancer centre between October and December 2024. Patients with VFFs were identified utilising an AI tool (Annalise Container v2.2, Annalise.ai) on CXR. Indications for imaging, fracture status (new vs. pre-existing), and suspected aetiology were assessed.
Results or Findings: 173 patients with a VFF were identified on CXR, 36/173 (21 male:15 female) representing newly detected vertebral fractures; the remaining 137 (79%) had a pre-existing fracture. All patients underwent CXR for infection screening, baseline pre-treatment evaluation, or post-treatment assessment. Among patients with newly detected fractures, 77% (28/36) were classified as osteoporosis-related based on radiological appearance and clinical context. None of the patients with a newly identified fracture had clinical suspicion or prior imaging for vertebral fracture at the time of CXR.
Conclusion: Opportunistic assessment augmented by AI of CXR revealed a substantial number of newly identified vertebral fractures, most of which were not pathological, but are fragility fractures related to cancer treatment. While early identification of such fractures is an important initial step, meaningful improvement in patient outcomes requires the establishment of robust management strategies and dedicated follow-up pathways to ensure timely and effective intervention.
Limitations: Results reflect findings from one large cancer centre, which may limit generalisability; the study focused on fracture detection and clinical impact was not established.
Funding for this study: Deployment of the AI tool was funded by the NHS AIDF Fund

Immunotherapy endpoint prediction through CT foundation models in the TANGERINE study (8 min)
Asier Rabasco Meneghetti; Dresden / Germany

Author Block: A. Rabasco Meneghetti[1], A. Marcos Morales[2], L. Riobó Mayo[2], O. Balacescu[3], N. Antone[3], J. Calderaro[4], R. Perez Lopez[2], V. Moreno Aguado[2], J. Kather[1]; [1]Dresden/DE, [2]Barcelona/ES, [3]Cluj-Napoca/RO, [4]Créteil/FR
Purpose: Cancer immunotherapy with immune checkpoint inhibitors (ICIs) is widely used in lung cancer, with proven benefits. However, response is not guaranteed, difficult to predict, and serious toxicity may occur. The TANGERINE study (funded through the EU Joint Call 2021 TRANSCAN-3) aims to develop artificial intelligence (AI)-based histology and radiology-based models for predicting immune features related to ICIs response. Here we present current results for radiological data using the subset of lung cancer patients.
Methods or Background: Pre-ICI treatment computerised tomography (CT) scans from lung cancer patients from 3 hospitals from Spain and Romania were retrospectively identified and included for a lung-multidrug model. Patients had received ICIs alongside prior or concomitant chemotherapies. Best overall response was obtained according to RECIST 1.1 criteria. Only CTs closest to the treatment start date were included. Whole-CT embeddings were generated through the MERLIN foundation model (Blankemeier et al. 2024). An attention-based multiple-instance learning (ABMIL) model was then trained to predict disease control rate (DCR) and PFS through 5-fold cross-validation (CV) in 80% of the patients (n=141) and deployed in a holdout test set (n=40).
Results or Findings: 181 patients with lung cancer were included (72% male, Treatments: 53% Pembrolizumab, 17% Nivolumab, 13% Durvalumab, 4% Atezolizumab, 13% others, DCR: 42%, median time to progression: 5.5 months). The lung-multidrug model for DCR classification showed an average CV AUC of 0.75 95% CI (0.57-0.79) in the training set and 0.60 (0.50-0.69) in the test set. Models significantly stratified patients into high and low-risk for PFS (p=0.023) with cause-specific hazard ratio:1.49 (1.05-2.10).
Conclusion: Pre-treatment CT scans show predictive value for ICI outcomes in lung cancer, specifically for PFS prognosis.
Limitations: Sample size was limited. Further study iterations will include more patients, and fully-external validation cohorts
Funding for this study: This study was financed through the EU Joint Call 2021 TRANSCAN-3 grant.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Protocol and informed consent for the TANGERINE project were approved by the IDIBELL´s Research Ethics Committee (coordinating centre for the TANGERINE study).

Automated Prostate Lesion Segmentation in mpMRI Using Multi-Input U-Net and Novel LSTM U-Net with Bi-ConvLSTM (8 min)

Saman Fouladi; Milan / Italy

Author Block: S. Fouladi, F. Darvizeh, R. Di Meo, I. Bossi Zanetti, G. Gianini, E. Damiani, A. Maiocchi, D. Fazzini, M. Alì; Milan/IT
Purpose: Prostate cancer (PCa) is the second most commonly diagnosed cancer in men, with an estimated 288,300 new cases and over 34,700 deaths annually in the United States. Early detection and accurate lesion localization are crucial for improving outcomes; however, manual segmentation of multiparametric MRI (mpMRI), including T2-weighted (T2W), diffusion-weighted imaging (DWI), and apparent diffusion coefficient (ADC) sequences, is labor-intensive and prone to interobserver variability. This challenge has motivated the development of automated deep learning solutions.
Methods or Background: We evaluated two datasets: PI-RADS 4–5 (220 training, 33 test) and PI-RADS 3–5 (270 training, 41 test). In the first stage, U-Net, Dense U-Net, and Attention U-Net were trained separately on T2W, DWI, and ADC to benchmark the contribution of each sequence. In the second stage, we implemented a multi-input U-Net with three parallel encoders, each dedicated to one sequence (T2W, DWI, ADC), enabling joint learning while preserving modality-specific features. Finally, building on the strong performance of ADC, we proposed a novel LSTM U-Net with a Bi-ConvLSTM bottleneck to capture temporal dependencies and improve lesion boundary delineation.
Results or Findings: ADC achieved the highest Dice scores (69% for PI-RADS 4–5 and 68% for PI-RADS 3, 4, and 5). The LSTM U-Net on ADC provided competitive accuracy and improved delineation of challenging lesions, highlighting the benefit of temporal modeling.
Conclusion: Segmentation depends on dataset composition and network design. Multi-input sequences improve accuracy, while temporal modeling refines lesion boundaries, supporting AI-assisted prostate cancer diagnosis.
Limitations: The number of images was limited due to the time-consuming process of manual mask creation. Despite this constraint, the results are promising, and performance is expected to further improve with the inclusion of larger datasets.
Funding for this study: Funding The work was partially supported by the MUSA-Multilayered Urban Sustainability Action project, funded by the European Union-NextGenerationEU, under the Mission 4 Component 2 Investment Line of the National Recovery and Resilience Plan (NRRP) Mission 4 Component 2 Investment Line 1.5: Strengthening of research structures and creation of R&D ”innovation ecosystems”, set up of ”territorial leaders in R&D” (CUP G43C22001370007, Code ECS00000037); Program ”piano sostegno alla ricerca” PSR and the PSR-GSA-Linea 6; Project ReGAInS (code 2023-NAZ-0207/DIP-ECC-DISCO-23), funded by the Italian University and Research Ministry, within the Excellence Departments program 2023-2027 (law 232/2016).

AI-derived Cardiopulmonary CT Biomarkers and COVID-19 Vaccination: Independent Predictors of Survival in Cancer (8 min)

Ekaterina Petrash; Moscow / Russia

Author Block: V. Chernina[1], V. Gombolevskiy[2], A. Meldo[3], E. Petrash[2], M. Valkov[1]; [1]Arkhangelsk/RU, [2]Moscow/RU, [3]St. Peterburg/RU
Purpose: Define the prognostic value of AI-derived CT biomarkers of COVID-19 pneumonia and assess the impact of vaccination on survival in oncology patients.
Methods or Background: Adults with cancer (April 2020–December 2021) underwent chest CT, linked with survival and vaccination data. AI extracted COVID-19 pneumonia and cardiopulmonary CT biomarkers. Endpoints: overall and cancer-specific survival; multivariable Cox regression adjusted for demographics, stage, AI detection, and vaccination status.
Results or Findings: The cohort included 1148 patients (66.2 ± 12.5 years; 52% female) (Fig. 1); 6.6% were vaccinated. AI detected COVID-19 pneumonia in 27.2%, emphysema in 36.4%, aorta aneurysm in 1.6%, main pulmonary artery enlargement in 13.6%, CAC ≥1 in 24.7%, and epicardial fat ≥125 mL in 17.8% (Fig. 2). Median follow-up was 38.4 months.
OS at 1/3/5 years was 70.2%, 48.3%, and 41.7%; CSS was 74.2%, 49.0%, and 47.8%, respectively. Patients without vs. with AI-detected pneumonia had 1-year OS of 80.8% vs. 65.9% and 3-year OS of 55.2% vs. 36.4% ($p < 0.001$); CSS was 84.1% vs. 63.2% ($p < 0.001$) (Fig. 3). Fig. 4 illustrates AI output.
Multivariable Cox analysis identified independent mortality predictors: COVID-19 pneumonia (HR 1.31; 95% CI 1.09–1.58; p=0.004), stage III–IV, male sex, and pulmonary/GI tumor site. Vaccination reduced mortality by 61% (HR 0.39; 95% CI 0.24–0.64; p<0.001), raising 1-/3-year OS to 99% and 80% vs. 68% and 45% in unvaccinated (Fig. 5).
Conclusion: AI-detected COVID-19 pneumonia was the sole independent CT biomarker, increasing mortality risk by 31% (HR 1.31) across all subgroups. Vaccination emerged as the only modifiable factor, reducing mortality by 61% (HR 0.39) in oncology patients.
Limitations: Single-region retrospective design limits causal inference. Excluding >70% of CTs and protocol variability may bias selection, but strict filtering and a certified, heterogeneity-trained AI improve robustness.
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Permission to conduct the study was obtained from the Local Ethics Committee of Northern State Medical University (No. 07/10-238, 2023).

Detection and Diagnosis of Breast Cancer Using an Explainable Radiomic Pipeline (8 min)

Arita Halder; Kharagpur / India

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: A. Halder, M. MAHADEVAPPA; Kharagpur/IN
Purpose: Breast cancer is a leading cause of cancer-related mortality among women, where early and accurate detection is essential. Ultrasound (US) is widely used due to its safety, affordability, and accessibility, especially in low-resource settings. An explainable radiomics-based pipeline could serve as a “virtual biopsy,” reducing unnecessary invasive procedures and supporting radiologists in confident decision-making.
Methods or Background: We developed an end-to-end radiomic pipeline using the publicly available BUSBRA dataset. Breast lesions were segmented using a Multi-Scale Feature Fusion Network (MulFF-Net). From each segmented region, 474 radiomic features capturing shape, texture, intensity, and wavelet-based descriptors were extracted. Recursive feature elimination with cross-validation (RFECV) was employed to select the most discriminative features. Five machine learning classifiers—Support Vector Machine (SVM), Random Forest, k-Nearest Neighbors, Logistic Regression, and Decision Tree—were trained and evaluated. To enhance interpretability, Shapley Additive Explanations (SHAP) were applied, providing insights into how individual features contributed to model predictions.
Results or Findings: Out of 474 features, 5 were retained (4 shape and 1 wavelet). Among classifiers, SVM achieved the best performance with a mean accuracy of 0.8689 ± 0.0183 and AUC of 0.9235 ± 0.0210. SHAP analysis identified sphericity and elongation as the most influential predictors of malignancy.
Conclusion: The proposed explainable radiomic pipeline demonstrates promising potential for breast cancer diagnosis using ultrasound, combining strong predictive performance with interpretability.
Limitations: This study was limited by reliance on a single dataset, and future validation on larger, multi-institutional cohorts is needed.
Funding for this study: No funding
Has your study been approved by an ethics committee? Not applicable

Intratumoral and Peritumoral Radiomics Based on Post-RFA Gadoxetic Acid Disodium-Enhanced MRI for Predicting Short-term Prognosis in Hepatocellular Carcinoma (8 min)

Yaxuan Pang; China / China

Author Block: Y. Pang; China/CN
Purpose: To evaluate the predictive value of intratumoral and peritumoral radiomics features extracted from the first post-RFA follow-up gadoxetic acid disodium (Gd-EOB-DTPA)-enhanced MRI for Short-term poor prognosis after radiofrequency ablation (RFA) in hepatocellular carcinoma (HCC) patients.
Methods or Background: A total of 181 HCC patients who underwent ultrasound-guided RFA at Lanzhou University First Hospital between 2017 and 2025 were retrospectively enrolled in this study.Gd-EOB-DTPA-enhanced MRI and clinical data from the first post-RFA follow-up were collected. Radiomics models based on MRI (arterial phase, portal venous phase, hepatobiliary phase) across various regions (entire tumor, Peri 3mm, Peri 5mm, Peri 7mm) were developed using the LASSO approach and logistic regression. To determine the best model, the Delong's test and area under the receiver operating characteristic curve (AUC) were used. A combined model was constructed using best radiomics model features and Clinical-radiological predictors. The performance, calibration, and clinical utilities were evaluated by ROC curve, calibration curve, and decision curve analysis, respectively.
Results or Findings: The peritumoral 3 mm radiomics model achieved the best predictive performance, with an AUC of 0.856 in the validation cohort. Alpha-fetoprotein (AFP) level and arterial phase peripheral enhancement are independent predictors of early poor prognosis following RFA□P□0.05□.The combined model yielded an AUC of 0.918 in the validation cohort, demonstrating significantly superior performance to both the radiomics and clinical imaging models.
Conclusion: The combined model incorporating Peri 3 mm radiomics feature and clinical-radiological risk factors have significant predictive value for short-term prognosis after RFA, may provide a valuable tool for optimize follow-up protocols and therapeutic decision-making.
Limitations: Hepatocellular carcinoma; Radiofrequency ablation; Radiomics; Magnetic resonance imaging; Prognosis prediction
Funding for this study: First Affiliated Hospital Fund Project of Lanzhou University(No. ldyyyn2021-104);

Ethics committee - additional information: This study was a retrospective study involving human participants and was approved by the LZU NO.1 Hospital Ethics Committee, with the approval number [LDYYLL-2025-856], the requirement for written informed consent was waived by the ethics committee.All participant data were anonymized to ensure confidentiality and compliance with ethical standards.

Self-Explainable AI and Attention for Interpretable Cancer Analysis with Image and Omics Data (Multi-Modal): A Systematic Review (8 min)

Muruganantham Jaisankar; Kaunas / Lithuania

Author Block: M. Jaisankar[1], A. Ostreika[1], B. García-Zapirain Soto[2]; [1]Kaunas/LT, [2]Bilbao/ES
Purpose: This systematic review synthesizes literature on attention mechanisms in Self-Explainable AI (SXAI) for the interpretable analysis of cancer using multimodal data. The primary objective is to evaluate how attention mechanisms enhance both model performance and explainability for clinical tasks (diagnosis, prognosis, treatment prediction), thereby improving clinical trust and facilitating adoption.
Methods or Background: Following PRISMA guidelines, the review analyzes studies using AI to integrate heterogeneous data, including histopathology whole-slide images (WSIs), MRI, and multi-omics. Combining these modalities offers complementary insights, but the "black box" nature of deep learning limits clinical utility. Attention mechanisms, core to architectures like Transformers, are widely explored to create inherently transparent SXAI models by enabling them to focus on and highlight the most relevant data features used in model's predictions.
Results or Findings: The literature consistently demonstrates that multimodal models significantly outperform unimodal approaches in cancer survival prediction and risk stratification, with some showing improvements of over 4.5% in the Concordance Index (C-index). These AI models accurately predict critical molecular features, such as TP53 mutations, directly from standard medical images. Attention mechanisms are central to this success, serving as a powerful tool for effective data fusion and model interpretability. Attention-based visualizations reveal biologically relevant morpho-molecular correlates, like identifying areas with high densities of tumor-infiltrating lymphocytes (TILs).
Conclusion: Attention-based SXAI models represent a robust and effective strategy for multimodal cancer analysis. By providing transparent, biologically relevant insights into their decision-making, these models enhance predictive accuracy, foster clinical trust, and serve as a promising pathway toward developing rapid, cost-effective biomarkers that can advance personalized oncology and improve patient outcomes.
Limitations: Common limitations identified include the retrospective nature of studies and heavy reliance on public datasets, which may lack demographic diversity and completeness.
Funding for this study: Erasmus+, Lithuanian State fund for PhD.

ESR Research 15 - Expanding the frontiers of multidisciplinary research in imaging

Categories: Research, Evidence-Based Imaging, Translational Imaging, Multidisciplinary, Artificial Intelligence

ETC Level: LEVEL II+III

Date: March 6, 2026 | 14:00 - 15:00 CET

CME Credits: 1

This session will explore the evolving landscape of multidisciplinary research in imaging, highlighting funding opportunities, practical experiences, and the creative aspects of designing and promoting research projects. Experts from medicine, AI, and engineering will share insights on integrating imaging across disciplines, navigating European grant opportunities, and fostering innovation through collaboration.

Moderators:

Evis Sala; Rome / Italy

Andrea Agostini; Fermo / Italy

Chairpersons' introduction (5 min)

Evis Sala; Rome / Italy

Andrea Agostini; Fermo / Italy

Imaging at the crossroads of medicine, AI, and engineering: grant opportunities (15 min)

Peter Gordebeke; Vienna / Austria

Exploring image-based biomarkers across disciplines: insights from pathology (15 min)

Zhuxian Guo; Créteil / France

Radiology meets archaeology – from CT scanning to virtual reality (15 min)

John Henderson Reid; Galashiels / United Kingdom

Panel discussion: How can multidisciplinary collaboration in imaging drive the future of research? (10 min)

E³ 1518 - Female genitourinary

Categories: Oncologic Imaging, Genitourinary, President's Choice

ETC Level: LEVEL II

Date: March 6, 2026 | 14:00 - 15:30 CET

CME Credits: 1.5

The aim of the session is to understand the importance of radiologic-pathologic correlation in ovarian tumours and to be aware of the importance of radiologic-pathologic correlation in uterine tumours.

Moderator:

Rosemarie Forstner; Salzburg / Austria

Chairperson's introduction (5 min)

Rosemarie Forstner; Salzburg / Austria

Ovarian tumours (35 min)

Isabelle Thomassin-Naggara; Paris / France

Justine Varinot; Paris / France

Uterine tumours (35 min)

Camilla Panico; Rome / Italy

Giulia Scaglione; Rome / Italy

Challenging case presentation by the moderator and discussed by the tandems (15 min)

Rosemarie Forstner; Salzburg / Austria

E³ 1519 - Reporting and data systems (RADS): addressing diagnostic challenges in the head and neck

Categories: Oncologic Imaging, Neuro, Head and Neck, President's Choice
ETC Level: LEVEL II+III
Date: March 6, 2026 | 14:00 - 15:30 CET

Moderator:
Alexandra Borges; Lisbon / Portugal

Chairperson's introduction (5 min)
Alexandra Borges; Lisbon / Portugal

Brain tumour-reporting and data system (BT-RADS) and beyond: assessing response to therapy in real-world practice (20 min)
Suyash Mohan; Philadelphia, PA / United States

1. To describe the BT-RADS system for assessing treatment response in brain tumours.
2. To learn how to apply this in clinical practice and impact on clinical management.
3. To appreciate how this compares to other systems and limitations of BT-RADS.

Thyroid imaging-reporting and data system (TI-RADS): dealing with incidental thyroid nodules (20 min)
Edith Vassallo; Msida / Malta

1. To describe the US TI-RADS risk stratification system for classifying thyroid nodules.
2. To learn about best practices and how to apply TI-RADS in clinical practice.
3. To understand the impact of TI-RADS on clinical management.

Neck imaging-reporting and data system (NI-RADS): is there tumour recurrence? (20 min)
Barton F. Branstetter IV; Wexford / United States

1. To learn about the rationale and development of the NI-RADS risk stratification system.
2. To appreciate how to apply it in clinical practice across the imaging modalities.
3. To understand the challenges and limitations of NI-RADS.

Case-based panel discussion: how reporting and data systems (RADS) help clinical practice (25 min)
Alexandra Borges; Lisbon / Portugal

E³ 1523 - Interventional

Categories: Interventional Radiology, Vascular
ETC Level: LEVEL I+II
Date: March 6, 2026 | 14:00 - 15:30 CET

Basic principles of angiography and image-guided interventions (28 min)
Philipp M. Paprottka; München / Germany

1. To understand the importance of pre-procedure imaging, the selection of an appropriate imaging technique for image guidance and procedure planning.
2. To describe the basic principles of angiographic imaging techniques (Fluoroscopy, DSA, Overlay, Roadmap, Cone beam CT).
3. To explain basic percutaneous image-guided techniques, including arterial access as well as biopsy and drainage.

Image-guided procedures in interventional oncology (28 min)
Miltiadis Krokidis; Athens / Greece

1. To describe the basic technical methodological principles and indications of imaging-guided interventions in oncological disorders, including different thermal ablation techniques (percutaneous and intraoperative).
2. To understand the principles and indications for vascular interventions in cancer, such as the transarterial treatment of liver tumours and embolisation before surgery.
3. To become familiar with posttreatment follow-up, highlighting normal and abnormal pathological imaging findings.

Vascular interventions (28 min)
Marcello Andrea Tipaldi; Rome / Italy

1. To describe the indications and techniques for treating peripheral arterial occlusive disease (PAOD, acute and chronic).
2. To explain the techniques of arterial embolisation in acute bleeding.
3. To understand the indication and technique of prostate artery embolisation (PAE) in benign prostatic hyperplasia in men and embolisation/sclerotherapy in female patients with pelvic congestion syndrome (PCS).

HF 3 - Smart Workflow: AI in Action

Categories: Professional Issues, Management/Leadership, Imaging Informatics, Artificial Intelligence

Proximie: Learning lessons from surgical workflow (12 min)
Nadine Hachach-Haram; London / United Kingdom

1. To appreciate where AI can be utilised to optimise efficiency in the operating environment.
2. To understand workflow bottlenecks and methods to improve throughput.
3. To be aware of the potential benefits and challenges of agentic AI in the radiology workflow.

Making AI real: an end-to-end imaging ecosystem to deliver workflow gains (12 min)
Antonio Luna Alcala; Madrid / Spain

1. To explain an end-to-end imaging IT ecosystem that enables the rapid and safe deployment of AI into clinical workflow.
2. To describe a scalable validation and governance pathway, including clinical safety assessment, performance monitoring, and clear accountability in real-world deployment.
3. To highlight high-impact clinical AI and NLP use cases that reduce operational bottlenecks.

Agentic AI in scheduling and reporting (12 min)
Nina Kottler; Carlsbad / United States

1. To appreciate where AI can be utilised to optimise efficiency in the operating environment.
2. To understand workflow bottlenecks and methods to improve throughput.
3. To be aware of the potential benefits and challenges of agentic AI in the radiology workflow.

Q&A (21 min)

JIIQ - Sparta vs Athens

Infectious ileocolitis: can microbiological diagnosis be made on imaging? (17 min)
Giovanni Maconi; Milan / Italy

1. To learn about the main infectious agents that cause ileocolitis in Western countries.
2. To learn about the role of US and imaging signs that can help guide a microbiological diagnosis.
3. To differentiate between primitive infectious colitis and colitis in reaction to a deep infectious process.

Acute inflammatory colitis: Crohn's or UC? (17 min)
Marta Zerunian; Rome / Italy

1. To review the histopathological differences between Crohn's disease and ulcerative colitis.
2. To define CT signs that can differentiate Crohn's from UC in an acute setting.
3. To review the complications of a colonic location of the disease.

Diverticulitis (17 min)
Matteo Bonatti; Bolzano / Italy

1. To learn about the imaging classification of diverticulitis.
2. To present tips on imaging that differentiate from other mimickers.
3. To discuss the radiologic follow-up and management guidance.

OB 15 - The musician's brain: when radiology and music resonate!

Categories: Imaging Methods, Neuro, Radiographers, Multidisciplinary, President's Choice

ETC Level: ALL LEVELS

Date: March 6, 2026 | 14:00 - 15:00 CET

CME Credits: 1

What happens inside the brain of a professional musician? By combining medical imaging, neuroscience, and musical practice, this presentation explores the cerebral mechanisms behind musical expertise.
Drawing on a functional MRI study of several professional musicians—including a pianist, flautist, harpist, violinist, and conductor—we will reveal fascinating insights. Discover which brain regions are universally activated across all musicians, and how others adapt depending on the instrument played, the learning method, and the musician's personal connection to music. To bring these concepts to life, musical illustrations will be performed on the piano during the presentation.

Deep Learning–Enhanced Post-Hoc Denoising Enables High-Quality Low-Dose Coronary CT Angiography in Obese Patients (6 min)

Sardi Hyska; Munich / Germany

Author Block: J. Osoria-Velasquez[1], S. Hyska[1], N. Fink[2], M. Vecsey-Nagy[3], T. S. Emrich[4], A. Varga-Szemes[1], M. T. Hagar[1]; [1]Charleston, SC/US, [2]Munich/DE, [3]Budapest/HU, [4]Mainz/DE
Purpose: To assess the incremental benefit of post-hoc convolutional neural network (CNN)–based denoising for coronary CT angiography (CCTA) performed at low radiation doses, compared with conventional iterative reconstruction.
Methods or Background: Consecutive patients who underwent clinically-indicated CCTA on a third-generation dual-source CT system were included. All examinations used a fast-pitch acquisition and a fully individualized contrast protocol comprising 56 tailored combinations of contrast volume and injection rate. Axial datasets were reconstructed with a vascular kernel (Bv40) using iterative reconstruction (Admire 3), with and without additional CNN-based denoising. Two blinded readers assessed signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), and image noise across proximal and distal coronary segments. Subjective image quality and sharpness were rated on a 4-point scale (4 = excellent). Linear mixed-effects models were used to analyze the impact of body mass index (BMI) on denoising performance.
Results or Findings: Fifty-six patients (51.7±12.8 years old; 57% women) were included, 35 (62.5%) were obese. The mean dose-length product was 99±86 mGy·cm. Compared with iterative reconstruction, CNN-denoising decreased image noise (21 ± 5 HU vs 35 ± 8 HU, p<0.001) and enhanced SNR (22 ±6 vs 12 ±3, p<0.001) and CNR (19 ±5 vs 11 ±3, p<0.001), without altering attenuation values (p>0.1). Subjective image quality improved (median 3 [3–4] vs 3 [2–3], p<0.001), while sharpness remained unchanged. Poor-quality segments decreased from 14.7% to 9.0%, and good-to-excellent quality rose from 52.6% to 75.0%. Noise reduction (−10.3 HU, p=0.007) and gains in SNR (+ 8.0, p=0.008) and CNR (+ 6.9, p=0.011) were consistent across BMI categories (p≥0.29).
Conclusion: Post-hoc CNN-based denoising enables high-quality, low-dose CCTA -even in obese patients- by markedly reducing image noise and improving SNR/CNR while preserving attenuation accuracy and vessel sharpness.
Limitations: The used denoising algorithm is proprietary.

Super-resolution deep learning reconstruction for coronary CT angiography□improved coronary stenosis assessment and CAD-RADS reclassification (6 min)

Limiao Zou; Beijing / China

Author Block: L. Zou; Beijing/CN
Purpose: A novel super-resolution deep learning reconstruction (SR-DLR) technique has been developed for coronary CT angiography (CCTA). The purpose of this study was to compare SR-DLR against conventional hybrid iterative reconstruction (HIR) in coronary stenosis assessment, using invasive coronary angiography (ICA) as a reference, and explore the possible impact on patient-level CAD-RADS classification.
Methods or Background: From September 2023 to November 2024, patients who underwent clinically indicated CCTA and ICA within 2-month interval were prospectively enrolled from 10 hospitals across China. CCTA images were reconstructed with both HIR and SR-DLR and percentage diameter stenosis of calcified, noncalcified, and mixed plaques were quantified and bias was determined from the ICA-derived quantitative coronary angiography measurements. Changes in patient-level CAD-RADS categories across the reconstructions were also assessed.
Results or Findings: 204 patients (mean age, 64.3 years ± 9.1 [SD]; 137 male patients) were included and 605 plaques (175 calcified, 140 noncalcified, and 290 mixed) were identified. Higher agreement with ICA was obtained with SR-DLR as compared to HIR across the plaque type(mean bias:11% vs. 17% for calcified plaques, 0% vs. -4% for noncalcified plaques, and 4% vs. 5% for mixed plaques). While 163 patients remained constant, 25 patients were assigned a lower CAD-RADS category using SR-DLR than assigned using HIR, whereas 16 patients were assigned a higher category.
Conclusion: SR-DLR outperformed HIR for coronary stenosis assessment and led to 20% patient-level CAD-RADS reclassification, potentially enhancing the role of CCTA in the diagnosis and patient management of CAD.
Limitations: Due to major differences in the image characteristics, observers may have been able to visually distinguish between the reconstruction methods. And further dedicated studies are warranted to investigate the possible impact of CAD-RADS reclassifications enabled by SR-DLR on downstream management and patient outcomes.
Funding for this study: This study was supported by the Beijing Natural Science Foundation [Grant No. Z210013, 2021], the National Science Fund for Distinguished Young Scholars [Grant No. 82325026, 2024], the CAMS Innovation Fund for Medical Science[2023-I2M-C&T-A-004], the Non-profit Central Research Institute Fund of Chinese Academy of Medical Sciences[2024-RC320-03] and the National High Level Hospital Clinical Research Funding [2022-PUMCH B-027, 2022-PUMCH B-068]

Predicting Mid-Term Risk of Coronary Plaque Progression in Subclinical Non-Obstructive Coronary Atherosclerosis Using Explainable Machine Learning (6 min)

Yanping Su; Lishui City / China

Author Block: Y. Su, J. Mei, R. Ye, J. Ji, C. Lu; Lishui/CN
Purpose: Coronary atherosclerosis (CAS) remains a major cause of cardiovascular morbidity and mortality. Subclinical non-obstructive CAS, though often overlooked, carries substantial risk. This study aimed to develop an interpretable machine learning (ML) model integrating conventional risk factors and quantitative coronary computed tomography angiography (CCTA) features to predict mid-term plaque progression.
Methods or Background: We retrospectively analyzed 644 adults with subclinical non-obstructive CAS from a community-based screening program, followed with serial CCTA over a median of 56 months. Candidate features were selected using Spearman correlation and bootstrap-enhanced LASSO (BOLASSO). Seven ML algorithms were compared, and the optimal model was interpreted with SHapley Additive exPlanations (SHAP).
Results or Findings: The cohort (mean age 62 years, 53.6% men) showed best performance with the Random Forest (RF) model. The final 8-feature RF model achieved an AUC of 0.875 (95% CI, 0.827–0.920), precision 0.863, accuracy 0.779, recall 0.726, F1 score 0.788, specificity 0.849, and NPV 0.702. SHAP identified fibrofatty plaque volume and coronary artery calcium as principal progression drivers.
Conclusion: This explainable ML framework enables individualized risk stratification for subclinical non-obstructive CAS, supporting early identification of high-risk individuals and timely implementation of preventive strategies such as intensive lipid-lowering, anti-inflammatory therapy, and lifestyle modification. Integration of imaging biomarkers with ML may help optimize longitudinal surveillance and improve cardiovascular prevention.
Limitations: As a single-center retrospective study, selection bias cannot be excluded. The mid-term follow-up may not capture long-term dynamics, and external validation is lacking. SHAP-derived thresholds require confirmation in larger, diverse cohorts. Finally, as an observational study, causal inference is limited, and randomized controlled trials are needed to determine real-world clinical utility and confirm patient benefit.
Funding for this study: This work was supported by National Key Research and Development Program of China (grant no. 2024YFC2417600 to Jiansong Ji); Natural Science Foundation of Zhejiang Province (grant no. LBZ24H100001 to Chenying Lu); Zhejiang Medicine and Health science and Technology Project (grant no. 2023KY418 and 2024KY563 to Yanping Su, grant no. 2025KY1916 to Jiayi Shen); Science and Technology Project of Lishui City (grant no. 2024GYX51 to Yanping Su).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This single-center retrospective cohort study was conducted in accordance with the principles of the Declaration of Helsinki and approved by the Ethics Committee of the Fifth Affiliated Hospital of Wenzhou Medical University (approval number: 2025 [I] -217-01).

Development of a LASSO-Cox Model for Predicting In-Stent Restenosis After Percutaneous Coronary Intervention (6 min)

Jinxia Ma; Lanzhou, China / China

Author Block: J. Ma, M. Jing, H. Zhang, X. Ming; Lanzhou, China/CN
Purpose: To construct and validate a predictive model for in-stent restenosis (ISR) following percutaneous coronary intervention (PCI)
.
Methods or Background: This retrospective study enrolled patients who underwent coronary computed tomography angiography (CCTA) within one week prior to PCI and follow-up CCTA or invasive coronary angiography (ICA) post-PCI. Fat attenuation index (FAI) was measured at the target lesion(FAIp), both proximally and distally(FAIpp). CT-derived fractional flow reserve (CT-FFR) at the lesion and the translesional gradient (ΔCT-FFR) were computed. The LASSO was used to screen for factors influencing ISR occurrence. These factors were incorporated into a multivariate Cox regression analysis to construct a nomogram model.
Results or Findings: CCTA-derived FAIp (HR=1.090, 95% CI 1.051–1.131, P < 0.001) and ΔCT-FFR (HR=5.335, 95% CI: 1.085-26.229, P < 0.001) were independent risk factors for ISR. The constructed nomogram model achieved a C-index of 0.869 (95% CI: 0.797-0.941), with good calibration curve fit. The clinical decision curve demonstrated high clinical utility of the model.
Conclusion: The integrated model combining FAIp and ΔCT-FFR based on CCTA enables early prediction of ISR after PCI.
Limitations: First, as a single-center retrospective study, it is potentially subject to selection bias. The extended follow-up period also contributed to a relatively small sample size. Despite this, the study yielded favorable outcomes. Future investigations will incorporate larger cohorts to enhance model stability and include prospective validation. Second, the use of a fixed tube voltage may limit generalizability; future work should explore other voltage levels. It is noteworthy, however, that consistent scanning equipment and parameters eliminated their potential confounding effects on FAI measurements. Finally, semi-automated quantification of FAI and CT-FFR (using Shukun software) may introduce some bias, although all results were reviewed and corrected by physicians, thereby ensuring a reasonable level of reliability.
Funding for this study: This work was supported by the Gansu Provincial Health Industry Research Program for Outstanding and Key Young Talents [Grant No. GSWSQN2023-04], the "Cuiying Graduate Supervisor" Mentorship Program of the Second Hospital of Lanzhou University [Grant No. CYDSPY202003], and the Natural Science Foundation of Gansu Province [Grant No. 23JRRA0997].
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study complied with the Declaration of Helsinki and was approved by the Institutional Ethics Committee (Approval No. 2025A-703).

Impact of DLR-based whole heart Motion Correction on inter and intra reader reproducibility of pre-TAVR CT measurements (6 min)

Mickaël Ohana; Schiltigheim / France

Author Block: G. Coutat[1], F. Tatsugami[2], D. Touitou-Gottenberg[1], W. Fukumoto[2], T. Higaki[2], A. Taniguchi[2], K. Haioun[2], Y. Nakamura[2], M. Ohana[1]; [1]Strasbourg/FR, [2]Hiroshima/JP
Purpose: Reproducibility of aortic annulus sizing and aortic valve opening area planimetry on pre-TAVR cardiac CT is crucial for procedural planning.
Whether a DLR-based whole heart Motion Correction algorithm (MC-DLR) combined with Super Resolution Deep Learning Reconstruction (SR-DLR) could affect inter and intra reader reproducibility of these measurements, particularly in heavily calcified aortic cusps, remains unknown.
This study aimed to compare inter and intra reader reproducibility of aortic annulus and aortic valve opening planimetry measurements on CT reconstructions without and with MC-DLR.
Methods or Background: 60 consecutive pre-TAVR CT scans stratified by heart rate (30 with HR<75bpm, 30 with HR>75) were retrospectively selected from 2 tertiary centers. Systolic phase was reconstructed with SR-DLR (1024 matrix size) without and with MC-DLR.
4 radiologists independently and randomly reviewed all 120 datasets to assess qualitative image quality, aortic annulus area and aortic valve planimetry.
2 readers repeated all measurements following a 4 weeks delay.
Statistical analysis was performed using Bland-Altman plots and intraclass correlation coefficient (ICC).
Results or Findings: Image quality was higher with MC-DLR (mean 2.82/3 vs 2.67, p=0.07)
Inter-reader agreement for aortic annulus area was excellent and similar without (ICC 0.81, 95% CI 0.78-0.83) and with MC-DLR (ICC 0.80, 95% CI 0.77-0.82).
Inter-reader agreement for aortic valve planimetry was higher with MC-DLR (ICC 0.90, 95% CI 0.86-0.92) than without (ICC 0.83, 95% CI 0.80-0.85).
Intra-reader agreement for both measurements was marginally improved with MC-DLR.
Conclusion: DLR-based whole heart MC may improve the reproducibility of aortic valve area planimetry in systolic pre-TAVR CT.
Limitations: Potential clinical implications of MC-DLR on device selection were not analyzed in this study.
Funding for this study: No funding was received for this study.

Ethics committee - additional information: Approved by the ethics committee of Strasbourg University Hospital

Assessment of coronary artery stenosis using virtual non-calcification in photon-counting detector CT (6 min)

Hao Shih; New Taipei / Taiwan, Chinese Taipei

Author Block: H. Shih[1], M-C. Liu[1], S-W. CHAN[1], W-H. Chen[1], J-H. Chen[2]; [1]Taichung/TW, [2]Kaohsiung/TW
Purpose: Blooming artifacts from calcified plaques may lead to overestimation of coronary arteries stenosis (OCAS) using virtual monochromatic imaging (VMI). The aim of this study was to test the ability of virtual non-calcification (VNC) of photon-counting detector CT (PCD-CT) to reduce OCAS in VMI.
Methods or Background: Retrospective analysis of subjects underwent coronary CT angiography from 2025 Jan. to Mar. was performed. Images acquired by PCD-CT were reconstructed by VMI and VNC. Percentage diameter stenosis (PDS) was compared between the two algorithms. Subgroup analyses by stenosis extent, CAD-RADS and calcium score were also performed.
Results or Findings: 344 subjects were initially included. 180 subjects were excluded, 159 due to zero calcium scores, and 21 with stent history. Totally, 164 subjects with 562 plaques were studied. VNC failed to remove calcium in 124 plaques (22.1%). Most of these plaques had density < 1000 HU (average density 887 HU). In 27 dense plaques, VNC erroneously removed intravascular contrast medium. PDS significantly decreased in VNC compared to VMI (VMI: 18.9 ± 16.7; VNC: 8.7 ± 10.5. P<0.01). VNC also showed significant decrease of PDS in three subgroup analyses (all Ps<0.01). For example, subjects with PDS> 50 in VMI decreased from 58.7 ±8.3 in VMI to 26.1 ±13.2 in VNC. Further, VMI may show false positive findings. A 67-year-old male subject showed moderate to severe stenosis (>50%) in VMI. While invasive angiography and VNC images showed no significant stenosis. Overall, subjects with more severe calcified plagues showed more prominent overestimation of stenosis in VMI images.
Conclusion: Our preliminary results showed the benefit of VNC to reduce the overestimation of stenosis evaluated by VMI. VNC may potentially reduce the unnecessary invasive coronary angiography.
Limitations: Our study lacked invasive angiography for most of the cases.
Funding for this study: No funding was provided for this study.

Feature-tracking CT assessment of LV global longitudinal strain in TAVI candidates: prospective comparison with echocardiography (6 min)

Markus Jean Staffan Irding; Jönköping / Sweden

Author Block: M. J. S. Irding; Jönköping/SE
Purpose: In patients referred for TAVI prospectively evaluate the determination of left ventricular ejection fraction (LVEF) and global longitudinal strain (GLS) measured by feature-tracking multi-detector CT (MDCT) versus transthoracic echocardiography (TTE).
Methods or Background: 77 consecutive TAVI candidates (mean age 80 ± 7 years; 54% women) underwent clinical TTE and multiphase MDCT. LVEF and GLS were analysed using commercially available software.
Results or Findings: Mean GLS −13.9 ± 4.2% (TTE) and −11.2 ± 4.1% (MDCT) where MDCT underestimated GLS versus TTE (mean bias 2.7 percentage points; $p < 0.001$). Moderate correlations were observed for LVEF ($r = 0.603$, $p < 0.001$) and GLS ($r = 0.452$, $p < 0.001$); correlations improved in a subgroup excluding 12 examinations with compromised image quality (LVEF $r = 0.688$; GLS $r = 0.622$). Reproducibility of MDCT measurements was high (intra-reader ICC for LVEF 0.90 and GLS 1.00; inter-reader ICC for LVEF 0.67 and GLS 0.96).
Conclusion: Our findings indicate that cardiac MDCT is a feasible and repeatable method for assessing LVEF and GLS in TAVI candidates. However, MDCT shows a tendency to underestimate GLS compared to TTE, warranting the establishment of modality-specific threshold values. Stricter quality criteria yield a higher agreement, suggesting that diagnostic modality selection should consider patient-specific factors. Future research should explore the integration of MDCT-derived GLS in clinical practice, particularly in cases where TTE quality is compromised.
Limitations: The main limitations include the variable time interval between echocardiography and MDCT and the relatively small sample size for reproducibility testing. Despite these, the study's prospective design and low intra- and inter-reader variability support the reliability and clinical relevance of our findings.
Funding for this study: Funding for this study was generously provided by Futurum, The Academy for Healthcare Region Jönköping County, and FORSS, the Medical Research Council of Southeast Sweden.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: It has been granted authorization from the Swedish ethical review authority.

High-Z Contrast Media for Coronary Photon Counting Detector CT Angiography: Improved Quantification of Calcified Stenoses (6 min)

Tristan Thorben Demmert; Zurich / Switzerland

Author Block: T. T. Demmert[1], K. Klambauer[1], B. Schmidt[2], V. Mergen[1], L. J. Moser[1], T. Allmendinger[2], T. Flohr[2], M. Eberhard[1], H. Alkadhi[1]; [1]Zürich/CH, [2]Forchheim/DE
Purpose: Blooming artifacts from calcified plaques obscure the vessel lumen and cause stenosis overestimation. Spectral coronary angiography with photon-counting CT (PCD-CT) provides virtual monoenergetic images (VMI). While higher VMI energies reduce blooming, iodine contrast is diminished. This study evaluated whether contrast agents with higher atomic numbers (high-Z) preserve vascular contrast at high energies and improve stenosis quantification.
Methods or Background: A phantom with 4 mm and 6 mm rods mimicking vessels containing eccentric calcified plaques (25%, 50%, 75% stenoses) was scanned with a dual-source PCD-CT. Five contrast agents (Iodine, Tungsten, Holmium, Hafnium, Bismuth) were tested. VMI were reconstructed from 40–190 keV in 1 keV increments. Vessel attenuation, contrast-to-noise ratio (CNR), and stenoses were measured. Image quality was qualitatively assessed.
Results or Findings: Iodine attenuation was high at low energies but dropped below 250 HU at >100 keV. Tungsten, Holmium, Hafnium, and Bismuth maintained >250 HU across the range. Iodine CNR was high at low but decreased at high energies, similar to Holmium and Bismuth. Tungsten and Hafnium showed lower CNR at low energies but stable at high keV; Tungsten rose to ~40. Stenoses were overestimated at low energies (24–32.5% at 40 keV) but decreased at high energies (0–13.5% at 190 keV). At 190 keV, Tungsten, Hafnium, and Bismuth showed ≤2.5% overestimation versus Iodine (10–13.5%). Image quality varied: very high-Z agents achieved highest scores, iodine peaked at 55–70 keV but performed worst overall at high energies.
Conclusion: Compared with iodine, very high-Z agents enable superior lumen definition and more accurate stenosis assessment at high VMI energies, minimizing calcium blooming.
Limitations: We used a static coronary phantom with uniform vessel diameters and calcified stenoses, not reflecting in vivo complexity. Patient factors including motion, tortuosity, and heterogeneous plaque morphology were not considered.
Funding for this study: There was no funding.

A practical rule-of-thumb to adapt the contrast media dose in photon-counting detector CT: The 10-to-5-rule (6 min)

Cécile RLPN Jeukens; Maastricht / Netherlands

Author Block: C. R. Jeukens, B. Martens, J. Vandewall, S. Jasper, G. M. Schrijnemaekers, J. E. Wildberger, T. Flohr; Maastricht/NL
Purpose: It is recognized practice to reduce the contrast media (CM) dose in CT as much as clinically feasible. For conventional CT a practical 10-to-10-rule indicates that a 10% lower CM dose can be used for each 10 kV reduction in tube voltage, while maintaining constant iodine enhancement.
This study aims to develop a practical rule how to reduce CM dose in photon-counting detector CT (PCD-CT) when lowering the energy of the reconstructed virtual mono-energetic images (VMI) for parenchymal CT and CTA.
Methods or Background: Spectral abdominal and chest CT phantoms, containing a range of iodine concentrations and ICRU muscle tissue, were scanned using a portal venous phase (PVP) abdominal and a high-pitch CTA protocol on a dual-source PCD-CT. Two fat equivalent rings were used to mimic different patient sizes. Iodine Contrast-to-Noise Ratio (CNR) was measured in VMIs at energies from 40 to 60 keV in 5 keV steps. In 15 abdominal and 15 CTA patient scans (body-mass-index 17-37 kg/m2), the CNR at different VMI energies was retrospectively determined.
Results or Findings: Each 5 keV reduction in the VMI energy range 60-40 keV maintained a similar CNR when reducing the iodine concentration by 11.7-14.4% for PVP scans and 11.8-14.5% for CTAs. Patient scan analysis showed that each 5 keV reduction resulted in a mean 11.4% and 13.7% increase in CNR for PVP and CTA scans. This can be translated to a corresponding reduction in CM dose at constant CNR. A robust, simple 10-to-5-rule was derived: for each 5 keV reduction of VMI energy, the CNR can be maintained with about 10% less CM dose.
Conclusion: Based on this phantom and retrospective proof-of-principle patient study, a practical 10-to-5-rule was derived for contrast-enhanced PCD-CT.
Limitations: Validation in larger patient study needed.
Funding for this study: N/A
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The proof-of-principle patient study received a waiver of written informed consent from the local ethical committee and institutional review board (METC 2024-0471), due to its retrospective nature.

Breaking the heart rate barrier: coronary CT angiography derived from stress dynamic myocardial perfusion on dual wide-coverage CT in patients with heart rate >90 bpm (6 min)

Shijie Xu; Shanghai / China

Author Block: K. Hou, L. Peng, J. Shen, S. Xu, M. Zeng; Shanghai/CN
Purpose: To report the initial experience and evaluate the clinical feasibility of acquiring stress perfusion-derived coronary CT angiography (CCTA) on a newly introduced dual wide-coverage CT, in patients with heart rate >90 bpm.
Methods or Background: This retrospective study included 35 patients with heart rate >90 bpm who underwent both stress dynamic myocardial CT perfusion (CTP) and CCTA within one examination on a dual wide-coverage CT. CTP was followed by a routine rest CCTA within a 10-minute interval, using two separate contrast medium injections. Perfusion-derived CCTA was obtained by manually selecting the peak arterial phase from the dynamic perfusion dataset. Two radiologists jointly evaluated the presence of ≥50% stenosis on both perfusion-derived CCTA and routine CCTA. The diagnostic performance was compared between the two CCTA datasets on a per-segment and per-vessel basis, using invasive coronary angiography as the reference standard. The overall image quality was evaluated using a 5-point scale (1=poor, 5=excellent).
Results or Findings: The mean heart rates during CTP and routine CCTA acquisitions were 102.3 ± 10.3 bpm and 78.9 ± 7.8 bpm, respectively. There was no significant difference in sensitivity, specificity, and accuracy between two CCTA datasets for diagnosing ≥50% stenosis in both per-segment (perfusion-derived CCTA: 92.0%, 96.4% and 95.7% vs. routine CCTA: 93.3%, 97.0% and 96.5%; all p>0.05) and per-vessel analyses (perfusion-derived CCTA: 96.1%, 95.5% and 95.7% vs. routine CCTA: 98.0%, 95.5% and 96.4%; all p>0.05). No significant difference was found in overall image quality between two CCTA datasets (perfusion-derived CCTA: 4.5±0.5 vs. routine CCTA: 4.6±0.5, p=0.508).
Conclusion: It is feasible to obtain stress perfusion-derived CCTA in patients with heart rate >90 bpm using dual wide-coverage CT, where the diagnostic performance of perfusion-derived CCTA was comparable to that of routine rest CCTA.
Limitations: N/A

Ultra-low-dose contrast via pulmonary artery for CT Angiography in TAVI Candidates with Chronic Kidney Disease (6 min)

Mario Babbaro; Milano / Italy

Author Block: M. Babbaro, L. Tondi, P. Spagnolo, F. BEDOGNI; Milan/IT
Purpose: Computed tomography angiography (CTA) is a cornerstone in preprocedural planning for transcatheter aortic valve implantation (TAVI). However, the high volume of iodinated contrast media (ICM) used poses a significant risk in patients with chronic kidney disease (CKD), who are susceptible to contrast-induced nephropathy (CIN). The aim of this study is to evaluate the feasibility of an ultra-low-dose CTA protocol using main pulmonary artery (MPA) contrast injection in patients with ≥stage 3b CKD (eGFR ≤45 mL/min/1.73 m²) referred for TAVI.
Methods or Background: In this prospective single-center study, 77 patients with CKD underwent pre-TAVI CTA between June 2018 and August 2023 using a tailored ultra-low-dose ICM protocol (8–20 mL) administered via a MPA catheter. ICM volume was stratified by BMI. Image quality, intraluminal attenuation and noise were assessed. Aortic annulus and vascular access measurements were performed. TAVI eligibility and postprocedural complications were recorded.
Results or Findings: CTA was successfully completed in all patients. Arterial attenuation at the aortic annulus exceeded 200 HU (mean: 352 ± 164 HU), with good image quality throughout the aorto-iliac axis. 74 patients (96%) underwent TAVI, with 97.3% treated via transfemoral access. There were no PA catheterization-related complications. Paravalvular leak ≥moderate was observed in 10 (14%) patients and 15 (20%) required new permanent pacemaker implantation. No cases of annular rupture, coronary occlusion or valve embolization occurred.
Conclusion: This study demonstrates the feasibility and safety of an ultra-low-dose CTA protocol via MPA injection in patients with advanced CKD undergoing pre-TAVI evaluation, allowing a comprehensive anatomical assessment while significantly reducing contrast exposure.
Limitations: Post-CTA serum creatinine was not measured; therefore, the incidence of contrast-induced nephropathy (CIN) following CTA could not be assessed.

CT-based epicardial adipose tissue change as a predictor of obstructive coronary artery disease progression (6 min)

Wenzhuo Zhang; Hangzhou, China / China

Author Block: W. Zhang, Q. Zhou, X. Xu; Hangzhou, China/CN
Purpose: To evaluate the predictive value of CT-based longitudinal changes in EAT for obstructive CAD progression.
Methods or Background: We included 583 suspected CAD patients underwent coronary computed tomography angiography (CCTA) between 01.06.2010 and 30.06.2017, and received follow-up CCTA at an interval of ≥ two years . 107 patients progressed to obstructive CAD. EAT and coronary artery calcium score (CACS) were measured on non-contrast CCTA. Annualized EAT volume change was calculated as the difference between two scans divided by the follow-up duration. Obstructive CAD progression was defined as new-onset ≥50% stenosis in initially non-obstructive patients. The association of EAT with obstructive CAD progression was evaluated using univariate and multivariate logistic regression.
Results or Findings: Annualized EAT volume change was 3.47 cm^3 (IQR, 0.33 to 6.73 cm^3) in the obstructive progression group and 2.07 cm^3 (IQR,–1.16 to 4.97 cm^3) in the no obstructive progression group (P = 0.006). In univariate analysis, only age, CACS, baseline largest luminal diameter stenosis, and annualized EAT volume change were significantly associated with obstructive CAD progression. In multivariate analysis, after including variables significant in univariate analysis, annualized EAT volume change remained an independent predictor of obstructive CAD progression (adjusted OR 1.06, P = 0.007).
Conclusion: The annualized EAT volume change is an independent predictor of obstructive CAD progression, suggesting that dynamic EAT monitoring on routine CT scans may improve risk stratification for obstructive CAD.
Limitations: First, this was a retrospective study and used single-center data. Although patients were included consecutively, selection bias could not be avoided. Second, there were differences in the scan interval, with a median of 3.33 years (IQR, 2.67 to 4.33 years). Therefore, the annualized changes may to some extent adjust the potential differences induced by the various follow-up intervals.
Funding for this study: No funding was received for this study.

A Scanner-Integrated Decision Support Solution for Optimized Protocol Selection in Coronary Angiography with Photon-Counting CT (6 min)

Christopher Schuppert; Heidelberg / Germany

Author Block: C. Schuppert[1], S. Barus[1], M. Soschynski[1], T. Allmendinger[2], F. Bamberg[1], T. Krauß[1], C. L. Schlett[1]; [1]Freiburg/DE, [2]Forchheim/DE
Purpose: Photon-counting CT (PCCT) introduces novel scan modes that assist coronary CT angiography (CCTA) but increase protocol complexity. We developed and evaluated a scanner-integrated decision support solution to optimize protocol selection.
Methods or Background: In this prospective, two-center study, adult patients referred for CCTA were scanned on identical dual-source PCCT systems (NAEOTOM Alpha, Siemens Healthineers) with standard preparation. One site used the decision support solution (myExamCompanion, Siemens Healthineers), whereas the control site relied on conventional operator-driven protocol selection. Patient flow was not controlled. The decision support solution considered pre- and intra-scan input parameters reflecting coronary artery disease risk and cardiac dynamics (age, BMI, stents, Agatston score, heart rate, heart rate variability). Guided by the principle of “minimized exposure, full diagnostic performance”, it automatically selected from Quantum (70/90 kVp), Quantum Plus (120/140 kVp), Ultra High-Resolution (UHR), and Spectral UHR acquisition modes, as well as ECG-gating strategies (high-pitch spiral, prospective sequence, retrospective spiral). Evaluation focused on radiation dose, diagnostic confidence, and image quality, as measured by coronary signal-to-noise ratio (SNR) in a low-risk subset.
Results or Findings: A total of 1,304 patients underwent CCTA, with 727 (56%) scanned using the decision support solution. Baseline patient characteristics were comparable between groups. Use of the decision support solution was associated with lower dose length product (median 269 vs. 370 mGycm), mainly through greater Quantum mode utilization (34% vs. 11%). SNR was slightly lower in Quantum vs. Quantum Plus mode (median 15.3 vs. 17.7, p=0.07). The incidence of CAD-RADS≥3 was 21% vs. 29% with vs. without the solution, while CAD-RADS N was <1% in both groups.
Conclusion: The decision support solution optimizes PCCT protocol selection for CCTA, preserving image quality and interpretability while lowering radiation dose.
Limitations: Single-vendor, two-center study with site-based, non-randomized allocation.
Funding for this study: No funding was provided for this study.

Coronary stent assessment: a comparison between photon counting CT and energy integrating detector CT (6 min)

Gioele Gambato; Confienza / Italy

Author Block: G. Gambato, D. Vignale, A. Palmisano, A. Esposito; Milano/IT
Purpose: To compare photon-counting CT (PCCT) and conventional energy-integrating detector CT (EID-CT) in the in-vivo evaluation of coronary artery stents.
Methods or Background: This retrospective study was conducted in patients with coronary stents undergoing cardiac PCCT between May 2024 and September 2025 (NAEOTOM Alpha, Siemens; slice thickness 0.4 mm; kernels: Bv56, n=26; Br56, n=3; Qr56, n=1; Bv48, n=2; Br40, n=1), who had undergone a prior examination with EID-CT (SOMATOM Definition FLASH, Siemens; 120 keV, I36f kernel). Stent models were known. Images were evaluated according to qualitative parameters (Overall Image Quality, Sharpness, Noise, Blooming, and Diagnostic Confidence) by a single rater with three years of experience in cardiovascular radiology, using a five-point Likert scale. Blooming was quantified by comparing nominal stent diameter (median 3.00[2.75,3.50] mm) with measured stent diameters and by assessing intra- and extra-stent attenuation. The Wilcoxon signed-rank test was used for comparisons.
Results or Findings: Sixty stents in 33 patients (M:F 32:1, 80.5 [IQR 72.5,84.0] years) were analyzed. PCCT yielded higher scores than EID-CT across all qualitative parameters ($p<0.001$). Median improvements were +1 [IQR 0–2] for image quality, +1 [IQR 0–2] for sharpness, +1 [IQR 0–2] for noise, +2 [IQR 1–2] for blooming, and +1[IQR 0–1] for diagnostic confidence. All quantitative comparisons were significant ($p<0.001$). PCCT measurements were closer to the nominal stent diameter (median difference -0.77[IQR -1.10,-0.54]mm) than EID-CT (-1.05[IQR -1.40,-0.75]mm, and PCCT yielded larger in-stent luminal diameters than EID-CT (median difference +0.30[IQR 0.00,0.50]mm). Moreover, PCCT showed less attenuation difference between intra- and extra-stent measurements compared to EID-CT (median 139 [IQR 37–213] vs 236 [IQR 158–312] HU), both indicating a reduction of blooming artifacts.
Conclusion: Compared to EID-CT, PCCT improves the in-vivo evaluation of coronary stents by reducing blooming.
Limitations: Small sample.

Automated CT Body Composition Analysis for Perioperative Risk Stratification (6 min)
Judith Kohnke; Essen / Germany

Author Block: J. Kohnke, K. A. Borys, C. Bojahr, Y. Wen, S. Warmer, C. S. Schmidt, F. Nensa, R. Hosch; Essen/DE
Purpose: To investigate whether body composition parameters derived from CT scans are associated with 90-day survival in patients undergoing surgery within 14 days before or after imaging.
Methods or Background: Body composition has emerged as a potential predictor of perioperative risk. Sarcopenia, myosteatosis, and cachexia may indicate vulnerability to poor postoperative outcomes.
Thorax and Abdominal CT scans of 1575 cancer patients (844 female, 731 male) who underwent surgery within ±14 days of imaging were retrospectively analyzed, and an automated in-house body composition analysis was performed. Two groups were classified based on 90-day survival (1333 survived, 242 deceased). Differences in sarcopenia, myosteatosis, and cachexia (abdomen and thorax) between survivors and non-survivors were assessed using the Mann–Whitney U test. Correlations between body composition parameters and survival were examined using Spearman's rank correlation.
Results or Findings: Mann–Whitney U test revealed significant differences between 90-day survivors and non-survivors for sarcopenia (abdomen: $p<0.001$; thorax: $p<0.001$) and myosteatosis (abdomen: $p<0.001$; thorax: $p<0.001$), but not for cachexia (abdomen: $p=0.203$; thorax: $p=0.072$). Spearman correlation analysis showed positive correlations of sarcopenia with mortality (abdomen: $r=0.283$, $p<0.001$; thorax: $r=0.295$, $p<0.001$), negative correlations of myosteatosis with mortality (abdomen: ρ=-r.331, $p<0.001$; thorax: $r=-0.273$, $p<0.001$), and no significant correlations for cachexia (abdomen: $r=0.009$, $p=0.728$; thorax: $r=0.025$, $p=0.314$).
Conclusion: Sarcopenia and myosteatosis are significantly associated with 90-day postoperative survival, suggesting that automated CT-based body composition analysis provides valuable prognostic information to aid perioperative risk stratification.
Limitations: This is a single-center study. The inclusion was limited to cancer patients, and potential confounding factors were not fully accounted for.
Funding for this study: No funding was provided for this study.

A CT-Based Habitat Region Heterogeneity Index Model Associated with Tumor Microenvironment Predicts Occult Liver Metastasis and Prognosis in Pancreatic Ductal Adenocarcinoma: a multicenter study (6 min)
Wei Wei; China

Author Block: W. Wei, M. Li; He Fei/CN
Purpose: To develope a tumor habitat-based model to capture ITH from CT imaging and evaluated its prognostic value for survival outcomes in PDAC patients.
Methods or Background: In this retrospective multicenter study, we analyzed venous-phase CT scans from 370 patients with PDAC from three centers. We then assessed tumor heterogeneity by identifying distinct subregions within the tumors using a Gaussian mixture model and analyzing their textural features. Using these features, we built a regularized logistic regression model to predict the risk of occult liver metastasis. Additionally, we evaluated patient survival using Cox regression and Kaplan-Meier analysis. Finally, we examined WSIs and used Spearman correlation to explore relationships between imaging-based heterogeneity and pathological findings.
Results or Findings: The ITH model surpassed clinical models in detecting occult liver metastasis, yielding AUCs of 0.919 (vs. 0.665) in the training cohort, 0.887 (vs. 0.639) in internal testing cohort, 0.834 (vs. 0.661) and 0.794 (vs. 0.603)in external validation cohorts 1 and 2, respectively. Risk stratification via Cox regression revealed high-risk groups with markedly reduced overall and progression-free survival ($P < 0.05$) in all cohorts. Habitat features correlated with WSI-derived cell spatial distributions, pointing to inflammation and stromal remodeling as drivers of tumor heterogeneity, with negative correlations to plasma and eosinophil cells suggesting an active immune microenvironment.
Conclusion: The ITH model provides a non-invasive preoperative assessment tool for PDAC patients with occult liver metastases, while the correlative pathology implies a stronger mechanistic basis for the prediction model.
Limitations: The ITH model provides a non-invasive preoperative assessment tool for PDAC patients with occult liver metastases, while the correlative pathology implies a stronger mechanistic basis for the prediction model.

LymphoGenAI: A regulatory-compliant, interoperable AI platform for multimodal lymph node staging in oncology (6 min)

Ruben Eduardo Pacios Blanco; Madrid / Spain

Author Block: R. E. Pacios Blanco, J. Vega, C. Martínez Cabezali, L. A. Herrera Galvez; Madrid/ES
Purpose: Lymph node status is a critical determinant of prognosis and treatment planning in oncology. Current diagnostic pathways rely on invasive procedures and fragmented data interpretation, creating variability and delays. LymphoGenAI addresses this gap by developing a multimodal, generative AI-based decision support system (AI-DSS) for predicting lymph node involvement in breast and head & neck cancers, fully aligned with European digital health and AI regulatory frameworks.
Methods or Background: The consortium platform integrates radiological imaging (CT, MRI, PET), digital pathology, structured clinical data and unstructured reports into a harmonized, GDPR-compliant dataset across multiple European hospitals. Built on interoperability standards (DICOM, HL7 FHIR, SNOMED), the system employs advanced vision–language architectures and radiomics pipelines to deliver explainable predictions. Development follows EU Medical Device Regulation (MDR 2017/745) and incorporates transparency, bias monitoring and human oversight in line with the EU AI Act. Clinical validation will be conducted through retrospective and prospective multicenter studies.
Results or Findings: The project is expected to deliver a CE-mark-ready AI-DSS that enables accurate, non-invasive lymph node staging, reducing the need for unnecessary biopsies and surgical procedures. By integrating multimodal data and explainable outputs, the system will improve diagnostic consistency across institutions and accelerate time-to-treatment. Its modular, interoperable architecture will allow seamless integration into diverse hospital IT environments and ensure compliance with the European Health Data Space framework. Additionally, it will provide a long-term resource for research in oncology AI.
Conclusion: By embedding regulatory compliance, interoperability and explainability from inception, LymphoGenAI sets a benchmark for trustworthy AI in oncology. Its modular design supports scalability to other cancer types, reinforcing Europe's leadership in ethical, human-centric AI for health.
Limitations: Compliance with evolving regulatory frameworks such as GDPR, MDR and the EU AI Act introduces complexity and may delay deployment.
Funding for this study: Presented to the Horizon Europe Programme – HLTH-2025-01-CARE-01, GenAI4EU.

Reproducibility of Manual, Semi-automated, and Fully Automated L3 CT Body-Composition Metrics in Metastatic Renal Cell Carcinoma (6 min)

Francesco Farioli; San Cesario Sul Panaro / Italy

Author Block: F. Farioli, L. Casarini, F. Fiocchi, M. Dominici, R. Sabbatini, G. Ligabue, P. Torricelli, C. Baldessari; Modena/IT
Purpose: To compare the reproducibility of three CT-based body-composition workflows—manual HU thresholding, semi-automated assisted thresholding, and fully automated open-source segmentation—for skeletal muscle and adipose compartments at L3 in patients with metastatic renal cell carcinoma (mRCC).
Methods or Background: We retrospectively included 68 patients with mRCC who underwent non-contrast abdominal CT at diagnosis. At the L3 level, cross-sectional area and mean attenuation (Hounsfield units, HU) were obtained for skeletal muscle (MT), subcutaneous adipose tissue (SAT), visceral adipose tissue (VAT), and intramuscular adipose tissue (IMAT). The manual reference applied fixed HU thresholds: adipose −190 to −30 HU; muscle −29 to +150 HU. Semi-automated software generated threshold suggestions with manual slice selection and contour adjustment (areas only). A fully automated open-source pipeline yielded areas and densities for all compartments. Agreement was assessed using two-way mixed-effects ICC(3,1) with 95% confidence intervals; density ICCs were computed only for manual vs automated methods (the semi-automated workflow lacked densities).
Results or Findings: Area agreement was excellent for SAT (ICC 0.944; 95% CI 0.918–0.963) and VAT (0.945; 0.920–0.964), and good for muscle (0.847; 0.783–0.897). For densities, reproducibility was moderate for muscle (0.574; 0.391–0.714) and SAT (0.811; 0.710–0.879), but poor for VAT (0.328; 0.099–0.524). IMAT showed low agreement for area (0.319; 0.089–0.517) and density (0.103; −0.138–0.331).
Conclusion: Across methods, SAT area, VAT area, and muscle area show high reproducibility, supporting interchangeability in research pipelines and potential clinical use. Density metrics are less robust—particularly for VAT and IMAT—and may require manual verification or method-specific calibration (including explicit threshold specifications) in semi-automated and fully automated pipelines. IMAT remains challenging for automated quantification and warrants algorithmic refinement.
Limitations: Single-center retrospective design; non-contrast CT; single-slice L3; semi-automated workflow lacked densities; modest sample; variability in slice selection and software parameters; no outcomes correlation.

Computed tomography-based Delta radiomics model for predicting response to antiangiogenic therapy in colorectal liver metastases (6 min)

Long Yuan; Lanzhou / China

Author Block: L. Yuan, J. Zhou; Lanzhou/CN
Purpose: To develop a delta radiomics model based on computed tomography (CT) for predicting the efficacy of bevacizumab in patients with CRLM.
Methods or Background: This multicenter retrospective study included 90 patients with CRLM and 255 liver metastases treated with bevacizumab. Center 1 was allocated to training and internal validation, and centers 2 and 3 to external validation. The initial texture features of liver metastases were extracted from pre- and post-treatment CT images, and temporal texture features (Ratio, Delta, and Delta ABS) were calculated. Based on statistically significant clinical and texture features, eight models were constructed using a logistic regression classifier. The performance of eight models was comprehensively evaluated according to the predictive efficacy of therapeutic response to liver metastases and patient efficacy.
Results or Findings: Among the eight models, the Ratio, Delta, and COMB models demonstrated the highest predictive performance for therapeutic response to liver metastases and patient efficacy. In the training cohort, AUC values for predicting liver metastasis treatment response and patient efficacy ranged from 0.858 to 0.956 and 0.806 to 0.963, respectively. In the internal validation cohort, the ranges were 0.891–0.899 and 1.000. In the external validation cohort, they were 0.833–0.891 and 0.858–0.896.
Conclusion: The Ratio, Delta, and COMB models based on clinical and pre- and post-treatment CT texture feature for predicting the efficacy of bevacizumab therapy in patients with CRLM.
Limitations: First, although designed as a multicenter retrospective analysis, the sample size remained relatively modest. Future investigations should expand cohort sizes to enhance the prediction performance. Second, manual segmentation of liver metastasis introduces potential variability; implementing semi-automated or fully automated segmentation methods would improve efficiency and reproducibility.
Funding for this study: This work was supported by grants of the National Natural Science Foundation of China (No. 82371914) and the Cuiying Scientific and Technological Innovation Program of Lanzhou University Second Hospital (CY2021-ZD-01).

Multi-task Deep Learning Model to Predict Grade and Lymph Node Metastasis in non-functional pancreatic neuroendocrine tumors（NF-PNETs） (6 min)

Wei Tang; Shanghai / China

Author Block: W. Tang; Shanghai/CN
Purpose: To develop and validate a multi-modality deep learning pipeline that first achieves accurate automated lesion segmentation, then integrates imaging features and clinical parameters to predict tumor grade and LNM status in NF-PNETs.
Methods or Background: Accurate preoperative assessment of tumor grade and lymph node metastasis (LNM) in NF-PNETs is critical for optimizing surgical strategies and patient outcomes.This multicenter retrospective prognostic study analyzed 931 patients with pathologically confirmed NF-PNETs who underwent preoperative CE-CT between October 2010 and December 2023. Data were collected from 3 tertiary medical centers and divided into internal training (n=425), testing (n=141), and validation (n=174) cohorts, plus two external cohorts (Beijing, n=84; Guangzhou, n=107). Main Outcomes and Measures Primary outcomes were under the receiver operating characteristic curve (AUC) for tumor grade and lymph node metastasis (LNM) predictions. The Dice coefficient quantified segmentation accuracy. Predictive performance was compared against established clinical guidelines and single-modality models.
Results or Findings: In this multi-center retrospective study of 931 NF-PNET cases (740 internal; 191 external), the deep learning pipeline achieved superior automated segmentation (Dice coefficient, 0.74) and, building upon this foundation, delivered robustness accross internal and external cohorts on Grading and LNM prediction. The areas under the receiver operating characteristic curve ranged from 0.809 in internal sets to 0.820 and 0.779 in two external sets for grade classification task. For LNM prediction, model ranged from 0.892 in internal sets to 0.710 and 0.872 in two external sets.
Conclusion: This study demonstrates that a CE-CT-based deep learning pipeline provides robust, generalizable performance for noninvasive prediction of NF-PNET grade and nodal involvement. This imaging biomarker could enable personalized surgical planning by identifying patients suitable for organ-preserving procedures versus those requiring extended lymph adenectomy, potentially improving surgical outcomes while reducing unnecessary morbidity.

Age- and Sex-Specific Trajectories of Muscle and Fat Depots: A CT Study of 25,092 Adults (6 min)

Philipp Reschke; Frankfurt / Germany

Author Block: P. Reschke, K. Eichler, T. Vogl, L. D. Grünewald; Frankfurt/DE
Purpose: Age- and sex-related changes in muscle and adipose tissue are key determinants of frailty, sarcopenia, and metabolic disease, but large-scale CT-based reference data are scarce.
Methods or Background: We retrospectively analyzed CT scans of 25,092 adults (8,949 females, 16,143 males; 18–100 years). Automated segmentation quantified skeletal muscle percentage, volumes of major muscle groups, intramuscular fat (IMF), muscle attenuation, and adipose depots (total [TAT], subcutaneous [SAT], visceral [VAT], epicardial [EAT], paracardial [PAT]) at thoracic and abdominal levels. Nonlinear regression characterized age- and sex-specific trajectories.
Results or Findings: Skeletal muscle percentage was higher in males than females (thorax: 31.3% vs. 25.9%; abdomen: 30.1% vs. 26.1%; $p < 0.001$) and declined faster in the thorax. Annual losses were −0.49%/year (thorax) and −0.31%/year (abdomen) in males versus −0.27%/year and −0.13%/year in females ($p < 0.001$). Decline peaked earlier and steeper in males (24–38 years) than in females (18–46 years). Muscle volumes were consistently larger in males, including iliopsoas (669 vs. 412 mL), back muscles (978 vs. 676 mL), and gluteus maximus (1,086 vs. 832 mL). IMF was higher in females ($p < 0.001$) and increased with age. Muscle attenuation declined significantly, with quality best preserved in the iliopsoas and poorest in autochthonous muscles. Females had significantly higher SAT and TAT ($p < 0.001$), while males had significantly higher VAT, EAT, and PAT ($p < 0.001$). VAT and especially PAT showed the steepest relative increases with age.
Conclusion: This large-scale CT study defines normative age- and sex-specific trajectories of muscle quantity, quality, and fat depots, supporting opportunistic screening, sarcopenia phenotyping, and individualized risk stratification.
Limitations: Lack of lifestyle and ethnicity information.

A novel model for predicting preoperative FDX1 status in hepatocellular carcinoma: Integrating clinical factors and MRI radiomics features (6 min)

Shunli Wang; Fuzhou City, Fujian Province, China / China

Author Block: S. Wang, X. Xiong, H. Chen; Fuzhou City, Fujian Province, China/CN
Purpose: Ferredoxin 1 (FDX1) is a key regulator of cuproptosis, a newly identified mechanism of cell death. this study aimed to develop a radiomics model based on multi-phase magnetic resonance imaging (mp-MRI) for the preoperative prediction of FDX1 expression in HCC.
Methods or Background: Patients who underwent mp-MRI examinations within two weeks before surgery were retrospectively enrolled. Whole-tumor volumes were manually delineated using 3D Slicer, followed by radiomic feature extraction. Feature selection was performed through maximum relevance minimum redundancy and recursive feature elimination algorithms. Subsequently, radiomics models including single-phase models and multi-phase model were established. A combined nomogram integrating clinical predictors and the fusion radiomics signature was constructed via multivariable logistic regression. Recurrence-free survival (RFS) between groups were compared using Kaplan–Meier curve.
Results or Findings: Aspartate aminotransferase level and tumor capsule were identified as significant predictive factors. All radiomics models demonstrated improved predictive performance when combined with these clinical indicators, and the multi-phase model outperformed all single-phase models.The nomogram incorporating multi-phase radiomics signature along with clinical variables achieved the optimal performance. SHAP analysis revealed T1_original_shape_Maximum3DDiameter as the most contributive feature. Patients stratified into the low-FDX1 group by the nomogram showed significantly worse RFS than those in the high-FDX1 group.
Conclusion: The proposed MRI-based radiomics nomogram showed favorable predictive performance in predicting both the FDX1 expression levels and prognosis noninvasively in patients with HCC.
Limitations: The limitations of the study are as follows: first, the retrospective design and single-center nature may introduce selection bias; second, the patient cohort was relatively homogeneous, with a high prevalence of hepatitis B history, which may limit the clinical application of our model; third, the FDX1 expression status was dichotomized using the median as the cut-off value, which may not represent the biologically optimal threshold.
Funding for this study: No funding was received for this study.

Deep learning-based pancreatic age estimation from MRI predicts incident diabetes beyond known risk factors in the general population (6 min)

Matthias Jung; Freiburg Im Breisgau / Germany

Author Block: M. Jung, R. T. Schirrmeister, M. Reisert, S. Rospleszcz, Z. Berkarda, C. L. Schlett, F. Bamberg, J. Weiß; Freiburg Im Breisgau/DE
Purpose: Individuals and organs age at different rates. Chronological age poorly reflects this variability, whereas organ-specific biological age measures could improve risk assessment. We propose a deep learning (DL) framework (MRI-PancAge) for estimating pancreas age from MRI and investigate its value for predicting incident diabetes.
Methods or Background: MRI-PancAge was developed using data from 30,389 individuals (20-75 years) from the German National Cohort. A pancreas segmentation model on abdominal MRI was followed by a second model that takes the 3D-pancreas-segmentation-mask as input and outputs MRI-PancAge in years. MRI-PancAge was converted to a z-score, where z-score>0 refers to older and z-score<0 to younger MRI-PancAge compared to chronological age. Validation was performed in 33,559 UK Biobank (UKB) participants free of diabetes at imaging. Primary outcome was incident diabetes. Associations between MRI-PancAge categories (younger:z<-1; reference:-1–1; older:z>1) and incident diabetes were tested using Cox regression adjusted for age, sex, BMI, race, pancreas volume and fat fraction, hypertension, alcohol consumption, and smoking status. Incremental predictive value of MRI-PancAge was assessed with Harrell's C-index.
Results or Findings: Among 33,559 UKB participants (64.8±7.7 years, 50.9% female; 1.9% incident diabetes; median follow-up 4.7 years), diabetes incidence was higher in older and lower in younger MRI-PancAge (log-rank p<0.001). Multivariable Cox regression revealed an independent association between older MRI-PancAge and incident diabetes (aHR: 1.35, 95%CI[1.10-1.65], p=0.005) after adjustment for all covariates. Adding MRI-PancAge to a baseline model with traditional risk factors showed a small but significantly improved discrimination for incident diabetes (C-index 0.780 to 0.781, p=0.009).
Conclusion: DL can estimate pancreas age from MRI and predict incident diabetes in the general population beyond chronological age, pancreas volume and fat fraction, and cardiometabolic risk factors.
Limitations: Results may not be generalizable to non-Whites or people outside the United Kingdom.
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Informed consent was obtained from all participants in the UK Biobank and the German National Cohort study. In addition, we received local IRB approval (IRB of the University of Freiburg: 23-1316-S1-retro and 24-1099-S1-retro).

Volumetric vs. Slice-Based CT Body Composition Analysis: Systematic Discordance and Prognostic Impact (6 min)

Katarzyna Anna Borys; Essen / Germany

Author Block: K. A. Borys, K. Arzideh, J. Kohnke, Y. Wen, C. Bojahr, L. Umutlu, J. Haubold, F. Nensa, R. Hosch; Essen/DE
Purpose: To investigate sex-specific and ECOG status-stratified differences in CT-derived body composition analysis (BCA) and to assess concordance between volumetric and slice-based BCA measures.
Methods or Background: Baseline whole-body CTs from 23,685 cancer patients (44% female) were automatically segmented to quantify skeletal muscle and adipose compartments both volumetrically (thoracic and abdominal regions) and slice-based (mid-slice at L3 and T4 levels). Prognostic value for overall survival was evaluated using Kaplan-Meier and Accelerated Failure Time models, stratified by sex, ECOG performance status, and metastatic status. Concordance between volumetric and slice-based BCA measures was assessed with Cohen's kappa.
Results or Findings: Volumetric muscle index (MI) provided substantially greater prognostic separation than slice-based measures, with a median survival difference of 94 months between lowest and higher tertiles in females (47 vs. 141 months) and 69 months in males (27 vs. 96), compared with ≤56 months for slice-based muscle area (MA). Subcutaneous adipose tissue also showed stronger volumetric effects, while visceral fat offered limited prognostic value. Increasing physical impairment (ECOG) was associated with muscle and fat loss. Accelerated Failure Time models confirmed consistently higher time ratios (TR) for volumetric vs. slice-based measures (abdominal MI TR=1.89, P<0.001 vs. abdominal MA TR=1.41, P<0.001 in males). Concordance analyses revealed substantial disagreement (~35%) between volumetric and slice-based muscle classifications of high- and low-risk patients, indicating systematic discordance.
Conclusion: Volumetric CT analysis provides superior prognostic value compared to slice-based markers, particularly across ECOG strata, highlighting its potential for individualized risk stratification.
Limitations: Despite adjusting for key clinical factors, unmeasured confounders such as treatment regimens, comorbidities, and nutritional habits were not assessed. Moreover, the results require external validation.
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The approval for this retrospective study was obtained by the Ethics Committee of the University Hospital Essen (approval number 21-10204-BO). Due to the study's retrospective nature, the requirement of written informed consent was waived by the Ethics Committee. All data were fully anonymized.

Algorithmic Fairness in Radiology: A Practical Deep Dive into AI Challenges (6 min)

Bahram Mohajer; Philadelphia / United States

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: B. Mohajer[1], A. Zain[2], H. Zhang[2], Z. Hu[3], R. Ball[4], J. Gichoya[5], A. E. Flanders[1], M. Ghassemi[2], E. Colak[3]; [1]Philadelphia, PA/US, [2]Boston, MA/US, [3]Toronto, ON/CA, [4]Bar Harbor, ME/US, [5]Atlanta, GA/US
Purpose: Machine learning (ML) models have demonstrated expert-level performance in radiology; however, concerns about fairness persist, potentially reinforcing healthcare inequities. AI competitions have advanced the field by providing the most diverse publicly available datasets and hosting AI challenges. However, even in these controlled settings, concerns remain about the fairness of ML models. This study assessed fairness in top-performing ML models from the Radiological Society of North America (RSNA) Cervical Spine Fracture and Abdominal Trauma Detection AI Challenges, focusing on demographic performance differences.
Methods or Background: Predictions from the 9 top-performing models were evaluated using private test sets stratified by age groups, sex, and geographical location. Performance metrics–including false positive rate (FPR), false negative rate (FNR), area under the receiver operating characteristic curve (AUC), and expected calibration error (ECE)–were compared across subgroups.
Results or Findings: The study included 788 participants from the Cervical Spine (64% male, mean-age 54.8 years) and 709 participants from the Abdominal Trauma (69% male, mean age 48.7 years) challenges. No significant AUC or FNR differences were observed across subgroups or between sexes. However, age- and region-specific FPR disparities emerged. For cervical spine fractures, older adults (≥61 years) had higher FPRs (9.7% vs. 2.6%, p<0.05). In abdominal trauma detection, older adults also showed elevated FPRs (11.6%, p=0.003). Geographic variation was notable–Asian patients had higher FPRs (28.0%), while Oceanian patients had lower rates (5.6%, p<0.05).
Conclusion: Despite being trained on the most diverse datasets available, subgroup-specific differences in FPR–particularly across age groups–persisted. These findings highlight that even diverse training data may not entirely eliminate disparities. Continued efforts to improve demographic representation and integrate fairness-aware approaches into ML development are essential.
Limitations: Limited subgroup sample sizes—especially from Africa and South America—may affect robustness of fairness estimates and limit generalizability.
Funding for this study: This study received no direct funding. In preparation of the dataset and AI challenges, funding was recieved from Radiological Society of North America (RSNA).

Preoperative Radiomics of Fat Stranding Enhancing the 2-Year Recurrence Prediction in Colorectal Cancer Patients (6 min)

Joanna Zofia Urbaniec-Stompor; Olsztyn / Poland

Author Block: J. Z. Urbaniec-Stompor[1], B. K. Budai[2], C. Zerbato[3], V. Damerell[2], S. Hardikar[4], C. Kahlert[2], C. Ulrich[4], H-U. Kauczor[2], B. Gigic[2]; [1]Olsztyn/PL, [2]Heidelberg/DE, [3]Padua/IT, [4]Utah, UT/US
Purpose: Preoperative computed tomography (CT) in colorectal cancer (CRC) is used for TNM staging at the initial diagnosis. Our study aimed to identify CT-based radiomics features of the tumor and peritumoral fat tissue that could be independent predictors of recurrence.
Methods or Background: This single-center analysis of a prospective cohort included 273 patients with venous phase preoperative CT scans from the Heidelberg site of the ColoCare Study recruited between 2010 and 2024. Single-slice tumor segmentation was performed, followed by the segmentation of peritumoral fat and radiomics feature extraction. Patients were divided into training (n=148) and test (n=126) datasets. Clinical and combined models were built to predict 2-year recurrence. Logistic regression was used for radiomics feature selection and model building. Receiver operating characteristic curve (ROC) analysis with area under the curve (AUC), likelihood ratio tests (LRT), Net Reclassification Index (NRI), and Brier scores were used for evaluation.
Results or Findings: This study evaluated 274 patients (96 female and 178 males, aged 62.64 ±11.78). TNM classification and T-stage were used as proxy labels guiding radiomics feature selection. The “GLCM-Autocorrelation” texture feature of peritumoral fat was a significant independent predictor (OR: 0.23 [0.07 - 0.88, p=0.031) of 2-year recurrence in the adjusted regression model. The combined model, including tumor and peritumoral fat radiomics features, outperformed the clinical models with an AUC, accuracy, and specificity of 0.912, 81.7%, and 80.8%, respectively, at a sensitivity of 85.2%. NRI of 0.111 and Brier score 0.074 vs. 0.119 ($p < 0.001$) also confirmed superiority
Conclusion: Radiomics features of peritumoral fat tissue significantly improve the prediction of 2-year disease recurrence when combined with conventional clinical and pathological factors.
Limitations: Single-center study design.
Funding for this study: This study was supported by National Institutes of Health (NIH)/National Cancer Institute (NCI) grants (U01206110, R01 CA189184, R01 CA207371, R01 CA211705, T32 HG008962, KL2TR002539, K07 CA222060, R03AG067994), German Federal Ministry of Education and Research (BMBF) project PerMiCCion (01KD2101D), and Stiftung LebensBlicke. B.K.B. was supported by the Medical Data Scientist Program of the Medical Faculty of Heidelberg University.

Validation of AI-Assisted RECIST Lesion Measurements in Follow-Up CT: A Multi-Center Reader Study (6 min)

Alessa Hering; Nijmegen / Netherlands

Author Block: M. J. J. De Grauw[1], R. Weber[1], M. Westphal[2], T. Lossau[2], J. H. Moltz[2], B. Van Ginneken[1], M. Prokop[1], E. J. Smit[1], A. Hering[1]; [1]Nijmegen/NL, [2]Bremen/DE
Purpose: To evaluate the effect of AI assistance on reading time, inter-reader variability, and RECIST 1.1 response in follow-up CT.
Methods or Background: In a retrospective, multi-center reader study, 23 readers (15 radiologists, 8 residents) evaluated follow-up chest–abdomen–pelvis CT of 212 oncology patients with in total 539 lesions under three conditions: unassisted, AI-assisted, and expert-assisted (using a prior radiologist’s measurement as a strong reference condition). To prevent bias, readers were informed that all support originated from AI. Reading time and inter-observer measurement variability were assessed, and outcomes were analyzed with a Bayesian generalized linear mixed model.
Results or Findings: AI assistance significantly reduced reading time per patient compared to unassisted reading (–35.96 s; 95% CI: –52.95, –22.07). At the lesion level, inter-reader variability relative to the consensus standard increased slightly with AI assistance (1.32 mm; 95% CI: 0.83, 1.91). In contrast, at the clinically relevant patient level, variability decreased substantially: differences in the Sum of Longest Diameters (SLD) of more than 20% between radiologists were observed in 43.4% of unassisted cases, 28.3% of AI-assisted cases, and 17.4% of expert-assisted cases. These effects were consistent across experience levels.
Conclusion: AI assistance reduces patient-level inter-observer variability in RECIST measurements, leading to fewer discrepancies in predicted clinical response, despite a slight increase in lesion-level variability. Combined with the significantly reduced reading time, AI systems have the potential to standardize follow-up assessments, minimize discordant treatment decisions, and increase efficiency in clinical practice. The expert-assisted condition illustrates that even higher consistency is achievable, highlighting both the progress made and potential for further refinement of AI tools.
Limitations: The use of national-level data may limit the generalizability of these findings to international populations. Further evaluation across imaging vendors and more diverse patient cohorts is warranted.
Funding for this study: This research is funded by the Dutch Research Council (NWO) under grant number Veni-21121 for Applied and Engineering Sciences (Spotting the Differences: AI-based change detection in medical images).

Dual-Habitat Multimodal Imaging with 3D Deep Learning for Predicting Lung Adenocarcinoma Invasiveness: A Radiogenomic Analysis (6 min)

XiaoYan Han; Xian City / China

Author Block: X. Han[1], L. XIAO[2], C. Zhang[1], C. Han[1]; [1]Xian City/CN, [2]Shanghai/CN
Purpose: To develop a novel deep learning framework integrating CT-defined anatomical and PET/CT-defined functional habitats to predict lung adenocarcinoma invasiveness and explore radiogenomic correlations.
Methods or Background: This retrospective study included 292 patients with separate preoperative diagnostic CT and 18F-FDG PET/CT scans, which were spatially aligned using deep learning-based deformable image registration. A dual-habitat analysis was then performed: tumors were partitioned into distinct anatomical habitats via two-stage clustering on CT data, and into functional habitats using PET/CT data. A multi-stream 3D residual network with a multi-stage intermediate fusion architecture was developed to integrate all imaging and resulting habitat maps. The model was trained to predict invasive (IAC) vs. minimally invasive (MIA) status, with performance evaluated by AUC and external validation on the TCIA TCGA-LUAD cohort.
Results or Findings: The analysis identified four distinct anatomical habitats (e.g., solid-core, ground-glass) and three functional habitats (e.g., metabolically active, necrotic). The dual-habitat deep learning model achieved significantly superior performance (Internal Validation AUC: 0.92) compared to single-habitat (AUC: 0.90) and whole-tumor models (AUC: 0.88). External validation on 69 TCIA cases yielded a robust AUC of 0.85, demonstrating strong generalizability. Explainable AI (XAI) maps visually confirmed the model's focus on the critical interface between high-density anatomical and metabolically active functional habitats. Furthermore, the volume of the metabolically active habitat correlated significantly with PD-L1 expression ($p<0.05$), establishing a key radiogenomic link.
Conclusion: Integrating anatomical and functional tumor habitats via a multi-stream deep learning model provides a comprehensive characterization of tumor heterogeneity. This dual-habitat approach significantly improves non-invasive prediction of lung adenocarcinoma invasiveness, offering a promising pathway toward a virtual "imaging biopsy".
Limitations: The limited sample size and single data source at the data level may affect the model's generalization ability and the promotion of research results.

Gaps in IVC filter retrieval: Benchmarking outcomes through a global multi-centre analysis (6 min)
Akash Sharma; Wylie / United States

Author Block: B. Miles, A. Sharma, W. Oza, T. Elwell, J. Moss; Dallas/US
Purpose: Despite multiple FDA safety communications (2010, 2014) and multidisciplinary guideline statements (CHEST 2016; SIR 2020) recommending timely retrieval of inferior vena cava (IVC) filters, retrieval rates remain low. This represents not a knowledge gap but an implementation failure. We leveraged a global, multi-institutional dataset to quantify morbidity and mortality associated with indwelling filters compared to retrieval, entirely in the post-guideline era.
Methods or Background: We queried the TriNetX Global Collaborative Network, encompassing more than 150 health systems and 150 million patient records to identify adults undergoing IVC filter insertion (CPT 37191) between 2018–2025. Patients were stratified into (1) Filter Remains (no retrieval) and (2) Filter Removed (retrieval CPT 37193 within one day to six months). Propensity score matching balanced demographic covariates. Outcomes included severe sepsis, haemorrhage, cerebral infarction, and all-cause mortality. Risk ratios (RR), risk differences, and numbers needed to treat (NNT) were calculated.
Results or Findings: A total of 58,549 patients across 155 health systems were analyzed (46,173 Filter Remains; 12,376 FilterRemoved). Despite clear guidelines, only 21% underwent retrieval. Retained filters were associated with significantly worse outcomes: Severe sepsis:
10.8% vs 2.5% (RR 4.3; NNT=12); Haemorrhage: 2.6% vs 1.1% (RR 2.3; NNT=69); Cerebral infarction: 10.0% vs 4.9% (RR 2.0; NNT=20); Mortality: 30.2% vs 4.2% (RR 7.2; NNT=4).
Conclusion: In a cohort spanning 2018–2025, only one in five filters was retrieved and retained filters were associated with sharply higher rates of infection, stroke, haemorrhage, and death. Absolute differences translate to one death prevented for every 4 filters retrieved. These findings demonstrate a persistent guidelines-to-practice gap and highlight the need for structured retrieval pathways, automated alerts, and institutional accountability to align practice with safety standards.
Limitations: Reasons for leaving IVC filters in place were not available.

Catheter-directed therapy vs anticoagulation alone for intermediate-risk PE: A propensity-matched global retrospective cohort study (6 min)
Shivam Patel; Dallas / United States

Author Block: B. Miles, S. Patel, T. Elwell, W. Oza, J. Moss; Dallas/US
Purpose: Management of intermediate-risk pulmonary embolism (PE), characterized by right ventricular (RV) strain without hemodynamic compromise, is complicated by a lack of comparative outcome data and variability in clinical guidelines. This study was conducted as a real-world comparative analysis using TriNetX, a federated EHR network with over 100 million patients across U.S. health systems. We evaluated the mortality and bleeding outcomes of CDT versus anticoagulation alone in intermediate-risk PE at one year.
Methods or Background: This retrospective cohort study used data from the TriNetX Global Collaborative Network. Adult patients with acute PE (ICD-10-CM I26.9) and evidence of RV strain (troponin ≥ 0.04 ng/mL or BNP ≥ 125 pg/mL) were included. Two cohorts were defined: (1) the CDT cohort, identified via CPT codes for mechanical thrombectomy (37184–37186), thrombolytic infusion (37211–37214), and/or alteplase administration (J2997); and (2) the anticoagulation-only group, defined by heparin or DOAC use within 24 hours of admission without CDT procedure codes. Following propensity score matching, 5,523 patients were included in each group. Primary outcomes included mortality and major bleeding (defined using ICD-10 codes I97.4, K92.2, and D62) within one year of treatment.
Results or Findings: One-year mortality was significantly lower in the CDT group (8.88% versus 10.57%), with an adjusted risk ratio (aRR) of 0.84 (95% CI: 0.75–0.90, $p < 0.0001$). Major bleeding occurred in 8.88% of CDT patients versus 11.25% in the anticoagulation cohort, with an aRR of 0.84 (95% CI: 0.76–0.94, $p < 0.0001$), indicating that CDT was not associated with increased bleeding risk.
Conclusion: CDT is associated with a mortality advantage without increased bleeding. CDT may be an effective and safer option than systemic anticoagulation for treatment of these patients.
Limitations: This study was retrospective. Prospective studies will be needed to confirm.

Renal tumor ablation; primary success rate following the shift to cryoablation, learning curve in multiprobe ablation (6 min)

Pär Erik Anders Dahlman; Uppsala / Sweden

Author Block: P. E. A. Dahlman, D. Arafat, A. Magnusson, M. Lönnemark, F. B. Berglund, P. Liss, M. Ahlberg; Uppsala/SE
Purpose: Renal cryoablation is now an established treatment for small renal masses and a nephron-sparing alternative in patients with unresectable tumors. The transition from radiofrequency ablation (RFA) and microwave ablation (MWA) to cryoablation has enabled treatment of larger and more centrally located tumors. This study reports primary success rates following CT-guided renal cryoablation.
Methods or Background: Since 2017, 337 patients with renal tumors have undergone multi-needle cryoablation, all patients are registred in an ablation registry.
A pre-ablation four-phase CT was performed one day before treatment. Follow-up CT was conducted at 6 months, 1 year, and annually for up to 5 years. Follow-up data were collected prospectively. Primary success was defined as the absence of residual tumor on 6-month multiphase CT.
Results or Findings: The overall primary success rate was 95%.
The mean tumor diameter was 3.4 cm, and the mean number of cryoprobes used per procedure was 4.2. In patients with residual tumor, the mean ablated tumor diameter was 4.6 cm (range: 2.0–6.9 cm), and the mean number of probes used was 3.9 (range: 2–6). The mean RENAL score in these patients was 9.4 (range: 7–11). Residual tumor incidence was higher in the early years of the program and due to suboptimal needle placement.
Conclusion: The adoption of cryoablation has expanded indications to include more advanced renal tumors and offers an alternative to nephrectomy, particularly in patients with solitary kidneys. This study demonstrates that cryoablation is a safe technique with a low complication rate. Residual tumor risk increases with tumor complexity, and outcomes reflect a learning curve. These findings were made possible by the creation of a dedicated registry of all ablated patients.
Limitations: Data collected from registry.
Funding for this study: Only institutional support (dept of Radiology, Uppsala University Hospital
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Since 2007 all ablated patients at Uppsala University Hospital are followed and included in a registry. The ethics committee has approved the study.

Risks and Outcomes of Vessel Perforations in Mechanical Thrombectomy: A retrospective multicenter study (6 min)

Maria Marta Taepper; Basel / Switzerland

Author Block: M. M. Taepper[1], A. Dmytriw[2], N. Ntoulias[1], A. Brehm[1], M-N. Psychogios[1], V. Schulze-Zachau[1]; [1]Basel/CH, [2]Oxford/UK
Purpose: Vessel perforation is a rare but severe complication of mechanical thrombectomy for acute ischemic stroke. We aimed to identify the procedural steps at which perforations most frequently occur and to compare bleeding duration, functional outcome, and survival across these steps.
Methods or Background: We conducted a retrospective cohort study of patients with vessel perforation during thrombectomy between January 2015 and September 2022 across 32 centers. Outcomes included bleeding duration, defined as angiographic extravasation; 90-day functional outcome, assessed by the modified Rankin Scale (mRS); and overall survival, evaluated by Kaplan–Meier analysis. Outcomes were stratified by the procedural step of perforation.
Results or Findings: Among 447 patients (mean age 73 years, 59% female), perforations occurred during retraction of a stent retriever or aspiration catheter in 45% (n=201), probing beyond the occlusion in 26% (n=117), access to the occlusion in 13% (n=58), device deployment in 9% (n=42), percutaneous transluminal angioplasty (PTA) or stent placement in 5% (n=24), and contrast injection or thrombolysis in 1% (n=5). Perforations during PTA/stent placement were associated with longer bleeding duration (1.82 [1.14 – 2.90 95% CI], p=0.01) and worse 90-day mRS (1.10 [0.33-1.80 95%CI], p=0.01) compared with all other steps. Survival also differed significantly by perforation step (p=0.01), with the lowest survival following PTA/stent-related perforations.
Conclusion: Vessel perforations most often occurred during device retraction and probing beyond the occlusion. Although less frequent, perforations during PTA or stent placement carried the poorest prognosis, likely due to prolonged bleeding.
Limitations: Retrospective design and incomplete anticoagulation data.
Funding for this study: None.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Ethical commission approval and patient consent were not required according to current local legislation as all data were anonymized before analysis and the project involved assessing safety and quality of routine patient management in the participating institutions.

MulticentRe rEal World outcomes of IrReversible Electroporation for small kDney cancers (REWIRED) (6 min)

Helen Ng; Leeds / United Kingdom

Author Block: T. M. Wah[1], V. Chan[1], H. Ng[1], A. Mahendra[2], G. Narayanan[2], J. M. Abadal[3]; [1]Leeds/UK, [2]Boca Raton, FL/US, [3]Madrid/ES
Purpose: Irreversible electroporation (IRE) is a novel, non-thermal energy that utilises high-voltage electrical pulses to cause nanopores in the cellular membrane leading to apoptosis of cancer cells. This international study on IRE for renal cancer aims to evaluate the efficacy and safety of IRE in RCC treatment.
Methods or Background: This is a retrospective analysis of a prospectively maintained database. Three experienced (UK, Europe and USA) centres were included in the study. Patients with biopsy proven, localised small renal cancers (<=6cm) and deemed unsuitable for surgery, or traditional ablation techniques after local tumour board review were included.
Results or Findings: A total of 58 patients from three sites were included in the study. Mean age at treatment was 65.8(±12.8) years, with majority (74%) of patients being male. Eleven patients (19%) have a proven diagnosis of hereditary kidney disease. The mean size of treated lesions were 3.01(±1.15)cm. Primary technical success and overall successful rate was 72.4% and 94.8%, respectively. No significant change in eGFR was observed pre- to postoperatively (p=0.08). Five (9%) patients experienced a clinically significant(>25%) drop in eGFR post-operatively. Over a medical follow up of 52(±30.2) months, overall survival and cancer-specific survival at 5 years were 88.5%(95% CI 76.1-94.7%) and 97.5%(95% CI 84.5-99.7%), respectively. Disease/recurrence-free survival and metastasis-free survival were 82.4%(95% CI 67.6-90.9%) and 89% (95% CI 75.3-95%), respectively.
Conclusion: IRE is an effective and safe modality for treatment of small renal masses when surgery or image-guided ablation is not suitable or appropriate for treatment.
Limitations: This study is limited by its retrospective and single arm nature. Dedicated studies with propensity-matched tumour characteristics are needed to directly compare the performance of IRE with cryoablation and establish the definitive role of IRE in managing complex tumours.
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki declaration and its later amendments or comparable ethical standards. For this type of study formal consent is not required. Institutional Review Board (IRB) approval was also not required.

Does Drug-coated Balloon Angioplasty for all Significant Dialysis Access Arteriovenous Fistula Stenoses Improve Circuit Patency? Preliminary Analysis of a Randomized Controlled Trial (6 min)

Bien Soo Tan; Singapore / Singapore

Author Block: B. S. Tan, A. J. W. Tan, S. Arjunana, W. Lee, Z. Tan, A. Patel, K. H. Tay, T. H. Heng, K. D. Zhuang; Singapore/SG
Purpose: To compare the efficacy of drug-coated balloon angioplasty (DCBA) (Ranger, Boston Scientific; Marlborough, Massachusetts, USA) to conventional balloon angioplasty (CBA) of all stenoses in the peripheral circuit of dysfunctional dialysis arteriovenous fistula (AVF). We present the preliminary analysis of a randomized controlled trial (RCT) comparing DCBA against CBA of our first 73 patients.
Methods or Background: This prospective single-center RCT recruited participants with stenoses in the peripheral circuit of failing mature AVF. Participants with central vein stenoses or AVF thrombosis were excluded. After successful angioplasty of all AVF stenoses in the peripheral circuit (lesion preparation achieving < 30% residual stenosis), 94 participants (72 male, 76.6%; mean age 66.8 ± 9.5 years) were randomized to DCBA or CBA in a 1:1 ratio, stratified by the number of AVF stenoses (single versus multiple). The primary outcome measure was clinically driven 6-month access circuit primary patency (ACPP). Participant follow-up for patency was up to 12 months post recruitment.
Results or Findings: The outcomes of 73 study participants (DCBA: 35, CBA: 38) (59 males, mean age: 66.2 years old) who had completed a minimum of six months follow-up were analyzed. The types of AVFs were radiocephalic (64.4 %), brachiocephalic (24.7%) and brachiobasilic (11%). In 43 patients, a single lesion was treated, while two or more lesions were treated in 30 patients. ACPP at six months was not significantly different between both groups (DCBA: 79.4%, CBA: 77.8%, p= 0.82).
Conclusion: In this initial report of our first 73 patients, the treatment of all peripheral AVF stenoses with DCBA did not yield a statistically significant difference in ACPP at six months when compared to CBA. Further analysis of the full cohort with longer follow-up may yield more definitive results.
Limitations: Preliminary results

Evaluating the Safety of Selective Internal Radiation Therapy for Primary and Secondary Liver Malignancies: A Study of 4,432 Patients (6 min)

Andreea-Ioana Nica; Frankfurt / Germany

Author Block: A-I. Nica[1], T. J. Vogl[1], F. Wacker[2], R. Klöckner[3], C. Booz[1], L. S. Alizadeh[1]; [1]Frankfurt/DE, [2]Hannover/DE, [3]Lübeck/DE
Purpose: To evaluate the safety profile of Selective Internal Radiation Therapy (SIRT) in the treatment of primary and secondary liver malignancies, with a specific focus on the incidence and management of periprocedural complications.
Methods or Background: We conducted a retrospective analysis of data from the national quality assurance registry maintained by the German Society of Minimally Invasive Therapies and Interventional Radiology (DeGIR), covering the period from 2018 to 2023. The study aimed to identify adult patients (aged >18 years) who underwent SIRT for liver tumors. We evaluated the incidence, types, and management of complications, classifying them as either 'procedure-related complications' (PRCs), occurring during or within 24 hours of the intervention, or 'post-procedure complications' (PPCs), defined as those arising more than 24 hours after the procedure.
Results or Findings: The study included 4432 patients (1563 females, 35.3%; 2869 males, 64.7%) with a mean age of 67.4 ± 11.4 years. Most SIRT-related complications were PRCs (36 cases, 0.8%), mainly due to drug side effects (5, 0.1%) and arterial bleeding (3, 0.1%). Nearly half (45.7%) were Category 2/B, requiring prolonged monitoring. One death (Category 6/F, 2.9%) occurred within 24 hours post-intervention. In 50% of cases (18), complications were managed by the interventional radiologist, 27.8% (10) by other specialties, 16.7% (6) required no treatment, and 5.6% (2) were unspecified. PPCs occurred in 4 patients (0.09%), for a total of 40 patients (0.9%) with periprocedural complications.
Conclusion: Our findings suggest that SIRT is a safe procedure for patients with liver tumors, as it demonstrates a low incidence of complications, with many being effectively managed within the same medical specialty.
Limitations: The main limitation of this study is its retrospective design.

Magnetic Resonance-guided Focused Ultrasound Surgery (MRgFUS) for ablation of osteoid osteoma: results from 10 years of experience (6 min)

Marica Adinolfi Falcone; L'Aquila / Italy

Author Block: M. Adinolfi Falcone, L. Rinvenuto, F. Arrigoni, L. Zugaro, A. Barile, E. Di Cesare; L'Aquila/IT
Purpose: Osteoid Osteoma (OO) is a benign but extremely painful bone lesion. Magnetic Resonance-guided Focused Ultrasound Surgery (MRgFUS) is an ablative technique in Interventional Radiology that combines high-intensity focused ultrasound (HIFU) with MR imaging. The aim of this study was to evaluate the long-term outcomes and effectiveness of MRgFUS in the treatment of OO compared with other therapeutic options.
Methods or Background: A retrospective analysis was performed on all MRgFUS procedures for OO conducted at our center over a 13-year period. 67 patients treated were included, all meeting the same inclusion criteria: radiological findings of OO, symptomatic lesions whit VAS > 7, and an adequate acoustic window for ultrasound beam penetration. Demographic data, morphological features, imaging findings and clinical outcomes wcre collected. All variables were statistically analyzed, and results were evaluated in terms of pain relief and nidus characteristics. Standard follow-up included clinical ooutcomes assessment at 7-10 days, 6 months, 1 year, 2 years, and 4 years; MRI at 6 and 12 months; and CT scan at 12 months.
Results or Findings: The procedure was successful in 61 out of 67 patients, with an overall success rate of 91%. All responders showed MRI resolution of bone edema and reduction of perilesional reactive changes. No complications were recorded. Treatment failure was significantly correlated with thick cortical bone overlying the nidus (p=0.014) and with a short nidus-to-ultrasound source distance (p= 0.002).
Conclusion: MRgFUS is a safe, minimally invasive, and effective therapy for OO, associated with absence of complications, rapid recovery, and a low recurrence rate. This study represent the largest reported single-center series with the longest follow-up (13 years), confirming the excellent safety profile and long-term efficacy of MRgFUS in the treatment of Osteoid Osteoma.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study.

Pectoral Nerve Block for Microwave Ablation of breast benign lesions: The Initial Clinical Experience (6 min)

JUAN LI; Sichuan / China

Author Block: J. LI, M. Lu; Chengdu/CN
Purpose: To investigate the effect of pectoral nerve block on pain management in microwave ablation (MWA) for multiple benign breast nodules.
Methods or Background: A total of 94 patients undergoing MWA for benign breast nodules were divided into three groups based on the analgesic method used: local anesthesia group (Group A, n = 31), pectoral nerve block group (Group B, n = 30), and local anesthesia combined with pectoral nerve block group (Group C, n = 33). Pain levels were recorded using the Numerical Rating Scale (NRS) during the procedure and at 2, 6, 12, 24, and 48 hours postoperatively. Postoperative analgesic requirements and complications were also documented.
Results or Findings: The consumption of lidocaine and ropivacaine during the procedure differed significantly among the groups ($p < 0.05$), with Group B showing the highest usage and Group C the lowest. Group C exhibited lower intraoperative and postoperative NRS scores compared to Groups A and B ($P < 0.05$), while no significant difference was observed between Groups A and B ($P > 0.05$). At 2 and 6 hours postoperatively, Group A had lower NRS scores than Group B ($P < 0.05$), but no significant differences were noted at 12, 24, and 48 hours ($P > 0.05$). The postoperative analgesic requirement was significantly lower in Groups B and C compared to Group A ($P < 0.05$). No serious complications occurred after the procedure.
Conclusion: The combination of local anesthesia and pectoral nerve block effectively reduces pain during and after MWA for multiple benign breast nodules and decreases the need for postoperative analgesia.
Limitations: No

Percutaneous Ultrasound-Guided Removal of 410 Retained Soft-Tissue Foreign Bodies: Does Composition Influence Inflammatory Reactions and Treatment Decisions? (6 min)

Marco Vanotti; Como / Italy

Author Block: M. Vanotti, M. Calvi, G. Botta, L. Tessitore, L. CALLEGARI; Varese/IT
Purpose: To assess whether the composition and size of retained foreign bodies (FBs) influence the development of inflammatory or granulomatous reactions and to evaluate the safety of ultrasound-guided percutaneous removal.
Methods or Background: Between Oct 2005 and Mar 2020, 398 patients with suspected FBs were examined using radiography and/or ultrasound. Extraction was performed via a minimally invasive percutaneous approach under continuous ultrasound guidance. Ultrasound and power Doppler evaluated the presence of inflammation or granulomas, and their correlation with FBs' material and size was analyzed.
Results or Findings: A total of 410 FBs of various materials were identified in soft tissues at different depths; 349 (90%) were removed without complications. Vegetal and wood FBs caused more inflammation ($p<.0001$), independently from their size ($p=.95216$). Metal, glass and stone were less reactive ($p=.017397$); the latter two independently from dimensions (metal $p=.89656$; glass $p=.8493$). Small metal fragments caused more granulomatous response than larger ones ($p=.01278$).
Conclusion: The composition of FBs influences tissue response and should guide management: vegetal and wood FBs require removal regardless of size, while metal, stone and glass can be left in place if asymptomatic. The ultrasound-guided technique proved effective and safe.
Limitations: No limitations were identified
Funding for this study: No fundings was received for this study

Bleomycin electrosclerotherapy (BEST) for extracranial slow-flow malformations treatment: a single-center experience (6 min)

Federica Lazzarotto; Firenze / Italy

Author Block: F. Lazzarotto, G. Falcone, A. L. Annese, D. A. Campanacci, F. Fanelli; Florence/IT
Purpose: BEST (Bleomycin Electrosclerotherapy) has been proposed as a novel approach for treating venous and linfatic malformations (VMs). This study reports a single-center initial experience in treating extracranial symptomatic slow-flow malformations.
Methods or Background: A retrospective observational study was conducted from March 2024 to Sep 2025, including 24 patients (28 lesions) with symptomatic VMs. Most had undergone previous unsuccessful treatments. Electrosclerotherapy was performed using reversible electroporation combined with bleomycin. Clinical records, magnetic resonance imaging (MRI) data, previous treatment history, intervention details, complications, and clinical outcomes were analyzed. A postoperative questionnaire assessed both functional and aesthetic effects.
Results or Findings: Of the 24 patients (mean age 23,8 ± 8,4 years; 8 females), 7 had undergone an average of 2.5 previous invasive treatments. A total of 34 electrosclerotherapy sessions were performed on 28 lesions. The median dose of bleomycin administered was 2,6 mg. Clinical and MRI follow-up schedules were established. The median MRI-derived lesion volume decreased in 73% of the patients . After a median follow-up of 6 months (range 3-9 mos), 14 patients reported complete symptom resolution, while 8 showed significant improvement, 2 no improvement. 6 minor complications occurred, including transient skin discoloration and swelling.
Conclusion: BEST is a safe and effective therapeutic option for LM and VMs, including those resistant to prior treatments.
Limitations: Despite promising results, the small sample size and limited FUP warrant further investigation to confirm these findings.
Funding for this study: No funding received for this study

Microwave thermal ablation in cirrhotic patients: comparison of actual ablation volumes to expected ablation volume following manufacturer charts (6 min)

Riccardo Muglia; Paderno Dugnano / Italy

Author Block: K. D. Martins De Mattos[1], R. Muglia[2], F. S. Carbone[2], M. Bertuletti[2], L. Dulcetta[2], P. Marra[2], S. Sironi[1]; [1]Milan/IT, [2]Bergamo/IT
Purpose: Microwave thermal ablation (MWTA) is an established therapy for HCC in cirrhotic patients, with a low rate of local recurrence. However, in some cases, despite optimal antenna placement and strict adherence to the ablation volume charts, residual disease may persist after treatment. We aimed to evaluate the immediate ablation volume after MWTA in cirrhotic livers, and compare it with the volumes estimated by the manufacturer chart.
Methods or Background: This single-center retrospective study was conducted at a tertiary referral center, including cirrhotic patients BCLC 0/A, treated for HCC by MWTA (Emprint™ HP, Medtronic, USA) between November 1, 2022, and August 31, 2025. HCCs were categorized by size (small <25mm; large 25<x<30mm) and anatomical location (subcapsular: ≤1cm from the liver capsule; perivascular: ≤1cm from a hepatic vein or intrahepatic portal branch).
All MWTAs were performed under CT-hepatic arteriography guidance; we calculated immediate post-ablation necrotic volumes, and compared them to expected ablation volumes, following the manufacturer chart. Volumes were calculated via multiplanar reconstruction (MPR) using the ellipsoid formula ($D1 \times D2 \times D3 \times \pi/6$).
Results or Findings: We analyzed 43 HCCs in 29 patients, treated at 100W/150W (36:7). Twelve nodules were perivascular (11 small - 1 large), 31 subcapsular (22 small - 9 large). No nodules were far from liver capsule or veins.
The mean achieved volume for perivascular nodules was 12.37cm³, 42.4% lower than the expected 21.48cm³ ($p<0.001$). For subcapsular nodules the mean achieved volume was 15.25cm³, 36.3% lower than the expected 23.96cm³ ($p<0.001$). This significant underestimation corresponded to a Bland-Altman systemic bias of -9.04 cm³. Only 2/43 outlying cases (subcapsular nodules) were identified.
Conclusion: Our findings suggest a systematic underestimation of achieved ablation volumes compared to expected volumes in cirrhotic livers. Increasing ablation volumes compared to manufacturer chart might improve MWTA efficacy.
Limitations: Retrospective-design

Use of resorbable gelatin microspheres in genicular artery embolization for treatment-resistant knee pain – Technique, Safety, and Results (6 min)

Arian Taheri Amin; Berlin / Germany

Author Block: A. Taheri Amin[1], L. M. Wilms[2], K. Jannusch[2], F. Ziayee[2], P. Minko[2]; [1]Berlin/DE, [2]Düsseldorf/DE
Purpose: Assess the safety, procedural aspects, and clinical outcomes of genicular artery embolization (GAE) with resorbable gelatin microspheres (RGM) in patients suffering from knee osteoarthritis (OA) or ongoing pain following total knee replacement (TKR)
Methods or Background: 45 patients were prospectively observed, 35 with knee OA (Kellgren–Lawrence grades 1–4) and 10 with post–TKR pain. GAE was performed using100–300 µm RGM, with embolic volume and treated vessels recorded. Clinical outcomes were measured using KOOS and NRS at baseline, 6 weeks, 3 and 6 months. The HADS questionnaire was used to screen for psychological comorbidities. Adverse events were monitored.
Results or Findings: At 6 months, the mean NRS decreased by 35% and the KOOS pain subscale improved by 55% ($p < 0.001$), with no significant differences observed between OA grades and post-TKR . A median of 3 vessels (range 2–6) were embolized, with an average embolic volume of 6.5 mL (range 2.1–18.0 mL) per procedure. Patients with HADS scores > 8 demonstrated smaller improvements in both KOOS and NRS, with up to 2.2 points less improvement per unit increase in HADS ($p < 0.05$). Total embolic volume was significantly higher in advanced OA and post-TKR cases, rising by an average of 2.7 mL with each OA grade ($p < 0.0001$). No major complications occurred.
Conclusion: GAE with RGM at doses exceeding 2 mL is safe and provides short-term clinical benefit in all OA grades as well as in post-TKR pain. Patients with advanced OA or post-TKR tend to require higher embolic volumes. Elevated HADS scores are linked to reduced clinical response.
Limitations: This study is limited by its small sample size, short-term follow-up, lack of a control group, and reliance on patient-reported outcomes without systematic imaging.
Funding for this study: No funding was recieved
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: All procedures performed were in accordance with the ethical standards of the institutional research committee Board (Study number: 2021-1777_5) and with the principles of the 1964 Declaration of Helsinki and its later amendments.

Connecting the Dots: The impact of Osteoarthritis, Synovitis and Evoked Pain on Embolization Endpoints in Genicular Artery Embolization (6 min)

Arian Taheri Amin; Berlin / Germany

Author Block: A. Taheri Amin[1], E. Kemmer[2], A-J. Hübner[2], K. Jannusch[2], D. Weiß[2], L. M. Wilms[2], F. Ziayee[2], P. Minko[2]; [1]Berlin/DE, [2]Duesseldorf/DE

Purpose: To evaluate the impact of osteoarthritis (OA), synovitis and evoked pain on embolic volume in genicular artery embolization (GAE).

Methods or Background: Radiographs, MRI and DSA images of patients undergoing GAE were retrospectively reviewed. OA was graded (Kellgren-Lawrence) and categorized by predominant location (medial/lateral). Synovitis was graded on unenhanced MRIs using the MRI Osteoarthritis Knee Score. Evoked pain during superselective angiography and embolic volume were systematically recorded. Embolic volume was correlated with OA grade, predominant OA location, synovitis grade and evoked pain. Clinical outcome was assessed using the numeric rating scale at six weeks and months.

Results or Findings: A total of 1,739 vessels were embolized in 450 patients (median: 4 ± 1 vessels per session). Pre-interventional radiographs were available in all patients, with additional MRI scans in 214 patients. Embolic volume correlated moderately with OA-grade (Spearman's ρ=0,51; $p<0.001$) and weakly with synovitis grade (ρ=0,20; $p<0.01$). In patients with predominantly medial OA, embolic volume applied in the medial compartment was significantly higher than in the lateral compartment (2.7±1.5 vs 1.5±1.2 mL; $p<0.001$), and vice versa for patients with predominantly lateral OA (2.2±1.1 vs 1.6±1.0 mL; $p<0.001$). Embolic volume was significantly higher in vessels with evoked pain than without (1.4±0.9 vs 0.8±0.3 mL; $p<0.001$). Pain scores improved significantly at all timepoints ($p<0.001$).

Conclusion: OA grade, predominant OA location, synovitis grade, and evoked pain influence embolic volume in GAE, illustrating that—similar to the multifactorial genesis of OA—embolization endpoints are likewise shaped by multiple variables.

Limitations: ChatGPT:

The study is limited by its retrospective design, reliance on NRS without long-term follow-up, and MRI data available in only half of patients.

Funding for this study: This work was supported by the local Research Committee of the Medical Faculty of Heinrich-Heine-University Düsseldorf (grant number: 9772841).

Has your study been approved by an ethics committee? Yes

Mapping Cognitive Signatures through Simultaneous EEG-fMRI Coupling: Insights from MoCA and MMSE across Alzheimer's Disease and Healthy Ageing (6 min)
Heng Zhang; Dazhou / China

Author Block: H. ZHANG[1], S. Laws[2], L. XIE[3], S. Ma[3]; [1]DaZhou/CN, [2]Joondalup, WA/AU, [3]Shantou, Guangdong/CN
Purpose: To test whether resting-state EEG–fMRI coupling strength (R^2) indexes cognitive performance across AD, MCI, and healthy ageing, and to identify stage- and domain-specific brain–cognition signatures via multimodal imaging.
Methods or Background: Simultaneous resting-state EEG–fMRI from 99 participants (AD=14, MCI=45, HC=40) was analyzed. EEG features were convolved with a canonical hemodynamic response function and regressed against voxel-wise fMRI via general linear models. Regional R^2 maps were derived and correlated with MoCA and MMSE within groups.
Results or Findings: In AD, MoCA correlated negatively with R^2 in the supplementary motor area (right; $r=-0.65$, $p=.012$), inferior temporal gyrus (left; $r=-0.72$, $p=.004$), and occipital superior gyrus (right; $r=-0.71$, $p=.005$), indicating lower cognition with higher coupling in sensorimotor/visual cortices. In MCI, MoCA showed negative correlations in thalamic regions (pulvinar anterior, left; $r=-0.37$, $p=.013$) and the parahippocampal gyrus ($r=-0.32$, $p=.028$). For MMSE, AD exhibited positive R^2 associations in cerebellar vermis 8 ($r=+0.76$, $p=.002$) and cerebellum lobule 10 (right; $r=+0.60$, $p=.022$), whereas MCI and HC showed widespread negative R^2–MMSE relationships, notably in superior temporal gyrus (right; $r=-0.57$, $p<.001$), Rolandic operculum ($r=-0.39$, $p=.012$), and thalamic anterior ventral nucleus ($r=-0.38$, $p=.018$). Overall patterns differed by group and cognitive domain, underscoring stage specificity.
Conclusion: EEG–fMRI coupling strength (R^2) delineates discrete, clinically meaningful neural signatures across the dementia continuum. Multidomain cognitive testing captures complementary vulnerability profiles, underscoring the value of coupling metrics for individualized diagnosis and monitoring. Coupling-based biomarkers show promise for early detection, risk stratification, and precision intervention, with clear potential for integration into multimodal clinical workflows.
Limitations: Single-center, cross-sectional cohort (n=99) with class imbalance (AD=14) and no external replication limits generalizability and causal inference; reliance on a canonical HRF and atlas parcellation may bias regional estimates.

DTI-derived radial diffusivity in the fornix as a potential early biomarker for preclinical Alzheimer's disease (6 min)
Forough Sodaei; Odense / Denmark

Author Block: F. Sodaei[1], M. Noroozian[2], T. M. Sheldrick-Michel[1], H. Salighe Rad[3]; [1]Odense/DK, [2]Tehran/IR, [3]tehran/IR
Purpose: Alzheimer's disease (AD) is the most prevalent neurodegenerative disorder, with amnestic mild cognitive impairment (aMCI) representing an early transitional stage. Subtle white matter changes may remain undetected using standard magnetic resonance imaging (MRI). Limbic tracts, crucial for memory, can be examined with diffusion tensor imaging (DTI) to detect microstructural alterations. This study investigates whether DTI-derived measures of limbic fiber bundles can act as sensitive early biomarkers for differentiating aMCI and mild AD from cognitively healthy controls and evaluates their diagnostic potential.
Methods or Background: This study involved 46 participants divided into three groups: 17 with AD, 17 with amnestic aMCI, and 12 cognitively normal controls. All participants completed neuropsychological assessments and MRI, including 3D T1-weighted and DTI sequences. Diffusion data were analyzed using ExploreDTI 4.8.6 with atlas-based parcellation of limbic white matter. Fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AxD), and radial diffusivity (RD) were extracted. Group differences were assessed with one-way ANOVA, correlations with cognition were examined, and diagnostic performance was evaluated using accuracy, sensitivity, specificity, and area under the curve (AUC).
Results or Findings: Region-of-interest analyses showed widespread group differences, including changes in DTI metrics within the cingulum bundle, higher MD in the uncinate fasciculus, and increased RD in the left fornix, all correlating with cognitive performance. Cross-validated diagnostic assessment of left fornix RD demonstrated strong performance (accuracy 83%, sensitivity 85%, specificity 80%, AUC 0.87), indicating early limbic white matter microstructural degeneration, with the fornix exhibiting particularly marked alterations.
Conclusion: DTI-derived radial diffusivity in the fornix appears to be a sensitive and non-invasive biomarker for early detection of Alzheimer's disease, which may facilitate the identification of at-risk individuals.
Limitations: The limitations of the study are the relatively small sample size and cross-sectional design.

Role of Arterial-spin labelling Magnetic Resonance Imaging in differentiation of Alzheimer's disease (AD) from frontotemporal dementia (FTD) (6 min)

Jaya Logre; New Delhi / India

Author Block: J. Logre, P. NARANG, K. Bansal, A. Ranga; New Delhi/IN
Purpose: To assess the role of arterial spin labeling (ASL-MRI) in detection of perfusion changes and patterns that distinguish Alzheimer's Disease (AD) from Frontotemporal Dementia (FTD).
Methods or Background: Fifteen patients each with AD, FTD and healthy controls underwent 3D-Pseudocontinous ASL-MRI in addition to routine structural imaging on 3T MRI. Assessment of regional atrophy was done using visual rating scales with quantification of mean cerebral blood flow (CBF) in various regions of brain.
Results or Findings: Regional patterns of atrophy were seen as asymmetrical bifrontal and temporal atrophy in FTD whereas, AD showed parietal and temporal predominance, with further progressive involvement of occipital as well as frontal lobes. Significant hypoperfusion was seen in the areas corresponding to regional atrophy, predominantly in anterior cingulate gyrus in FTD which helped in differentiation of AD from controls with specificity of 80% and sensitivity of 86.6 at a cut-off mean CBF value of 31.91 ml/100gm/min in the anterior cingulate gyrus. There was significant hypoperfusion in posterior cingulate gyrus seen in AD which differentiated it from controls satisfactorily, with a specificity and sensitivity of 73.3% and 86.6% respectively, at a cut-off mean CBF value of 38.29 ml/100gm/min.
Conclusion: The use of functional neuroimaging techniques like ASL as an adjunct to conventional MRI can provide unique insights into the changes seen in neurodegenerative diseases as disease-specific patterns of differences in perfusion without radiation exposure, contrast administration or significant increase in scan time.
Limitations: The cross-sectional design and duration of study didn't allow establishment of a temporal relationship, hence, limiting our ability to draw inferences.The sample may not be a true representation of the disease population. Since, histopathological examination couldn't be done due to humanitarian reasons, there was a lack of confirmation of the diagnosis.

Multimodal advanced MRI evaluation in patients with Alzheimer's disease and mild cognitive impairment undergoing transcranial pulse stimulation (TPS) (6 min)

Federico Bruno; L'Aquila / Italy

Author Block: F. Bruno, G. Saporito, G. Saltarelli, A. Innocenzi, G. Di Cerbo, C. De Felici, E. Di Cesare, F. Pistoia, A. Splendiani; L'Aquila/IT
Purpose: To assess structural and functional brain changes on advanced MRI in patients with Alzheimer's disease (AD) and mild cognitive impairment (MCI) undergoing transcranial pulse stimulation (TPS).
Methods or Background: Seventeen consecutive patients with AD/MCI scheduled for TPS underwent 3T MRI at baseline and 6 months. The protocol included structural MRI with volumetry, diffusion tensor imaging (DTI) with whole-brain and hippocampal/cingulate reconstructions, single-voxel spectroscopy of the cingulate cortex, and arterial spin labeling (ASL) perfusion. Brain volumes were segmented with dedicated software; DTI was processed in DSI-Studio; ASL was analyzed in MRI Cloud Brain Mapping to derive absolute and relative cerebral blood flow (CBF).
Results or Findings: Spectroscopy showed no significant post-treatment change in CH ratio (mean $\Delta = +0.09$; $p = 0.076$) or NAA ratio, with a non-significant trend toward higher CH ratio. In the hippocampus, fractional anisotropy (FA) and mean diffusivity (MD) decreased after TPS (FA $\Delta = -0.093$; $p = 0.021$; MD $\Delta = -0.255$; $p = 0.039$), while quantitative anisotropy was unchanged. ASL revealed widespread CBF increases, with significant cortical rises bilaterally and in the right frontal lobe ($p = 0.03$), left parietal lobe ($p = 0.05$), right parietal lobe ($p = 0.01$), and right temporal lobe ($p = 0.04$). Among subcortical regions, CBF increased in the right thalamus ($p = 0.05$) and left cingulate gyrus ($p = 0.05$). No significant changes were observed in white matter, occipital and insular cortices, basal ganglia, limbic system, or cerebellum.
Conclusion: Advanced MRI sequences, combining volumetry, DTI, spectroscopy, and ASL, can detect subtle structural and perfusion modifications after TPS in AD and MCI.
Limitations: These exploratory findings support the feasibility of MRI for monitoring TPS-related effects; larger controlled studies are warranted to confirm clinical significance and durability.

Correlation of Volumetric Changes and Functional Connectivity using rs-fMRI in MCI Patients (6 min)

Weronika Natalia Machaj; Wrocław / Poland

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: W. N. Machaj, P. Podgórski, J. Maciaszek, D. Szcześniak, J. Rymaszewska, P. Piotrowski, A. Zimny; Wrocław/PL
Purpose: Mild cognitive impairment (MCI) is considered a transitional state between normal aging and dementia, characterized by subjective
complaints, measurable cognitive decline, and preserved daily functioning. The aim of this study was to investigate alterations in resting-state functional connectivity and brain structure in individuals with MCI, with particular emphasis on the medial temporal lobe and its interactions with other brain regions.
Methods or Background: We included 27 patients with MCI and 25 age-matched healthy controls. 3D T1 volumetric imaging followed by resting-state fMRI were performed on a 3T Philips Ingenia scanner equipped with a 32-channel head and neck coil. Seed-to-voxel functional connectivity analyses were performed using the bilateral hippocampi and anterior/posterior parahippocampal gyri as seed regions. Volumetric analysis was conducted with the Desikan-Killiany and Destrieux atlases to assess cortical thickness.
Results or Findings: MCI patients demonstrated significantly increased functional connectivity between bilateral medial temporal lobe regions and the right thalamus compared to controls. Volumetric analysis revealed reduced cortical thickness in temporal, frontal, orbitofrontal, limbic, parietal, sensorimotor, and occipito-temporal regions.
Conclusion: Increased medial temporal-thalamic connectivity together with widespread cortical atrophy indicates early neurodegenerative changes in MCI. These alterations may represent compensatory mechanisms in response to cognitive decline and highlight the value of combining functional and structural MRI for early detection of cognitive impairment.
Limitations: The main limitations of the study are its cross-sectional design and the small sample size.
Funding for this study: This study was supported by Wroclaw Medical University grants SUBZ.C270.24.078 and SUBK.C230.23.065.

The role of cardio-cerebral oxygenation reserve in cognitive dysfunction of heart failure patients: a multimodal MRI assessment (6 min)

Lei Yang; Kunming / China

Author Block: L. Yang, F. Zhou, Y. Yang, G. F. Sun, S. Tang; Kunming/CN
Purpose: To assess cardio-cerebral oxygenation reserve in heart failure (HF) patients using OS-MRI and BOLD techniques, and explore its correlation with cognitive decline and potential mediating role in HF-related cognitive impairment.
Methods or Background: 160 heart failure (HF) patients and 40 age- and sex-matched healthy controls (HC) were enrolled. HF patients were stratified into four subgroups according to the NYHA functional classification (Class I–IV). All participants underwent cardiac oxygen-sensitive magnetic resonance imaging (OS-MRI) and cerebral blood oxygen level–dependent (BOLD) imaging to determine parameters including myocardial oxygenation reserve (MORE), cerebral oxygenation reserve (CORE), left ventricular ejection fraction (LVEF), and stroke volume (SV). Cognitive function in HF patients was assessed using the Montreal Cognitive Assessment (MoCA) scale. Statistical analyses included intergroup comparisons, correlation analysis, and mediation effect testing.
Results or Findings: Myocardial oxygenation reserve (MORE), cerebral oxygenation reserve (CORE), and MoCA scores were significantly lower in heart failure (HF) patients compared to healthy controls (HCs) (all $P < 0.05$). Notably, Among early-stage patients (NYHA Class I-II) with preserved LVEF (≥50%), these indicators, although better than those in advanced-stage (NYHA Class III-IV) patients (all $P < 0.05$), were already significantly lower than in the healthy control group (all $P < 0.05$). MoCA scores showed positive correlations with MORE ($r=0.648$, $P=0.014$), CORE ($r=0.783$, $P=0.025$), and LVEF ($r=0.462$, $P=0.033$). Furthermore, MORE and CORE played significant mediating roles in the relationship between LVEF and MoCA scores.
Conclusion: The decline in cardio-cerebral oxygenation reserve is a key factor associated with cognitive dysfunction in HF, including its early stages, and holds potential value as an imaging biomarker for early warning of cognitive impairment.
Limitations: The cross-sectional design precludes causal inference. The single-center sample may limit generalizability, and residual confounding cannot be ruled out.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective study was approved by the Institutional Review Board of [Yan'an Hospital Affiliated to Kunming Medical University] (Approval No. [2024-143-02]), and the requirement for written informed consent was waived due to the observational design.

Examining the independent and additive effect of arterial stiffness and cerebral blood flow on total hippocampal and hippocampal subfield volumes (6 min)

Michelle Therese Horan; Dublin / Ireland

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: M. T. Horan, J. F. Meaney, R-A. Kenny, C. DeLooze; Dublin/IE
Purpose: There is a critical link between vascular disease and the progression to dementia. The hippocampus has been implicated in the development of memory decline and whole hippocampal atrophy has been identified consistently in patients with cognitive decline.
Methods or Background: We investigate the independent and moderating effects of increased arterial stiffness (AS) and reduced cerebral blood flow (CBF) on total hippocampal volume (HV) in a large MRI sample of community-dwelling older adults (n=395) from a nationally representative population-based study, the Irish Longitudinal Study on Ageing (TILDA). We also examine if these effects are specific to certain hippocampal subfields which are known to be selectively vulnerable to ischemia. Arterial spin labelling MRI was used for CBF quantification. Automated Segmentation of the Hippocampal was performed using FreeSurfer v6.0.
Results or Findings: This four-year follow up longitudinal study demonstrated that (i) prolonged elevated AS (at baseline and at four-year follow-up), (ii) the interaction between higher AS at baseline and lower CBF at follow-up 3 and (iii) the interaction between prolonged elevated AS (at baseline and four-year follow-up) and reduced CBF at follow-up were associated with smaller hippocampal volumes. We propose that the subsequent reduction in cerebral blood flow observed with elevated arterial stiffness may be the missing link in the pathway linking arterial stiffness to hippocampal atrophy.
Conclusion: Our study shows that increased AS and reduced CBF are not independently associated with whole hippocampal or subfield volumes. However, when combined, increased arterial stiffness for a longer duration in combination with a reduction in cerebral blood flow is associated with lower hippocampal volumes. These effects were equally exerted across all hippocampal subfields tested in this study.
Limitations: There are reported limitations to automated segmentation tools in the literature.
Funding for this study: Funding for The Irish Longitudinal Study on Ageing (TILDA) is provided by the Irish Government, the Health Research Board (HRB), The Atlantic Philanthropies, and the Irish Life PLC. CDL is supported with funding from the Health Research Board (HRB) of Ireland under an Emerging Investigator Award (EIA-2017-012).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was approved by the Trinity College Faculty of Health Sciences Research Ethics Committee, Dublin, Ireland. Protocols conformed with the Declaration of Helsinki. Signed informed consent was obtained from all respondents prior to participation. Additional ethics approval was received for the magnetic resonance imaging (MRI) sub-study from the St James's Hospital/Adelaide and Meath Hospital, Inc. National Children's Hospital, Tallaght (SJH/AMNCH) Research Ethic Committee, Dublin, Ireland. Those attending for MRI also completed an additional MRI-specific consent form.

Field Strength and Sequence Effects on Cerebral Microbleed Detection in Alzheimer's Disease: Relevance for Anti-Amyloid Antibody Therapy Eligibility (6 min)

Jonathan Kottlors; Cologne / Germany

Author Block: T. Schömig, J. Kottlors, M. Schlamann, M. Schönfeld; Köln/DE
Purpose: Cerebral microbleeds (CMBs) are a safety concern in patients considered for anti-amyloid antibody therapy in Alzheimer's disease. More than four CMBs constitute an exclusion criterion for Lecanemab or Donanemab. Detection rates vary with MRI field strength and sequence type. This study evaluated the impact of these parameters on CMB detection and their relevance for treatment eligibility in a clinical cohort.
Methods or Background: We retrospectively analyzed 284 of 1575 patients from two memory clinics classified within the Alzheimer's continuum, defined by a pathological cerebrospinal fluid amyloid-β 1-42/1-40 ratio and/or a positive amyloid-PET scan (visual assessment by standardized criteria). CMBs were quantified when a hemorrhage-sensitive MRI sequence was available. Patients were grouped by field strength (1.5T vs. 3T) and sequence type (T2* vs. SWI). Detection rates, CMB counts, and the proportion exceeding exclusion thresholds (>4 CMBs) were compared using Mann–Whitney U and Chi² tests.
Results or Findings: Of 284 eligible patients, 263 (mean age 71.3 years, 53 % female) were screened. A total of 162 underwent 1.5T MRI (all T2*) and 101 underwent 3T MRI (66 T2*, 35 SWI). CMBs were detected significantly more often at 3T than at 1.5T (43.6 % vs. 23.5 %, p<0.001), with higher mean counts (1.86 ± 4.7 vs. 1.12 ± 3.9, p=0.004). Within the 3T subgroup, SWI showed a non-significant trend toward higher detection than T2* (54.3 % vs. 37.9 %, p=0.057). Importantly, the proportion with >4 CMBs—rendering them ineligible—was significantly higher at 3T than at 1.5T (10.9 % vs. 4.3 %, p = 0.040).
Conclusion: MRI field strength and sequence type substantially affect CMB detection and may directly alter eligibility for anti-amyloid antibody therapy. Standardization of imaging protocols is required to ensure consistent patient selection and reliable risk assessment.
Limitations: None

Neurodegeneration contributes more to cognitive impairment than microvascular injury in middle-aged and young-old patients with type 2 diabetes combined with NAFLD or high BMI (6 min)

Xin Li; Nanjing / China

Author Block: X. Li, B. Zhang; Nanjing/CN
Purpose: Neurodegeneration and microvascular injury were associated with cognitive decline in type 2 diabetes (T2D). Overweight/obesity or non-alcoholic fatty liver disease (NAFLD) were also related to brain damage. We aimed to investigate the gray and white matter changes in T2D patients with NAFLD or high body mass index (BMI).
Methods or Background: The 451 patients with T2D and 65 normal controls were enrolled. The patients were further divided into four subgroups based on the presence of NAFLD or high BMI: 156 with both NAFLD and high BMI, 66 with NAFLD, 76 with high BMI, and 153 with neither NAFLD nor high BMI. All participants underwent magnetic resonance, clinical assessments, and cognitive tests. Brain gray volume and cortical thickness represent neurodegeneration, and peak width of skeletonized mean diffusivity (PSMD) and white matter hyperintensity (WMH) reflect microvascular injury. Partial correlation, canonical correlation, and mediation effect were employed to assess relationship between metabolic measures, imaging markers and cognitive performance.
Results or Findings: 1) The patients with T2D exhibited widespread brain atrophy involving global gray matter, subcortical structures, and hippocampal subfields. Both NAFLD and high BMI were independently associated with neurodegeneration, with no significant interaction effect; 2) No significant differences were found in PSMD or WMH volume between the T2D and normal controls groups, and neither NAFLD nor high BMI had significant impacts on white matter injury; 3) The T2D group showed multiple damage in cognitive domains, and both NAFLD and high BMI independently effected executive function; 4) Mediation analysis indicated that neurodegeneration mediated the association between metabolic dysregulation and cognitive impairment, while white matter injury did not.
Conclusion: The results revealed neurodegeneration contributes more to cognitive impairment than cerebral small vessel injury in middle-aged and young-old patients with T2D.
Limitations: Not applicable

Diagnostic Performance of Qualitative and Quantitative PET/MRI Biomarkers: Distinct Patterns of Atrophy and Hypometabolism in Dementia (6 min)

Sonja Petrović; Novi Sad / Serbia

Author Block: S. Petrović[1], M. Nguyen[2], N. Villain[2], F-X. Lejeune[2], A. Kas[2], M-O. Habert[2], N. Pyatigorskaya[2]; [1]Novi Sad/RS, [2]Paris/FR
Purpose: The aim of this study is to identify distinct patterns of atrophy and hypometabolism for differential diagnosis of dementia and compare qualitative and quantitative biomarker classification performance.
Methods or Background: The study included 274 patients from Pitié-Salpêtrière Memory Clinic who underwent PET/MRI scanning with the diagnosis of Alzheimer's disease (AD), frontotemporal dementia (FTD), Lewy Body dementia (LBD). Qualitative and quantitative region of interest (ROI) analysis of T1W and FDG-PET images was performed. ROI were chosen according everyday clinical practice and functional characteristics. Statistical Data Integration Analysis for Biomarker Discovery using the Latent components was performed.
Results or Findings: Quantitative metabolism showed good separation of FTD from other groups, mainly involving the temporal pole and caudate, while visual metabolism distinguished FTD from LBD, with hypometabolism in the prefrontal and insular regions versus parietal regions, respectively. AD was separated from the other groups by hypometabolism in the mesial temporal region in both visual and quantitative metabolism, and by posterior cingulate hypometabolism in the quantitative block. The AUC was higher in metabolism blocks (0.778–0.954) compared to volume blocks (0.691–0.864), with the best performance from visual metabolism (LBD vs. others 0.954; FTD vs. others 0.938; AD vs. others 0.81). Qualitative volume contributed mainly to FTD separation, involving temporal pole, prefrontal, and anterior cingulate, while quantitative volume showed no clear separation. No significant AUC differences were found between qualitative and quantitative approaches for both metabolism and atrophy ($p>0.05$).
Conclusion: FTD demonstrated a characteristic pattern across both modalities and analytic approaches, allowing easier differentiation from other dementias. FDG-PET added sensitivity to functional changes, while MRI highlighted complementary structural alterations. Visual and quantitative analyses showed comparable diagnostic performance, suggesting no significant added value of implementing quantitative software in clinical practice.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study.

MCI-specific white matter-cognition interactions in dementia transition characterization using OpenMAP-T1 analysis (6 min)

Masumi Kawaguchi; Nagareyamashi,Chiba / Japan

Author Block: M. Kawaguchi, D. Yoshimaru, Y. Nakamura, K. Touma, K. Saito; Nishishinnjyuku,Tokyo/JP
Purpose: While MCI is traditionally viewed as an intermediate stage to AD, the dynamic nature of brain-cognition relationships during this transition remains unclear. This study investigated disease-specific white matter-cognition interaction patterns and their correlations using automated OpenMAP-T1 analysis to characterize the pathological continuum of cognitive decline.
Methods or Background: We analyzed 74 participants: 10 healthy controls (68.3±9.1 years), 16 MCI (75.4±4.0 years), and 48 AD patients (78.8±7.5 years). White matter regions were automatically segmented from 3D T1-weighted images using OpenMAP-T1. Multiple regression analyses with/without disease-by-cognition interaction terms were performed for MMSE and MoCA-J, adjusting for TIV, age, and sex. Spearman correlations between white matter volumes and cognitive scores were calculated for interaction-significant regions in the healthy-MCI combined group.
Results or Findings: Disease-by-cognition interactions were exclusively observed in MCI but completely absent in AD and controls. MoCA-J demonstrated superior sensitivity, detecting interactions in five regions (SS_R, IFO_L, IFO_R, SS_L, SLF_R; all $p<0.05$) versus one for MMSE (SS_L, $p=0.024$). Correlation analysis in MCI revealed that interaction-significant regions maintained strong positive correlations with MoCA-J (SS_L: $\rho=0.767$, $p=0.001$; IFO_R: $\rho=0.725$, $p=0.002$; SS_R: $\rho=0.702$, $p=0.004$; SLF_R: $\rho=0.632$, $p=0.011$; IFO_L: $\rho=0.622$, $p=0.013$), indicating preserved brain-cognition relationships in MCI. In baseline regression, cognition-related significant regions progressively decreased from controls (MMSE: 17, MoCA-J: 18) through MCI (MMSE: 13, MoCA-J: 12) to AD (MMSE: 4, MoCA-J: 9), demonstrating stage-dependent network disruption.
Conclusion: Our findings reveal MCI as a unique dynamic state with active brain-cognition remodeling and preserved correlations, fundamentally distinct from AD's terminal state with disrupted relationships. This distinction indicates MCI represents a critical therapeutic window. MoCA-J emerged as the optimal detection tool, providing important implications for early diagnosis and intervention strategies.
Limitations: Cross-sectional design limits assessment of longitudinal changes. Small sample size, particularly in controls (n=10).

Correlation between visual scales of brain atrophy and volumetric analysis using artificial intelligence software in patients with cognitive impairment and Brain MRI (6 min)

María Belen Nallino; Rosario / Argentina

Author Block: M. B. Nallino, P. Acevedo, L. Gangui Araoz, M. I. Cañizares, L. Zamer, A. A. Ojeda; Rosario/AR
Purpose: In patients with cognitive impairment (CI), identifying atrophy patterns and assessing white matter integrity is crucial for accurate diagnosis and treatment. This study aims to correlate visual scales of atrophy, including Medial Temporal Atrophy (MTA), Global Cortical Atrophy (GCA), KOEDAM score, Evans Index and evaluation of leukoaraiosis (Fazekas scale) in brain magnetic resonance imaging (bMRI), with automated volumetric analyses using artificial intelligence software.
Methods or Background: The retrospective study involved 104 patients (49 women and 55 men) with CI who underwent bMRI at our institution between January 2023 and August 2023. Visual assessments were performed using scales (MTA), (GCA), (KOEDAM), Evans Index, and Fazekas scale by a neuroradiologist with over 15 years of experience. Additionally, automated brain volumetric analyses were conducted using the Entelai artificial intelligence software. Spearman correlation coefficients were computed to assess the relationship between brain volumes and the corresponding visual atrophy scales.
Results or Findings: Results revealed a moderate inverse correlation between global brain volume and GCA scores (-0.47), particularly pronounced in patients over 70 years old. Grey matter volume showed a strong inverse correlation with GCA (-0.62). Both right and left hippocampal volumes had significant inverse correlations with MTA (-0.568 and -0.577, respectively). Furthermore, the Evans Index exhibited a strong positive relationship with ventricular volume (0.789), especially in older patients.
Conclusion: The results show a consistent association between visual measures of cerebral atrophy and quantitative volumes obtained through software. As scores on the visual scales (GCA, MTA, Koedam, Evans) increase, a reduction in brain volumes or an increase in ventricular volume is observed, with a more significant impact on the older age groups. This supports the validity of the scales used and suggests that automatic quantification could be a useful supplement.
Limitations: Patient number

Dynamic Monitoring of Glymphatic System and Hemodynamic Changes in Alzheimer's Disease During Anti-Aβ Therapy Using 5.0T MRI DTI-ALPS and ASL Sequences A Quantitative Analysis (6 min)

Liu Chang; Hefei / China

Author Block: L. Chang; Hefei/CN
Purpose: This study aimed to longitudinally evaluate the dynamic changes in glymphatic system function and regional cerebral hemodynamics during anti-Aβ therapy in patients with Alzheimer's disease (AD) using multimodal MRI techniques, specifically the DTI-ALPS index and arterial spin labeling (ASL).
Methods or Background: Forty-five clinically diagnosed patients with mild-to-moderate AD undergoing 6 months of anti-Aβ monoclonal antibody therapy
underwent brain MRI at baseline and post-treatment. We analyzed diffusion tensor imaging along the perivascular space (DTI-ALPS index, bilateral hemispheres) and ASL-derived CBF. Neurocognitive function was assessed using the Clinical Dementia Rating (CDR) and the Alzheimer's Disease Assessment Scale-Cognitive Subscale (ADAS-Cog).
Results or Findings: Glymphatic Function and Cognitive Improvement The left hemispheric ALPS index significantly increased post-treatment (baseline: 1.22 ± 0.21 vs. post□treatment: 1.38 ± 0.19, $p < 0.01$), positively correlating with improvements in the ADAS-Cog (18.6% reduction) and CDR total scores ($r = 0.43$, $p = 0.008$). In contrast, the right ALPS index showed no significant change ($p = 0.23$) or clinical correlation. Hemodynamic CharacteristicsASL imaging revealed a significant elevation in CBF in the PCC and posterior temporal parietal lobe post-treatment (12.5% increase, $p = 0.015$). Notably, the improvement in PCC perfusion inversely correlated with the reduction in ADAS-Cog scores ($r = -0.51$, $p = 0.002$).
Conclusion: Anti-Aβ therapy may exert neuroprotective effects by enhancing glymphatic clearance efficiency in the left hemisphere and restoring PCC perfusion. The left ALPS index and PCC CBF serve as sensitive imaging biomarkers for dynamic therapeutic monitoring. This study underscores the synergistic value of multimodal DTI-ALPS and ASL in evaluating treatment responses for Alzheimer's disease, providing imaging evidence for personalized strategies targeting glymphatic-hemodynamic coupling mechanisms.
Limitations: 5.0T MRI effectively quantifies neurorestoration induced by anti-Aβ therapy in Alzheimer's disease.

Ultra-high-resolution photon-counting CT versus 50keV monoenergetic imaging: Superior spatial resolution for distal HCC feeding artery delineation in pre-TACE planning (6 min)
Ping Hou; Zhengzhou / China

Author Block: P. Hou; Zhengzhou/CN
Purpose: To evaluate the ability of 50-keV virtual monoenergetic images (VMI) with conventional energy-integrating detector CT (EID-CT) to depict abdominal feeding arteries compared with ultra-high-resolution (UHR) 0.2-mm imagings with photon-counting detector CT (PCD-CT) for pre-TACE assessment of HCC.
Methods or Background: Fifty consecutive patients who underwent multiphase abdominal scans for assessment of HCC between April and December 2024 were included. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were quantitatively assessed for the celiac artery (CeA), common hepatic artery(CHA), proper hepatic artery(PHA), left and right hepatic arteries (LHA/RHA)at both 50kev VMI with a 1-mm slice thickness (SR-50keV) and T3D with 0.2mm slice thickness (UHR-T3D). In addition, 3D images from CTA were analyzed to measure arterial lengths and evaluate the visualization of distal branches using 5-point Likert scales. Results were compared with DSA for arterial detection rates.
Results or Findings: UHR-T3D demonstrated significantly longer visualized arterial lengths (RHA: 192.6 vs. 190.4 mm; LHA: 160.9 vs. 155.7mm, all $P<0.05$), lower noise (SD: 14.3 vs. 18.9, $p<0.001$), and superior subjective scores (4.5 vs. 3.8, $p=0.002$) compared to SR-50keV , despite higher SNRs and CNRs in SR-50keV (eg. CeA SNR: 22.39 vs. 19.09; CNR: 48.38 and 29.15, $p<0.001$). Correlation with DSA confirmed that the UHR-T3D images had enhanced detection of distal branches, achieving a 100% recognition rate, in contrast to the 92% recognition rate of SR-50keV.
Conclusion: PCD-CT UHR outperforms conventional 50-keV EID-CT in spatial resolution and clinical utility for HCC feeding artery mapping, despite lower contrast metrics, offering critical advantages for TACE procedural planning.
Limitations: Not applicable.

Role of PMFI-CEUS in the differential diagnosis between ICC and HCC (6 min)
Giovanni Antonio Risoleo; Vibo Valentia / Italy

Author Block: G. A. Risoleo, M. Ferrari, G. Tripodi, A. Teti, G. Casuscelli, D. Ierace, R. Maccarone, M. Lico, F. Loria; Vibo Valentia/IT
Purpose: CEUS is used in the differential diagnosis between intrahepatic cholangiocarcinoma (ICC) and hepatocellular carcinoma (HCC). ICC typically shows earlier arterial enhancement and faster wash-out than HCC.
Parametric Micro-Flow Imaging (PMFI) provides further information providing a color-coded map of vascularization and allow to make a differential diagnosis.
The purpose of this study was to evaluate the diagnostic value of PMFI-CEUS in the differential diagnosis between ICC and HCC.
Methods or Background: We retrospectively reviewed CEUS examinations, recorded on digital data, of 52 patients with histologically
proven ICC, after CEUS the lesions were analyzed using PMFI which produces a color-coded map of vascularization. During post-processing, the PMFI software generated light-blue for the wash-in phase and red-yellow for the wash-out phase, providing a detailed view of microbubble dynamics within the lesions.
For each lesion we assessed: wash-in and wash-out timing; PMFI color pattern, and time–intensity curve (TIC) parameters, including arrival time and time-to-peak. These findings were compared with a control group of 160 patients affected by HCC.
Results or Findings: ICC showed earlier wash-in (11–22 s) compared with control group of HCC (20–30 s,). Wash-out occurred between 22–35 s in ICC, while in HCC started after 50–60s. On PMFI-CEUS, ICC were predominantly blue-light color coded, while HCC were more red-color coded. TIC confirmed shorter arrival time and time-to-peak in ICC. These findings showed sensitivity 100%, specificity 100% and accuracy 100% to differentiate ICC from HCC.
Conclusion: PMFI-CEUS provides reproducible parameters for differentiating ICC from HCC. Early wash-in with blue-light color coded map support ICC, while delayed wash-in with more red-coded PMFI indicates HCC, improving diagnostic accuracy and clinical decision-making in primary liver tumors.
Limitations: The sample is relative small. A multicentric confirmation is needed.

LI-RADS MRI Phenotype Predicts SR vs. RFA Outcomes for Early HCC: A PSM Analysis Background (6 min)

Lin Deng; Yulin City, Shaanxi Province / China

Author Block: L. Deng, Z. Jia; Yulin/CN
Purpose: Surgical resection (SR) and radiofrequency ablation (RFA) are curative options for early hepatocellular carcinoma (HCC), but optimal patient selection is challenging. As tumor biology, not just size, dictates recurrence, preoperative biomarkers are needed to guide therapy. This study aimed to evaluate MRI-based LI-RADS v2018 classification as a predictive biomarker for differential response to SR versus RFA in a propensity score-matched (PSM) cohort.
Methods or Background: This retrospective, dual-center study included 182 patients with early HCC (≤2 tumors, each ≤5 cm) treated with SR (n=137) or RFA (n=45). To correct for selection bias, 1:1 propensity score matching (PSM) balanced 15 baseline variables, creating two matched cohorts of 42 patients each. Two radiologists independently classified preoperative MRIs by LI-RADS v2018 criteria, identifying LR-5 and LR-M phenotypes. The primary endpoint was 1-year early recurrence-free survival (eRFS).
Results or Findings: After PSM, baseline characteristics were well-balanced. In the overall matched cohort, 1-year eRFS did not differ between SR and RFA (68.2% vs. 59.5%, p=0.215). However, a strong treatment-phenotype interaction emerged. For LR-5 tumors (n=58), eRFS was similar (71.0% vs. 66.7%, p=0.482). In stark contrast, for LR-M tumors (n=26), SR yielded significantly higher 1-year eRFS than RFA (64.3% vs. 16.7%, p=0.008). On multivariable analysis, LR-M was the strongest independent predictor of early recurrence after RFA (HR: 3.85; 95% CI: 1.91-7.76; p<0.001).
Conclusion: In a bias-corrected cohort, preoperative LI-RADS MRI is a powerful predictive biomarker. HCCs with the LR-M phenotype, a surrogate for aggressive biology, respond poorly to RFA and have a high risk of early recurrence. These findings support using MRI phenotyping to guide individualized treatment decisions, prioritizing patients with LR-M tumors for surgical resection to improve outcomes.

Preliminary application of time-dependent diffusion MRI based on 5.0T ultra-high field in the diagnosis and pathological grading of HCC (6 min)

Shao-Peng Peng Li; Hefei / China

Author Block: S-P. P. Li[1], D. Yin[1], X. Song[2], Z. Feng[2], Y. Liu[1], W. Wei[1], L. Liu[1]; [1]Hefei/CN, [2]Shanghai/CN
Purpose: To investigate the feasibility of microstructure analysis using 5.0T ultra-high-field MRI based on time-dependent diffusion imaging(td-dMRI) in differentiating benign and malignant liver lesions and assessing the pathological grading of HCC
Methods or Background: 51 patients with clinically confirmed focal liver lesions were enrolled. Td-dMRI were acquired using a 5.0T scanner with pulsed and oscillating gradient spin-echo MRI sequences at equivalent diffusion times ranging from 4.0 to 44 msec. The imaging microstructural parameters using limited spectrally edited diffusion (IMPULSED)–based parameters derived from td-dMRI including cell diameter(d), intracellular volume fraction(vin), cellularity, and extracellular diffusivity(Dex). Differences in these parameters between malignant and benign lesions were compared.
Results or Findings: 1. 14 patients had benign lesions and 37 had malignant lesions (including 23 HCC, 5 ICC, and 9 metastases). Benign lesions exhibited lower vin and cellularity but larger cell diameter, with statistically significant differences, and the diagnostic efficacy of cellularity is the highest(AUC=0.714). Dex was higher in benign lesions but not statistically significant.
2. Among 23 HCC cases, 18 were pathologically confirmed, including 7 low-grade (I-II) and 9 high-grade (III-IV) HCC. The high-grade HCC group showed higher vin and cellularity but smaller cell diameter and lower Dex. Statistically significant differences were observed in cellularity and vin between the two groups.
3. When patients were divided into a normal liver group and a hepatitis B virus (HBV)-infected or cirrhotic group, the HBV/cirrhotic group exhibited increased hepatic cellularity and vin, with reduced cell diameter and Dex.
Conclusion: Time-dependent diffusion MRI-based microstructural characterization is a feasible and effective method for differentiating benign and malignant liver lesions and assessing HCC pathological grades, with structural correlations to histopathology.
Limitations: Its potential value in evaluating post-hepatitis B cirrhosis warrants further investigation.

Prognostic modeling using early CT features after TACE in HCC – comparison with established imaging response systems (6 min)

Christian Bijan Fink; Düsseldorf / Germany

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: C. B. Fink, F. Ziayee, J. Böven, K. Jannusch, G. Antoch, P. Minko, E. Tietz; Düsseldorf/DE
Purpose: To assess the prognostic utility of early contrast-enhanced CT after drug-eluting bead transarterial chemoembolization (DEB-TACE) in hepatocellular carcinoma (HCC), focusing on validation of CT as a diagnostic tool and development of a simplified prognostic imaging model compared to established response criteria.
Methods or Background: We retrospectively analyzed 80 HCC patients who underwent DEB-TACE between 2014–2021. Multiphasic CT was performed before and within 7 days after treatment. Two radiologists evaluated morphologic features including arterial phase hyperenhancement (APHE), non-peripheral washout, and capsule enhancement. Regression was defined as disappearance of each feature. Tumor shrinkage was quantified. A Cumulative Regression Score (CRS, 0–3) was derived, and a CT-based Early Response Model (CERM) combining APHE regression and tumor shrinkage was developed. The primary endpoint was progression-free survival (PFS). Survival analysis used Kaplan–Meier and Cox regression; model performance was compared with mRECIST and LI-RADS TR.
Results or Findings: APHE regression was observed in 60.6% of patients and independently predicted longer PFS (HR = 0.49, p = 0.01). was also independently prognostic (HR 0.60; p = 0.03). Washout regression was significant only in univariate analysis; capsule regression was not prognostic. Higher CRS values correlated with stepwise PFS improvement (HR per regressed feature 0.74, p = 0.03). CERM achieved the best prognostic performance (C-index = 0.65), surpassing mRECIST and LI-RADS TR. Internal validation confirmed minimal overfitting and stable calibration.
Conclusion: Early CECT after DEB-TACE is feasible and provides reproducible biomarkers for early PFS prediction. The proposed CERM enables individualized risk stratification within one week, without additional laboratory or functional imaging.
Limitations: Retrospective single-center design; external validation is needed.

Associations between the SMARS score derived from CT and MRI with histopathological features in HCC (6 min)

Daniele Romeo; Palermo / Italy

Author Block: D. Romeo[1], T. Denecke[2], H-J. Meyer[2]; [1]Palermo/IT, [2]Leipzig/DE
Purpose: Complex associations exist between imaging phenotype and underlying histopathology for hepatocellular carcinoma (HCC). SMARS score discriminates proliferative and non-proliferative HCC in a non-invasive way, associated with treatment outcomes. Systematic validation is needed and it is unclear whether associations between this score with histopathology features exist. This study elucidates correlations between the CT and MRI-defined SMARS score with immunohistochemistry of the pathological specimens in a curatively-treated HCC cohort.
Methods or Background: 44 patients (mean age: 59.6±10.7 years) with histologically confirmed HCC after curative surgical resection were included. Contrast-enhanced MRI and CT were performed before surgery and the SMARS score was calculated. Samples were analyzed for programmed death ligand 1 (PD-L1), Glypican-3, CD3-tumour infiltrating lymphocyte, CD68+ cells, CD34+ microvessel density (MVD).
Results or Findings: The median MRI-derived SMARS score was 1.4 (IQR: -0.32; 2.18) and the CT-derived was − 0.32 (IQR: -1.08; 0.56). According to the proposed threshold, 29 tumours were categorized as proliferative (82.9%) and six as nonproliferative HCC (17.1%) accordingly to the MRI-derived SMARS score. According to the CT-derived SMARS score 24 tumours were categorized as proliferative (61.5%) and 15 as nonproliferative HCC (38.5%). A moderate association was shown between the MRI-derived SMARS score with the Glypican-3 expression ($r = 0.37$, $p = 0.03$). CT-derived SMARS score showed correlations with two PD-L1 parameters (PD-L1 tumour positive score $r=-0.37$, $p = 0.02$; PD-L1 combined positive score $r=-0.35$, $p = 0.03$). No other association with the remaining parameters was detected.
Conclusion: SMARS score is a promising imaging score associated with Glypican-3 and PD-L1 expression in curatively-treated HCC patients. Differences between the CT and MRI-defined score need to be investigated in further trials on larger cohorts.
Limitations: Retrospective single-center design, small patient sample, different time periods between imaging and histopathology.

The impact of extrahepatic metastases in patients with hepatocellular carcinoma: A longitudinal analysis (6 min)

Aline Mähringer-Kunz; Mainz / Germany

Author Block: A. Mähringer-Kunz[1], L. Müller[1], M-T. Rüßmann[1], I. Schmidtmann[1], M. Moos[1], D. Pinto Dos Santos[1], T. Bäuerle[1], A. Weinmann[1], R. Klöckner[2]; [1]Mainz/DE, [2]Lübeck/DE
Purpose: Extrahepatic metastatic disease (EMD) in patients with hepatocellular carcinoma (HCC) is classified as advanced stage by BCLC. Evidence on prognostic impact of EMD is limited. We investigated the prognostic relevance of EMD — with a special focus on anatomical sites — using a longitudinal approach.
Methods or Background: Patients with HCC treated between 01/2007-12/2021 were included. All cross-sectional imaging was re-evaluated by a radiologist to determine the timing and anatomical sites of EMD. Overall survival (OS) was analysed using a multivariable Cox model with site-specific metastases as time-dependent covariates, adjusting for established risk factors.
Results or Findings: Of 1,563 patients included, 429 (27.4%) had EMD: 190 (12.2%) at diagnosis (synchronous) and 239 (15.3%) during follow-up (metachronous). Median OS was 5.6 months with synchronous EMD vs 20.0 months in those without EMD or with metachronous EMD ($p<0.001$). The distribution of metastatic sites and corresponding hazard ratios (HR, 95% CI) was: lung (n=183; HR=1.62 (CI=1.32-2.00)), regional lymph nodes (n=168; HR=1.55 (CI=1.27-1.90)), bone (n=102; HR=1.37 (CI=0.84-2.25)), peritoneum (n=101; HR=1.78 (CI=1.40-2.27)), adrenal glands (n=79; HR=1.42 (CI=1.02-1.99)), distant lymph nodes (n=53; HR=2.38 (CI=1.74-3.27)), and soft tissue (n=43; HR=1.79 (CI=1.23-2.60)). Metastases at the sites lung, lymph nodes, peritoneum, adrenal glands, and soft tissue were independent predictors of survival. Each additional site increased the HR by 1.64 (95% CI: 1.54-1.74).
Conclusion: Importantly, the presence of any metastasis is associated with adverse outcomes and an unfavorable hazard ratio. However, bone involvement appears comparatively less detrimental than other forms of extrahepatic spread, whereas distant lymph node metastases are particularly unfavorable. Moreover, prognosis deteriorates progressively with the number of metastatic sites, with each additional site conferring a substantial increase in risk. Thus, regular re-staging with detailed imaging evaluation is crucial.
Limitations: Limitations include the retrospective, single-center design.
Funding for this study: No funding was received for this study.

Ethics committee - additional information: Approval was not required due to the retrospective nature of the study

Noninvasive Prediction of Intratumoral Fibrosis and Prognostic Stratification Using an Intra-tumor heterogeneity-Derived Model in Hepatocellular Carcinoma (6 min)

Bo Liu; Lanzhou / China

Author Block: B. Liu[1], Y. Xu[2], W. Zhou[2]; [1]Jinan/CN, [2]Lanzhou/CN
Purpose: Stromal fibrosis is a critical component of the intratumoral microenvironment in hepatocellular carcinoma (HCC), influencing tumor progression, therapeutic response, and prognosis. However, its assessment typically relies on invasive histopathology. Intra-tumor heterogeneity (ITH) scores have been widely used to characterize tumor heterogeneity but have rarely been applied to evaluate fibrosis. This study aimed to develop and validate an ITH-based model for predicting intratumoral fibrosis (IF) and to explore its utility in stratifying early recurrence (ER) risk in patients receiving adjuvant hepatic arterial infusion chemotherapy after resection.
Methods or Background: We retrospectively included HCC patients undergoing curative resection at three tertiary centers. IF was quantified as the proportion of fibrosis on Masson-stained pathological sections, and its prognostic significance was evaluated. Tumor ROIs were segmented from the portal venous phase of preoperative contrast-enhanced CT, and unsupervised clustering with global pixel distribution features was used to calculate ITH scores. The ITH model was combined with clinical and imaging variables to establish a fusion fibrosis model (FFM).In the prognostic cohort (patients receiving adjuvant infusion chemotherapy), Kaplan–Meier analysis was performed to assess the model's ability to stratify recurrence-free survival (RFS).
Results or Findings: Among 302 patients, 164 (54.3%) exhibited high IF(>30%), which was significantly associated with worse prognosis. The FFM demonstrated robust predictive performance with AUCs of 0.892, 0.781, and 0.811 in the training and two external validation cohorts. In the prognostic cohort, the model effectively stratified RFS risk (P = 0.035).
Conclusion: The ITH-based FFM enables noninvasive prediction of intratumoral fibrosis and provides prognostic risk stratification in HCC patients receiving adjuvant chemotherapy, underscoring its potential clinical utility.
Limitations: The retrospective design may introduce selection bias, and potential mismatch between CT segmentation regions and pathological sampling sites could affect the accuracy of fibrosis labeling.
Funding for this study: This work was supported by grants from the Natural Science Foundation of China (82260555), ,Major Science and Technology Projects of Gansu Province (22ZD6FA021-4), Joint Research Fund General Projects of Gansu Province (23JRRA1508), Shandong Provincial Natural Science Foundation（ZR2022QB250）, Gansu Provincial Top-notch Talent Program(（2023）9), Cuiying Science and Technology Innovation Project of the Second Hospital of Lanzhou University（CY2024-CQ-01）and Public Hospital High-quality Development of Scientific Research Project of Chinese Health Promotion Foundation(GL-C032).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This is a study that follows the Declaration of Helsinki and good clinical practice guidelines, and was approved by the Ethics Committee of our hospitals(approval no. 2025A-541). As a retrospective analysis without any intervention in patient treatment, the Ethics Committees waived the requirement for individual informed consent.

Beyond size and morphology: multiparametric MRI for functional characterization and therapy monitoring in hepatocellular carcinoma (6 min)

Emily Hoffmann; Münster / Germany

Author Block: E. Hoffmann, B. Noto, F. Rennebaum, W. Roll, M. Köhler, M. Masthoff, P. Schindler; Münster/DE
Purpose: The tumor microenvironment (TME) plays a crucial role in the progression and treatment response of hepatocellular carcinoma (HCC). This proof-of-concept study examined whether multiparametric magnetic resonance imaging (mpMRI) could noninvasively characterize the TME and detect early, therapy-induced alterations following transarterial chemoembolization (TACE).
Methods or Background: 18 patients with HCC underwent comprehensive mpMRI at 3T, including diffusion-weighted imaging (DWI), T1 and T2* mapping, as well as dynamic contrast-enhanced (DCE) MRI. 8 patients underwent scans before and after TACE. Quantitative imaging biomarkers were derived to assess perfusion, endothelial permeability, cellular microstructure, hemorrhage and edema in tumorous and nontumorous liver tissue.
Results or Findings: Preliminary quantitative analysis revealed significant differences in TME characteristics between HCC lesions and non-tumor liver tissue. HCC lesions showed disrupted microvascular architecture with increased permeability and altered perfusion [e.g., mean Ktrans (10^{-3}/min) HCC: 796 ± 330, non-tumor: 227 ± 165, p = 0.0036]. These vascular alterations were paralleled by restricted diffusivity [mean ADC (10^{-3} mm²/s) HCC: 1.30 ± 0.29, non-tumor: 2.23 ± 0.20, p < 0.0001] and prolonged T2* relaxation times [mean T2* (ms) HCC: 39 ± 4, non-tumor: 18 ± 5, p = 0.004], indicating intratumoral hemorrhage, edema and microstructural disorganization. Early post-TACE scans demonstrated that mpMRI can detect therapy-induced remodeling of the TME before changes in size or morphology become apparent.
Conclusion: MpMRI allows for noninvasive characterization of the TME of HCC and demonstrates sensitivity to early treatment-related changes. These findings underscore the potential of mpMRI-derived biomarkers to support personalized therapeutic decisions and improve response evaluation in targeted oncologic therapies.
Limitations: These results are limited by the small preliminary sample size. A prospective clinical trial has recently begun to validate these findings and establish robust imaging biomarkers for MRI-based characterization of the TME of HCC.

Prediction of microvascular invasion in hepatocellular carcinoma using multiparameter spectral CT and clinical radiological features (6 min)

Subhash Chandra Singh; Lalitpur / Nepal

Author Block: S. C. Singh[1], C. Xie[2], Z. Song[2], Y. Liao[2]; [1]Lalitpur,Kathmandu/NP, [2]Guangzhou/CN
Purpose: This study aims to evaluate the performance of dual-layer spectral CT (DLCT) multi-parameter imaging combined with clinical-radiological features in predicting microvascular invasion (MVI) in hepatocellular carcinoma (HCC), and to develop a logistic regression-based predictive model for clinical decision support.
Methods or Background: This study included 67 patients with pathologically confirmed HCC who underwent preoperative multiphase DLCT between Oct 2022 and Oct 2024. Clinical variables, radiological features and DLCT parameters (electron density, iodine density, MONO-E 40/70/100 keV, Zeff) were collected, and normalized iodine concentration was calculated. Univariate tests compared patients with and without MVI. Variables with clinical relevance and low collinearity (VIF < 5, r < 0.7) entered multivariable logistic regression to build four models (DLCT, clinical, radiological and combined). Model performance was assessed using AUC, sensitivity, specificity, accuracy, predictive values, DeLong's test, decision curve analysis, and a nomogram.
Results or Findings: Among 67 patients, 21 (31.3%) had MVI. Univariate analysis identified PIVKA-II, tumor size, non-smooth margin, and TTPVI as significant factors, while multivariate analysis retained only TTPVI. Selected DLCT parameters were included for modeling despite non-significance. The combined model demonstrated the highest predictive performance (AUC = 0.880) with balanced diagnostic accuracy (accuracy 0.82, sensitivity 0.76, specificity 0.85). It significantly outperformed the individual models (all $p < 0.05$), and decision curve analysis indicated clinical benefit. The nomogram provided a straightforward tool for individualized risk estimation.
Conclusion: Combining DLCT multi-parameters with clinical-radiomics features significantly improves preoperative prediction of MVI in HCC, supporting individualized treatment decisions.
Limitations: Single-center study with a small cohort; external validation and comparison with advanced machine learning models are needed.

Photon-Counting CT for Interventional Oncology: Improving Vascular Mapping, Tumor Detection, and Personalized Treatment Strategies (6 min)

PiYi Chang; Taichung / Taiwan, Chinese Taipei

Author Block: P. Chang[1], W. Chiou[2]; [1]Taichung/TW, [2]Taithung/TW
Purpose: To illustrate the clinical applications of photon-counting CT (PCCT) in abdominal interventional radiology (IR) through a series of representative cases, with emphasis on hepatocellular carcinoma (HCC), metastases, and rare hepatic neoplasms.
Methods or Background: We collected abdominal PCCT cases performed at a tertiary referral center between April–August 2025. The cases covered three main clinical scenarios: (1) vascular mapping for TACE and Y-90 treatment; (2) detection of recurrence and follow-up after locoregional therapy or immunotherapy; and (3) evaluation of rare hepatic neoplasms. Each case was analyzed for the incremental value of PCCT compared with conventional energy-integrating detector CT. Specific techniques assessed included virtual monoenergetic imaging (VMI), iodine mapping, virtual non-contrast (VNC), and vessel reconstruction.
Results or Findings: Across the case collection, PCCT consistently provided higher lesion conspicuity, especially at 40–50 keV VMI, allowing better visualization of arterial-phase hyperenhancement and washout in HCC and metastases. Vascular mapping was improved, with clearer identification of segmental/subsegmental feeders, anatomical variants, and arterioportal shunts—crucial for TACE and Y-90 planning. Dose- and contrast-saving protocols achieved reliable imaging with contrast volumes as low as 45 ml. Surveillance cases demonstrated PCCT's ability to differentiate recurrent HCC from pseudoprogression or ablation changes. Rare tumors such as mucinous cystic neoplasm and IPMN were also better characterized.
Conclusion: PCCT is a promising next-generation imaging tool for safe and personalized interventional strategies in liver cancer and abdominal disease.
Limitations: Single-center retrospective review.

Limited case numbers, especially for rare hepatic neoplasms.

Lack of quantitative outcome correlation with treatment efficacy.

Predictive Value of IVIM-Based Habitat Radiomics for Pathological Grading of Hepatocellular Carcinoma (6 min)

jiangyang pan; Shi Jia Zhuang / China

Author Block: j. pan[1], J. Dai[2], Q. Wang[1], L. Gao[1]; [1]shijiazhuang/CN, [2]Shanghai/CN
Purpose: To explore the predictive value of habitat radiomics based on intravoxel incoherent motion (IVIM) for the pathological grading of hepatocellular carcinoma (HCC).
Methods or Background: Clinical and imaging data were retrospectively collected from 83 patients with pathologically confirmed and Edmondson-Steiner graded HCC (96 lesions in total) between May 2018 and June 2025. HCC was categorized as low-grade (Ⅰ-Ⅱ) or high-grade (Ⅲ-Ⅳ). Lesions were randomly split into a training set (n=67) and validation set (n=29) at a 7:3 ratio. All patients underwent preoperative IVIM scans on a 3.0 T MRI system. Based on the k-means clustering results of IVIM parametric maps, the tumor region of interest (ROI) was segmented into multiple subregions, from which radiomic features were subsequently extracted. Univariate/multivariate analyses screened clinical features to construct a logistic regression (LR) clinical model. For habitat features, Spearbvtman correlation and LASSO selected variables used to build multiple classifiers (LR, RF, SVM, k-NN, Bayesian), with the optimal model determined by 5-fold cross-validation. Model performance (AUC, calibration, decision curves) and comparisons (Delong test) were evaluated.
Results or Findings: Univariate and multivariate analyses identified age as an independent predictor for HCC pathological grading. The tumor region was partitioned into four subregions using k-means clustering. After radiomic feature screening, 10 features were retained. Among habitat-based models, the RF model performed best (training set AUC: 0.926, 95% CI: 0.851–0.980; validation set AUC: 0.863, 95% CI: 0.712–0.971). The combined model showed the highest diagnostic performance (training set AUC: 0.950, 95% CI: 0.894–0.990; validation set AUC: 0.926, 95% CI: 0.810–1.000).
Conclusion: IVIM-based habitat radiomics has favorable predictive value for HCC pathological grading. The combined model further improves performance, providing a novel methodological reference for preoperative non-invasive HCC grading.
Limitations: Not applicable.

Evaluation of Liver Imaging Reporting and Data Systems (LI-RADS)® in Treatment Response Assessment following Locoregional Therapy among Patients with Hepatocellular Carcinoma (6 min)

Judd Loy Berano; Iloilo / Philippines

Author Block: J. L. Berano; Iloilo City/PH
Purpose: This study aims to identify, evaluate, and summarize the findings of all relevant individual studies that assess LI-RADS® treatment response assessment following locoregional therapy among patients with HCC thereby making the available evidence more accessible to decision makers.
Methods or Background: This systematic review employed data-based convergent synthesis design. Records were identified through PubMed, Embase, ClinicalTrials.gov, ICTRP (WHO), Cochrane Central Register of Controlled Trials, MEDLINE and Embase. The study endpoints of the study are prediction of pathologic tumor viability and overall survival.
Results or Findings: A total of 46 studies were screened and only 12 studies were included in the qualitative synthesis. There were 10 studies that evaluated prediction of pathologic tumor viability, 2 studies for overall survival, and 1 study for both endpoints. LI-RADS treatment response algorithm has moderate sensitivity and high specificity for detecting residual tumor and complete or incomplete tumor necrosis across studies. Moreover, 2 studies reported that LI-RADS treatment response categories show a strong association with overall survival. There was one study, however, that demonstrated that LI-RADS treatment response algorithm was not an independent predictor for overall survival nor time to disease progression.
Conclusion: LI-RADS treatment response algorithm can be applied for prognostication and early detection of pathologic tumor viability.
Limitations: There is a need for multicenter prospective studies to further validate its performance.
Funding for this study: Self funding

Quantitative analysis of spectral CT multi-parameter imaging for evaluating residual tumor activity after transarterial chemoembolization in hepatocellular carcinoma (6 min)

Xiaomin Liu; Guangzhou / China

Author Block: C. Liu[1], W. Liang[1], J. Meng[1], X. Liu[2], D. Liu[1]; [1]Wuzhou/CN, [2]Guangzhou/CN
Purpose: To investigate the diagnostic value of spectral CT multi-parameter imaging in detecting residual tumor activity in hepatocellular carcinoma (HCC) lesions after transarterial chemoembolization (TACE).
Methods or Background: Thirty-nine HCC patients with 43 lesions (26 with lipiodol deposition, 17 with residual tumor) who underwent TACE were retrospectively analyzed. Pathology or digital subtraction angiography (DSA) served as the reference standard. All patients received spectral CT plain and four-phase enhanced scans. Quantitative parameters, including conventional CT, virtual mono-energetic images (VMIs at 40/70 keV), iodine concentration (IC), normalized iodine concentration (NIC), effective atomic number (Zeff), spectral slope (λHU), electron density (ED), arterial enhancement fraction (AEF), and extracellular volume fraction (ECV) were measured in the early arterial (EAP), late arterial (LAP), venous (VP), and parenchymal (PP) phases. ROC analysis was performed to assess diagnostic performance.
Results or Findings: Significant differences between lipiodol deposition and residual tumor were observed in Zeff, λHU, IC, and NIC in EAP; Zeff, VMI 40 keV, λHU, IC, and NIC in LAP; and ED in PP (all $P < 0.05$). AEF(EAP/VP), AEF-(LAP/VP), AEF-(EAP/PP), AEF-(LAP/PP), and ECV showed no significant differences. The best single-parameter performance was obtained with Zeff and λHU in LAP (cut-off values: 8.24 and 3.44; AUC = 0.725 and 0.724). The combined multi-parameter model achieved excellent diagnostic accuracy (AUC = 0.953, 95% CI: 0.896–1.00, $P < 0.001$), with 100% sensitivity and 76% specificity.
Conclusion: Spectral CT multi-parameter imaging enables comprehensive and quantitative evaluation of HCC lesions after TACE, overcoming the limitations of conventional imaging obscured by lipiodol deposition. This approach may facilitate early detection of tumor recurrence and guide personalized treatment strategies.

6 Days of a Country Doctor : A Student-Led Rural Healthcare Expedition in the mountainous regions of Georgia (8 min)
Nino Pangani; Tbilisi / Georgia

Author Block: N. Pangani; Tbilisi/GE
Purpose: Lack of equipment makes practicing medicine difficult for rural doctors in Georgia. Often they face critical shortages in diagnostic imaging, physicians rely on physical examination in cases of fractures or internal injuries. Medical students experienced challenging environments which helps them understand community needs and develop professional empathy. The project aimed to expose students to the daily realities of rural healthcare, advocate for improved diagnostic resources and to raise public awareness about rural health challenges.
Methods or Background: Over 3 years, students from Tbilisi Medical Academy visited four of Georgia's high-mountain regions. They lived with rural doctors, observed health dynamics in the community. They documented their experiences with photos, videos, and reflections. After the project, the students organized an exhibition, published a journal, and offered support free online English lessons. They also set up a fund to keep community screenings going.
Results or Findings: Students reported a better understanding of doctor-patient relationships, and awareness of social factors affecting health. They recognized the situation in rural clinics and provide support for building outpatient clinics. This would help doctors and patients have access to heating every day and transportation from home to the clinic during the mountainous season. The project showcased the resilience, commitment, and flexibility of healthcare providers in resource-limited areas. It also demonstrated how student involvement can change community awareness.
Conclusion: "Six Days of a Country Doctor" shows how hands-on, student-led programs in rural areas can support professional growth, build community ties, and encourage social responsibility in future doctors. The key for students is desire. The desire to help and not abandon the patient. By blending real-world learning with advocacy and practical support, these programs benefit both education and health outcomes in rural areas.
Limitations: No limitations were identified.
Funding for this study: Funding was provided by Tbilisi Medical Academy.

Diagnostic Accuracy and Safety of ChatGPT-5 and Gemini-2.5 Applied to CT and MRI Imaging (8 min)
Khalid Abuelsamen; AS_Salt / Jordan

Author Block: K. Abuelsamen[1], A. Sbool[1], M. Abouda[2], J. Al-Nawaiseh[1], Z. I. Al-Fasfous[1], R. Hattar[3], J. Qawasmi[1], E. Almashtoub[4]; [1]Zarqa/JO, [2]Cairo/EG, [3]Irbid/JO, [4]Balamand/LB
Purpose: This study compares the diagnostic accuracy and safety of ChatGPT-5 and Gemini-2.5 in CT and MRI imaging across multiple body systems. It aims to assess whether including clinical context improves diagnostic performance and evaluate the potential patient safety implications of missed diagnoses.
Methods or Background: A retrospective analysis was performed on 800 radiology case reports from Radiopaedia.org (400 CT and 400 MRI) covering neurological, chest, musculoskeletal, gastrointestinal, obstetric/gynaecological, and urological systems. Each case was reviewed once by ChatGPT-5 and once by Gemini-2.5 under two conditions: imaging alone and imaging plus clinical presentation. Diagnostic accuracy and errors were recorded, with missed diagnoses classified by possible consequential harm using the WHO harm severity scale. Statistical comparisons used chi-squared and t-tests, with $p < 0.05$ considered significant.
Results or Findings: ChatGPT-5 accuracy rose from 14.6% without clinical presentation to 34.4% with it ($p < 0.001$). Gemini-2.5 improved from 15.2% to 31.3% ($p < 0.001$). Accuracy differences between models were not significant, either without ($p = 0.746$) or with ($p = 0.093$) presentation. Missed diagnoses with potential major harm or death decreased when clinical context was added: ChatGPT from 28.5% to 22.1% and Gemini from 26.6% to 21.9% (both $p < 0.001$). No significant inter-model difference in harm severity was observed ($p = 0.110$ without; $p = 0.919$ with presentation).
Conclusion: Clinical context enhances diagnostic performance for both models across systems and modalities. These findings support the adjunctive role of AI chatbots in clinical workflows and highlight the necessity for prospective validation and careful integration to reduce harmful errors.
Limitations: The limitations of this study include reliance on publicly available Radiopaedia cases and variable case complexity. These factors may affect generalisability, emphasising the value of broader validation and integration into generalisability.
Funding for this study: No funding was received for this study.

ROENTGENIUS: an individual competition for diagnostic radiology residents as a way to shape the future of healthcare (8 min)

Elizaveta Aleksandrovna Kirillova; St. Petersburg / Russia

Author Block: E. A. Kirillova, R. Shtentsel, P. Kozlova, I. Mashchenko, G. Trufanov; St. Petersburg/RU
Purpose: In Russia, there has been no individual competition for radiology residents that comprehensively evaluates professional knowledge and essential soft skills (communication, self-presentation, creativity etc.). To address this gap, the first nationwide individual competition for diagnostic radiology residents, ROENTGENIUS, was created to identify and support the most talented young specialists, to shape diagnostic radiology leaders of tomorrow.
Methods or Background: The one-day competition comprises three sequential stages. First, candidates independently analyse complex multimodal clinical cases by reviewing DICOM files and answer open-ended questions within a limited period of time. Second, a challenge entitled «Myself in the World of Radiology» requires residents to present their personal journey in a creative format (for example, a video presentation, a stand-up performance, or an original poem). Third, participants present a clinical case prepared according to CARE Guidelines and engage in discussion with the expert radiologists of the jury. All stages are scored by the jury according to the pre-set criteria.
Results or Findings: Between 2023 and 2025, three competitions were held with a total of 48 participants from seven Russian cities. The project was supported by major national radiological societies. This format allowed participants to demonstrate and refine hard (image analysis, report preparation, competence in choosing imaging modalities, clinical reasoning) and soft skills (communication, creativity, self-presentation), while also facilitating networking with fellow residents and jury members.
Conclusion: ROENTGENIUS is the first competition for radiology residents in Russia that highlights individual performance alongside traditional team events. It promotes a new generation of radiologists who combine clinical competence with strong communication and creative skills that are essential for real-world clinical practice. This competition provides a reproducible model that can be adapted and tested in other national contexts.

Patient-Reported and Health Related Quality of Life Outcomes After Percutaneous Renal Cryoablation (8 min)

Maariyah Bajibhai; Blackburn / United Kingdom

Author Block: M. Bajibhai; Blackburn/UK
Purpose: The study aim was to assess the impact on health-related quality of life (HRQoL) and patient-reported outcome measures (PROM) following renal tumour cryoablation.
Methods or Background: This prospective study recruited patients undergoing renal cryoablation between October 2024 and February 2025. HRQoL was assessed using the EQ-5D-5L, covering five dimensions with five severity levels and a visual analogue scale. Assessments were at baseline, day 1, day 8, and 1, 3, and 6 months; 6-month data were incomplete at abstract submission.
Results or Findings: A total of 45 patients were recruited. Median overall health scores remained stable at 80 from baseline to month 3 (range 20–100 at baseline, 20–98 at month 3). By day 8, improvements were observed across multiple domains, with mobility and self-care increasing by 30%, usual activities by 40%, and pain/discomfort by 20% compared with baseline. By month 1, only usual activities maintained a modest 20% improvement, while other domains returned to baseline. From month 3 onwards, no further significant changes were noted, suggesting that the majority of functional recovery occurs within the first 1–2 weeks post-treatment, followed by long-term stabilisation.
Conclusion: Renal cryoablation has a minimal impact on QoL with return to baseline scores for the majority of patients after one month and improvements in HRQoL outcomes for some patient
Limitations: This study has a few notable limitations. Although HRQoL outcomes were assessed up to 12 months, longer-term effects beyond one year remain unknown. HRQoL was measured using a self-reported questionnaire, which may be influenced by patient expectations or recall bias. The lack of a control group limits the ability to attribute changes solely to cryoablation, and early post-operative assessments may reflect transient effects. Finally, as a prospective, non-randomised study, causal relationships cannot be definitively established

Epicardial adipose tissue radiomics distinguishes heart failure with reduced ejection fraction: comparison of manual and CNN-based segmentation with autoencoder and conventional classification (8 min)

Maciej Mazuruk; Warszawa / Poland

Author Block: M. Mazuruk, M. Kacperska, P. Laba, M. Mączewski, I. Michalowska, M. Mączewski; Warsaw/PL
Purpose: Epicardial adipose tissue (EAT) is a metabolically active fat depot surrounding the myocardium. Histological analyses have shown that in end-stage heart failure with reduced ejection fraction (HFrEF) adipocyte size alterations occur within 3 mm of the myocardium. These changes correspond to higher attenuation of perimyocardial EAT on cardiac CT. Building on these findings, this study evaluated whether radiomic analysis of perimyocardial EAT can differentiate HFrEF from controls, comparing a fully automated artificial intelligence–based workflow with manual analysis.
Methods or Background: 140 patients (70 HFrEF, 70 controls) underwent cardiac CT. EAT was segmented manually (single-slice and three-slice methods) and with a convolutional neural network (CNN) focusing on a 3 mm perimyocardial layer. Radiomic features were extracted for each segmentation. Two classification models (LASSO regression and ElasticNet) were trained to differentiate HFrEF from controls. The feature space was defined either by the top 10 radiomic features (bootstrapped selection) or by a 10-dimensional latent space from an autoencoder.
Results or Findings: Automated CNN segmentation was faster (4 vs 7 minutes per case), avoided interobserver variability, and yielded the highest classification performance. With CNN segmentation, both L1 and ElasticNet models attained AUC ≈0.95, and ElasticNet achieved 91.4% accuracy (vs 80% for L1). This outperformed the manual single-slice segmentation results (AUC ~0.93, accuracy ~86%). The three-slice manual method performed worst.
Conclusion: Radiomic EAT features can robustly distinguish HFrEF from controls. A histology-inspired perimyocardial segmentation improved classification accuracy and can be fully automated using CNN segmentation with autoencoder-derived features. This reproducible approach provides high accuracy and shows promise as an imaging biomarker for HFrEF.
Limitations: The limitations of the study are single-center design, modest sample size and lack of external validation. The automatic myocardial segmentation algorithm requires refinement for severely dilated ventricles in HFrEF.
Funding for this study: This study was supported by the Agency for Medical Research (ABM) under grant no. KPOD.07.07-IW.07-0149/24.

Radiography of knowledge: Effects of a didactic module in radiological anatomy (8 min)

Vitor Campelo; Salvador / Brazil

Author Block: V. Campelo, M. Silva, J. Neves Soussa, L. Santana, L. FROTA, G. Queiroz, K. Gama, F. D. Lôpo, C. Lins; Salvador/BR
Purpose: This study evaluated medical students' perceptions and cognitive performance in radiological interpretation within a Radiological Anatomy module during the preclinical phase of medical education.
Methods or Background: This cross-sectional observational study involved third-semester medical students enrolled in the Radiological Anatomy module. A questionnaire collecting sociodemographic data, course expectations and evaluations (using a 5-point Likert scale), as well as radiological knowledge (multiple-choice questions), was administered both before and after the module. Incomplete questionnaires were excluded, and informed consent was obtained from all participants. Quantitative variables were presented as means and standard deviations. Statistical analyses included paired comparisons using the Wilcoxon signed-rank test and unpaired comparisons using the Mann–Whitney U test, depending on variable distribution. A p-value ≤ 0.05 was considered statistically significant.
Results or Findings: The sample consisted of 150 students (20±2.4 years; 57.6% female). The questionnaires demonstrated high internal consistency, with a Cronbach's alpha of 0.93. The mean number of correct answers increased significantly from 8.9±2.8 before the module to 15.6±2.7 after ($p < 0.001$). Following the module, 98.5% of students rated their ability to interpret radiological images as above average or excellent. Additionally, 93.8% and 92.7% rated sessions with radiologists and the integration with other curricular components, respectively, at the same level. Furthermore, 91% of students considered the module's contribution to their future medical practice and 94% its clinical relevance to be above average or excellent.
Conclusion: The Radiological Anatomy module during the preclinical phase of medical education facilitated significant improvements in technical skills and subjective appreciation of the teaching process, demonstrating its value for the early development of clinical competencies in medical training.
Limitations: Single-centre study limited to one academic semester.
Funding for this study: No funding was received.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Institutional review board approval (No. 7.295.056 ; CAAE: 80990524.9.0000.5544) was obtained and informed consent collected from all participants.

Utility of artificial intelligence in the detection of pleuroparenchymal abnormalities on chest X-ray (8 min)

Claudia Argüelles Llera; Santander / Spain

Author Block: C. Argüelles Llera, L. garcía del barrio, A. Ezponda Casajus; Pamplona/ES
Purpose: To evaluate AI performance in detecting pleuroparenchymal abnormalities (pneumothorax [PTX], pleural effusion [PEF], pulmonary lesion/nodule [LES], consolidation [CO], and atelectasis [AT]) on posteroanterior chest X-ray, comparing AI, an experienced thoracic radiologist, and their combination (Radiologist+AI), using the radiologist supported by AI (Radiologist_IA) as reference.
Methods or Background: In this prospective cohort, an expert radiologist reported images blinded to AI output. AI results (AI-Rad Companion Chest X-Ray, Siemens Healthineers) were recorded separately, then the radiologist reviewed AI findings. The final report (Radiologist_IA) served as reference. Sensitivity, specificity, weighted kappa (κ), and AUC were calculated. DeLong's and McNemar's tests were used.
Results or Findings: Agreement between AI and the radiologist was moderate, highest for PEF ($\kappa = 0.63$) and PTX ($\kappa = 0.475$). The radiologist achieved near-perfect sensitivities (~100%) and specificities (>98%). AI showed high sensitivity for PTX (100%) but lower for AT (35.3%) and CO (53.1%). For LES, AI sensitivity (0.803) exceeded the radiologist (0.727), though specificity was higher for the radiologist (0.994 vs. 0.855). Radiologist AUC was superior to AI for PEF, CO, and AT (all $p < 0.001$). Radiologist+AI increased LES sensitivity (0.97 vs. 0.727; $p = 0.178$), not significant. LES AUC was 0.8608 (radiologist) vs. 0.9121 (Radiologist+AI, $p = 0.178$).
Conclusion: AI shows acceptable performance in detecting pleuroparenchymal abnormalities on chest X-ray, especially PTX. Radiologist interpretation remains most reliable; AI integration enhances sensitivity, supporting its role as a clinical adjunct.
Limitations: Not applicable.
Funding for this study: None.

Radiological education for preschool and elementary school children – Introduction and design of imaging stations at the "Teddydocs from Wörthersee – Stuffed Animal Clinic in Klagenfurt/W.", Austria (8 min)

Corinna Anna Berta Hofer; Graz / Austria

Author Block: C. A. B. Hofer[1], A. J. Schlemmer[1], M. Trapp[2], E-M. Trapp[2]; [1]Graz/AT, [2]Klagenfurt am Wörthersee/AT
Purpose: The aim of the project "Teddydocs from Wörthersee" is to show children in a calm and fun environment how a hospital works and to take away the children's fear of examinations with realistic rebuilds of the different imaging methods.
Methods or Background: The "Teddydocs from Wörthersee – Stuffed Animal Clinic Klagenfurt" had its premiere in July 2025. It is a joint project between KABEG (Carinthian State Hospitals Operating Company) and the Medical University of Graz.
150 preschool and elementary school children were invited to have their stuffed animals examined by medical students ("Teddydocs") in a hospital simulation. This also included imaging stations like X-ray, MRI, CT and Ultrasound. Starting with the "Teddy Clinic" in Graz back in 2017, the imagine stations were improved and expanded. A university course was introduced specifically for this purpose. Together with volunteers and medical students new devices were planned and built.
Results or Findings: New CT and MRI scanners were crafted to show the difference between these two modalities. Ultrasound probes that were no longer needed and videos from echocardiography and renal ultrasound simulated an ultrasound examination. X-rays were simulated by illuminating images with light and projecting them onto a table. The medical students used Chat-GPT to design X-rays of stuffed animals with broken bones as well as other pathologies.
Conclusion: This newly introduced project allows children to gain insight in the common diagnostic methods and to have first encounters in a playful way. It could be an alternative or at least an addition to mock scanners. Furthermore, it can be included in health education for children of this age.
Limitations: The crafted imaging devices cannot take away the children's fear completely, but they can make an upcoming examination a little easier.
Funding for this study: No funding.

Endovascular thrombectomy – from life-saving procedure to "mission impossible": does the anatomical idiosyncrasy really matter? (8 min)

Natalia Anatolieva Yosifova; Shumen / Bulgaria

Author Block: N. A. Yosifova, G. N. Todorov, C. Bachvarov, M. Nanev, M. Tsalta-Mladenov, V. Dimitrova-Kirilova, T. Drenski; Varna/BG
Purpose: To investigate how the outcome of an endovascular thrombectomy (EVT) after a large vessel occlusion (LVO) depends on the anatomical characteristics of the vessels. We aimed to evaluate the efficacy of the EVT based on the present intraprocedural complications and the postprocedural imaging findings.
Methods or Background: In this retrospective study, for a 6-month time period, all patients underwent EVT in the therapeutic window and patients with tortuosity or kinking of major extracranial vessels (planned for EVT, not accomplished) were included. Additional inclusive criterion was presence of imaging data proving LVO.
Results or Findings: Of 20 eligible patients, there were 14 (70%) achieved a favourable outcome – full patency of the previous occluded segments. In 28.5% of this subgroup we simultaneously performed carotid arterial stenting. 4 patients (20%) of the cohort presented with significant kinking of the vessels (associated calcinosis in 5%) – in half of them we tried EVT without successful outcome, the anatomical peculiarity of the other 2 patients could not allow us to place the aspiration devices in the occluded segment. In 10% we distinguished slightly enlarged hypodense zones – the undesirable result was due to working at the end of the therapeutic window in the first case and "multi-thrombi" state during aspiration in the second.
Conclusion: EVT in patients with common anatomy features and data for LVO is a life-saving intervention, leading to recanalization and excellent postprocedural results. The destiny of patients with anatomical idiosyncrasy depends on the complexity of the abnormality and the opportunity of reaching occluded segments with aspiration devices.
Limitations: The main limitation of this study is the number of the patients in the current cohort – 20 patients for a 6-month period due to the highly specific area of interest.
Funding for this study: No funding was received for this study.

SF 15a - Patient-centred care education in radiography

Categories: Radiographers, Professional Issues, Evidence-Based Imaging, Multidisciplinary, Artificial Intelligence
Date: March 6, 2026 | 14:00 - 15:30 CET
CME Credits: 1.5

Moderators:
Christina Malamateniou; London / United Kingdom
Chiara Pozzessere; Lausanne / Switzerland

Chairpersons' introduction (6 min)
Christina Malamateniou; London / United Kingdom
Chiara Pozzessere; Lausanne / Switzerland

Patient and public involvement in education (15 min)
Caroline Justich; Vienna / Austria

1. To learn how the insights and perspectives of patients contribute to the overall efficiency of the medical system, saving time, money, and resources.
2. To appreciate the role of patient and public involvement in education and training and to recognise the crucial contributions of radiographers and radiologists to patients.
3. To recognise the importance of collaboration in enhancing education in medical imaging for all participants.

Specific training for specific patients (15 min)
Claudia Sa Dos Reis; Lausanne / Switzerland

1. To identify the unique radiographic considerations and challenges associated with imaging special patient populations (paediatric, geriatric, bariatric, neurodivergent, or those with physical or cognitive impairments).
2. To demonstrate appropriate patient care techniques and communication strategies (tailored to meet the needs of special patients during radiographic procedures, ensuring comfort, safety, and cooperation).
3. To present appropriate modifications to standard medical imaging and treatments to accommodate the needs of these patients that are being practised in some European countries.

How can radiographers provide the human touch in an AI era? (15 min)
Emily Skelton; London / United Kingdom

1. To describe the potential impact of AI technologies on the patient-radiographer interaction.
2. To understand common patient perspectives related to the use of AI in healthcare and imaging.
3. To identify strategies that radiographers can use to promote and maintain human connection.
4. To discuss how radiographers can act as a bridge of connection between patients and AI.

How to train the trainer to deliver empathic and inclusive care (15 min)
Ilaria Salvatori; Bologna / Italy

1. To define and interpret the concept of compassionate care in healthcare education as a relational presence rooted in empathy and inclusivity.
2. To critically reflect on how “walking with the other” and “offering authentic attention” can transform educational relationships into spaces of ethical and professional growth.
3. To develop and propose educational strategies for radiography training that integrate compassionate presence into technical instruction, fostering a balanced professional identity.

Panel discussion: What is required in order to better prepare healthcare professionals in medical imaging to deliver patient-centred care? (24 min)

SF 15b - Update on interstitial lung disease

Categories: Chest, Multidisciplinary, President's Choice
ETC Level: LEVEL III
Date: March 6, 2026 | 14:00 - 15:30 CET
CME Credits: 1.5

Moderator:

Interstitial lung abnormalities (ILAs): what are they, and what should we do? (20 min)
Mariana Benegas Urteaga; Barcelona / Spain

1. To understand the definition of ILAs.
2. To appreciate how and when to report CTs with ILAs.
3. To understand the clinical significance of ILAs.

CT imaging of connective tissue disease ILD (20 min)
Lisa Jungblut; Zurich / Switzerland

1. To understand the typical and atypical CT features of CTDs.
2. To appreciate the clinical significance of CT markers of disease severity in CTD.
3. To understand the impact of technological developments in CTD imaging with CT.

Imaging of pulmonary toxicity from systemic cancer therapy (20 min)
Guillaume Chassagnon; Paris / France

1. To appreciate the different patterns of pulmonary toxicity on CT.
2. To be aware of key systemic cancer therapies that cause pulmonary toxicity.
3. To develop knowledge on how to optimally report CT findings of pulmonary toxicity.

CT imaging of hypersensitivity pneumonitis (18 min)
Judith Babar; Shelford / United Kingdom

1. To be aware of the classifications of hypersensitivity pneumonitis and the role of imaging.
2. To understand the important diagnostic and prognostic CT features of hypersensitivity pneumonitis.

Panel discussion: The link between ILAs and ILD (8 min)

US 15 - What should a radiologist know? Kidney from a paediatric and adult perspective

Categories: General Radiology, Paediatric, Genitourinary, Abdominal Viscera, Multidisciplinary

ETC Level: LEVEL II+III

Date: March 6, 2026 | 14:00 - 15:30 CET

CME Credits: 1.5

The session provides an overview of current methods, trends, and future innovations in renal ultrasound. Starting with the standardised examination technique in the context of multiparametric sonography, insights will be given into paediatric ultrasound, trauma patients, kidney transplants, and the frequent question of the classification of cystic lesions.

Moderators:

Annamaria Deganello; London / United Kingdom

Thomas Fischer; Berlin / Germany

EFRS 16 - CPD for Radiographers

Categories: Radiographers, Professional Issues, Students, Education

Date: March 6, 2026 | 15:30 - 16:30 CET

CME Credits: 1

The EFRS CPD Committee explores and defines the evolving role and increasing importance of Continuing Professional Development (CPD) in radiography practice. CPD is understood as a structured, reflective, and forward-looking process through which radiographers articulate its value in professional practice, critically evaluate their own learning and growth in line with service and patient needs, and develop actionable plans to strengthen CPD practices within their institutions or professional networks.

Moderators:

Christian Schneckenleitner; Vienna / Austria

Nina Dalen Dalen Seime; Oevre Ervik / Norway

Chairperson's introduction (5 min)

Christian Schneckenleitner; Vienna / Austria

What Radiographers and their professional bodies are telling us (12 min)

Christoph Kamp; Vienna / Austria

1. Compare and contrast how national radiographer societies and individual radiographers perceive the purpose, value, and implementation of CPD.
2. Interpret key findings from the surveys to identify trends, challenges, and gaps in CPD engagement across Europe.
3. Discuss the implications of these findings for future CPD policy development, professional support structures, and educational planning.

Reframing CPD: From Compliance to Competence (12 min)

Francis Zarb; Msida / Malta

1. Understand current European and international frameworks guiding CPD in radiography.
2. Critically evaluate the shift from mandatory CPD tracking to reflective, outcome-based models.
3. Identify strategies to enhance personal engagement and professional accountability in CPD.

Creating Meaningful CPD in Clinical Radiography Practice: From Opportunities to Measurable Outcomes (12 min)

Ruth Mary Strudwick; Ipswich / United Kingdom

1. Explore innovative, practice-based models for embedding CPD into everyday clinical work and fostering a culture of continuous learning in radiography.
2. Apply strategies and tools to assess and evidence the impact of CPD on professional performance, service quality, and patient outcomes.
3. Critically reflect on how meaningful CPD initiatives can drive measurable improvements in clinical practice and career development.

Panel discussion (19 min)

CUBE 18 - Tumour ablation: what indication, what energy?

Categories: Interventional Radiology, Interventional Oncologic Radiology

ETC Level: LEVEL II+III

Date: March 6, 2026 | 15:45 - 16:15 CET

CME Credits: 0.5

This advanced session will provide a comprehensive overview of tumour ablation modalities, focusing on the selection of appropriate indications and energy sources. The session features presentations on thermal ablation techniques, including radiofrequency ablation (RFA), microwave ablation (MWA), cryoablation, and non-thermal electrical ablation methods such as irreversible electroporation (IRE) and electrochemotherapy (ECT). The session will highlight current evidence, technical considerations, and clinical decision-making to optimise ablation strategies.

Boris Brkljačić; Zagreb / Croatia

Optimising radiation protection in paediatri imaging: the Radiation, Health, Safety and Quality for Youth: A Comprehensive Approach to Justification, Optimisation, and Education (RHYTHM) project (12 min)

Claudio Granata; Trieste / Italy

1. To introduce the RHYTHM project on radiation, health, safety, and quality for youth.
2. To explain the sensitivity of children, adolescents, and young adults to ionising radiation, and the need for optimised imaging practices.
3. To discuss key issues related to justification, optimisation, availability, and accessibility of imaging services for young patients, as well as the education of professionals and communication of risk to parents and patients.

From incidents to improvement: Medical Applications of Radiation -Learning from Incidents and Near Misses (MARLIN) lessons for radiology practice (12 min)

Deniz Akata; Ankara / Turkey

1. To understand the role of incident learning systems (ILS) in promoting safety and quality in diagnostic and interventional radiology.
2. To recognise common sources of error in radiology practice and their potential impact on patient outcomes.
3. To apply the MARLIN project's recommendations for reporting, justifying, and learning from significant events and near misses in radiology departments.

Updating EC criteria for radiological equipment acceptability: the SAMIRA Study on the criteria for acceptability of medical radiological equipment (CARE) project (12 min)

Marco Brambilla; Novara / Italy

1. To learn how suspension levels for radiological equipment are currently established across the EU and the role of EC publication RP 162.
2. To appreciate the need for an updated and extended list of acceptability criteria in line with the current state of technical and equipment standards, methods for assessing relevant technical parameters, and the applicable Euratom and EU legal provisions.
3. To understand the methodology used for the revision and process of consultation with member states and other stakeholders on the proposed updated and extended list of acceptability criteria.

Clinical audit implementation in Europe (CLAUD-IT) (12 min)

Roman Klöckner; Lübeck / Germany

1. To learn about the impact of clinical audit on patient and staff safety.
2. To discuss the potential impact of clinical audit campaigns in the EU on clinical audit implementation.
3. To understand the importance of learning materials and training in popularising clinical audit, especially the Guide to Clinical Audit in Radiology (AUDITRAD), the clinical audits guide for nuclear medicine (NuCline), and the audit "cookbook" developed under CLAUD-IT.

Key performance indicators for quality and safety of ionizing radiation use in medicine (12 min)

Anoushka Davé; Brighton / United Kingdom

1. To list a set of KPIs that can be used to monitor the quality and safety of radiological procedures.
2. To reflect on which KPIs could be applied in their own organisational or country context and how.
3. To actively contribute to the design and implementation of an EU-wide monitoring system for quality and safety of medical applications of ionising radiation.

Towards a joint action to support the implementation of quality and safety of medical ionising radiation applications (12 min)

Ritva Bly; Vantaa / Finland

1. To introduce the Joint Action AURORad, Advancing Unified Roadmap on implementation of the strategic agenda for medical ionising radiation applications.
2. To understand the possibilities for collaboration on the national level to support the implementation of quality and safety of medical ionising radiation applications.
3. To discuss key issues related to improving quality and safety: justification, optimisation, learning from incidents and improving practice through clinical auditing.

Discussion (15 min)

ESR eHealth 16 - Data exchange in the EU

Categories: Professional Issues, Management/Leadership, Imaging Informatics, Medico-legal, Artificial Intelligence

ETC Level: LEVEL III

Date: March 6, 2026 | 16:00 - 17:30 CET

CME Credits: 1.5

The session focuses mainly on the European Health Data Space (EHDS) and what can be expected in the following years. It also addresses interoperability, data formats, and requirements to electronic health record (EHR) providers. Some regulatory aspects will be discussed, and benefits and challenges to data sharing across borders in the EU will be highlighted.

Moderator:

Michail Klontzas; Heraklion / Greece

Health Technology Assessment and value-based healthcare (20 min)

Andria Joseph; London / United Kingdom

Panel discussion: Are we doing the right things to get to value-based radiology? (20 min)

EU 16 - Radiation safety in interventional radiology: minimising radiation exposure by a change in culture

Categories: Professional Issues, EuroSafe Imaging/Radiation Protection, Interventional Radiology, Education

ETC Level: LEVEL II+III

Date: March 6, 2026 | 16:00 - 17:30 CET

CME Credits: 1.5

This session focuses on strategies to reduce radiation exposure in interventional radiology (IR) by promoting a cultural shift in practice. Experts will present the latest standard operating procedure from CIRSE and SIR, virtual training tools, and clinical approaches to minimising radiation doses for both staff and patients in high-dose procedures.

Moderator:

Peter Reimer; Karlsruhe / Germany

Chairperson's introduction (5 min)

Peter Reimer; Karlsruhe / Germany

Reducing occupational radiation and improving the working environment in IR rooms: insights from the new CIRSE and SIR SOP (10 min)

Peter Reimer; Karlsruhe / Germany

New tools teaching IR staff by virtual training, visualising exposure (15 min)

Silas Fuchs; Kiel / Germany

Radiation exposure: cerebral thrombectomy (15 min)

Elke Ruth R Gizewski; Innsbruck / Austria

Radiation exposure: TACE and pelvic embolisation (30 min)

Andreas H. Mahnken; Bochum / Germany

Peter Reimer; Karlsruhe / Germany

Panel discussion (15 min)

E³ 1619 - Breast imaging-reporting and data System (BI-RADS): 30 years on

Categories: Oncologic Imaging, Breast, Artificial Intelligence, President's Choice
ETC Level: LEVEL II+III
Date: March 6, 2026 | 16:00 - 17:30 CET
CME Credits: 1.5

Moderator:
Ritse Mann; Nijmegen / Netherlands

Chairperson's introduction (5 min)
Ritse Mann; Nijmegen / Netherlands

Breast imaging-reporting and data system (BI-RADS): 30 years on (20 min)
Michael Fuchsjäger; Graz / Austria

1. To learn how BI-RADS has evolved in the last 30 years.
2. To describe the current version of BI-RADS for mammography, US and MRI.
3. To understand the impact of key changes in the current version of BI-RADS.

Breast imaging-reporting and data system (BI-RADS): managing challenging category 3 lesions (20 min)
Gamze Durhan; Ankara / Turkey

1. To describe the imaging, pathologic and clinical features of category 3 lesions.
2. To describe the common pitfalls associated with interpretation.
3. To highlight ongoing challenges to their management.

Breast imaging-reporting and data system (BI-RADS): the future is AI? (20 min)
Linda Moy; New York / United States

1. To describe the current limitations of BI-RADS.
2. To highlight the current status of AI for breast imaging.
3. To understand how AI and other technologies may change future BI-RADS.

Panel discussion: What next for breast imaging-reporting and data system (BI-RADS)?
All speakers and (25 min)
Caroline Justich; Vienna / Austria

How 16 - From panic to precision: how we handle urgent neuro cases in 10 minutes

Categories: Musculoskeletal, Emergency Imaging, Neuro, Head and Neck, President's Choice

How we read the unconscious brain under pressure (15 min)
Maureen Dumba; London / United Kingdom

1. To explain the radiologist's approach to imaging the comatose patient in the emergency department (ED).
2. To review the key radiological patterns across differential diagnoses of coma.
3. To learn how to report the imaging findings essential for comatose patient management.

Not just a migraine: how we image "the headache of my life" (15 min)
Mikko Juhani Nyman; Turku / Finland

1. To explain when "just a migraine" might signal a serious pathology.
2. To review imaging strategies for acute headache in different clinical scenarios.
3. To learn how to interpret imaging findings essential for ED decision making.

Clearing the cervical spine: what to look for and what to report (15 min)
David M. Yousem; Baltimore / United States

1. To explain the decision support guidelines and imaging approach for cervical spine evaluation in trauma.
2. To review the most common cervical spine injuries and associated complications.
3. To learn how to report the essential findings for rapid patient management.

Open forum discussion: How radiologists balance speed and accuracy in high-pressure ER settings: sharing strategies, pitfalls, and real-world decision-making insights (13 min)

HW Uh 16 - Head and neck practical ultrasound

Categories: Head and Neck
ETC Level: ALL LEVELS
Date: March 6, 2026 | 16:00 - 17:30 CET
CME Credits: 1.5

Moderators:

IF 16 - From realism to surrealism: AI painting the picture

Categories: General Radiology, Imaging Methods, Evidence-Based Imaging, Artificial Intelligence, President's Choice

ETC Level: ALL LEVELS

Date: March 6, 2026 | 16:00 - 17:30 CET

CME Credits: 1.5

AI is poised to greatly impact how radiological images are reconstructed in the future. However, it can be assumed that a fine line exists between the amount of data that is needed for a truthful representation of a patient's condition and the amount of data where the resulting image is more the dreamlike invention of the AI. This session will discuss how the benefits of AI-powered reconstruction can already be harnessed without losing sight of the honest representation of physical reality.

Moderator:

OF 16R - Cardiac imaging: frontiers and integration in clinical practice

Categories: Radiographers, Vascular, Cardiac
Date: March 6, 2026 | 16:00 - 17:00 CET
CME Credits: 1

Moderator:
Moreno Zanardo; Milan / Italy

Chairperson's introduction (5 min)
Moreno Zanardo; Milan / Italy

Why cardiac imaging is at the heart of precision medicine (10 min)
Michelle Claire Williams; Edinburgh / United Kingdom

1. To understand the contribution of each imaging professional with a focus on how radiographers can enhance diagnostic value through optimal preparation, acquisition and collaboration with radiologists.
2. To explore the clinical application of multimodal imaging, and how radiologists and radiographers can support treatment planning and disease monitoring.
3. To gain practical clinical insights from a radiologist's perspective: covering tips and best practices for radiographers in cardiac imaging.

The new era of cardiac CT (10 min)
Martin Weber Kusk; Esbjerg / Denmark

1. To learn about recent technological advancements that are transforming cardiac CT, including high-speed scanning, ECG less, and AI integration.
2. To appreciate the evolving role of cardiac CT in diagnosing and managing cardiovascular disease across diverse clinical settings.
3. To understand how cardiac CT is being integrated into routine clinical workflows to support faster, safer, and more accurate patient care.

Mapping the heartbeat: cardiac MRI (10 min)
Jure Mišič; Ljubljana / Slovenia

1. To understand the role of cardiac MRI in assessing cardiac structure, function, and tissue characterisation.
2. To explore how cardiac MRI contributes to early diagnosis and personalised treatment planning in cardiovascular care.
3. To recognise the expanding role of radiographers in delivering high-quality cardiac MRI services within multidisciplinary teams.

Radiographers in the cath lab: expanding interventional cardiac radiology (10 min)
Marvin Grech; Ghaxaq / Malta

1. To understand the evolving role of radiographers in interventional cardiac procedures within the catheterisation lab for optimised image acquisition and radiation protection.
2. To explore the skills and knowledge required to support precision-guided cardiac interventions.
3. To recognise the impact of radiographer involvement on workflow efficiency, patient and professional safety, as well as clinical outcomes.

The EU-REST project: current workforce status and guidelines for the future (15 min)
Adrian Brady; Cork / Ireland

1. To understand the EU-REST project's purpose, conduct and outcomes.
2. To consider the new guidelines for the EU radiologist workforce availability.
3. To appreciate what needs to be done to have these guidelines implemented.

Radiologist's perspective in US (15 min)
Geraldine B. McGinty; New York / United States

1. To learn how the US health system is addressing workforce issues in radiology.
2. To appreciate the importance of coordinated planning and governance in addressing workforce issues.
3. To understand how individual radiologists can contribute to shaping the future.

A look at Asia and Middle East (15 min)
Laura Oleaga Zufiria; Barcelona / Spain

1. To learn about differences in radiology training.
2. To appreciate the importance of international communication in harmonising and advancing radiology training.
3. To understand the potential of diplomas – the role of EDiR for Asia and the Middle East.

A look into the future of radiologists (15 min)
Merel Huisman; Nijmegen / Netherlands

1. To learn about the expectations of young radiologists.
2. To appreciate the importance of learning to balance speed and quality.
3. To understand the importance of AI in training and clinical practice.

Panel discussion: Is it still worth becoming a radiologist? (25 min)

RPS 1601 - Updates on pancreatic cysts and gland dysfunction

Long-term outcomes of branch-duct IPMN ≤2 cm: a 10-year MRI follow-up study (6 min)
Denise Squecco; Modena / Italy

Author Block: A. Saccomanno[1], D. Squecco[2], G. Morana[3]; [1]Varese/IT, [2]Modena/IT, [3]Treviso/IT
Purpose: To assess the risk of progression and clinical outcomes in patients with Branch-Duct Intraductal Papillary Mucinous Neoplasms (BD-IPMN) ≤2 cm followed by magnetic resonance imaging (MRI) for at least 10 years, stratified by initial cyst size (1–10 mm vs 11–20 mm).
Methods or Background: We performed a retrospective observational study at Ca' Foncello Hospital, Treviso. A total of 174 patients with BD-IPMN ≤2 cm diagnosed between 2007 and 2025 were included, all undergoing MRI follow-up for ≥10 years. Outcomes were time to progression, defined as appearance of worrisome features (WF) or high-risk stigmata (HRS), time to surgery, and overall survival (OS). Kaplan–Meier survival analysis and multivariate Cox regression were used to identify independent predictors.
Results or Findings: Median follow-up was 12 years. New WF/HRS occurred in fewer than 15% of patients, with cumulative progression rates of 10.8% at 5 years and 12.6% at 10 years. Stratified by size, 10-year progression was 8.5% in cysts 1–10 mm and 21.4% in cysts 11–20 mm (p=0.028). Surgery was required in 11 patients (6.3%), yielding one high-grade dysplasia and two pancreatic ductal adenocarcinomas. Ten-year OS exceeded 87% in both groups. Multivariate analysis confirmed age at diagnosis (HR 1.22, p<0.001) and active smoking (HR 4.69, p=0.042) as independent predictors.
Conclusion: BD-IPMN ≤2 cm show indolent long-term behavior, with most patients free from WF/HRS even after 10 years. Lesions 11–20 mm have a slightly higher risk of progression, but overall rates remain low.
Limitations: This is a retrospective, single-center study; not all follow-up MRIs were performed with contrast media; the number of surgical and oncological events was limited.
Funding for this study: No external funding was received for this study.
Has your study been approved by an ethics committee? Not applicable

Are We Over-Surveilling Branch-Duct IPMNs? Ten-Year MRCP Follow-up Shows Minimal Progression (6 min)
Hüseyin Ertuğrul Özay; Istanbul / Turkey

Author Block: N. Gündüz, H. E. Özay, M. F. TAPAN, F. Buyuker, O. Alimoglu; Istanbul/TR
Purpose: To assess growth kinetics and radiological changes of branch-duct IPMNs (BD-IPMNs) without baseline worrisome features (WF) or high-risk stigmata (HRS), and to evaluate whether MRCP surveillance intervals recommended by the Fukuoka guidelines may be extended.
Methods or Background: We retrospectively included 76 patients with BD-IPMN diagnosed between 2015–2025, each with ≥2 MRCPs. Demographics, cyst size at baseline and last follow-up, number of MRCPs, follow-up duration, cyst localization, and interval development of WF/HRS were recorded. Growth rates were calculated and correlations tested with clinical factors.
Results or Findings: Mean age was 65.6 ± 10.7 years; 58% were female. Median follow-up was 39.5 months (IQR 27.8–72.0) with a median of 3 MRCPs. Median cyst size increased only from 10.0 mm to 11.0 mm, corresponding to a median absolute growth of 0.0 mm (IQR 0.0–3.25) and annual growth of 0.11 mm/year. No patient developed HRS, and only three patients (3.9%) developed new WF. No surgical intervention was required. Multifocality was present in 39%, multiloculation in 15%. Growth correlated weakly with age (ρ=0.283, p=0.015) and number of MRCPs (ρ=0.249, p=0.032), suggesting a surveillance bias.
Conclusion: BD-IPMNs without WF or HRS remained radiologically stable over a median 3-year follow-up, with minimal growth and negligible progression. Our findings indicate that longer surveillance intervals may be safely considered, supporting a less intensive, individualized approach and questioning the necessity of current frequent MRCP follow-up schedules.
Limitations: The main limitation of this study is its retrospective, single-center design with a relatively small sample size, which may limit the generalizability of the findings.
Funding for this study: No funding was provided for this study.
Has your study been approved by an ethics committee? Not applicable
Ethics committee - additional information:

Comparison of single- vs dual-source photon-counting detector CT scanners: phantom and clinical assessment of radiation dose and image quality of abdominal scans (6 min)
Ibolyka Dudás; Budapest / Hungary

Author Block: I. Dudás, Z. Somogyiné Nagy, A. Kubovje, A. I. Vigh, T. Marjai, P. Maurovich-Horvat, B. K. Budai; Budapest/HU
Purpose: This study aimed to compare image quality and radiation dose between single-source and dual-source photon-counting detector CT (PCD-CT) for pancreatic cystic lesion (PCL) follow-up imaging.
Methods or Background: We retrospectively identified 20 patients with pancreatic cystic lesions scanned with single-source PCD-CT between 2024 October and 2024 December who had previous dual-source PCD-CT scans at our institution with the same abdominal imaging protocol as part of their follow-up. In addition, anthropomorphic phantoms were scanned on both systems. Virtual monoenergetic images (VMI) at 40 and 70 keV were reconstructed. Circular regions of interest were placed in the aorta, pancreas parenchyma, liver parenchyma, cyst fluid, subcutaneous fat, and iliopsoas muscles. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated. Pancreatic duct depiction, PCL delineation, image noise, and overall quality were assessed using a 5-point modified Likert scale.
Results or Findings: The radiation dose was not significantly different between the scanners in either the unenhanced, pancreatic, or venous phases. At 70 keV, postcontrast CNR did not differ between scanners, whereas at 40 keV, single-source PCD-CT demonstrated significantly higher CNR in the aorta ($p=0.014$), pancreas ($p=0.002$), liver ($p<0.001$), and iliopsoas ($p=0.017$) for the venous phase. SNR was significantly higher for single-source in multiple tissues at both 40 and 70 keV, most prominently in the venous phase. Subjective assessments favored single-source PCD-CT for image quality, though phantom-based noise power spectrum analysis showed no significant differences.
Conclusion: Single-source PCD-CT provides improved SNR, CNR, and subjective image quality compared with dual-source PCD-CT for pancreatic cystic lesion imaging, without increased radiation dose. However, distinction cannot be made whether these improvements originate from hardware or software differences.
Limitations: This was a single-center study with a retrospective study design.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the institutional ethics committee.

IPMNs: Imaging Features, Growth, and Outcomes in a Large Cohort (6 min)

Bahareh Abdolalizadeh; Værløse / Denmark

Author Block: B. Abdolalizadeh, N. Madrid Scheller, S. Jawad, T. Skårup Kristensen, C. Palnæs Hansen, C. Ewertsen; Copenhagen/DK
Purpose: Intraductal papillary mucinous neoplasms (IPMNs) are common pancreatic cystic lesions with variable malignant potential, making management and surveillance challenging. This study aimed to evaluate imaging characteristics, demographic factors, and clinical outcomes of patients with IPMNs referred to multidisciplinary team conferences at a tertiary reference center between 2019 and 2023.
Methods or Background: We included all patients referred to the weekly IPMN MDT conference from January 1, 2019, to December 31, 2023. Exclusion criteria were cystic lesions other than IPMN, uncertain IPMN diagnosis, patients with only a single CT scan available, and cysts <5 mm. Demographic data, imaging features including baseline and newly developed worrisome features (WFs), and histological outcomes of surgically resected patients were collected from electronic health records.
Results or Findings: A total of 1082 patients were included (mean age 69.8 years, 57.1% female). Branch-duct IPMN was the predominant subtype (95.3%). Worrisome features (WFs) were present in 207 patients (19.1%) at baseline, and an additional 47 patients (4.1%) developed new WFs during follow-up. Rapid cyst growth was observed in 6.8% according to Fukuoka criteria and in 10.3% according to the updated Kyoto 2024 criteria. Surgical resection was performed in 62 patients (5.7%), with malignant transformation or high-grade dysplasia confirmed in 31 cases (2.9%).
Conclusion: Malignant transformation was infrequent. The presence of worrisome features, including rapid cyst growth did not predict malignancy. These findings support a more individualised and potentially less intensive surveillance strategy.
Limitations: The limitations of the study are its single-centre , potential selection bias, and interobserver variability in WF assessment.
Funding for this study: No funding was provided for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: legal department at Rigshospitalet (ref. 23052217) and the Danish Data Protection Agency (RH -2015-07, nr. 03616)

Surveillance of Branch-Duct IPMNs: Comparing Abbreviated and Comprehensive MRI Protocols in Terms of Accuracy, Reproducibility, and Resource Utilization (6 min)

Christian Reca; Milano / Italy

Author Block: C. Reca, R. Levi, C. Bonifacio, A. Laghi; Milano/IT
Purpose: To compare the diagnostic value of Abbreviated MRI protocols (APs)(with/without DWI) versus a comprehensive protocol(CP) for Branch-Duct Intraductal Papillary Mucinous Neoplasms(BD-IPMN) surveillance, evaluating inter-reader agreement, cost-effectiveness and time efficiency.
Methods or Background: This single-center retrospective study included patients with BD-IPMN undergoing baseline and follow-up MRI between January2018 and April2024. CP included axial and coronal T2WI, axial fat-saturated T1-weighted images before and after contrast injection (T1WI), 2D and 3D MR MRCP and DWI images.The two APs were obtained from CP follow-up examinations: AP with DWI consisted of axial and coronal T2WI, 2D-3D MRCP, axial fat-saturated T1WI images and DWI, AP without DWI comprised only axial and coronal T2WI and 2D-3D MRCP. A senior radiologist(>20 years of experience in pancreatic imaging) and a junior radiologist(4th-year-radiology resident) independently and blinded analyzed each protocol using Kyoto criteria and recommended management. Inter-reader and inter-protocol agreement were analyzed using Cohen's and Fleiss' Kappa. Acquisition times and healthcare costs were compared using national reimbursement rates($p<0.05$ statistical significant).
Results or Findings: Overall, 40 patients(25 women and 15 men) with a median age of 67 years(range 48-87) were included. No statistically significant differences were observed among the 3protocols in identifying worrisome features, including high-risk stigmata, cyst size, main pancreatic duct dilation, and mural nodules.The inter-reader agreement was almost perfect(Fleiss' Kappa=0.82). Substantial inter-reader agreement(Cohen's Kappa>0.6) was observed for all protocols, with almost perfect agreement(Cohen's Kappa>0.8) in some instances. APs demonstrated up to a 48%reduction in acquisition time and a 27.4%cost reduction compared to CP. The addition of DWI did not significantly improve diagnostic accuracy.
Conclusion: APs, particularly without DWI, are reliable and cost-effective alternatives to CP for BD-IPMN follow-up, maintaining comparable diagnostic performance. Substantial inter-reader agreement highlights the reproducibility of APs, even among less experienced radiologists.
Limitations: Retrospective
Funding for this study: n/a

Radiomic MRI model for predicting the development of worrisome features in branch duct-intraductal papillary mucinous neoplasms (BD-IPMNs) (6 min)

Silvia Bogani; Florence (FI) / Italy

Author Block: S. Boccioli, S. Bogani, C. Badii, G. Danti, S. Paolucci, V. Miele; Florence (FI)/IT
Purpose: The aim of the study was to develop a radiomic MRI model able to predict the future development of worrisome features (WF) in branch duct-intraductal papillary mucinous neoplasms (BD-IPMNs). By analyzing quantitative imaging features from MRI scans, we try to identify biomarkers that could be used as early indicators of disease progression, helping personalized management and reducing unnecessary interventions.
Methods or Background: We performed a single-center retrospective study including patients with BD-IPMNs who had at least two contrast-enhanced MRI exams between January 2011 and March 2025. Patients were divided into two groups depending on whether they developed WF or HRS during follow-up. Lesions were manually segmented on T2-weighted images and 107 radiomic features were extracted using PyRadiomics. Feature selection and model building were done using LASSO logistic regression with weighting to account for class imbalance.
Results or Findings: A total of 194 patients were included. After a mean follow-up of 4 years and 5 months, 143 patients did not develop WF/HRS (Group 0) while 51 did (Group 1). Out of 107 radiomic features, 52 were initially associated with progression and 9 shape-based features remained significant after correction. The predictive model achieved an AUC of 0.70 (95% CI 0.62–0.79) and a precision-recall AUC of 0.49, showing moderate predictive ability.
Conclusion: Radiomic MRI models may help identify BD-IPMN patients at higher risk of developing WF or HRS. By providing quantitative information beyond conventional imaging, it could support earlier and more personalized clinical decisions. Further studies are needed to confirm and refine these findings.
Limitations: This study was retrospective, conducted at a single center and included a relatively small sample, which may limit generalizability. MRI scans from different vendors could introduce variability. Moreover the biological significance of radiomic features remains unclear.
Funding for this study: No
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the local Ethical Committee of Careggi University Hospital (July 13th, 2021; protocol number: 20256_oss) and conducted in accordance with the Declaration of Helsinki and its later amendments.

Follow-up of side-branch intraductal pancreatic mucinous neoplasms – radiological and clinical outcomes of patients with lesions of different sizes (6 min)

Rivka Kessner; Tel Aviv / Israel

Author Block: A. Chernomorets, D. Ben-Ami Shor, R. Tzadok, H. Yashar, S. Lazar, Y. Katz, R. Kessner; Tel Aviv/IL
Purpose: -To evaluate the growth of Side-Branch Intraductal Pancreatic Mucinous Neoplasm (SB-IPMN) lesions during a long follow-up period.
-To compare between SB-IPMN lesions of different sizes.
Methods or Background: The final reports of all the patients that underwent MRI-MRCP at our institution between the years 2011-2021 were reviewed for the diagnosis of SB-IPMN. 483 adult patients were diagnosed with SB-IPMN, however 115 patients were excluded due to: misclassification at diagnosis, clinical or radiological follow-up of less than 12 months, non-detectable lesion on revision or pancreatic malignancy at diagnosis. We evaluated the growth of the largest cystic lesion during follow-up, according to the first and last examinations of the patients. The medical records of the patients were reviewed for demographic data, history of hepatobiliary diseases, and history of non-pancreatic malignancy. Finally, we compared between 3 size groups of SB-IPMN: < 1 cm at diagnosis (smallest), 1-1.9 cm (intermediate) and >= 2 cm (largest).
Results or Findings: Our final study population included 368 patients, 254 females and 114 males. The mean radiological follow-up was 54.3 months and the mean clinical follow-up was 67.4 months. The mean absolute growth of the largest cystic lesion during follow-up was 1.3 mm, for the entire population. Only two patients (0.5%) developed pancreatic malignancy, one from the smallest lesions group and one from the largest lesions group. The comparison between the size groups revealed no differences regarding the mean follow-up length, growth during follow-up and development of malignancy. The mean growth during follow-up was 1.4 mm in the smallest and intermediate lesions groups and 0.4 mm in the largest lesions group.
Conclusion: Our results suggest that the follow-up guidelines for SB-IPMN should be less strict than for other types of IPMN.
Limitations: The study is retrospective.
Funding for this study: None.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Tel Aviv Sourasky Medical Center Institutional Review Board approval (2021-2025)

Evaluation of Virtual Non-Contrast Reconstructions from Dual-Layer Spectral CT in Abdominal Imaging (6 min)

Antonella Del Gaudio; Rome / Italy

Author Block: A. Del Gaudio, D. De Santis, B. Masci, B. Catalano, M. Zerunian, G. Tremamunno, T. Polidori, D. Caruso, M. Francone; Rome/IT
Purpose: To evaluate the feasibility of replacing true non-contrast (TNC) images with virtual non-contrast (VNC) reconstructions generated with dual-layer spectral CT (DLCT).
Methods or Background: From December 2024 to February 2025, consecutive inpatients who underwent contrast-enhanced abdominal-CT using DLCT scanner (Spectral CT 7500, Philips Healthcare) were retrospectively enrolled. Each examination included a TNC acquisition, followed by arterial and portal venous phases. VNC images were reconstructed from the arterial (VNCa) and portal venous (VNCp) datasets using vendor-provided spectral decomposition algorithms. An independent radiologist measured attenuation values (HU) on TNC, VNCa, and VNCp images for the liver, spleen, pancreas, kidneys, abdominal aorta, portal vein, and hypodense liver and kidney lesions. Signal-to-noise ratio (SNR) and contrast-to-noise ratio(CNR) were calculated for parenchymal organs and vessels across all image types. Lesion size was assessed on TNC, VNCa,and VNCp images.
Results or Findings: One hundred patients (mean age: 67.1 ± 11.4 years; 52 males)with 160 hypodense abdominal lesions were analyzed.
VNCa and VNCp reconstructions showed lower attenuation than TNC in the liver, spleen, and pancreas(all $P < .001$).No significant HU differences were observed in the portal vein and kidneys(all $P > .540$). Aortic HU was higher in VNCa but lower in VNCp compared with TNC($P < .001$).Mean HU of hypodense lesions was significantly higher in TNC compared with both VNCa and VNCp($P < .001$).
SNR was consistently higher in VNCa and VNCp compared to TNC($P < .001$).
CNR was significantly higher in VNCa compared with TNC for the aorta and spleen, and higher in VNCa than VNCp for the aorta. No other significant differences were observed.
Conclusion: VNC images from DLCT underestimated attenuation relative to TNC but provided comparable or higher objective image quality and preserved lesion size measurement.
Limitations: Retrospective single-center study, single-vendor reconstruction

Cystic neuroendocrine tumors of the pancreas: imaging features (6 min)

Federica Omboni; Verona / Italy

Author Block: F. Omboni[1], M. Ronot[2], C. R. A. Corallo[3], C. Triantopoulou[4], N. Kartalis[5], M. Zins[2], G. Zamboni[1]; [1]Verona/IT, [2]Paris/FR, [3]Leeds/UK, [4]Athens/GR, [5]Stockholm/SE
Purpose: To describe a series of cystic panNETs to determine specific imaging features in a large cohort of patients
Methods or Background: This is a retrospective multicenter observational study (5 centers in 4 countries) which included cystic panNETs diagnosed with FNA/pathology or by 68GaDOTATOC-PET-CT. Cross-sectional imaging was reviewed for each patient (145 MRI, 11 CT with contrast, 1 non-contrast CT).
Results or Findings: 157 patients (85 women, 72 men, mean age 57,5 yrs) with 166 cystic panNETs were included; 9 had multiple lesions. Diagnosis was made by FNA/pathology (143 lesions) or by positivity at DOTATOC-PET-CT (23 lesions). Nine lesions were functioning. ki-67 ranged from 1% to 19% (G1:103; G2: 21; G3: 0). Ki-67% was not available/indeterminate for 42 lesions.
Lesions were predominantly located in the body-tail (125) with a mean diameter of 24mm (5-90mm) and a mean wall thickness of 1.9mm. Most patients (130/157) had a solitary lesion; 36 panNETs were associated with other pancreatic lesions (18 IPMN, 14 solid/cystic panNETs, 4 nonspecific cysts). 142 lesions had round margins.
On MRI, cyst fluid was predominantly hyperintense on T2-weighted sequences (139/166 lesions) and hypointense on T1-sequences (152/166 lesions). Five lesions contained enhancing mural nodules. MPD was dilated in 13 patients, in 12/13 caused by the cystic lesion.
Contrast-enhancement was present in 162 lesions, in 96/162 constant in all phases; 4 lesions showed no enhancement. 15 lesions had wall calcifications. No lesion showed macroscopic nodal or metastatic spread at baseline.
Conclusion: In our retrospective multicenter series, we analyzed radiologic features of cystic panNETs. The lack of extra-pancreatic spread at diagnosis, even in large tumors with high Ki67, raises the possibility of an indolent course. Long-term follow-up studies are needed to confirm this hypothesis.
Limitations: Retrospective study

Natural evolution of cystic neuroendocrine tumors of the pancreas (6 min)

Federica Omboni; Verona / Italy

Author Block: F. Omboni[1], M. Ronot[2], C. R. A. Corallo[3], C. Triantopoulou[4], N. Kartalis[5], M. Zins[2], G. Zamboni[1]; [1]Verona/IT, [2]Paris/FR, [3]Leeds/UK, [4]Athens/GR, [5]Stockholm/SE
Purpose: To evaluate a population of resected or followed-up cystic panNETs to determine natural evolution.
Methods or Background: This retrospective multicentric study included 121 patients (69 women, 52 men, mean age 60 yrs) with 126 cystic panNETs diagnosed by FNA/histology (115 lesions) or 68Ga-DOTATOC-PET-CT (11 lesions). Ki-67 was available for 90 lesions (range 1%-15% (79 G1; 11 G2). For each patient, all available imaging was assessed, at least baseline and most recent scans (119 MRI; 7 CT). Patients were divided in two subgroups: resected versus followed-up.
Results or Findings: At baseline, no lesion showed macroscopic nodal or metastatic spread.
Resected group (55 lesions): mean diameter 29,9 mm (17 pT1, 26 pT2, 12 pT3). Thirty-three were resected after ≥ 6 months follow-up (mean interval 29 months). Three tumors >40 mm (44, 52, 70 mm), showed peripancreatic nodal involvement (all T3N1M0; 2G1 + 1G2). No lesion < 40 mm have nodal spread. After a median 31,7 months follow-up, no recurrence was observed in 49/55 (6 lost to follow-up).
Follow-up group (71 lesions): fifty-nine were followed for >6 months (mean 46,9 months). Mean diameter was 17,5 mm; among the 15 lesions >20 mm, 10 remained stable. Eleven progressed radiologically after a mean of 65.2 months. Detailed data were available for 8/11 growth was limited (<50% of initial diameter). None developed nodal or metastatic spread.
Conclusion: In this series, cystic G1-G2 cystic panNETs <40 mm showed an indolent course, with no nodal or metastatic spread during follow-up. In such cases, surveillance may represent a safe alternative to upfront resection.
Limitations: Retrospective study

Radiomics-Based CT Analysis for Diagnosis and Staging of Chronic Pancreatitis (6 min)

Surenth Nalliah; Gistrup / Denmark

Author Block: S. Nalliah[1], S. N. F. Hostrup[1], E. B. Mark[1], M. H. Liedenbaum[2], T. Engjom[2], I. H. S. Haldorsen[2], A. M. Drewes[1], S. S. Olesen[1], J. B. Frøkjær[1]; [1]Aalborg/DK, [2]Bergen/NO
Purpose: To evaluate whether a radiomics-based AI model can (1) classify patients with chronic pancreatitis (CP), (2) identify CP-related complications, and (3) provide quantitative imaging biomarkers of disease severity on routine CT.
Methods or Background: CP is a progressive inflammatory disease associated with pain, diabetes, and exocrine pancreatic insufficiency (EPI). Conventional imaging typically detects advanced disease, limiting early diagnosis and accurate staging. Radiomics can reveal subtle imaging alterations beyond visual assessment, offering an opportunity for earlier detection and monitoring. We evaluated whether CT-based radiomics could classify CP, detect complications, and provide biomarkers of disease severity. The study included 468 participants: a training cohort of 359 from Aalborg (201 CP, 148 controls) and a test cohort of 109 (68 external CP patients from Bergen, 41 Aalborg controls). CT scans underwent automated pancreatic segmentation, followed by radiomics feature extraction (PyRadiomics) and feature selection using LASSO regression. AI models were trained to classify CP and complications (EPI, diabetes, pain). Performance was evaluated on the test cohort, and model probability scores were correlated with fecal elastase levels and disease severity.
Results or Findings: Forty-six radiomics features were associated with CP and its complications, including markers related to pancreatic volume, calcifications, and ductal dilatation. The CP vs. healthy classification model achieved excellent performance (AUC = 0.97). For complications, AUCs were 0.80 for EPI, 0.63 for diabetes, and 0.59 for pain. Model probability scores correlated with fecal elastase levels ($p < 0.001$) and increased with disease severity ($p = 0.004$).
Conclusion: Radiomics-based CT analysis allows accurate CP classification and provides quantitative markers of disease severity and complications. These results support its potential as a non-invasive tool for diagnosis, staging, and longitudinal monitoring of CP
Limitations: Retrospective design, and no prospective clinical validation limit this study.
Funding for this study: The study was funded from the North Denmark Region Health Innovation Fund (journal number: 2024-0015).

Ethics committee - additional information: This retrospective, multi-center study was approved by the Danish National Committee on Health Research Ethics (Ref: 2308560) and The Regional Ethical Committee in Western Norway (Ref: 2019/1037), with data-sharing agreements between Aalborg University Hospital and Haukeland University Hospital approved by the Scandinavian Baltic Pancreas Club (SBPC) steering committee.

CT-guided percutaneous biopsies of suspect pancreatic lesions: Accuracy and safety (6 min)

Thomas J. Vogl; Frankfurt / Germany

Author Block: T. J. Vogl, H. Adwan, I. Al Haj Ibrahem; Frankfurt/DE
Purpose: To retrospectively analyze the accuracy and safety of CT-guided percutaneous core-needle biopsies of pancreatic lesions suspected to be malignant based on MRI or CT scans.
Methods or Background: This study evaluated CT-guided percutaneous biopsies of suspicious pancreatic lesions performed at our university hospital. Biopsy was performed using a 17G coaxial needle and an 18G core biopsy needle. Data on patient characteristics, lesions, procedures, and histologic results were recorded.
Results or Findings: In total, 90 patients (58.9% males, mean: 65±12.2 years) underwent CT-guided percutaneous biopsies. The lesions had a mean size of 36.8±12.2 mm and were predominantly located in the pancreatic head 61.1% (55/90). Technical success was achieved in all biopsies 100% (90/90). 96.7% of the procedures (87/90) were performed using direct access routes, while 3.3% (3/90) required indirect transhepatic or transgastric approaches. Among the biopsies, 65.6% (59/90) confirmed malignancy, with adenocarcinoma as the most common malignant subtype representing 55.6% (50/90) of all cases. The rate of non-malignant findings was 26.7% (24/90) including chronic pancreatitis at a rate of 5.6% (5/90) as well as pancreatic pseudocysts and pancreatic cystadenoma each at a rate of 2.2% (2/90). Seven cases were identified as false negative, but malignancy was later confirmed after re-biopsy or surgery. The diagnostic accuracy was 92.2% (83/90). The rate of major complications was 1.1% (1/90), of minor complications 2.2% (2/90).
Conclusion: This study shows that CT-guided pancreatic biopsy is a safe procedure with high diagnostic accuracy.
Limitations: Retrospective study design

Multiparametric MRI for Differentiating Late-Onset Autoimmune Diabetes and Type 2 Diabetes Mellitus: A Prospective Study (6 min)

Sinan Seyrek; Istanbul / Turkey

Author Block: S. Seyrek, A. AVCIOGLU, S. S. Taflan, B. Tozlu, Ö. B. Kuş, M. G. Kartal, B. Gultekin, A. Sadic, A. K. Uzum; Istanbul/TR
Purpose: Late-onset autoimmune diabetes mellitus (LADA) and type 2 diabetes mellitus (DM) are are often misdiagnosed (10–20%) but differ in treatment and prognosis. In this study, multiparametric MRI techniques capable of reliably distinguishing between these two entities within the clinical gray zone were compared.
Methods or Background: This prospective single-center study enrolled 104 outpatients (51 LADA, 53 type 2 DM) during July 2024–August 2025. Participants underwent non-contrast abdominal MRI. Pancreatic volume (PV, cm^3), proton density fat fraction (PDFF, %), T1 relaxation time (ms), and T2* relaxation time (ms) were measured. In addition, C-peptide levels and fecal elastase were assessed to evaluate endocrine and exocrine pancreatic function.
Results or Findings: Compared with type 2 DM, patients with LADA demonstrated significantly lower PV (35.7 vs. 50.1 cm^3, $p = 0.0002$), with consistent reductions across the head ($p < 0.0001$) and corpus ($p = 0.0069$). PDFF values were significantly lower in LADA patients both in the whole pancreas (2.3 vs. 5.6%, $p = 0.0005$) and pancreatic head ($p = 0.012$). C-peptide was reduced in LADA (0.83 vs. 1.62 ng/ml, $p < 0.0001$), whereas fecal elastase showed no difference ($p = 0.71$). Anthropometric measures, including body mass index (26.1 vs. 29.6 kg/m^2, $p = 0.0007$) was also significantly lower in LADA patients. Regarding relaxation times, no significant differences were observed for pancreatic T1 ($p = 0.28$) or T2* ($p = 0.028$). Additional analyses revealed smaller psoas muscle area (2.98 vs. 4.97 cm^2, $p < 0.0001$) and reduced vertebral bone marrow fat fraction (42.0 vs. 49.0%, $p = 0.003$) in LADA.
Conclusion: Multiparametric MRI, particularly pancreatic volume and PDFF, provides reliable markers to distinguish LADA from type 2 DM within the clinical gray zone.
Limitations: Patient compliance

Prediction of postoperative complications severity after pancreatoduodenectomy using clinical, volumetric, and radiomic analyses of abdominal aortic calcification (6 min)

Takashi Ota; Suita / Japan

Author Block: T. Ota[1], A. Busse-Coté[2], M. Hori[1], R. Sartoris[2], A. Vanzulli[2], V. Vilgrain[2], N. Tomiyama[1], M. Ronot[2]; [1]Suita/JP, [2]Paris/FR
Purpose: Abdominal aortic calcification (AAC) has been linked to complications after pancreatoduodenectomy (PD), but the value of volumetric calcification score (VCS) and radiomic features (RFs) remains unclear. We aimed to evaluate whether volumetric AAC metrics and RFs predict postoperative complication severity and to develop integrated prediction models (PMs).
Methods or Background: This retrospective study included 380 patients undergoing PD. Clinical variables was summarized as propensity score (PS). AAC was segmented on non-contrast CT to calculate ACV volume (ACV), VCS, and 107 RFs. PMs combining PS, VCS, and selected RF were built using multivariate logistic regression, support vector machine (SVM), and neural network (NN), and PMs were validated by two radiologists. Performance was assessed using area under the receiver operating characteristic curve (AUC) and accuracy.
Results or Findings: Of 380 patients, 177 with measurable AAC were included for radiomic analyses, and randomly assigned to training (n=141) and validation (n=36) cohorts. PS was significantly higher in patients with major versus minor complications ($p < 0.0001$). Neither ACV nor VCS differed significantly between groups. Among RFs, "busyness" showed the strongest discriminatory potential ($p = 0.078$). Three PMs incorporating PS, VCS, and busyness were constructed. In training, NN-based PM2 (PS + busyness) achieved the best performance (AUC 0.94; accuracy 86.5%). In validation, PM2 with SVM and NN maintained robust accuracy (~80%) and AUCs of 0.86–0.88.
Conclusion: Volumetric AAC measures alone were insufficient predictors of complication severity. Combining clinical data with radiomic texture “busyness” in non-linear models improved accuracy, offering a promising preoperative tool for PD risk stratification.
Limitations: Single-centre, retrospective design.

Effect of an integrated CT-based lung cancer detection and diagnosis AI tool on radiologists evaluating lung nodules: A multi-reader multi-case study (6 min)
Andrew Scarsbrook; Leeds / United Kingdom

Author Block: M. Santos[1], C. Santos[1], J. H. R. Cairns[2], M. Darby[2], A. Johnstone[2], C. Arteta[1], A. Scarsbrook[2]; [1]Oxford/UK, [2]Leeds/UK
Purpose: Integration of AI-based computer-aided detection and diagnosis tools into lung cancer screening has the potential to improve and standardize CT reporting, streamline follow-up recommendations, reduce diagnostic errors, and increase efficiency. This multi-reader, multi-case (MRMC) study evaluated the impact of a new AI tool, assessing influence on risk stratification of pulmonary nodules by radiologists.
Methods or Background: A fully crossed MRMC design involved twelve radiologists, with varying experience and sub-speciality expertise, retrospectively reviewing 240 screening and non-screening thoracic CTs (95 lung cancers), with and without AI support. AI assistance consisted of automated localisation, measurement, and characterisation of detected lung nodules, including a per-nodule lung cancer risk score. A 30-day washout period separated the two reads of any given case. Sequencing was randomised with AI-assistance occurring either during the first or second read.
Percentage likelihood of malignancy was estimated by the reader or AI tool. Performance of AI-assisted versus unassisted read against ground truth was compared using area under the curve (AUC) analysis, averaged across readers. Statistical significance of mean AUC difference was performed using Dorfman-Berbaum-Metz methodology.
Results or Findings: Mean effect size between assisted and unassisted reads was 3.92%, 95% confidence interval (CI) [2.00, 5.85] ($p < 0.001$). When stratified by reader subspeciality, mean effect size for cardiothoracic radiologists (n=7) was lower (2.54%, [0.75, 4.34], p=0.009) compared to other subspecialties (5.86%, [3.52, 8.2], p<0.001). Similarly, when comparing experienced (n=4) versus less experienced participants, mean effect size was lower 2.62%, [-0.16, 5.4], p=0.06 and 4.58%, [2.25, 6.9], p<0.001, respectively.
Conclusion: The study illustrates the potential utility of an integrated detection and diagnosis AI tool to support lung cancer screening CT reporting, with higher impact for less experienced and non-specialist radiologists.
Limitations: Provisional evaluation with 12 participants in the MRMC study.
Funding for this study: The study was jointly funded by the National Institute for Health and Care Research (NIHR) and the Office for Life Sciences (OLS) under project ID NIHR207547.

Computational modeling of pulmonary hemodynamics in the context of chronic thromboembolic pulmonary hypertension (6 min)
Sara Benchara; Courbevoie / France

Author Block: S. Benchara[1], A. Marchi[2], Q. Herszkowicz[2], A. Decoene[3], S. Jan[2], D. Rodriguez[2], O. Meyrignac[1]; [1]Kremlin-Bicetre/FR, [2]Orsay/FR, [3]Bordeaux/FR
Purpose: Pulmonary hypertension (PH) is a chronic, progressive disease defined by a mean pulmonary arterial pressure (mPAP) > 20 mmHg at rest. Right heart catheterization (RHC), the diagnostic gold standard, is invasive, costly, and requires specialized expertise. This study aimed to evaluate a fully open-source, non-invasive computational fluid dynamics (CFD) pipeline for estimating hemodynamic biomarkers in chronic thromboembolic pulmonary hypertension (CTEPH).
Methods or Background: A fully open-source workflow, from CT imaging to biomarker extraction, was developed with optimized modeling and simulation steps. The model incorporated flow and resistance data from RHC, assumed rigid vessel walls, and used simplified distal vasculature. Biomarkers included simulated mPAP, wall shear stress (WSS), time-averaged WSS (TAWSS), relative residence time (RRT), oscillatory shear index (OSI), turbulence, and stagnation indices. This workflow was applied to 45 confirmed CTEPH patients (15 with post-treatment follow-up) and 10 healthy controls.
Results or Findings: Numerical simulation results were consistent with clinical measurements (simulated vs. measured mPAP: 33.2 ± 17.5 vs. 32.7 ± 12.5 mmHg; $r = 0.913$, $p < 0.0001$). The model accurately differentiated patients from controls and effectively captured treatment effects. For example, compared with controls, patients had lower TAWSS (0.81 ± 0.37 vs. 2.47 ± 1.14 $g \cdot mm^{-1} \cdot s^{-2}$, $p < 0.0001$) and higher RRT (2.55 ± 1.30 vs. 0.80 ± 0.30 $mm \cdot s^2 \cdot g^{-1}$, $p < 0.0001$). Post-treatment, all biomarkers tended toward normalization (0.70 ± 0.25 to 1.37 ± 0.73 $g \cdot mm^{-1} \cdot s^{-2}$, $p < 0.0001$ for TAWSS and 3.12 ± 1.73 to 1.48 ± 0.63 $mm \cdot s^2 \cdot g^{-1}$, $p < 0.0001$ for RRT, for instance).
Conclusion: This validated CFD model support personalized PH management by providing robust non-invasive biomarkers, differentiates patients from controls, and detects therapeutic response.
Limitations: Model assumptions include rigid vessel walls and simplified distal vasculature, which may affect local flow accuracy.
Funding for this study: This research was supported by Siemens Healthineers.

Impact of using artificial intelligence-based lung nodule evaluation assistant tool for reading low-dose chest CTs : A randomized controlled trial (6 min)

Eui Jin Hwang; Seoul / Korea, Republic of

Author Block: E. J. Hwang, J. M. Goo; Seoul/KR
Purpose: We aimed to evaluate the impact of using an artificial intelligence (AI)-based lung nodule evaluation assistant tool for reading low-dose chest CT (LDCT) on the reading time and lung nodule detection rate.
Methods or Background: Consecutive individuals undergoing LDCTs for health check-ups in a single institution were enrolled and randomized into an intervention group and a control group in a 1:1 ratio. For the intervention group, an AI tool for automated lung nodule detection and measurement was integrated into the picture archiving and communication system (PACS) for reading LDCTs. All LDCTs were read by thoracic radiologists, using a structured report, including information regarding the presence, number, consistency, location, and size of pulmonary nodules with a diameter of ≥4 mm. The primary endpoint of the trial was the reading time (time interval between opening the image and completing the structured report), while secondary endpoints included the frequency of detecting lung nodules, the number of detected nodules per exam, and the frequency of recommendations of follow-up LDCT for detected nodules.
Results or Findings: We enrolled 901 individuals (male-to-female ratio, 507:394; mean age 62 years; intervention-to-control group ratio, 456:445). The reading time of LDCT did not differ significantly between the two groups (intervention group, 179 seconds; control group, 168 seconds; P=.258). The frequency of detecting nodules (34.6% vs. 25.8%; P=.004), the number of detected nodules (0.4 vs. 0.6 per exam; P=.005), and the frequency of recommendations for follow-up LDCT (13.4% vs. 9.2%; P=.049) were significantly higher in the intervention group.
Conclusion: Using a PACS-integrated AI-based lung nodule evaluation assistant tool for reading LDCTs led to increased detection of pulmonary nodules requiring follow-up, without a significant change in the reading time.
Limitations: The reproducibility of our result in different populations remains unclear.

Dual-Source Photon-Counting CT for Thoracic Arteries: Enhancing Image Quality and Diagnostic Assessability with Low Energy Virtual Monoenergetic Imaging (6 min)

Andreea-Ioana Nica; Frankfurt / Germany

Author Block: A-I. Nica[1], C. Booz[1], T. J. Vogl[1], G. M. Bucolo[1], T. D'Angelo[2], H-L. Kaatsch[3], S. Waldeck[3], D. Overhoff[3]; [1]Frankfurt/DE, [2]Messina/IT, [3]Koblenz/DE
Purpose: This study aimed to investigate the impact of low energy virtual monoenergetic imaging (VMI) on quantitative and qualitative image characteristics, as well as its effect on the diagnostic assessability of thoracic arteries in photon-counting computed tomography angiography (CTA).
Methods or Background: We retrospectively evaluated 125 patients who underwent dual-source photon-counting CTA scans of the thoracic arteries. We reconstructed standard CT images at 120 kV and VMI series at 15 keV intervals, ranging from 40 to 100 keV, and conducted quantitative and qualitative image analyses. For quantitative analysis, we assessed vascular CT numbers, signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR). For qualitative evaluation, three board-certified radiologists independently rated image quality, vascular contrast, and diagnostic assessability of the thoracic arteries using a five-point scale.
Results or Findings: Quantitative image analysis revealed that 40 keV VMI reconstructions exhibited the highest mean attenuation (HU: 1205 ± 286), SNR (30.4 ± 9.17), and CNR (29.22 ± 9.13), followed by 55 keV series (HU: 679 ± 161, SNR: 24.31 ± 7.57, CNR: 22.54 ± 7.36), significantly improved compared to higher keV levels and the standard 120 kV CT series ($p < 0.001$). Qualitative analysis showed the highest rating scores for 55 keV reconstructions, significantly higher than those of VMI series at higher energy levels and the standard 120 kV series ($p < 0.001$).
Conclusion: VMI reconstructions at low energy levels (40-55 keV) significantly enhance vascular attenuation, SNR, and CNR, offering superior image quality and diagnostic assessability for thoracic arteries compared to standard CT series in photon-counting CTA.
Limitations: Limitations of the study include its retrospective nature.
Funding for this study: No funding.

Deep-learning analysis on HRCT for predicting progression and mortality in systemic sclerosis related interstitial lung disease (6 min)

Ignazio Friscia; Rome / Italy

Author Block: I. Friscia, G. Cicchetti, L. Calandriello, F. Scrocca, L. Cerquiglini, E. De Lorenzis, S. L. Bosello, L. Natale, A. R. Larici; Rome/IT
Purpose: Interstitial lung disease (ILD) is a major complication in systemic sclerosis (SSc) patients. Artificial intelligence (AI) application on high-resolution Computed Tomography (HRCT) has emerged as a tool that may ensure an objective assessment of ILD. The aim of this study is to correlate measures extracted from HRCT images by a deep-learning based software to assess ILD progression and disease-related mortality in SSc patients.
Methods or Background: HRCT scans from a cohort of consecutive SSc-ILD patients at baseline and after 24±3 months were analyzed using AVIEW software (Coreline Soft, South Korea). Quantitative analyses included lung volume, texture, airway, and vascular measurements. Baseline metrics were assessed for their association with ILD progression, defined by criteria based on the INBUILD trial. Changes in AI-derived measurements between two consecutive HRCT scans over the 24-month follow-up were analyzed for their association with SSc-related mortality during the subsequent 36 months.
Results or Findings: A total of 146 HRCT scans from 73 SSc-ILD patients were assessed (mean age 58.4±14.3 years). Thirty-one patients (42.4%) experienced ILD progression over 24 months, which was predicted at baseline by higher percentages of ground glass opacities (GGO) ($p=0.05$) and reticulation ($p=0.05$), higher subpleural vessel volumes ($p=0.017$), and a tendency toward larger distal airways ($p=0.066$). Serial evaluations demonstrated that progression was associated with a reduction in the percentage of normal lung ($p=0.044$), and absolute volumes ($p=0.009$). Patients in the upper quartile for changes in reticular score and airway volume exhibited a higher mortality risk, independently from INBUILD progression (reticular score: OR 3.30, 95%CI 1.03–10.61, $p=0.045$; airway volume: OR 3.37, 95%CI 1.08–10.51, $p=0.036$).
Conclusion: Deep learning-based assessment in SSc-ILD identified distinct modifications in lung anatomical components with significant prognostic implications, potentially enabling a precise patient evaluation and stratification.
Limitations: Single center population

Artificial Intelligence for Detecting Interstitial Lung Disease in Radiation Therapy Planning CTs (6 min)

Sonja Kandel; Toronto / Canada

Author Block: S. Kandel, A. Hope, P. Rogalla; Toronto, ON/CA
Purpose: Interstitial lung disease (ILD) is a significant risk factor for radiation pneumonitis in patients receiving pulmonary stereotactic body radiotherapy (SBRT) for cancer. Pre-treatment CT used for planning offer an opportunity to identify patients with ILD prior to therapy. However, manual CT review by thoracic radiologist isn't always available and labor intensive. We developed and clinically implemented a deep learning tool to automatically detect ILD on planning CTs to support risk stratification and workflow efficiency.
Methods or Background: A three-dimensional convolutional neural network (3D VGG16) was trained using 4,393 diagnostic CT scans, including 1,366 ILD cases, normalized for slice thickness and reconstruction algorithm. The algorithm was validated on a cohort of 537 patients treated with SBRT, where ILD prevalence and pneumonitis risk were known. A prospective “silent mode” evaluation was performed on 111 patients prior to live deployment. Two operating thresholds were defined: a low-risk threshold (higher sensitivity) and a high-risk threshold (higher specificity). Clinical integration occurred with automated email notifications to radiation oncologists.
Results or Findings: In the validation cohort, ILD was associated with higher rates of pneumonitis (G2+: 20.5% vs. 5.8%; G3: 10.3% vs. 1%; G5: 2/3 patients had ILD features; all $p<0.01$). In the silent mode phase, the low-risk threshold flagged 52% of patients (missed 1 ILD case), while the high-risk threshold flagged 14% (missed 1 ILD case). Since clinical implementation, 99 patients have been reviewed, with 16 flagged for ILD. Two previously unrecognized ILD cases were detected through the AI tool, leading to changes in patient management.
Conclusion: An AI-based screening tool for ILD can be integrated into radiation therapy planning workflows, identifying high-risk patients and improving clinical decision-making without delaying treatment. Ongoing work involves expansion to multi-center clinical trials.
Limitations: Single center study.
Funding for this study: None.

Personalized Medicine in COPD: AI-based Chest CT Analysis Uncovers Body Composition’s Effect on the Bone–Vascular Axis of Osteoporosis (6 min)

Bettina Katalin Budai; Heidelberg / Germany

Author Block: B. K. Budai, A. Wagner, O. Havlicek, P. Konietzke, F. Trudzinski, J. Biederer, C. P. Heußel, H-U. Kauczor, V. Palm; Heidelberg/DE
Purpose: This study aimed to investigate the association between vertebral bone density (T12 BMD) and total thoracic vascular calcification (TTVC) volume, with a special focus on the effect of body composition. Moreover, we aimed to determine whether body composition indices modify the bone-vascular axis in patients with chronic obstructive pulmonary disease (COPD).
Methods or Background: In this prospective multicentric study on 539 COPD patients (COSYCONET Study), chest CT scans were investigated with AI-based tools for T12 BMD, TTVC, and volumetric body composition analysis. Adjusted regression models were constructed to assess the impact of conventional body phenotypes (normal, sarcopenic, non-sarcopenic obesity, and sarcopenic obesity). Stepwise interaction model building included T12 BMD, the intermuscular adipose tissue (IMAT), their interaction, adding BMI, clinical and metabolic covariates, lung function, physical performance, and age.
Results or Findings: A consistent inverse association was observed between T12 BMD and TTVC in all phenotypes, reaching significance in normal nutritional status ($\beta = -0.38$, $p < 0.01$), sarcopenia ($\beta = -0.36$, $p < 0.01$), and non-sarcopenic obesity ($\beta = -0.24$, $p < 0.01$). However, the interaction model for TTVC with T12 BMD could not confirm the conventional phenotype’s significant effect. In a fully adjusted linear regression model, IMAT was identified as an independent predictor of TTVC. Interaction models confirmed age and pack-years as the strongest risk factors of calcification; moreover, IMAT consistently remained a significant independent predictor even in the fully adjusted model ($\beta=0.15$, 95% CI 0.015–0.28, $p=0.029$), while the interaction between T12 BMD and IMAT lost significance only once age was included.
Conclusion: Thoracic IMAT is independently associated with vascular calcification in COPD, although the modifying effect of IMAT on the bone-vascular axis suggests an age-dependent interaction.
Limitations: The absence of a non-COPD control group.
Funding for this study: This study was conducted within the framework of COSYCONET and further partially funded through a collaboration with PERMED-COPD (No: 01EK2203A and 01EK2203B). B.K.B. was supported by the Medical Data Scientist Program of the Medical Faculty of Heidelberg University.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The COSYCONET study was approved by the Ethical Committee of Philipps University Marburg (reference no. AZ 2010-28), as well as the ethics committees of each center.

Impact of AI-assisted reading on detection of progressive pulmonary fibrosis (PPF) on serial CT (6 min)

Logan Sun; London / United Kingdom

Author Block: L. Sun[1], G. Bailey[1], B. Rawal[1], C. Marrocchio[2], P. M. George[1], S. Gerry[3], S. R. Desai[1], A. Devaraj[1]; [1]London/UK, [2]Parma/IT, [3]Oxford/UK
Purpose: To evaluate the impact of AI-assisted reading using quantitative CT (qCT) on the performance of thoracic radiologists in identifying clinically significant PPF on serial CT, in patients with marginal forced vital capacity (FVC) decline.
Methods or Background: 102 patients (median age, 60 years [range 34–82]; M=40) with non-IPF fibrotic interstitial lung disease (ILD) with serial CTs >6 months apart and contemporaneous FVC decline of 5.0-9.9% were retrospectively evaluated. Five thoracic radiologists, blinded to clinical data, independently reviewed serial CTs side-by-side, categorising cases as either stable disease (SD) or progressive disease (PD), based on visually estimated changes in ILD extent. Quantitative CT biomarkers of ILD severity were also generated using commercially available AI software (e-Lung, Brainomix). Cases initially categorised as SD, but with a qCT biomarker increase of ≥1.5% on serial CT were re-reviewed in conjunction with software generated fibrosis segmentation overlays, and radiologists then either retained categorisation as SD or changed to PD. Radiologists' performance with and without AI support was analysed using a Cox proportional hazards model based on progression-free survival (defined as time to death, lung transplantation or 10% FVC decline).
Results or Findings: During a median follow-up of 1085 days (IQR 522–1694), 44 patients died and 3 had lung transplants. Without AI, hazard ratios (HR) for visually-identified PD were 1.83-2.33 (p=0.001–0.017) for all readers. QCT identified 22 to 40 cases per reader for re-evaluation, leading to readers changing PPF categorisation in 45%-94% (n=10-29) of these cases. With AI-assisted reading, HRs increased for all radiologists to 2.34–3.25 (p<0.001–0.002).
Conclusion: In patients with non-IPF fibrotic ILD and marginal FVC decline, AI-based qCT decision support improves reader performance in identifying clinically significant PPF.
Limitations: Retrospective, single-centre study
Funding for this study: Nil sought.

Ultra-low-dose CT lung cancer screening with AI-integrated thin-slice reconstruction: biopsy validation and comparison with radiologist and machine learning" (6 min)

REEFATH JABARAJ PRABAGARAN; Chennai / India

Author Block: R. J. PRABAGARAN[1], K. venugopal[1], N. D. Kanase[2], M. P. Ghate[2], P. Moorthy[1]; [1]Chennai/IN, [2]Mumbai/IN
Purpose: To evaluate AI-based ultra-low-dose CT (Delta, 0.5 mm) for lung cancer screening in smokers and non-smokers, validated against histopathology, and compared with a radiologist and machine learning (ML) classifier.
Methods or Background: 179 patients undergoing ultra-low-dose CT chest, all suspicious nodules were biopsied. Histopathology was the reference. AI, radiologist, and ML provided binary malignant/benign predictions. Diagnostic accuracy was assessed per-patient (positive if any malignant lesion) and per-lesion. Sensitivity, specificity, PPV, NPV, and accuracy were calculated with 95% confidence intervals. Subgroup analyses were performed in smokers and non-smokers. False positives were reviewed by histopathology. McNemar's test compared paired methods.
Results or Findings: Ninety-seven of 179 patients (54.2%) had malignancy. Per-patient accuracy was 81.6% for AI, 88.8% for radiologist, and 87.2% for ML. Sensitivity/specificity were: AI 80.8%/82.9%, radiologist 88.6%/89.0%, ML 87.6%/86.6%. In smokers, radiologist sensitivity/specificity were 86.3%/89.5%; in non-smokers 91.3%/88.6%. False positives were mainly benign fibrosis and granuloma. McNemar's test showed no significant difference between methods.
Conclusion: AI applied to ultra-low-dose CT demonstrates clinically useful accuracy for lung cancer screening across smokers and non-smokers, but radiologist and ML interpretation remain superior. Novelty lies in combining AI-integrated ultra-thin reconstruction with systematic biopsy validation, highlighting benign mimics as the main limitation. AI holds promise as an adjunct in screening workflows
Limitations: Single-center cohort: Conducted at one institution, which may limit generalizability to broader screening populationsNo longitudinal follow-up: Interval cancers and long-term outcomes were not assessed; thus, the study reflects diagnostic performance at baseline onlyHistopathology spectrum: Benign conditions such as fibrosis, granuloma, and infection were frequent; while biopsy was the reference, some benign diagnoses may evolve over time.
Funding for this study: This research received no external funding and was conducted as part of institutional academic activity.No specific grant from funding agencies in the public, commercial, or not-for-profit sectors was received for this study."
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the Institutional Ethics Committee and written informed consent was obtained from all patients.
This prospective study was conducted in accordance with the Declaration of Helsinki and approved by the Institutional Review Board

Development and validation of an explainable machine learning-based model for predicting the interval growth of pulmonary subsolid nodules: a retrospective multicenter cohort study (6 min)

Zhang Zhedong; Hangzhou / China

Author Block: Z. Zhedong; Beijing, China/CN
Purpose: This multicenter study aimed to develop and validate a machine learning model for predicting the growth of pulmonary subsolid nodules (SSN) at different time intervals using CT radiomics. The model is intended to guide personalized follow-up strategies in clinical practice.
Methods or Background: We retrospectively analyzed data from 642 patients with 717 SSNs, collected from three medical centers, who underwent long-term follow-up. Patients were classified into growth and non-growth groups based on SSN growth within 2 or 5 years and were randomly divided into training and internal testing sets. Predictive models were developed using optimal ML algorithms for clinical, radiomics, and clinical-radiomics fusion models to assess SSN growth risk. An independent external test set, including 95 patients with 105 SSNs from a health examination center, was used for validation. Model performance was assessed using the AUC. The SHAP method was used to clarify model rationale.
Results or Findings: XGBoost and LightGBM showed the highest discriminative ability among eight ML models. For 2-year growth prediction, AUCs were 0.823, 0.889, and 0.911 (internal set), and 0.712, 0.734, and 0.734 (external set). For 5-year growth, AUCs were 0.796, 0.838, and 0.849 (internal set), and 0.672, 0.773, and 0.776 (external set). These insights were integrated into a clinical management framework, enhancing clinical utility.
Conclusion: Our interpretable ML model, based on multicenter longitudinal data, accurately predicts SSN changes over 2 years and offers guidance for 5-year follow-up.
Limitations: As a multicenter retrospective study, site-to-site variation in follow-up likely introduced selection and temporal bias and precluded robust subgroup analyses. The exclusively Asian cohort limits generalizability to other ethnicities, underscoring the need for international external validation. Moreover, not all enlarging nodules were pathologically confirmed, indicating that surgical thresholds after progression require further study.
Funding for this study: Not applicable
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study received approval from the Institutional Review Boards (IRBs) of three tertiary comprehensive medical centers (No. 2022PHB031-001, No. 2022-0601-01, and No. 2022002).

Ultralow-dose 60kVp Chest CT with the Artificial Intelligence Iterative Reconstruction for Diagnosing Lobar Pneumonia in Children (6 min)

Lu Bai; Xi'an / China

Author Block: L. Bai[1], S. Xu[2], A. Li[1], J. Yang[1]; [1]Xi'an/CN, [2]Shanghai/CN
Purpose: Repeated chest CT is crucial for monitoring children with severe lobar pneumonia, but radiation exposure is a major concern. This study aimed to evaluate the diagnostic feasibility of the ultralow-dose CT at 60kVp with artificial intelligence iterative reconstruction (AIIR) for pediatric pneumonia, compared to routine-dose CT.
Methods or Background: Thirty-three pediatric patients with severe lobar pneumonia (20 boys; mean age, 7.7±3.5years) undergoing follow-up CT within one-week of baseline routine-dose imaging were prospectively enrolled. Routine-dose protocols were age-specific: 100kVp, reference 70mAs (≤5 years); 120kVp, reference 30mAs (6–18 years), and images were reconstructed with hybrid iterative reconstruction (HIR). Follow-up scans used 60kVp, reference 70mAs, and were reconstructed with AIIR. Image noise was defined as the standard deviation of the CT number in chest-wall fat. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were quantified at aortic root. Two blinded radiologists scored anatomical visualization and diagnostic confidence by consensus using 5-point Likert scale (1=poor, 5=excellent). The paired-t test and Wilcoxon signed-rank test were used. The performance of 60kVp-images for demonstrating pneumonia-related imaging findings was evaluated, with routine-dose CT as the reference standard.
Results or Findings: The effective radiation doses were 0.17±0.03mSv at 60kVp and 1.14±0.37mSv at routine dose, respectively ($p<0.05$). Compared to routine-dose images, 60kVp-AIIR images demonstrated significantly lower noise, higher SNR and CNR (all $p<0.05$). Subjective anatomical visualization and diagnostic confidence scores were comparable between 60kVp and routine-dose scans (4.00±0.74 vs. 4.42±0.67, $p=0.13$; 4.25±0.62 vs. 4.50±0.67, $p=0.51$). Sensitivity, specificity, negative predictive value, positive predictive value, and accuracy of 60kVp-scans were 95.45%, 100%, 91.67%, 100%, and 96.30%.
Conclusion: The 60kVp ultralow-dose chest CT with AIIR provides diagnostic image quality comparable to routine-dose CT while reducing radiation exposure by approximately 85%, demonstrating high potential for safely monitoring pediatric lobar pneumonia.
Limitations: Not applicable.

Quantitative emphysema thresholds for defining combined pulmonary fibrosis and emphysema in idiopathic pulmonary fibrosis relevant to disease progression monitoring (6 min)

Jaeyeon Choi; Seoul / Korea, Republic of

Author Block: J. Choi, J. Choe, H. J. Hwang, S. M. Lee, E. Chae, J. B. Seo; Seoul/KR
Purpose: In idiopathic pulmonary fibrosis (IPF), coexisting emphysema may attenuate declines in forced vital capacity (FVC), masking progression. Visual thresholds have been used to define combined pulmonary fibrosis and emphysema (CPFE), but no quantitative CT (QCT)–based thresholds have been clinically validated. We aimed to identify a QCT-defined emphysema threshold on HRCT relevant to monitoring disease progression.
Methods or Background: We retrospectively analyzed IPF patients with baseline and 1-year pulmonary function tests. Emphysema and fibrosis extent were quantified using deep learning–based texture analysis. Prognostic value of 1-year decline in FVC (≥5%) and diffusing capacity of carbon monoxide (DLco,≥10%) for survival was assessed across QCT emphysema thresholds using multivariable Cox models. Longitudinal trajectories were modeled with linear mixed-effects analysis. In a subgroup with follow-up HRCT, prognostic association of QCT-fibrosis progression (≥4.52% increase in fibrosis, predefined DLco-anchored threshold) was evaluated in relation to emphysema burden.
Results or Findings: Among 944 patients (mean age, 66.6 ± 7.9 years; 80.6% male), mean QCT emphysema was 1.75±4.29% and fibrosis extent 11.7±9.95%. FVC decline predicted mortality across subgroups based on different emphysema thresholds but showed no significant association in patients with >10% emphysema (HR, 1.54[95%CI: 0.50–4.69]; P=0.45). DLco decline remained robustly associated with mortality regardless of emphysema extent (all, P<0.001). QCT-fibrosis progression also significantly associated with survival across emphysema strata. FVC trajectories differed by the 10% QCT-emphysema threshold (P<0.001), with stability in >10% versus decline in ≤10%. DLco declined in both groups without slope difference (P=0.36).
Conclusion: A QCT-emphysema threshold of ≥10% defines a CPFE-IPF phenotype in which FVC is less sensitive for monitoring progression. DLco decline and QCT-fibrosis extent change may serve as preferred surrogate markers.
Limitations: Retrospective, single-center study; small sample size for HRCT follow-up subgroup analysis.
Funding for this study: This work was supported by the National Research Foundation of Korea (NRF) grant funded by the Korea government (MSIT) (No. RS-2025-16067456).

Optimizing 0.55T MRI Lung Visualization Through High-Resolution Respiratory Motion-Resolved 4D UTE: Performance Assessment Against Standard Techniques (6 min)

Guillaume Fahrni; Lausanne / Switzerland

Author Block: D. C. Rotzinger, G. Fahrni, A. Mackowiak, S. Rapacchi, J-B. Ledoux, M. Stuber, C. W. W. Roy, C. Pozzessere; Lausanne/CH
Purpose: To assess the performance of free-running 4D (respiratory motion-resolved) ultrashort-echo-time (UTE) sequences at 1.25mm3 and 0.98mm3 resolution on low-field MRI, compared with commercially available 3DT1VIBE (1.25mm3) and 2DT2HASTE (1.56mm2×6mm) for contrast-free lung imaging.
Methods or Background: We scanned fourteen volunteers on low-field MRI (0.55T). Three experienced radiologists independently rated image quality/artifacts and vessels/airways conspicuity (4-point Likert scale). We calculated median/IQR ratings and assessed differences of pooled and individual ratings via Kruskal-Wallis with Dunn's post-hoc tests. Inter-rater agreement was evaluated with weighted Cohen's Kappa and interpreted according to Landis & Koch (1977). Quantitative analysis included pulmonary artery-to-parenchyma contrast ratio (CR).
Results or Findings: UTE1.25 vs. UTE0.98's pooled qualitative ratings were not significantly different (p=0.757). However, UTEs ratings (average median±SD: 3.25±0.5) outperformed other sequences; 3DT1VIBE ranked third (3.0±0) and 2DT2HASTE last (2.25±0.5), all p.adj<0.001. When looking at individual rating categories, UTEs excelled especially in vessel (median[IQR]: 4[1]) and airways conspicuity (3[1]), outperforming 2DT2HASTE (2[1.75] and 2[1], p.adj<0.001) and 3DT1VIBE (3[1] and 3[1], respectively, p.adj<0.01). UTEs had milder artifacts than 3DT1VIBE, p.adj<0.05, but were not significantly better than 2DT2HASTE (p.ajd>0.19). Inter-rater agreements were as follows (averages): image quality 0.32 (fair), artifacts 0.15 (slight), vessels 0.50 (moderate), airways 0.64 (substantial). In quantitative analysis, 3DT1VIBE outperformed UTE0.98 (CR 4.4±1.6 vs. 1.92±0.5, p.adj<0.01) and 2DT2HASTE (CR 0.64±0.2, p.adj<0.001), but was not significantly superior to UTE1.25 (CR 2.89±1.1, p.adj=0.09), favoring UTE1.25 over UTE0.98 due to its higher contrast ratio.
Conclusion: UTE1.25 balanced qualitative superiority and quantitative reliability for low-field 0.55T lung MRI, offering superior depiction of vessels and airways compared to 3DT1VIBE and 2DT2HASTE and less artifacts.
Limitations: Pilot study with limited clinical cohort size; no clinical endpoint

RPS 1605 - Hot Topic: generative AI in radiology

Categories: Imaging Methods, Imaging Informatics, Multidisciplinary, Artificial Intelligence
Date: March 6, 2026 | 16:00 - 17:30 CET
CME Credits: 1.5

Moderator:
Keno K. Bressem; Berlin / Germany

Keynote Lecture (10 min)
Ramprabananth Sivanandan; Asker / Norway

Development and Initial Evaluation of a Generative AI Tool for Personalized Automatic Breast Imaging Reporting (6 min)
Gianmarco Della Pepa; Milan / Italy

Author Block: G. Della Pepa, G. Irmici, V. Molinari, C. De Berardinis, E. D'Ascoli, L. Corradini, G. Rossini, C. Depretto, G. P. Scaperrotta; Milan/IT
Purpose: To design and evaluate a generative artificial intelligence (AI) tool that automatically produces personalized and structured breast imaging reports (mammography, ultrasound, and interventional procedures) from minimal user input.
Methods or Background: A prototype based on a large language model (LLM) was developed to learn each radiologist's unique reporting style. For each user, 50 anonymized previous breast imaging reports were combined and analyzed to generate an automatically created JSON (JavaScript Object Notation) structure encoding linguistic patterns, recurrent terminology, and section hierarchy. A second, handcrafted JSON file defined the functional core of the LLM, including task logic, prompts, and behavioral instructions. The system combines both components to generate full reports from brief notes summarizing the current exam, optionally integrating previous reports for automated comparison. Internal testing was conducted comparing reporting time and usability across manual typing, voice dictation, and the AI-assisted workflow.
Results or Findings: The AI tool, tested by five breast radiologists, generated complete, correct, and style-consistent reports within a few seconds from brief inputs. Reporting time was significantly reduced compared with both manual typing and voice dictation. Radiologists reported smoother workflow and lower cognitive load after the initial setup. Mean satisfaction scores were 9.2/10 for usability and 9.0/10 for accuracy. Generated reports required only minimal editing before validation.
Conclusion: The developed tool demonstrates that personalized, fast, and consistent breast imaging reporting can be achieved through generative AI, improving workflow efficiency and ensuring high reporting accuracy.
Limitations: Preliminary single-center testing. A refined model with expanded parameters and larger datasets is under development to improve precision and scalability

Deep-Learning augmented contrast enhancement improves image quality of CTPE: A multi-scanner study (6 min)
Sebastian Steinmetz; Mainz / Germany

Author Block: M. Meyer, S. Steinmetz, A. Othman, D. Graafen; Mainz/DE
Purpose: Pulmonary embolism (PE) is a potentially life-threatening event requiring accurate imaging and diagnostics. CT pulmonary angiography (CTPA) is widely established as imaging standard for PE detection but can face difficulties in poorly contrasted images or in the detection of small, peripheral PEs. This study aims to evaluate the potential benefits of Deep Learning-based iodine contrast enhancement and denoising in CTPA (DLe-CTPA) compared to conventional CTPA (c-CTPA).
Methods or Background: This retrospective, multi-center study analyzed data from 224 patients who underwent CTPA for suspected pulmonary embolism (PE). Imaging data were collected from eight different CT scanners, and a vendor-agnostic Deep Learning algorithm was utilized to enhance iodine contrast. For the quantitative analysis, Signal intensity (SI), Signal-to-Noise Ratio (SNR) and Contrast-to-Noise Ratio (CNR) where obtained at eleven distinct pulmonary artery segments using a Matlab tool. For the qualitative analysis, two radiologists independently evaluated both data sets and performed qualitative assessments using a 4-point Likert scale to evaluate various parameters, including image quality, contrast, image noise and diagnostic confidence.
Results or Findings: DLe-CTPA significantly enhanced SI, SNR, and CNR across all pulmonary artery sites and scanners compared to c-CTPA (SI, CNR: $p<0.001$; SNR: $p<0.03$). Qualitative assessment showed improvements for overall image quality, contrast, image noise and diagnostic confidence for DLe-CTPA (all $p<0.001$).
Conclusion: The application of DLe-CTPA significantly improves SI, SNR and CNR for all pulmonary artery segments and CT scanners, as well as the qualitative measures overall image quality, contrast, image noise and diagnostic confidence when compared to c-CTPA.
Limitations: We are limited by retrospective study design.
Funding for this study: No.

Synthetic post-contrast MRI in brain metastases using generative AI: A GAN framework for contrast enhancement (6 min)

Merve Solak; Rize / Turkey

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: M. Solak, M. TÖREN, B. ASAN, E. Kaba, M. Beyazal, F. BEYAZAL ÇELİEKR; Rize/TR
Purpose: Contrast-enhanced MRI (CE-MRI) is essential for diagnosing and monitoring brain metastases (BM). However, potential risks of gadolinium-based contrast agents (GBCA) call for alternative methods. This study aimed to generate synthetic CE-T1 and CE-FLAIR from non-contrast MRI in BM patients using Generative adversarial networks (GAN)-based models.
Methods or Background: This retrospective study utilized brain MRI scans (3.0T GE Discovery MR750w) acquired between January 2023 and April 2025 from 183 patients with brain metastases (T1: 83, T2: 100). The dataset included 16,250 T1-related and 2,810 T2-related images (T1, CE-T1, T2, and CE-FLAIR sequences). For CE-MRI synthesis, four GAN models (Pix2PixHD, CycleGAN, C-CycleGAN, and CGAN) were applied using sample boundary maps instead of semantic labelling. Data were divided into training (70%), validation (20%), and testing (10%) sets. Generator realism was assessed via G_GAN loss, and visual quality via VGG-based perceptual loss. Model outputs were quantitatively evaluated using MSE, SSIM, PSNR, and RMSE. Qualitative evaluation was performed through a visual Turing test by experts and repeated after one month.
Results or Findings: G_GAN losses generally decreased, and T1 and T2 VGG losses showed strong correlation ($r = 0.90$). Pix2PixHD achieved thr best performance (T1: SSIM 0.80, PSNR 29.2 dB; T2: SSIM 0.90, PSNR 27.3 dB), while CGAN performed worst (T1: SSIM 0.30, PSNR 19.1 dB; T2: SSIM 0.20, PSNR 18.5 dB). Qualitative evaluation showed 61.4% accuracy with moderate inter-observer agreement; repeat testing showed 60% accuracy.
Conclusion: GAN-based models can generate CE-T1 and CE-FLAIR images from non-contrast MRI, achieving strong quantitative metrics and moderate diagnostic accuracy, supporting their potential to reduce exposure GBCA in neuro-oncologic imaging.
Limitations: Not applicable.

Generation of dynamic MR Fingerprinting maps from conventional MRI for enhanced brain lesion characterisation (6 min)

Gaoyang Zhao; Zhengzhou / China

Author Block: G. Zhao, S. Zhao, W. Luo, Y. Zhang, J. Cheng, Y. Zhang; Zhengzhou/CN
Purpose: To explore a generative framework for synthesising dynamic MR fingerprinting (MRF) maps from conventional MR images, aiming to improve brain lesion characterisation and support pharmacokinetic (PK) modelling.
Methods or Background: MRF provides accurate T1/T2 maps but is limited by equipment and reconstruction algorithms. DCE is widely available but offers only semi-quantitative information. We developed a multi-stage framework: 1. Weighted-to-Quantitative: A U-Net model was trained to generate quantitative T1/T2 maps from weighted images, using corresponding pre- and post-contrast MRF imags as reference. 2. DCE-to-Dynamic Quantitative Mapping: We leveraged the distribution learned above and explored a CycleGAN model using weakly paired DCE and Dyn-MRF data from the same patient. Although lesion status may have changed, normal brain tissue remains relatively stable. 3. Temporal Enhancement of Dyn-MRF: A Transformer module was designed to increase the temporal resolution (from 30s/phase to 2s/phase), enabling accurate signal curve reconstruction critical for PK analysis. 4. Weighted-to-Quantitative Signal Curve: Finally, we investigated the feasibility of generating tissue signal curves from conventional Weighted and DCE images, supporting future PK parameter estimation. Our dataset includes over 400 cases across multiple brain pathologies.
Results or Findings: Preliminary results indicate that generated maps closely approximate reference MRF maps across diverse lesions. Temporal enhancement improved curve fidelity, which is critical for accurate PK modelling. Integration of DCE and Dyn-MRF data under weak supervision was feasible; quantitative validation is ongoing.
Conclusion: This early-stage study demonstrates the feasibility of generating quantitative maps and signal curves from conventional MR images. Our proposed framework may enhance tissue characterisation and broaden the clinical utility of quantitative MRI in neuroradiology.
Limitations: DCE and Dyn-MRF scans were not temporally aligned. Lesion evolution may affect consistency. Validation of PK parameters and correlation with clinical outcomes remain future work.

Overcoming Scanner Variability: MRF-Powered Synthesis of Multiparametric MRI for Glioblastoma (6 min)

Yimin Ni; Hong Kong / China

Author Block: Y. Ni, C. Liu, W. Li, H. F. V. Lee, A. E. Helali, Y-L. Wong, G. Ren, J. Cai, T. Li; Hong Kong/HK
Purpose: Multiparametric MRI (mpMRI) is essential for glioblastoma (GBM) management but is protracted and costly. Deep learning synthesis from conventional MRI suffers from poor generalizability across scanners. We propose a novel solution: a quantitative synthesis network (QS-Net) that generates diagnostic-quality mpMRI contrasts directly from quantitative Magnetic Resonance Fingerprinting (MRF) maps, inherently bypassing scanner-specific contrast variability.
Methods or Background: A generative adversarial network with deep-supervised residual blocks was developed to synthesize standard mpMRI (T1w, T2w, FLAIR, SWI) from core MRF-derived T1/T2 maps. The model was trained on 32 healthy volunteer scans and fine-tuned on 9 GBM patient scans, with hold-out testing on 9 independent GBM patients. Performance was quantitatively (MAE, SSIM, PSNR) and qualitatively compared against Res-Unet, cGAN, and Swin-Transformer models. A critical generalizability test evaluated all architectures when trained on MRF maps versus conventional MRI inputs.
Results or Findings: QS-Net significantly outperformed all state-of-the-art models, achieving superior quantitative metrics across all synthesized contrasts: T1w, T2w, FLAIR, and SWI (e.g., MAE: 1.01-1.45e-02; SSIM: 0.926-0.939; PSNR: 27.56-29.69) and qualitatively reproducing critical tumor boundaries and internal texture. Crucially, models trained on quantitative MRF inputs demonstrated consistently superior generalizability ($p < 0.005$) across all architectures compared to those trained on conventional qualitative MRI.
Conclusion: QS-Net establishes a new paradigm for rapid, high-fidelity mpMRI synthesis by leveraging quantitative MRF as a scanner-agnostic source. This directly addresses the critical limitation of generalizability in prior methods, with immediate clinical potential to streamline GBM imaging protocols, reduce acquisition time, and standardize diagnostics across healthcare institutions.
Limitations: The study's cohort size, while sufficient for a proof-of-concept, is limited. Further validation on a larger, multi-scanner cohort is necessary to confirm robust clinical deployment.

Deep Learning Amplifies the Benefits of High Relaxivity in Brain MRI: A Quantitative Assessment of a Contrast Boosting Algorithm Using Gadopiclenol (6 min)

Sonia Colombo Serra; Colleretto Giacosa / Italy

Author Block: S. Pasumarthi Venkata[1], S. Colombo Serra[2], J. Vymazal[3], A. Shankaranarayanan[1]; [1]Menlo Park, CA/US, [2]Colleretto Giacosa/IT, [3]Prague/CZ
Purpose: Higher-relaxivity gadolinium-based contrast agents (GBCAs) like Gadopiclenol have recently been introduced which are being used at lower dose levels to achieve comparable lesion visualization. In this work, we show that a deep learning (DL) based contrast boosting algorithm further amplifies the benefits of such higher-relaxivity GBCAs, by improving lesion visualization and image quality without increasing the dosage.
Methods or Background: T1w pre-contrast and standard-contrast (SC) images from 20 patients (2D and 3D scans) were obtained for this study. The patients were injected with 0.05 mmol/kg of Gadopiclenol. The pre-contrast and SC images were used to generate contrast boosted (CB) images using an FDA-cleared DL algorithm that boosts the contrast signals present in the SC images. Rectangular regions-of-interest (ROIs) were drawn on all enhancing lesions and on the healthy parenchymal tissues. These ROIs were used to compute the contrast-to-noise ratio (CNR), lesion-to-brain ratio (LBR) and contrast enhancement percentage (CEP).
Results or Findings: The mean CNR, LBR and CEP of CB images (10.38±1.56, 5.12±1.03 and 1.96±0.35) were greater than that of SC images (2.52±0.85, 2.55±1.85 and 0.99±0.28). The percentage increase of CNR, LBR and CEP from SC to CB images are 314.19%, 118.12% and 335.18% respectively. We separately calculated the percent increase of CNR, LBR and CEP for patients injected with Gadobenate dimeglumine (at 0.1 mmol/kg) and found it to be 205.97%, 60.50% and 83.19%.
Conclusion: Quantitative analysis has shown that the CB algorithm has improved the benefits of Gadopiclenol. From the percent increase in CEP it can be seen that the CB images are equivalent to a double dose injection. Comparative analysis with normal GBCAs has revealed that the CB algorithm performance is better in higher relaxivity GBCAs.
Limitations: The study is limited to a small sample size.

Favorable Contrast MRI Synthesis From Non-Contrast Using a 22 fps Diffusion Model (6 min)

Thomas Campbell Arnold; Philadelphia / United States

Author Block: D. Wang[1], S. Pasumarthi Venkata[1], T. C. Arnold[1], A. Shankaranarayanan[1], G. Zaharchuk[2]; [1]Menlo Park/US, [2]Stanford/US
Purpose: Gadolinium-based contrast agents (GBCAs) are widely used in brain MRI to enhance lesion visibility for diagnosing and monitoring brain tumors. However, due to safety concerns such as long-term gadolinium retention in tissues, there is growing interest in dose-reduction strategies. In this study, we investigate the feasibility of a fast diffusion model to synthesize contrast-enhanced images from pre-contrast scans.
Methods or Background: The proposed method integrates a conditional denoising diffusion probabilistic model with adversarial learning to achieve high-fidelity medical image synthesis. The model maps source domain images to conditioning features to guide the diffusion model during generation. During inference, the model runs on latent features, thus enabling high throughput at 22 fps. The studied dataset includes 126 clinical cases (113 for training and 13 for testing) acquired using a Philips Insignia 3T scanner with Gadoterate meglumine contrast agent. The cohort consists of 55 female and 71 male patients, with a mean age of 48 ± 16 years. All pre-contrast and SOC-Gad images were mean-normalized, skull-stripped, and affine co-registered using the pre-contrast scan as reference.
Results or Findings: The Syn-Gad images showed strong similarity to SOC-Gad images, with a mean PSNR of 34.13, SSIM of 0.8906, RMSE of 0.0202, and CNR of 0.0523, further supporting the fidelity of the synthesized images. Qualitative analysis shows that Synth-Gad images preserve enhancement patterns comparable to those in SOC-Gad, particularly around enhancing tissue regions.
Conclusion: The proposed diffusion-based synthesis model demonstrates strong potential for contrast dose reduction in brain MRI. This approach offers a promising path toward reducing patient and environmental exposure to gadolinium-based contrast agents in routine brain MRI exams.
Limitations: The work still requires clinical validation in larger, pathology-rich cohorts.

Towards Deterministic Synthesis of Lesion Progression: Mask-Guided Brownian Bridge Diffusion for Multiple Sclerosis Imaging (6 min)

Brendan S Kelly; United Kingdom / United Kingdom

Author Block: P. Mathur, B. S. Kelly, R. P. Killeen, A. Lawlor; Dublin/IE
Purpose: To investigate the determinism and consistency of diffusion-based generative models for synthesising longitudinal magnetic resonance imaging (MRI) progression in Multiple Sclerosis (MS), comparing a state-of-the-art diffusion model, Brownian Bridge Diffusion (BBDM), and its Mask-Guided extension (MGBBDM).
Methods or Background: Baseline and follow-up brain MRI slices from 110 patients were used for training, 30 for validation, and 30 for testing, yielding approximately 6,000 paired slices for model training. Three diffusion-based generative models were trained to simulate follow-up images conditioned on baseline scans and corresponding lesion masks (except BBDM). For each model, five synthetic samples were generated per input to assess pixel-wise variability and reproducibility. Consistency was quantified using the coefficient of variation (CV) across Peak Signal-to-Noise Ratio (PSNR), Structural Similarity Index (SSIM), and L1 distance metrics.
Results or Findings: The MGBBDM demonstrated the lowest inter-sample variability, achieving PSNR CV = 9.41% and SSIM CV = 8.89% (both Excellent), with moderate L1 CV = 20.64%. In contrast, the Improved Diffusion and standard BBDM exhibited higher variability (PSNR CV ≈ 12–13%, L1 CV > 30%). The BBDM without mask guidance showed no consistent lesion progression, producing follow-up images resembling the baseline. These findings indicate that mask guidance is essential for achieving deterministic and clinically meaningful lesion evolution.
Conclusion: Mask-Guided Brownian Bridge Diffusion offers superior reproducibility and anatomical stability compared to standard diffusion models. By enforcing lesion-specific constraints during synthesis, it produces consistent and clinically interpretable MS progression—an essential step toward reliable generative modelling in longitudinal neuroimaging. Deterministic synthesis supports the creation of reproducible imaging datasets, enabling clinically trustworthy simulation and validation for Multiple Sclerosis tracking.
Limitations: The study is limited to 2D modelling with a moderate dataset. Future work will extend to 3D evolution and clinical validation.
Funding for this study: This research was supported by Science Foundation Ireland (SFI) under Grant Number SFI/12/RC/2289_P2 and the Irish Centre for High-End Computing (ICHEC)

Cross-modality synthesis: conditional diffusion-based generation of MRI from FDG-PET scans (6 min)

Noor Benchekroun; Londin / United Kingdom

Author Block: N. Benchekroun, G. Webber, M. Alshammari, A. Hammers; London/UK
Purpose: Combined MRI and PET imaging enables fusion of anatomical and metabolic information in neuroimaging, but simultaneous acquisition is limited by the availability of hybrid PET-MR scanners, cost, and patient burden. Shortage of paired PET-MRI datasets further constrains research requiring both modalities. This study aims to evaluate generative AI methods for synthesising MRI brain images from FDG-PET scans.
Methods or Background: A Denoising Diffusion Probabilistic Model (DDPM) with U-Net architecture was developed for cross-modality synthesis from FDG-PET to MRI. The model was trained on over 1,400 axial slices extracted from 149 paired PET-MRI volumes and evaluated on 62 independent test subjects. Two approaches were systematically compared: a 2D method processing slices independently, and a 2.5D method incorporating adjacent slice context to enhance spatial consistency and inter-slice coherence. Quantitative performance was assessed using structural similarity index measure (SSIM) and Pearson correlation coefficients, while visual assessment evaluated anatomical structure preservation and artefact patterns.
Results or Findings: Both approaches achieved reasonable synthesis quality with modest improvements for the 2.5D method. Quantitative evaluation demonstrated 3-10% improvements across metrics for the 2.5D approach, with SSIM increasing from 0.626±0.064 to 0.651±0.062 and correlation improving from 0.798±0.043 to 0.822±0.049. Visual assessment revealed that while both approaches adequately preserved anatomical structures, the 2.5D method produced more systematic error patterns concentrated at tissue boundaries, with more randomly scattered artefacts for the 2D approach.
Conclusion: Diffusion-based cross-modality synthesis can generate structurally coherent MRI images from FDG-PET scans, with the 2.5D context-aware approach providing modest but consistent improvements in synthesis quality. These methods demonstrate potential for supplementing missing MRI data in research and clinical applications.
Limitations: While results are promising, SSIM is still limited, and clinical validation outstanding.
Funding for this study: The School of Biomedical Engineering and Imaging Sciences is supported by the Wellcome EPSRC Centre for Medical Engineering at King's College London (WT 203148/Z/16/Z) and the Department of Health via the National Institute for Health Research (NIHR) comprehensive Biomedical Research Centre award to Guy's & St Thomas' NHS Foundation Trust in partnership with King's College London and King's College Hospital NHS Foundation Trust. MA is supported by the Saudi Arabia Cultural Bureau in London under the Saudi scholarship program. NB was supported by a CDT summer studentship.

Deep learning-based virtual dynamic contrast enhanced image generation for prostate (6 min)

Julian Pfann Hossbach; Erlangen / Germany

Author Block: J. Pfann Hossbach, H. Schreiter, L. Brock, T-T. Nguyen, S. Heidarikahkesh, A. George, R. Janka, M. Uder, S. Bickelhaupt; Erlangen/DE
Purpose: Avoiding dynamic contrast enhanced (DCE) prostate MRI acquisition can accelerate clinical workflows, increasing the use of prostate MRI. We aim to generate virtual DCE (vDCE) images from multiparametric non-contrast-enhanced sequences using artificial intelligence as potential substitute.
Methods or Background: This IRB-approved retrospective study included n=2092 patients who underwent clinical prostate examinations with T1w-DCE at 3T scanners (Siemens Healthineers MAGNETOM Skyra/Vida). T1w, T2w, and DWI (b-values: 50, 800, 1500 s/mm²) acquisitions were used to train a GAN network; a 2.5D U-Net with 2 discriminators (full/half resolution). Data were resampled to a mutual FOV/resolution, sequence-wise normalized, and split into train=1450, validation=419, and test=213 subjects (⌀25 slices). To standardize and reduce temporal resolution, DCE images at 15, 30, 45 and 60s after acquisition start were selected and registered with a separately trained VoxelMorph-Network forming the targets. The training for 100 epochs minimized the combined adversarial (binary cross entropy), perceptual, L1 and SSIM loss between predicted and target slices using the non-DCE images with their ±1 neighboring slices as input.
Results or Findings: The generated test data achieved a MS-SSIM of 0.9649, 0.9298, 0.8762 and 0.853, SSIM of 0.9251, 0.8516, 0.7801 and 0.7407 and NRMSE of 0.0318, 0.0484, 0.0657 and 0.0713, respectively, outperforming state-of-the-art single timepoint predictions. Radiologist classified the overall image quality of n=200 targets/predictions into real/generated, yielding near-equal counts: real (n=140 real, n=138 generated) and generated (n=60 real, n=62 generated).
Conclusion: Multi-timepoint vDCE image generation was technically feasible and indistinguishable from real images for the reader. Further work is necessary to improve the method and to assess its potential for prostate MRI in clinical practice.
Limitations: A lesion enhancement comparison and diagnostic value evaluation was not conducted in this retrospective single-centre study. Furthermore, truly dynamic image generation was not addressed.
Funding for this study: This research was funded by the Bavarian State Ministry of Economic Affairs, Regional Development and Energy.

Invisible Biases in AI-Generated Medical Images: Implications for Diagnostic Algorithm Equity (6 min)

Kateryna Nechypurenko; Kyiv / Ukraine

Author Block: K. Nechypurenko, T. Nechypurenko; Kyiv/UA
Purpose: To synthesize evidence on hidden feature propagation and demographic bias in generative AI models for synthetic medical image generation, evaluating implications for diagnostic algorithm performance and equity across patient populations.
Methods or Background: Narrative synthesis of peer-reviewed literature (2024-2025) examining generative AI in radiology. We analyzed 8 key publications including: one systematic survey of 103 diffusion model studies, three foundation model validation studies with datasets exceeding 20 million images (SA-Med2D-20M, TotalSegmentator, UK Biobank), two multi-institutional bias assessments, and two radiologist evaluation studies. We extracted data on diagnostic performance metrics, demographic bias patterns, and validation methodologies across CT, MRI, chest radiography, and histopathology.
Results or Findings: Synthetic image quality varied by modality. Pathologists could not distinguish synthetic histopathology images while radiologists identified 96.6% of synthetic radiological images as non-authentic. Algorithms trained with combined synthetic-authentic data showed improvements: isocitrate dehydrogenase mutation prediction area under curve 0.75, glioma volumetry concordance 0.782, lesion detection (sensitivity improvements up to 25% for specific tasks). However, foundation models exhibited persistent demographic disparities: decreased accuracy for female patients (normal chest radiographs) and patients of African ancestry (pleural effusion), despite massive training datasets. Algorithms extracted patient race through hidden features imperceptible to radiologists. Demographic-balanced fine-tuning provided only partial mitigation.
Conclusion: Synthetic medical images enhance diagnostic algorithm performance for rare pathologies and data-scarce scenarios but systematically propagate demographic biases through hidden features undetectable by visual assessment. Clinical deployment requires demographic-stratified validation protocols and continuous performance monitoring across patient populations to ensure equitable diagnostic accuracy.
Limitations: Secondary literature synthesis with heterogeneous validation methodologies across studies. Limited long-term clinical outcome data. Geographic and demographic representation varied across included datasets.
Funding for this study: No funding was received for this study

Non-Contrast MRI Versus Contrast-Enhanced CT for Active Surveillance of Small Solid Renal Masses: An International Multi-Observer Agreement Study (6 min)
Jens Borgbjerg; Aalborg / Denmark

Author Block: B. Stensby Breen[1], H. Søgaard Christensen[2], J. Brøndum Frøkjær[2], O. Graumann[3], M. Kleivane[1], A. Negard[1], I. Mjåland Salte[1], J. Borgbjerg[1]; [1]Oslo/NO, [2]Aalborg/DK, [3]Aarhus/DK
Purpose: To assess the agreement of maximum tumor diameter and tumor nearness between non-contrast MRI and contrast-enhanced CT for SRM surveillance, and to compare diagnostic confidence in tumor delineation across modalities.
Methods or Background: Active surveillance (AS) of small renal masses (SRMs) typically relies on contrast-enhanced CT for serial size measurement. Non-contrast MRI protocols may provide an alternative.
We retrospectively identified 50 patients (mean age, 62.9 years; 44% women) who underwent both contrast-enhanced CT and axial T2-weighted MRI within 3 months as part of AS protocol. Nine radiologists from five hospitals independently assessed maximum tumor diameter (axial plane) and tumor nearness to the collecting system (TN, three-tier scale) and subjectively graded their diagnostic confidence in delineating the tumor contour (DC, 5-point scale) in 50 CT and MRI scans across four randomized reading sessions. Observer agreement for diameter assessment was quantified using the limits of agreement with the mean (LOAM), whereas TN and DC was analyzed using Gwet's AC2.
Results or Findings: Mean tumor diameters were 19.9 mm for CT and 19.5 mm for MRI (mean difference, 0.4 mm; p=0.051). Reproducibility LOAMs were ±2.9 [2.7-3.2] mm (CT) and ±3.1 [2.9-3.4] mm (MRI), with overlapping confidence intervals. TN ratings and agreement were similar for CT and MRI (p=0.61; AC2=0.67 each), whereas DC ratings were higher for CT (p<0.001).
Conclusion: Non-contrast axial T2-weighted MRI demonstrated agreement comparable to contrast-enhanced CT for tumor diameter and tumor nearness, while diagnostic confidence favored CT without affecting agreement.
Limitations: A variety of MRI systems with a span in scan parameters.
Retrospective study design with patients from a single center.
Renal mass sample size is relatively small, albeit comparable to previous studies.
Maximum axial tumor diameter was evaluated to remain consistent with clinical standards and previous research.

Quantitative MRI in WHO/ISUP Grading of Clear Cell Renal Cell Carcinoma: A Systematic Review and Meta-analysis (6 min)
Iman Kiani; Tehran / Iran

Author Block: I. Kiani[1], S. Mohammadzadeh[1], N. Pourakbar[2], S. Woo[3], M. Fujiwara[4], S. Yoshida[5], T. Kwee[6], Y. Arita[7]; [1]Tehran/IR, [2]Tabriz/IR, [3]New York, NY/US, [4]Tokyo/JP, [5]Bunkyo-ku/JP, [6]Groningen/NL, [7]San Francisco, CA/US
Purpose: Accurate, noninvasive grading of renal cell carcinoma (RCC) informs prognosis and treatment planning. We systematically evaluated the diagnostic performance of quantitative MRI biomarkers for WHO/ISUP grade discrimination, specifically distinguishing high (grades 3–4) from low (grades 1–2) tumors.
Methods or Background: We conducted a PRISMA-compliant systematic review of PubMed, Embase, Scopus, and Web of Science through August 2025 to identify studies assessing quantitative MRI biomarkers against histopathology. When feasible, random-effects meta-analysis pooled diagnostic performance. For diffusion-weighted imaging, apparent diffusion coefficient (ADC) values and study-level accuracy for high versus low grade were synthesized. For radiomics, pooled sensitivity, specificity, and area under the receiver operating characteristic curve (AUC) were extracted or pooled where reported. Risk of bias was assessed with QUADAS-2, and radiomics reporting quality was appraised using the METRICS framework.
Results or Findings: Of 798 records screened, 21 studies met inclusion criteria. Seven ADC studies yielded pooled sensitivity of 0.76 (95% CI, 0.68–0.82) and specificity of 0.75 (95% CI, 0.62–0.85) for discriminating high from low grade; low-grade RCCs showed higher mean ADC (mean difference, 0.24 × 10^{-3} mm^2/s). Five radiomics studies showed pooled sensitivity of 0.69 (95% CI, 0.60–0.76) and specificity of 0.76 (95% CI, 0.62–0.86); reported AUCs were generally moderate to high. Limited data suggest that relaxometry and chemical exchange saturation transfer may also achieve high accuracy, though evidence remains preliminary.
Conclusion: Quantitative MRI, particularly ADC, demonstrates moderate accuracy for RCC grade stratification and may assist preoperative risk assessment. To support clinical translation, standardized acquisition and analysis protocols, cross-center harmonization, and prospective cohorts with external validation are required in routine care.
Limitations: Most cohorts were retrospective; protocols varied in b-values, echo times, and saturation schemes; and confounders such as microscopic necrosis and partial-volume effects were imperfectly controlled.
Funding for this study: None

CCLS and beyond: are there any additional MR features that can help characterizing Small Renal Masses? (6 min)

Giulio Imperiale; Milano / Italy

Author Block: G. Imperiale, G. Brembilla, C. Rodolfi, F. Cei, A. Larcher, G. Rosiello, U. Capitanio, F. De Cobelli; Milan/IT
Purpose: Evaluate the frequency of Clear Cell Likelihood Score (CCLS) features of Small Renal Masses (SRMs) on multi-parametric Magnetic Resonance (mpMRI) and investigate additional imaging characteristics to improve diagnostic accuracy and better define Renal Cell Carcinoma (RCC).
Methods or Background: Preoperative multiparametric mpMRI of patients with SRMs subject to surgery were retrospectively evaluated by two radiologists with intermediate experience blinded to the histological diagnosis (gold standard). CCLS features evaluated were: T2 signal intensity, microscopic fat, cortex vascularity, segmental enhancement inversion (SEI), arterial-delayed enhancement ratio (ADER >1.5); additionally, T2-heterogeneity, peritumoral-pseudocapsule and heterogeneity were assessed.
Results or Findings: 80 patients with 33 clear cell RCCs (41.25%), 25 papillary RCCs (31.25%), 9 oncocytomas (11.25%), 9 chromophobe RCCs (11.25%) and 4 fat-poor angiomyolipomas (5%) were evaluated. Clear cell RCCs (ccRCC) showed T2-hyperintensity (75,76%), heterogeneous signal (81,82%), pseudocapsule (72,73%), microscopic fat (54,55%) and marked hypervascular enhancement (96,97%), with heterogeneous pattern (81,82%). Papillary RCCs (pRCC) were predominantly T2-hypointense (64%), with lower frequency of pseudocapsule (52%), reduced vascularity (64% hypovascular) and rare heterogeneous pattern of enhancement (24%).
Conclusion: MRI characterization of the major renal tumor histotypes confirms established features from the CCLS, such as hypervascularity and T2-hyperintensity in ccRCC and hypovascularity and T2-hypointensity in pRCC. It also identified T2-signal intensity and enhancement heterogeneity and the presence of a pseudocapsule as discriminators. These findings may aid radiologists in refining non-invasive differentiation among renal tumor subtypes and may be added to the CCLS in order to increase specificity.
Limitations: These include the retrospective single center design. Confirmation of features identified vs gold standard in this preliminary evaluation should be confirmed on larger cohorts.
Funding for this study: This study received no external funding.

Clear Cell Likelihood Score: A Categorizing and Grading Tool for Small Renal Masses (6 min)

Osama Mohamed Soliman Mahmoud Sherif; Mansoura / Egypt

Author Block: O. M. S. M. Sherif, A. Mousa, M. Zaky, A. Abdelhamid, M. E. Abou El-Ghar, T. A. El-Diasty; Mansoura/EG
Purpose: We aimed prospectively to assess effectiveness of Clear Cell Likelihood Score in small renal masses and its role in predicting tumor grade.
Methods or Background: The detection of small renal masses has increased due to recent widespread of cross-sectional imaging . Clear cell renal cell carcinoma (ccRCC) is the most common subtype with rapid progression and metastasis.
We utilized MRI Clear Cell Likelihood Score to investigate its ability to distinguish and grade different subtypes.
Results or Findings: In total, 103 patients with small solid renal masses of stage T1a (≤4 cm) were identified. Mean tumor size was 3.4 ± 0.6 cm. According to our study results, the clear cell Likelihood Score (ccLS) had sensitivity of 75.6 %, specificity of 93.5%, PPV of 88.6 %, NPV of 85.3 % and accuracy of 86.4 % in diagnosing ccRCC using a ccLS threshold of 4 and 5. As regard the assessment of ccLS threshold of 1 or 2 in excluding ccRCC pathological subtype, our study found that out of 29 patients with ccLS 1 or 2, there was only 1 ccRCC case with false result (3% false positive). It was also noted that there is significant relation between Arterial-to-delayed-enhancement-ratio (ADER) value and the grade of the ccRCC. The median interquartile range (IQR) of ADER parameter was statistically significant higher in grade II compared to grade I (Median was 1.6 and 0.9 respectively) and much higher in grade III compared to grades I and II (Median was 2.9) with P value < 0.001.
Conclusion: This ccLS showed promising efficacy in prediction and exclusion of ccRCC subtype. Moreover, it aids in predicting the ccRCC grade.
Limitations: Few cases of fat poor angiomyolipoma was interpreted as a high risk for being clear cell carcinoma.
Funding for this study: Self funding.

IRM K01: DIAGNOSTIC VALUE OF MULTIPARAMETRIC MR IMAGING OF SMALL SOLID RENAL TUMORS – A Prospective Multicenter Study (6 min)

Eva Jambon; Mérignac / France

Author Block: E. Jambon, A. Crombé, G. Margue, N. Grenier, F. H. Cornelis, J-C. Bernhard; Bordeaux/FR
Purpose: Purpose: Small renal solid tumors (SRST) are increasingly being detected incidentally, posing diagnostic challenges. Up to 20% of SRST result in non-contributive biopsies. The aim was to assess the diagnostic accuracy of multiparametric MRI (mpMRI) in differentiating malignant from benign SRST in patients with suspected renal malignancy without no evident signs of malignancy.
Methods or Background: Methods or Background: This is a prospective multicentric French study. A cohort of 387 patients in 18 centers with non-hereditary, SRST between 1.5 and 4 cm in diameter was enrolled between November 2018 and May 2022. mpMRI protocols included T1w, T2w, diffusion-weighted imaging, and dynamic contrast-enhanced sequences. Two radiologists performed blinded readings with a centralized review in case of discordance. The primary endpoint is the negative predictive value (NPV) of a dichotomized Likert scale score, targeting a 98% NPV.
Results or Findings: Results or Findings: Among 287 patients analyzed for the primary endpoint, mpMRI achieved high sensitivity (97.4%) and PPV (83.2%) in detecting malignant tumors, but specificity (9.8%) and NPV (45.5%) remained low, limiting its ability to rule out malignancy. Likert scores varied significantly across histological subtypes, with oncocytomas and chromophobe RCCs often misclassified as malignant. In clear cell RCC ($n = 121$), higher Fuhrman grades were significantly associated with extensive diffusion restriction ($p < 0.001$) and T2 hypointensity ($p = 0.001$). The median Likert score increased with tumor grade ($p = 0.004$), suggesting that certain MRI features may reflect histological aggressiveness in this subtype.
Conclusion: Conclusion: MpMRI remains limited in its ability to distinguish benign from malignant tumors based on the predefined criteria used in this study. However, it may offer a noninvasive means of assessing tumor grade in clear cell renal cell carcinoma.
Limitations: Predefined criteria
Funding for this study: National funding (PHRC)

Ethics committee - additional information: The trial protocol (ClinicalTrials.gov identifier: NCT03470285) was approved by the CPP Sud-Méditerranée 5 (Committee for the Protection of Persons – French equivalent of an Ethical Committee) and the authorized by the authorisarion from ANSM (the French National Agency for the Safety of Health Products).

Analysis of clinicopathologic features and imaging findings of TFE3-rearranged renal cell carcinoma Abstract (6 min)

Jianqiang Liu; Lanzhou / China

Author Block: J. Liu, J. Zhao; Lanzhou/CN
Purpose: To examine the imaging features and clinicopathologic features of TFE3-rearranged renal cell carcinoma and highlight key imaging findings for clinical decision-making.
Methods or Background: The imaging and clinicopathological data of 49 pathologically confirmed cases of TFE3-rearranged renal cell carcinoma from multiple institutions between January 2018 and December 2024 were retrospectively analyzed.
Results or Findings: Of the 49 patients, 17 were male and 32 were female; aged 44 ± 15 years (range: 10-82 years) , 22 were asymptomatic and 27 were symptomatic. Tumor size averaged 7.0 (range: 2.0–14.9) cm. Imaging showed 28 round-like and 21 lobulated lesions; 18 had distinct margins, while 31 had indistinct margins. A pseudocapsule was present in 36 cases, 24 of which were incomplete. Additionally, 42 tumors showed uneven density with necrosis or cystic degeneration; there were 25 cases of hemorrhage, 27 cases of irregular calcification, Peritumoral vessels were noted in 23 cases. Imaging modalities included CT (44 cases: 41 with both plain and enhanced scans, 3 with plain only), MRI (13 cases with plain and enhanced scans), and ultrasonography (15 cases, including 5 with contrast enhancement). Treatment included partial nephrectomy (21 cases), total nephrectomy (22 cases) , and biopsy (6 cases).With a median follow-up of 30 months (range: 1–72 months) until December 2024, 6 patients experienced tumor recurrence, 14 developed metastasis, and 7 died, while 5 patients were lost to follow-up.
Conclusion: TFE3-rearranged renal cell carcinoma is a rare renal tumor with distinct imaging and clinical features that can inform preoperative diagnosis, treatment, and prognosis.
Limitations: This is a retrospective single-center study whose results have not been validated in an independent cohort.
Funding for this study: No.

Photon-Counting CT-Based Iodine Quantification for Characterization of Clear Cell RCC and Non-Clear Cell Renal Tumor Subtypes (6 min)

Anqi Zhang; Henan Province / China

Author Block: A. Zhang, Z. Zhao; Henan Province/CN
Purpose: This study aimed to evaluate the diagnostic performance of iodine concentration (IC) and normalized iodine concentration (NIC) derived from photon-counting computed tomography (PCCT) in differentiating clear cell renal cell carcinoma (ccRCC) from non–clear cell subtypes, and in assessing the WHO/ISUP histological grade of ccRCC.
Methods or Background: Sixty-seven patients with pathologically confirmed renal cell carcinoma underwent prospective PCCT (NAEOTOM Alpha) scans. IC and NIC values were quantitatively assessed during nephrographic and corticomedullary phases. The Mann–Whitney U test and ROC analysis were applied for statistical evaluation.
Results or Findings: Among 57 CCRCC cases, median nephrographic phase IC and NIC were 4.8 mg/ml (IQR: 2.8–6.8) and 33.4% (IQR: 17.9–48.9), while corticomedullary phase values were 3.8 mg/ml (IQR: 2.7–4.9) and 81.1% (IQR: 61.4–110.8). For 10 non-CCRCC cases, corresponding values were 2.1 mg/ml (IQR: 0.9–3.3), 15.7% (IQR: 4.4–27.0), 2.0 mg/ml (IQR: 1.3–2.7), and 41.4% (IQR: 29.1–53.7). All parameters showed significant differences ($p < 0.05$), with AUCs ranging 0.865–0.940. Grade III CCRCC ($n = 10$) demonstrated higher values than grade I/II ($n = 36$): 6.0 vs. 4.7 mg/ml, 45.0% vs. 33.1%, 4.2 vs. 3.5 mg/ml, and 94.3% vs. 81.8% ($p < 0.05$).
Conclusion: Quantitative IC and NIC measurements from PCCT show significant potential for non-invasive differentiation between ccRCC and other renal tumor subtypes, as well as for evaluating ccRCC histological grade. Further validation in larger cohorts is warranted before clinical application.
Limitations: Lack of external validation
Funding for this study: Research funds of the research group

Differentiating Fat-Poor Angiomyolipoma from Chromophobe Renal Cell Carcinoma Using Preoperative Non-Contrast CT Histogram Analysis (6 min)

Jinyan Wei; Lanzhou / China

Author Block: J. Wei, X. Zhang, J. Liu, J. Zhou; Lanzhou/CN
Purpose: To investigate the value of clinical-radiologic features and whole-tumor histogram analysis derived from non-contrast CT in differentiating fat-poor angiomyolipoma (fp-AML) from chromophobe renal cell carcinoma (ChRCC).
Methods or Background: This retrospective study enrolled 89 patients with pathologically confirmed fp-AML (n=36) or ChRCC (n=53). Clinical, imaging, and pathological data were collected. Demographic data and conventional CT features (sex, age, symptoms, location, shape, margin, attenuation on non-contrast CT, tumor volume) were recorded. Using FireVoxel software, volumetric regions of interest were drawn on axial non-contrast CT images to extract histogram parameters (minimum, maximum, mean, standard deviation, variance, coefficient of variation, skewness, kurtosis, entropy, and percentiles). Statistical analyses included the Chi-square test, Mann-Whitney U test, and independent samples t-test. Multivariable logistic regression was used to identify independent predictors for differentiation and to construct clinical-radiologic and histogram models. Receiver operating characteristic (ROC) curve analysis was performed to evaluate diagnostic performance.
Results or Findings: Multivariable analysis identified non-contrast CT attenuation (OR=1.178, 95% CI: 1.087-1.277, P<0.001), tumor volume (OR=0.952, 95% CI: 0.928-0.976, P<0.001), mean attenuation (OR=0.764, 95% CI: 0.589-0.946, P=0.015), skewness (OR=0.135, 95% CI: 0.046-0.396, P<0.001), and the Perc.75 (OR=1.522, 95% CI: 1.169-1.983, P=0.002) as independent predictors for differentiating fp-AML from ChRCC. Both models demonstrated good performance. The clinical-radiologic model achieved an AUC of 0.905 (95% CI: 0.843-0.967), with a sensitivity of 77.8% and specificity of 90.6%. The histogram model achieved an AUC of 0.964 (95% CI: 0.932-0.996), with a sensitivity of 88.9% and specificity of 75.5%.
Conclusion: Clinical-radiologic features and whole-tumor histogram analysis based on non-contrast CT can help noninvasively differentiate fp-AML from ChRCC preoperatively, providing valuable guidance for clinical management.
Limitations: This study is limited by its retrospective, single-center design, and the findings have not been validated in an independent cohort.

Preoperative Prediction of Renal Cell Carcinoma Risk Stratification Using Multiphase CT Features and R.E.N.A.L. Score (6 min)

Jinyan Wei; Lanzhou / China

Author Block: J. Wei, X. Zhang, J. Liu, J. Zhou; Lanzhou/CN
Purpose: To investigate the association of multiphase computed tomography(CT) features, and R.E.N.A.L. score with Leibovich risk stratification in localized renal cell carcinoma (RCC).
Methods or Background: This retrospective study analyzed 265 pathologically confirmed RCC patients. Clinical data, CT semantic features, and R.E.N.A.L. scores were collected. Patients were classified into low-risk (n=124) and intermediate-high-risk (n=141) groups per Leibovich criteria. Clinical characteristics included symptoms, albumin level, neutrophil-to-lymphocyte ratio (NLR), systemic immune-inflammation index (SII), systemic inflammation response index (SIRI), and tumor extracellular volume fraction (ECV). CT semantic features included maximum tumor diameter, location, shape, margin, cystic change/necrosis, calcification, enhancement homogeneity, perinephric neovascularity, and R.E.N.A.L. score. Statistical analyses involved χ^2 tests, t-tests, Mann-Whitney U tests. Univariate and multivariate logistic regression analyses were employed to identify independent predictive factors for Leibovich risk stratification.
Results or Findings: Patients in the intermediate-high-risk group were more likely to have clinical symptoms, higher SII, and lower albumin levels compared to the low-risk group ($P < 0.05$). Tumor shape, margin, cystic change/necrosis, calcification, enhancement homogeneity, and perinephric neovascularity significantly differed between the two groups ($P < 0.05$). The maximum tumor diameter was larger in the intermediate-high-risk group, while the parenchymal phase enhancement ratio was lower ($P < 0.05$). Perinephric neovascularity was more frequent in the intermediate-high-risk group ($P < 0.05$). The R.E.N.A.L. score significantly differed between groups, R.E.N.A.L. score complexity was significantly higher in the intermediate-high-risk group ($P<0.05$). Multivariate analysis identified cystic change/necrosis, perinephric neovascularity, and R.E.N.A.L. score as independent predictors of intermediate-high Leibovich risk stratification in RCC.
Conclusion: Tumor cystic/necrotic change, perinephric neovascularity, and R.E.N.A.L. score are independent preoperative biomarkers for predicting intermediate-high Leibovich risk in RCC.
Limitations: This study is limited by its retrospective, single-center design and by the lack of xternal validation

Ethics committee - additional information: This study was approved by the Medical Ethics Committee of the Second Hospital of Lanzhou University (approval number: 2025A-585) and informed consent was waived.

Is the Clear Cell Likelihood Score Applicable Across MRI and CT? Evidence from a Single-Center Study (6 min)

Giulio Imperiale; Milano / Italy

Author Block: G. Imperiale, G. Brembilla, C. Rodolfi, F. Cei, A. Larcher, G. Rosiello, U. Capitanio, F. De Cobelli; Milan/IT
Purpose: Systematically evaluate the concordance of enhancement patterns between MRI and CT in small renal masses. This comparison aims to support the feasibility and broader application of the Clear Cell Likelihood Score (CCLS) in clinical contexts where contrast-enhanced MRI may be impractical, contraindicated or where optimization of healthcare resources is desirable.
Methods or Background: Patients with both preoperative CT and MRI were included, with histopathology serving as the reference standard. Two radiologists with intermediate experience, blinded to histology, independently assessed the enhancement patterns on MRI and CT; evaluated parameters included vascularity (hyper-, iso-, hypovascular), presence of segmental enhancement inversion (SEI) and arterial-delayed enhancement ratio (ADER >1.5). Lastly, CCLS was assessed both on MRI alone and on CT-derived enhancement pattern combined with MRI features.
Results or Findings: The cohort consisted of 47 patients, with 20 clear cell RCCs (42.6%), 12 papillary RCCs (25.5%), 9 oncocytomas (19.1%), 4 chromophobe RCCs (8.5%) and 2 fat-poor angiomyolipomas (4.3%).
Enhancement type was concordant in 41 cases (87.2%). Concordance for SEI was observed in 42 cases (89%) and for ADER in 44 cases (94%). Overall, the CCLS was consistent in 85% of the cohort between MRI only and CT-MRI combined.
Conclusion: MRI and CT showed a high level of concordance in the characterization of enhancement patterns in small renal masses, supporting the potential role of CT as a complementary tool when MRI with contrast is not feasible. Importantly, as CT is usually performed before MRI in clinical practice, sparing contrast in MRI could be reasonable, with CT-MRI combined CCLS representing a viable option.
Limitations: This study is limited by its single-center design, small cohort and histotype imbalance favoring clear cell and papillary RCCs. Findings should be considered preliminary, with validation in larger, multicenter populations warranted.
Funding for this study: This study received no external funding.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the Ethics Committee.

Automated Radiomics-Based Machine Learning for Differentiating Clear Cell from Non-Clear Cell Renal Cell Carcinoma Using Multi-Parametric MRI (6 min)

Chun-Han Liao; Taichung / Taiwan, Chinese Taipei

Author Block: M. Liu, S-C. Lin, Y-T. Lin, W-H. Chen, Y-J. Liu, C-H. Liao; Taichung/TW
Purpose: This study aimed to develop an automated radiomics-based machine learning framework using multiple MRI weightings to distinguish clear cell renal cell carcinoma (ccRCC) from non-clear cell renal cell carcinoma (ncRCC). Accurate preoperative identification of RCC subtypes is critical for selecting optimal surgical strategies and guiding targeted therapies, especially for patients unable to undergo contrast-enhanced imaging.
Methods or Background: RCC accounts for 85% of malignant kidney tumors, with ccRCC comprising ~75% of cases. MRI provides diverse weighted sequences (T2WI, T1WI, CE-T1WI, In/Out phase, DWI/ADC) useful for RCC differentiation. Radiomics enables extraction of thousands of quantitative features from tumor ROIs, which can be processed with machine learning. This study employed AutoML via TPOT to identify optimal feature sets and classifiers. MRI data from 76 patients (49 ccRCC, 27 ncRCC) between 2014–2023 were analyzed. Tumor ROIs were segmented in 2D, 3D, and combined formats; features were extracted and reduced through feature selection, followed by AutoML training with 10-fold cross-validation.
Results or Findings: Among classifiers, LinearSVC and SGD achieved the best performance. In 3D analyses, AUCs reached 0.81–0.86 across image sets. Importantly, models trained without contrast-enhanced images (C−) still attained robust accuracy (AUC up to 0.81–0.86 when combining 2D and 3D data). This demonstrates that non-contrast MRI radiomics can yield reliable subtype classification, potentially avoiding gadolinium-related risks.
Conclusion: The AutoML-based radiomics approach successfully differentiated ccRCC from ncRCC using multiparametric MRI, achieving high performance even without CE-T1WI. This method offers a clinically valuable tool for preoperative planning, particularly in patients with renal dysfunction or contrast contraindications.
Limitations: The study's retrospective design and modest cohort size, especially the smaller ncRCC subgroup, may affect generalizability. Larger multicenter datasets and prospective validation are needed to confirm robustness and clinical applicability.
Funding for this study: There is no funding for this study

Diagnostic Accuracy of Contrast-Enhanced Ultrasound in Differentiating Renal Cell Carcinoma from Angiomyolipoma in Small Hyperechoic Renal Masses (≤3 cm): A Retrospective Study (6 min)

Nicoletta Giordano; Nola / Italy

Author Block: N. Giordano[1], F. Urraro[2], V. Patanè[1], M. Piscopo[1], A. Russo[1], S. Cappabianca[1], A. Reginelli[1]; [1]Naples/IT, [2]Roma/IT
Purpose: To assess the diagnostic accuracy of contrast-enhanced ultrasound (CEUS) in differentiating renal cell carcinoma (RCC) from angiomyolipoma (AML) in small (≤3 cm), hyperechoic renal masses and to identify predictive enhancement patterns in routine clinical practice.
Methods or Background: This retrospective single-center study included 104 patients with incidentally detected hyperechoic renal lesions ≤3 cm examined by CEUS between December 2021 and July 2024. Two blinded radiologists independently assessed wash-in/wash-out dynamics, peak intensity, homogeneity, and perilesional rim-like enhancement. Histopathology was the reference standard when available; lesions stable for ≥18 months on follow-up were considered benign. Diagnostic metrics were calculated, and multivariate logistic regression identified independent predictors. Interobserver agreement was assessed by intraclass correlation coefficient (ICC)
Results or Findings: Of 104 lesions, 80 were managed as AMLs, with 4 biopsied during follow-up (2 papillary RCCs, 2 AMLs). Twenty-eight lesions underwent biopsy, confirming 26 RCCs (53% papillary, 32% chromophobe, 15% clear cell) and 2 atypical AMLs. RCCs typically demonstrated heterogeneous hyperenhancement with rapid wash-out and perilesional rim-like enhancement, whereas AMLs showed iso- or homogeneous enhancement with delayed wash-out. Rapid wash-out achieved sensitivity of 87% and specificity of 94% (AUC 0.91), while perilesional rim-like enhancement reached specificity of 98% and PPV of 92%. Combined CEUS features yielded an AUC of 0.93. Interobserver agreement was good (ICC 0.75–0.9).
Conclusion: CEUS provides excellent diagnostic accuracy in distinguishing RCC from AML in small hyperechoic renal masses. Rapid wash-out and perilesional rim-like enhancement are independent predictors of malignancy, supporting CEUS as a reliable, radiation-free tool to guide clinical decision-making
Limitations: This was a retrospective, single-center study with limited sample size. Histological confirmation was not available for all AMLs, relying on imaging stability as a surrogate of benignity. Larger prospective multicenter studies are required to validate these findings.
Funding for this study: No external funding was received for this study

Peritumoral Radiomics Improves Prediction of Occult pT3a in Clear Cell Renal Cell Carcinoma: A Multicenter Study (6 min)

Shichao Li; Wuhan / China

Author Block: S. Li, Z. Li; Wuhan/CN
Purpose: Occult pathological T3a (pT3a) upstaging in cT1b–T2a clear cell renal cell carcinoma (ccRCC) correlated with poor prognosis and necessitates modifications in surgical planning. However, predicting it preoperatively remains challenging. Conventional imaging emphasizes intratumoral features, yet early invasion frequently manifests as subtle alterations in peritumoral tissue. This study aimed to evaluate the diagnostic value of peritumoral tissue and to test whether combining peritumoral and intratumoral radiomics improves prediction of occult pT3a.
Methods or Background: This multicenter retrospective analysis included 1240 patients initially staged as cT1b–T2a ccRCC. Tumor and peritumoral regions were segmented using nnU-Net, and 107 radiomic features were extracted. Logistic regression, support vector machine, decision tree, and random forest classifiers were trained using tumor-only, peritumor-only, and combined features. Model performance was assessed with AUC, sensitivity, specificity, and accuracy across internal and external cohorts, with DeLong tests for AUC comparisons. SHAP analysis was used to evaluate feature contributions and tumor–peritumor interactions.
Results or Findings: In the internal validation cohort, the Radiomics_Combined model achieved an AUC of 0.800, significant outperforming the Radiomics_peritumor model (AUC 0.709, p = 0.020) and showing a nonsignificant improvement over the Radiomics_tumor model (AUC 0.787, p = 0.798). Similar trends were observed in external validation cohorts. SHAP analysis identified 30 peritumoral features among the top 40 predictors, with peritumor_shape_Maximum3DDiameter ranked highest. SHAP dependence plots further demonstrated nonlinear tumor–peritumor interactions, indicating that the model captures cross-regional effects reflecting subtle morphologic changes associated with local invasion.
Conclusion: Peritumoral tissue contributes distinct and complementary signatures of early invasion. Integrating tumor and peritumoral features enables accurate, interpretable prediction of occult pT3a upstaging in cT1b–T2a ccRCC and may improve surgical dicision-making.
Limitations: Retrospective design.
Funding for this study: This study was supported by grants from the National Natural Science Foundation of China (No. 82371942).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The ethical approvals for this multi-center retrospective study were provided by the Institutional Review Board of Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology; the Institutional Review Board of the First Affiliated Hospital of Nanjing Medical University; and the Institutional Review Board of Xiangyang Central Hospital.

RPS 1611 - Neuroimaging: innovation in techniques and contrast agents

Pathology-Aware Targeted T1 synthesis from T2 and FLAIR images using Multi-Contrast Multi-Scale Vision Transformers (6 min)
Thomas Campbell Arnold; Philadelphia / United States

Author Block: S. Pasumarthi Venkata, T. Campbell Arnold, A. Shankaranarayanan; Menlo Park, CA/US
Purpose: Multi-contrast brain MRI images offer complimentary information that aids in differential diagnosis and treatment. The acquisition of high-quality multi-contrast images is time consuming and is often susceptible to artifacts. In this work, we propose the synthesis of T1w images from T2 and FLAIR images using a multi-contrast multi-scale vision transformer (MMT). T1w images are usually acquired at the start of any brain protocol and provide a structural baseline. Other contrasts like T2, FLAIR and T1C provide additional pathological information. It was found that the basic structure in T1 can be faithfully reconstructed from T2 and FLAIR images thus cutting down on the acquisition time (~4 mins for 3D; ~1.5 mins for 2D). We quantitatively evaluate the synthesized and acquired T1w images using PSNR, SSIM and RMSE.
Methods or Background: MMT was pre-trained on all subsets of T1,T1C,T2,FLAIR as input and the missing sequence(s) as the output. This model was further fine-tuned by fixing T2&FLAIR as inputs, and T1 as output. Reconstruction L1-loss was weighted on the lesion maps generated from T1C images using a pre-trained lesion segmentation algorithm. Multi-contrast (T1w,T2&FLAIR) brain MRI images from 45 patients were quantitatively evaluated using PSNR, SSIM and RMSE computed between real and synthesized T1.
Results or Findings: The average PSNR, SSIM and RMSE over the 45 patient studies are 33.53±1.75, 0.91±0.13 and 0.18±0.02 respectively. The synthesized T1w images had better overall image quality with less artifacts.
Conclusion: In this study, we have shown the quantitative performance of synthesizing T1w images from T2 and FLAIR to reduce acquisition time. The synthesized T1w images provide similar structural information as that of the acquired T1w images.
Limitations: Detailed qualitative assessment is missing. Future studies will evaluate different downstream tasks using the synthesized T1 image.

Gadoquatrane Demonstrates Similar Pharmacokinetics and Imaging Compared to Other Macrocyclic Extracellular GBCAs in Phase 2 and 3 CNS CE-MRI Studies (6 min)
Benjamin P Liu; Chicago / United States

Author Block: B. P. Liu[1], C. Deuschl[2], K. Kudo[3], A. Liu[4], G. Sutter[5], B. M. Hofmann[5], P. Palkowitsch[5]; [1]Chicago, IL/US, [2]Essen/DE, [3]Sapporo/JP, [4]Whippany, NJ/US, [5]Berlin/DE
Purpose: Compared to macrocyclic gadolinium (Gd)-based contrast agents (GBCA) used at 0.1 mmol Gd/kg body weight (bw), gadoquatrane's tetrameric structure enables high relaxivity, allowing for a reduction of 90% molecule and 60% Gd dose. This analysis of Phase (ph) 2 and 3 data explores the potential effect of the gadoquatrane structure and larger molecular size on imaging and pharmacokinetics (PK) vs. gadoterate meglumine, gadoteridol and gadobutrol.
Methods or Background: Two controlled clinical trial studies were conducted in patients with known or suspected CNS pathologies. Patients underwent two CE-MRIs, one with gadoquatrane (0.01 mmol/kg body weight (bw), equal to 0.04 mmol Gd/kg bw) and one with comparator GBCA (0.1 mmol Gd/kg bw).
In ph3, MRIs followed clinical practice; in ph2 scans were taken at 5-, 10- and 15-min post injection. Images were evaluated in a blinded central read using 3 visualization parameters: contrast enhancement, delineation, morphology. Signal intensity was also assessed quantitatively in ph2. PK were evaluated via plasma samples taken at predefined time windows.
Results or Findings: The integrated analysis included 362 adult CNS patients, with 326 evaluable for efficacy, and 338 for pharmacokinetics.
Gadoquatrane MRI was non-inferior to the comparator MRI for all visualization parameters. Quantitative enhancement was similar for gadoquatrane and gadobutrol. Dose normalized plasma concentration-time curves showed overlapping concentrations up to 24 hours post dose, indicating dose-proportionality and essentially the same PK behavior over time for all GBCAs.
Conclusion: Gadoquatrane at a 60% reduced Gd dose is non-inferior to comparator GBCAs for CNS CE-MRI. For later imaging time points, qualitative and quantitative assessments were similar to comparator GBCAs. There is no relevant impact of the larger molecular size on imaging properties or PK behavior.
Limitations: The integrated analysis includes patients with CNS pathologies only.
Funding for this study: Both studies referenced were sponsored by Bayer AG.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The studies were approved by Institutional Review Boards at all participating investigation sites of these multicenter trials.

Population PK Modeling of Gadoquatrane: Supporting Regulatory Submission for Use in Patients of All Ages (6 min)

Gabriele Sutter; Berlin / Germany

Author Block: G. Sutter[1], E. Vendel[2], P. Vis[2], J. Zisowsky[1], M. Feldmueller[1], B. M. Hofmann[1]; [1]Berlin/DE, [2]Leiden/NL
Purpose: An integrated population-pharmacokinetic (popPK) modeling approach was chosen to thoroughly evaluate the pharmacokinetics (PK) of the extracellular macrocyclic gadolinium-based contrast agent (mGBCA) gadoquatrane, in adults and children, utilizing data from all Phase 1-3 clinical trials, including a pediatric study, to support regulatory submission for the use in patients of all ages with CNS or body pathologies.
Methods or Background: Data from eight clinical Phase 1-3 studies, covering doses of 0.0025 – 0.05 mmol/kg body weight (bw) gadoquatrane (corresponding to 0.01 – 0.2 mmol Gd/kg bw), and a Phase 1/3 study in pediatric patients aged 0-<18 years (0.04 mmol Gd/kg bw) were analyzed. Non-linear mixed-effects methods were applied for popPK model development including covariate assessment. Analysis started with data from 871 adults (4054 Gd plasma concentrations), forming the basis for the pediatric analysis by applying and adjusting the adult model to pediatric data (92 children with 276 Gd plasma concentrations). Exposure parameters were compared across populations (age, gender, race/ethnicity, renal function, health status) and with other mGBCAs.
Results or Findings: The adult model was a linear three-compartment model with allometric scaling based on lean body mass (LBM) and estimated glomerular filtration rate as covariate on clearance (CL). The pediatric data allowed only for identification of two compartments, the resulting model included LBM-based allometric scaling and a maturation factor on CL based on postmenstrual age. Gadoquatrane demonstrated consistent PK behavior across populations, closely matching the patterns observed with other mGBCAs.
Conclusion: This integrated popPK modeling approach enabled a thorough and efficient characterization of gadoquatrane's PK in both adults and children, supporting regulatory submission across all indications and ages.
Limitations: Limitations included limited representation of some groups (Patients aged <6 months, Black participants, individuals with severe renal impairment).
Funding for this study: All studies referenced were sponsored by Bayer AG.

Experience with gadopiclenol in the detection of brain metastases: Single and double doses, comparison of standard and delayed imaging (6 min)

Aaron Rulseh; Prague / Czechia

Author Block: A. Rulseh, Z. Ryznarová, R. Liščák, J. Vymazal; Prague/CZ
Purpose: To demonstrate the role of gadopiclenol in MR imaging of brain metastases at standard (0.05 mmol/kg) and double doses (0.1 mmol/kg), including delayed examination (~15 minutes post-contrast).
Methods or Background: One hundred sixty-two subjects with known brain metastases underwent MRI prior to radiosurgery (75 female, mean age 63.67 years ± 12.7 SD). A standard T1W 3D SPACE sequence was acquired post-contrast in all subjects (5 subjects at 1.5T, 157 at 3T), followed by a delayed acquisition. In roughly half of subjects (n=83), the delayed acquisition was preceded by additional contrast administration (cumulative double dose). After randomization, 3 blinded readers evaluated each subject in 2 sessions, minimally 4 weeks apart. A one-sided paired t-test was used to compare the number of lesions detected in the 2 groups: single dose (early versus delayed), and double dose (early versus delayed [double]).
Results or Findings: Agreement between all blinded readers was used for evaluation. The delayed single dose exam revealed 288 metastases compared to 279 metastases on the early exam. Delayed double-dose exam revealed 258 metastases compared to 221 metastases on the early single dose exam. In subjects that received a double dose, the number of lesions detected on the early versus delayed (double) dose exams differed significantly (p=0.002), while in subjects that received only a single dose no significant difference in the number of lesions detected on early versus delayed exams was detected (p=0.24).
Conclusion: Significantly more metastases were detected on delayed double dose imaging, while no difference was detected on early versus delayed single dose acquisitions. Our results suggest that a delayed, double dose gadopiclenol acquisition may improve the detection of metastases.
Limitations: The study was performed at a single institution. Only the SPACE sequence was used for blinded reading.
Funding for this study: Ministry of Health CZ, IG244302.

Performance of gadopiclenol in dynamic susceptibility contrast magnetic resonance imaging (DSC-MRI) perfusion of brain gliomas (6 min)

Simonetta Gerevini; Cremona / Italy

Author Block: S. Gerevini[1], G. Hutóczki[2], A. G. Bagó[3], A. Pichiecchio[4], S. Gaudino[5]; [1]Cremona/IT, [2]Debrecen/HU, [3]Gdansk/PL, [4]Pavia/IT, [5]Rome/IT
Purpose: To demonstrate the non-inferiority of DSC-MRI perfusion using gadopiclenol at 0.05 mmol/kg compared to gadoterate meglumine at 0.1 mmol/kg in terms of diagnostic quality of Cerebral Blood Volume (CBV) perfusion map.
Methods or Background: In this multicentre randomized controlled trial, 138 adult patients with primary glial tumour scheduled for a follow-up DSC-MRI were randomized to receive either gadopiclenol or gadoterate meglumine. The primary outcome was the CBV map diagnostic quality assessed by two independent blinded readers, using a 4-point scale (poor, fair, good, excellent). Secondary outcomes included glioma grade differentiation by relative CBV (rCBV) quantification, and safety. Non-inferiority was defined as proportion of patients with excellent or good diagnostic quality images for gadopiclenol of no more than 12% below that for gadoterate meglumine.
Results or Findings: Per-protocol analysis included 60 patients with gadopiclenol and 64 with gadoterate meglumine. The proportion of patients with CBV map images assessed as “excellent or good” was 96.7% with gadopiclenol and 98.4% with gadoterate meglumine, respectively, with a difference of -1.8% [two-sided 95% CI: - 8.9% to 5.3%], demonstrating the non-inferiority. Overall, rCBV values were significantly different between high-grade and low-grade gliomas with both contrast agents, with a median of 3.11 vs 1.51 (p =0.003) for gadopiclenol and 2.47 vs 1.41 (p <0.001) for gadoterate meglumine.
Three patients receiving gadopiclenol and two receiving gadoterate meglumine experienced non-serious adverse events of mild intensity, none related to the contrast agent.
Conclusion: DSC-MRI perfusion using gadopiclenol at 0.05 mmol/kg was non-inferior to gadoterate meglumine at 0.1 mmol/kg on diagnostic quality of CBV perfusion map and both enabled brain glioma grade differentiation. This study additionally confirmed the safety profile of gadopiclenol.
Limitations: No limitations were identified

First prospective evaluation of post-contrast ultra-low field brain MRI across diverse neurological pathologies (6 min)

Barbara Daria Wichtmann; Bonn / Germany

Author Block: B. D. Wichtmann[1], K. Teichmann[1], N. Lehnen[1], T. Tonguc[1], F. Padormo[2], A. Rastogi[1], Z. Bendella[1], A. Radbruch[1], J. Faber[1]; [1]Bonn/DE, [2]Guilford, CT/US
Purpose: Portable ultra-low-field-(pULF)-MRI enables bedside neuroimaging in resource limited settings. However, lower signal and relaxivity differences at 64mT limit contrast enhancement (CE). This prospective study provides first evaluation of CE-pULF-MRI in a heterogeneous cohort compared to high-field-(HF)-MRI for lesion detection and diagnostic confidence.
Methods or Background: This IRB-approved prospective study included 39 patients (58.1±15.7years; 20♀) undergoing clinically indicated CE-HF-MRI at 1.5/3T for oncologic, demyelinating, inflammatory, vascular, postoperative, or degenerative conditions between 04-05/2025. Patients received native pULF-MRI (SWOOP,Hyperfine,Guilford,CT) with axial T1w standard (std) and synthetic echo train length (sETL) sequences, FLAIR, T2w, and DWI. HF-MRI followed clinical protocols with pre-/post-contrast T1w-imaging after IV-administration of 1.0mmol/mL gadobutrol (Gadovist). CE-pULF-MRI was then repeated using the same axial T1w std and sETL sequences.
4 blinded (neuro-)radiologists independently evaluated all T1w scans from both field strengths for post-contrast hyperintense lesions, rating diagnostic confidence per lesion on a 5-point Likert scale (1=very uncertain; 5=very certain).
Results or Findings: 29/39 patients had ≥ 1 lesion on CE-HF-MRI. Up to 100 lesions per rater were marked on HF-MRI.
On pULF-MRI 23% of lesions were missed, thereof 59% <6 mm, 89% <8 mm. The remaining 11% were located infratentorial, near the venous sinus, subcallosal at the frontal sinus, or outside the pULF-MRI scan volume. One lesion missed on pULF-MRI showed minimal CE, detected on HF-MRI by only two readers with low confidence (2).
Diagnostic confidence was slightly higher for pULF T1w std than sETL. In pULF T1w std, ≥2 readers marked 3 false positives; in sETL, 4 false positives, all with low confidence.
Conclusion: CE pULF MRI enables detection of enhancing brain lesions ≥6–8 mm and is feasible for bedside imaging. T1w std outperforms sETL.
Limitations: Limitations exist for smaller lesions and those in anatomically challenging locations.
Funding for this study: None.

Ethics committee - additional information: The study was conducted under the ethical approval “Gehirnentwicklung von Früh- und Neugeborenen während des Aufenthaltes auf der neonatologischen Intensivstation” granted by the local institutional review board (Ethics Committee of the University Hospital Bonn). All participants provided written informed consent.

Rationales for non-standard GBCA dosing – Low? - High? - When? & Why? A literature-based study (6 min)

Jan Siegfried Endrikat; Berlin / Germany

Author Block: J. S. Endrikat[1], I. Siddiqui[2], H. Khater[1], M. Blankenburg[1]; [1]Berlin/DE, [2]Reading/UK
Purpose: To systematically explore rationales for non-standard dosing of GBCAs and discuss the potential future impact of high-relaxivity contrast agents.
Methods or Background: A systematic literature review was conducted using Embase, covering 1991 to 2024. Publications were categorized by indication, GBCA dose, study design, and rationale for non-standard dosing. The dose of 0.1 mmol Gd/kg body weight was defined as the 'standard' reference for comparison.
Results or Findings: Eighty-four publications comparing non-standard dosing regimen with the standard dose were included: 43 high-dose and 55 low-dose studies. The rationales for high-dose administration were to achieve better contrast (25/43; 58%) and improve lesion detection (15/43; 35%). High-dose studies were primarily performed in CNS until 2006.

Rationales for using low-dose administration were related to 1) NSF (28/55; 51%); 2) Gd exposure (22/55; 40%); 3) cost (22/55; 40%); 4) unspecified safety (18/55; 33%); 5) Gd retention/presence (16/55; 29%); and 6) environment (6/55; 11%). From 1991 to 2006, cost was the sole rationale for lower dose administration. From 2008, NSF was noted; from 2017 onwards, Gd retention/presence, and most recently, environmental impact emerged as important rationales. Forty-six of 55 studies (84%) investigating low-dose regimen reported comparable outcomes, 7 studies (13%) inferior outcomes. However, 35 of 46 low-dose studies reporting comparable outcomes modified also other parameters or used a study design potentially impacting study strength.
Conclusion: For over 34 years, there has been a consistent demand to lower GBCA doses, with an increasing number of rationales over time. The next generation of high-relaxivity, low-dose mGBCAs shows promise for reducing Gd dose while maintaining high image quality, potentially defining a new standard dose.
Limitations: The impact of advances in scanner technology and software was beyond the scope of this review.

Feasibility of ultra-fast MRI with DeepRecon combined with ACS in diagnosing acute stroke: A comparison with conventional MRI (6 min)

Zurui Che; GuiYang / China

Author Block: Z. Che; GuiYang/CN
Purpose: To evaluate the feasibility of an ultra-fast MRI protocol (scan time: 3 min 10 s) with Deep Learning Reconstruction (DeepRecon) combined with AI Compressed Sensing (ACS) in diagnosing acute stroke, and compare it with the conventional MRI protocol (scan time: 6 min 36 s).
Methods or Background: Fifty-six prospectively enrolled suspected acute stroke patients (onset < 6 h) underwent 3.0T MRI with both protocols. The conventional protocol included T2WI/T2-FLAIR/DWI/TOF-MRA (6 min 36 s); the ultra-fast one used DeepRecon+ACS for the same sequences (3 min 10 s). Three neuroradiologists performed double-blind evaluations. ICC, McNemar test, Bland-Altman analysis and Wilcoxon test were used for statistics (SPSS 26.0, α=0.05).
Results or Findings: The two protocols had 100% consistency in acute infarct detection (κ=1.0), 94.4% agreement in large vessel occlusion (LVO) detection (κ=0.89), and 97.2% in minor findings (e.g., microbleeds). The ultra-fast protocol had slightly lower but diagnostic image quality (4.1±0.4 vs 4.8±0.3, P=0.002), 63% less motion artifact (5.6% vs 27.8%, P=0.003), and 58.1% shorter scan time.
Conclusion: The DeepRecon+ACS ultra-fast MRI (3 min 10 s) maintains high diagnostic efficacy (consistency >94%) for acute infarcts/LVO, shortens scan time, reduces motion artifact, and meets the needs of stroke green channels.
Limitations: 1. Small sample size (56 patients) with no subgroup analysis (e.g., age, comorbidities), limiting external applicability.
2. Single scanning device (only 3.0T MRI); efficacy on low-field MRI (e.g., 1.5T) unproven, poor device compatibility.
3. No "gold standard" imaging (e.g., CTA, DSA) as reference; no subgroup analysis by onset time, incomplete study dimensions.

Study on the Protocol of Multi-Slice Simultaneous Acquisition High-Resolution ASL Imaging Technique in the Brain (6 min)

Yong Xiang; Guiyang / China

Author Block: Y. Xiang; Guiyang/CN
Purpose: To investigate the 2D MultiBand EPI ASL imaging technique for obtaining quantitative results of Cerebral Blood Flow (CBF) and Arterial Transit Time (ATT). Subsequently, open-source post-processing software BASIL was used to analyze the data, and the results were compared with those from the conventional 3D ASL sequence to verify the quantitative accuracy of this technique.
Methods or Background: The study was conducted using a United Imaging uM880 3.0T magnetic resonance scanner equipped with a 48-channel head and neck coil. The scanning parameters were as follows: Field of View (FOV) = 220 × 220 mm², voxel size = 2.5 × 2.5 × 2.3 mm, interslice gap = 10%, number of slices = 48, scanned in a bottom-to-top sequential order. The MultiBand factor was set to 6, bandwidth = 2600 Hz/pixel, Echo Time (TE) = 16.4 ms. The labeling time was 1500 ms, and a total of 5 Post-Labeling Delays (PLDs) were used: 0.2 / 0.7 / 1.2 / 1.7 / 2.2 sOne M0 image was acquired for calibration. The total scanning time was 5 minutes and 36 seconds.After acquisition, two independent radiologists evaluated the overall image quality of both the mPLD ASL and the conventional 3D ASL sequences using a five-point Likert scale in terms of signal-to-noise ratio (SNR), clarity, and accuracy.
Results or Findings: Compared with the conventional 3D ASL sequence, the mPLD ASL demonstrated a significant improvement in overall image quality, particularly in SNR. Additionally, it reduced motion sensitivity and image blurring. Most importantly, the mPLD ASL technique enabled the acquisition of two sets of quantitative images for CBF and ATT, showing enhanced quantitative accuracy.
Conclusion: The mPLD ASL sequence not only improves SNR and image clarity but also provides superior quantitative accuracy.
Limitations: No

New horizons in brain tumor surgery: feasibility and diagnostic value of DSC and ASL perfusion in intraoperative MRI (6 min)

Manuel Rafael López De La Torre Carretero; Pamplona / Spain

Author Block: M. R. López De La Torre Carretero, D. A. Zambrano, C. Mbongo, A. M. Delgado Brito, C. D. Solano, M. A. Fernández Seara, M. Calvo Imirizaldu; Pamplona/ES
Purpose: The main aim of this study was to assess the diagnostic value of perfusion imaging during intraoperative MRI (iMRI) for detecting residual lesions. We evaluated the image quality of intraoperative dynamic susceptibility contrast (DSC) and arterial spin labeling (ASL) sequences in a cohort of patients undergoing brain surgery, and then compared their ability to identify residual lesions with that of conventional techniques.
Methods or Background: Twenty-seven patients (13 men; mean age 60±14) undergoing intraoperative MRI during brain tumor resection were prospectively imaged with structural MRI, DSC, and ASL. Two independent readers rated image quality (1–4; 1–2 non-diagnostic, 3–4 diagnostic) and scored tumour remnants on structural MRI, DSC-CBV, and ASL-CBF as present, absent, or non-evaluable (artifacts); only perfusion studies rated diagnostic were included for the remnant analysis, and interobserver and intermodality agreement were assessed with Cohen's kappa.
Results or Findings: Consensus diagnostic quality was slightly higher for DSC (25/27 cases) compared to ASL (23/26). Interobserver agreement was excellent for DSC (κ=1.00) and substantial for ASL (κ=0.75). Concordance between DSC and ASL in evaluable cases was moderate (κ=0.26). When compared with structural MRI, perfusion-based assessment of residual tumor demonstrated substantial agreement for both DSC (κ=0.89) and ASL (κ=0.69).
The performance of the two techniques was not interchangeable: DSC was generally more resilient to image degradation, whereas ASL enabled interpretation in one case where DSC failed.
Conclusion: Intraoperative perfusion MRI is feasible. DSC yields slightly better image quality and structural agreement, but ASL proves to be useful when contrast is contraindicated, not needed (i.e. non-enhancing tumors) or DSC is compromised, providing complementary value for the detection of tumor remnants during brain surgery. Their complementary roles support combined use to enhance intraoperative confidence.
Limitations: Tumour heterogeneity
Qualitative analysis
No histopathological gold-standard

Magnetic resonance neurography for evaluating diabetic peripheral neuropathy in type 1 diabetes (6 min)

Suganthiya S. Croosu; Aalborg / Denmark

Author Block: S. S. Croosu, J. Røikjer, S. M. Tahami, T. M. Hansen, J. Brøndum Frøkjær, N. Ejskjaer, C. D. Mørch; Aalborg/DK
Purpose: Diabetic peripheral neuropathy (DPN) is a frequent complication of type 1 diabetes mellitus (T1DM), causing sensory loss and pain, but reliable imaging biomarkers of nerve damage are lacking. This study investigated whether tibial and sciatic nerve integrity is affected by T1DM with painful or painless DPN using diffusion tensor imaging magnetic resonance neurography (DTI-MRN), and whether these measurements associate with clinical outcomes.
Methods or Background: Fifty-eight participants with T1DM were divided into painful DPN(n=20), painless DPN(n=19), and no DPN(n=19), along with 20 healthy controls (HC). DTI-MRN was performed at 10% and 40% above the patella to evaluate the tibial and sciatic nerves, respectively. Fractional anisotropy (FA) and apparent diffusion coefficient (ADC) were measured. Correlations with age, diabetes duration, HbA1c, nerve conduction, and pain scores were assessed.
Results or Findings: Higher FA indicates better fibre integrity and coherence, while lower ADC reflects more restricted diffusion, consistent with intact nerve fibres and myelin. Mean tibial nerve FA was lower in painful DPN(0.25±0.08) and painless DPN(0.24±0.05) versus T1DM without DPN(0.33±0.06) and HC(0.32±0.07) (all $p<0.002$). Tibial ADC was higher in painful DPN(912.2±338.2 $\times10^{-6}$ mm^2/s) compared with T1DM without DPN(622.0±152.6 $\times10^{-6}$ mm^2/s) and HC(673.6±185.4 $\times10^{-6}$ mm^2/s) (all $p<0.007$). No differences in the sciatic nerve were detected (all $p>0.05$). Lower FA and higher ADC of the tibial nerve were associated with poorer sural amplitude and velocity, impaired warm/cold detection, and greater pain intensity (all $p<0.03$).
Conclusion: DTI-MRN detects tibial nerve alterations in T1DM with DPN. FA reduction occurred in both painful and painless DPN, while ADC increase was specific to painful DPN. Tibial FA and ADC correlated with nerve dysfunction and pain, suggesting potential as biomarkers of neuropathy severity.
Limitations: Sample size and cross-sectional design limit causal interpretation. Longitudinal studies are needed.

Dose management of head CT scans in 2025: the importance of the human factor in the age of artificial intelligence (6 min)

Enrico Armando; Caraglio / Italy

Author Block: E. Armando[1], M. Porzio[2], G. Salmè[3], E. Rachetta[1], F. Groppo Marchisio[1]; [1]Caraglio/IT, [2]Borgo San Dalmazzo/IT, [3]Collegno/IT

Purpose: To evaluate brain CT scan doses in a radiology department with different CT scanners, with different algorythms, from filtered back projection to deep learning reconstructions and with or without camera based patient postioning.
Methods or Background: Dose data of all the brain CT scan examinations obtained by seven different scanners between January and September 2025 were included in the analysis, using the dose tracking software (Gray detector, EL.Co, Cairo Montenotte, Italy). DLP and CTDI data were analysed using SAS Studio on demand for academics using the Kruskall Wallis test. Children examinations were excluded
Results or Findings: 5064 head CT scans were included in the analysis. There were no statistical differences in CTDI and DLP among the scanners despite differences in technology and protocols. The most recent CT scanner with deep learning reconstruction and a camera for automated positioning of the patient had a 15% lower median DLP than other scanners. This improvement was not immediate but it was obtained after protocol revision, reducing the minimum mA in the protocol setting oif the current modulation.
Conclusion: Brain CT scan is the most frequent examination in most radiology departments. However it is the examination with the lowest reduction of CTDI and DLP despite the introduction of iterative and deep learning reconstruction algorythms, as low noise images are needed.
New scanners with deep learning based algorythms do not necessarily lead to dose reduction unless protocols are carefully revised to exploit these improvements
Limitations: This is a retrospective study and is the basis for further research

Multiphasic Contrast-Enhanced CT Radiomics and Deep Learning Models for Predicting Tumor Budding Grading in Colorectal Cancer (6 min)
Guihan Lin; Lishui / China

Author Block: G. Lin, W. Chen, M. Chen, J. Ji; Lishui/CN
Purpose: To evaluate whether multiphasic contrast-enhanced CT radiomics combined with deep learning can predict the grading of tumor budding (TB) in colorectal cancer (CRC).
Methods or Background: This retrospective two-center study included 676 CRC patients who underwent surgery (center 1: n=467; center 2: n=209) in the training, internal validation, and external validation cohorts. Postoperative pathology categorized patients into low-to-moderate TB or high TB groups. Tumour regions were manually segmented on arterial, venous, and delayed phase CT images. Radiomics and deep learning features were extracted, followed by feature reduction using minimum redundancy maximum relevance, and least absolute shrinkage and selection operator. Radiomics and deep learning scores were calculated. Independent predictors were identified with logistic regression, which was used to construct clinical, radiomics, deep learning, and combined models. Model performance was assessed using the area under the receiver operating characteristic curve (AUC), calibration curves, and decision curve analysis.
Results or Findings: Eleven radiomics and seventeen deep learning features were selected. Histological differentiation, radiomics score, and deep learning score were independent predictors of TB grading. The combined model achieved the highest AUCs (internal validation: 0.897; external validation: 0.846), significantly outperforming the clinical model (internal validation: 0.721; external validation: 0.655) and the radiomics model (internal validation: 0.817; external validation: 0.776) (all $P < 0.05$). Calibration demonstrated excellent agreement between predicted and observed outcomes, while decision curve analysis showed the greatest net clinical benefit for the combined model.
Conclusion: A multiphasic contrast-enhanced CT model integrating radiomics, deep learning, and clinical factors can accurately predict TB grading in CRC and may facilitate personalized treatment planning.
Limitations: First, the generalizability of findings is restricted by the retrospective design and relatively small sample size. Second, it exclusively examined intratumoral features, overlooking the potential value of peritumoral features.
Funding for this study: This research was funded by the Key Project of Joint Construction by Provincial and Ministerial Authorities (WKJ-ZJ-2452).

Prognostic impact of lateral nodes size in patients with locally advanced rectal cancer treated with neoadjuvant CRT (6 min)
Pietro Varotto; Vicenza / Italy

Author Block: P. Varotto, G. Sussan, F. Scannapieco, G. Spolverato, E. Quaia, F. Crimì; Vicenza/IT
Purpose: The evaluation of pelvic lymph nodes in rectal cancer has traditionally emphasized mesorectal nodes, whereas the role of lateral pelvic lymph nodes (LLNs: obturator, internal and external iliac) remains less clearly defined. Their prognostic significance, particularly after neoadjuvant chemoradiotherapy (CRT), is debated. International guidelines diverge: some Western centers favor a conservative, rectum-sparing approach, while Japanese guidelines support more radical strategies. Assessment of LLN size, especially short-axis diameter, may provide valuable prognostic and therapeutic insights.
Methods or Background: A cohort of 138 patients with locally advanced rectal cancer was retrospectively analyzed (mean age 66 years, range 27–87; 44% female). All patients underwent baseline and restaging pelvic MRI after pCRT. Among the cohort, 96 underwent total mesorectal excision (TME) or Abdomino-Perineal Resection (APR) and 42 were managed with rectum-sparing strategies (watch and wait and transanal local excision). LLNs were evaluated in baseline MRI and considered positive when the short-axis diameter was ≥7 mm.
Results or Findings: At baseline, LLNs were detected in 50% of patients. One patient was lost at follow up. Among 137 patients, the median OS was 58 months (IQR 4-96 months). No patient developed metastases in LLNs. The cohorts of patients with short axis of LLNs ≥7 mm and LLNs< 7 mm showed no significant differences in Overall Survival (OS) p=0.2 and Distant Metastases Free Survival (DMFS) p=0.22.
Conclusion: This study demonstrates that LLN size is not associated with OS and DMFS in locally advanced rectal cancer treated with CRT. Routine LLN excision, an invasive procedure associated with increased morbidity and functional sequelae, does not appear to provide survival benefit. Our findings support conservative management.
Limitations: This was a single-center, retrospective study with a relatively small sample and variable follow-up (4–96 months).
Funding for this study: None

Quantitative Peritumoral Fat Assessment by Dual-layer Spectral Detector CT for Predicting Preoperative Tumor Budding in Colorectal Adenocarcinoma (6 min)

Jianbo Xu; Guangzhou / China

Author Block: J. Xu, Y. Que, J. Zhang, W. Zhong, S-E. Cao, X. Liu, R. Guo; Guangzhou/CN
Purpose: To evaluate the value of dual-layer spectral detector CT (DLCT) in preoperative assessment of tumor budding (TB) grade in patients with colorectal adenocarcinoma (CRAC).
Methods or Background: This retrospective study included 83 patients with pathologically confirmed CRAC who underwent DLCT before treatment. Patients were classified into TB-positive and TB-negative groups. Spectral parameters of tumors and peritumoral fat, including effective atomic number (Zeff), iodine concentration (IC), normalized iodine concentration (NIC), virtual monoenergetic images (VMIs, 40–70 keV), and arterial enhancement fraction (AEF), were measured in arterial (AP) and venous (VP) phases. Group comparisons were performed with the Mann–Whitney U test, and predictive performance was evaluated using receiver operating characteristic (ROC) analysis.
Results or Findings: In tumors, AP-VMIs (40–70 keV), AP-IC, AP-Zeff, and AEF were significantly higher in TB-positive compared with TB-negative patients (all $P < 0.05$). In peritumoral fat, AEF, AP-Zeff, and VP-Zeff were also significantly elevated in the TB-positive group (all $P < 0.05$). Multivariable analysis identified AP-VMI 40 keV, AP-Zeff, VP-VMI 50 keV, and VP-VMI 70 keV in peritumoral fat as independent predictors of TB grade (all $P < 0.05$).
Conclusion: Quantitative parameters from DLCT, particularly AP-VMI 40 keV, AP-Zeff, VP-VMI 50 keV, and VP-VMI 70 keV in peritumoral fat, are independent predictors of TB grade in CRAC. Incorporating DLCT-based peritumoral fat assessment may enhance preoperative risk stratification and prognostic evaluation in CRAC.

Preoperative Prognostic Value of Gadoxetic Acid–Enhanced MRI in Patients with Colorectal Cancer Liver Metastases after Chemotherapy (6 min)

Philip Eckwolf; Wien / Austria

Author Block: P. Eckwolf, S. Pötter-Lang, A. Ba-Ssalamah, C. Kuntner, I. PASHKUNOVA-MARTIC, U. I. Attenberger, N. Bastati-Huber; Wien/AT
Purpose: To evaluate the prognostic value of gadoxetic acid–enhanced MRI (gaMRI) for predicting treatment response (TR) and overall survival (OS) in patients with colorectal cancer liver metastases (CRCLM).
Methods or Background: In this retrospective study, 79 patients (mean age, 61.8 ± 9.7 years) with 124 CRCLM underwent gaMRI after chemotherapy and before hepatic resection. Hepatobiliary phase (HBP) enhancement was qualitatively assessed by two independent readers and categorized as homogeneous hypointensity (favorable) or heterogeneous hypointensity (unfavorable). Apparent diffusion coefficient (ADC) values were measured. The primary outcome was residual vital tumor (RVT). Correlations of HBP pattern, TR, and ADC with RVT were analyzed, and OS was assessed using the log-rank test.
Results or Findings: Interobserver agreement was substantial (κ = 0.80). Median RVT was 37.8% (range, 0–95%) and was significantly associated with HBP pattern ($p < 0.001$) and ADC ($p = 0.021$). Heterogeneous hypointensity correlated with higher RVT ($r = 0.510$, $p < 0.001$), unfavorable regression categories ($r = 0.501$, $p < 0.001$), lower ADC ($r = –0.207$, $p < 0.05$), and higher vitality ($r = 0.264$, $p < 0.05$). Conversely, homogeneous hypointensity strongly predicted major pathological response (≤10% RVT, $r = 0.547$, $p < 0.001$) and, to a lesser degree, response ≤50% RVT ($r = 0.309$, $p < 0.001$). OS analysis showed a trend toward improved survival in patients with homogeneous hypointense lesions, although not statistically significant ($p = 0.066$).
Conclusion: Homogeneous hypointensity on HBP after gaMRI is a favorable biomarker, predicting major pathological response and higher ADC values, while heterogeneous hypointensity indicates poor response, greater residual vitality, and restricted diffusion.
Limitations: The retrospective, single-center design and modest sample size limit generalizability. OS analysis did not reach statistical significance.
Funding for this study: No funding was provided for this study.

Body composition as a predictor of cancer specific death in colon cancer: an AI-based volumetric analysis (6 min)

Daniela Capece; Roma / Italy

Author Block: D. Capece, M. Polici, B. Masci, L. Nardoni, S. Nardacci, F. Pacelli, M. Zerunian, D. Caruso, M. Francone; Rome/IT
Purpose: To investigate body composition as a predictive biomarker of cancer specific death in patients with non-metastatic colon cancer.
Methods or Background: Patients with colon cancer (stage II-III) treated with up-front surgery, with availability of baseline CT, clinical, and histological data, survival data were retrospectively enrolled. Patients with stage IV disease or those with CT unavailability were excluded. Body composition parameters were derived from baseline abdominal CT using AI-based automatic segmentation software. Up to 76 parameters regarding adipose visceral fat (AVF), subcutaneous fat (SF), bone density, liver density and fat-fraction were automatically extracted from both whole segmentation volume and multi-slices region (last rib-iliac crest). According to the Colon Cancer specific death (CC-specific death), the population was divided into Group 1 (CC-specific death) and Group 2 (non CC-specific death). Body composition features were compared between the two groups. Predictive model and survival analysis were performed with ROC curves, Cox regression and the Kaplan-Meier method. $P<0.05$ was considered significant.
Results or Findings: 293 patients were included in the study, 101/293 (34.5%) with CC-specific deaths. Mean HU of AVF (Group1 vs Group2, -77 HU vs -82 HU) and SF (Group1 vs Group2, -87 HU vs -90 HU) resulted directly correlated with CC-specific death ($P=0.004$ and $HR=1.03$, $P=0.002$ and $HR=1.04$, respectively) for the multislice analysis. Mean HU of AVF resulted in direct correlation with CC- CC-specific deaths, also for the volumetric analysis ($P=0.04$ and $HR=1.02$). In the Kaplan-Meier analysis, the AVF and SF for the multislice analysis resulted in statistically significant differences ($P=0.033$ and <0.001, Chi-Square=4.56 and 11.7, respectively).
Conclusion: In conclusion, our study demonstrated that the body composition metrics of visceral and subcutaneous fat was significantly associated with cancer-specific death in non-metastatic colon cancer patients.
Limitations: Retrospective study, lack of validation cohort
Funding for this study: Funded by AIRC IG 2020–ID 24974
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective analysis was conducted within the framework of a 5-year multicenter trial, approved by the ethical committee of Sant'Andrea University Hospital (ref. nr. CE 6597/2021), registered on ClinicalTrials.gov (NCT06108310).

CT-derived visceral adiposity and sarcopaenia demonstrate stronger correlation with epigenetic age compared to age by birth in early onset colorectal cancer (EOCRC) treated with curative intent (6 min)

Aine Daly; Co. Clare / Ireland

Author Block: A. Daly; Craughwell/IE
Purpose: EOCRC is increasing globally and in Ireland. One hypothesis is accelerated aging (AA). Epigenetic Age (EpiAge) is calculated using a blood-based algorithm and correlates strongly with age in whole body tissue/cell testing and is considered a more accurate predictor of DNA methylation than age by birth. This study aimed to examine the strength of relationship between dysmetabolic body composition with EpiAge and age by birth to better understand why it is prognostic of worse outcomes in EOCRC.
EOCRC patients diagnosed in the MidWest of Ireland from 2015-2024 (inclusive) and treated with curative intent (Stage I-III) were included. EpiAge was calculated using a validated blood-based algorithm. CT-derived body composition was measured on staging CTAP. Visceral adipose area was quantified on a single CT slice 6 cm above L4-L5, and skeletal muscle area at L3. Pearson and Spearman correlation coefficients were used depending on data distribution, significance was observed <0.05.
Results or Findings: Ninety one patients were suitable for inclusion (N=49 colon, n=42 rectal). 41% (n=37) had high visceral adiposity and 35% (n=32) sarcopaenia. EpiAge was older than age by birth in 77% (n=70) EOCRC and 83% (n=35) rectal cancers. Visceral adiposity correlated with EpiAge stronger than age by birth in EOCRC (r=0.69, p=0.005; r=0.25, p=0.1). This difference was more significant in colon cancer (r=0.79, p=<0.001; r=0.35, p=0.55) than rectal cancer. Sarcopenia correlated with EpiAge stronger than age by birth also (r=0.94, p=<0.01; r=0.48, p=0.65). EpiAge was significantly associated with disease specific mortality unlike age by birth [OR 6.6 (95%CI 0.84-0.95), p=0.028].
Conclusion: EpiAge correlates strongly with dysmetabolic body composition in EOCRC further strengthening the aetiological relationship between accelerated aging and EOCRC.
Limitations: Interpretation is limited by the retrospective design and sample size, but the findings highlight important associations warranting further study.
Funding for this study: No funding received for this study.

Delta total tumour volume and radiomics as predictive biomarkers in MSI-H metastatic colorectal cancer treated with immunotherapy (6 min)

Jules Dupont; Villejuif / France

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: J. Dupont[1], S. JOURNO[1], R. Barbe[1], P-H. Cournède[2], Y. Menu[1], C. S. Balleyguier[1], A. HOLLEBECQUE[1], T. André[3], N. Lassau[1]; [1]Villejuif/FR, [2]Gif-Sur-Yvettes/FR, [3]Paris/FR
Purpose: To evaluate whether variations (delta-) in total tumour volume (TTV) and radiomic features can early predict Overall Survival (OS) in rare cohort of patients with metastatic colorectal cancer (mCRC) with high microsatellite instability (MSI-H) undergoing immunotherapy.
Methods or Background: One hundred forty-five patients diagnosed with MSI-H mCRC (mean age, 56 ± 15 years; 89 men) were retrospectively included from two centers. Radiologists manually annotated all tumours on chest-abdomen-pelvis computed-tomography at baseline (BL) and first evaluation (E1) scans. The median time between BL and E1 was 50 days (interquartile range: 45 - 64 days).

Tumour volume and radiomics were extracted for each lesion to predict OS. Every scan was resampled to isotropic voxel spacing of 1×1×1 mm3 to reduce variability. The delta-TTV and delta-radiomics were defined as their relative between BL and E1.

The ability to stratify patients into long- and short-term survival groups was assessed using the Restricted Mean Survival Time (RMST) ratio, AUC at 3 years, and C-index. Generalization was assessed through 75 train/test cohort splits.
Results or Findings: A total of 2079 lesions at BL and 2112 at E1 were annotated.

Delta-TTV outperformed TTV at BL and E1 across all metrics (p<0.001). Specifically, delta-TTV achieved an RMST ratio of 2.215 (95% CI: [2.106-2.324]), an AUC of 0.854 [0.840-0.868], and a C-index of 0.830 [0.819-0.841], with a cut-off of 17.31% relative increase in TTV.

Combining delta-radiomics with delta-TTV enhanced performance, yielding an RMST ratio of 2.450 (2.248-2.652, p=0.019), an AUC of 0.875 (0.862-0.888, p<0.001), and a C-index of 0.839 (0.819-0.841, p<0.001).
Conclusion: Delta-TTV is a strong predictor of survival in MSI-H mCRC patients. Adding radiomic features enhances this biomarker's efficiency for early survival prediction.
Limitations: External validation is recommended for this two-center retrospective study.
Funding for this study: No fundings to disclose

The Efficacy of Interventional Transarterial Treatments for Unresectable Colorectal Carcinoma (6 min)

Andreea-Ioana Nica; Frankfurt / Germany

Author Block: T. J. Vogl, A-I. Nica, C. Booz, I. Yel, C. Wolfram, H. Adwan; Frankfurt/DE
Purpose: To evaluate the efficacy of transarterial chemoperfusion (TACP) and transarterial chemoembolization (TACE) as palliative and symptomatic treatments for unresectable colorectal carcinoma (CRC), focusing on local tumor response and survival outcomes.
Methods or Background: Between January 2000 and October 2023, 67 consecutive patients diagnosed with unresectable CRC underwent 318 TACP and 80 TACE procedures. Of these, 48 patients were treated with TACP, 14 with TACE, and 5 received a combination of both therapies. We retrospectively assessed local tumor response using the Response Evaluation Criteria in Solid Tumors (RECIST) and calculated overall survival (OS) and progression-free survival (PFS) using the Kaplan-Meier estimator.
Results or Findings: No major complications were reported. A total of 49 patients (73%) exhibited stable disease, while 3 patients (5%) achieved a partial response. The rate of progressive disease was 22%. The median OS for the entire cohort was 16.17 months, and the median PFS was 11.25 months. There were no statistically significant differences in OS (p=0.82) or PFS (p=0.37) between patients receiving TACP, TACE, or both treatments.
Conclusion: TACP and TACE are minimally invasive procedures that provide a viable treatment option for patients with unresectable CRC who cannot tolerate, refuse, or do not respond to chemotherapy. These treatments can serve as both palliative and symptomatic measures, potentially preventing tumor progression and improving quality of life. However, their benefits in the treatment of CRC warrant further investigation.
Limitations: Limitations of the study include its retrospective nature.
Funding for this study: No funding.

Ethics committee - additional information: Ethics Committee approval was obtained for this study.

The Utility of Quantitative Parameters from Dual-Layer Spectral CT in Differentiating Metastatic and Non-Metastatic Lymph Nodes in Colorectal Cancer (6 min)

Liyan Tang; Guangzhou / China

Author Block: L. Tang, X. Liu, C. FengPing, G. Liu, X. Lv, X. Liu, W. C. Chen; Guangzhou , China/CN
Purpose: To evaluate the diagnostic utility of quantitative parameters derived from dual layer spectrum CT (DLSCT) in distinguishing between metastatic and non-metastatic lymph nodes (LNs) in colorectal cancer (CRC).
Methods or Background: In this retrospective study, 78 metastatic LNs and 133 non-metastatic LNs were analyzed. Morphological characteristics and quantitative DLSCT parameters were evaluated and compared between the two groups. Univariate and multivariable logistic regression analyses were performed to identify independent factors for LN metastasis. Diagnostic performance and clinical utility were evaluated using receiver operating characteristic (ROC) curve analysis and decision curve analysis (DCA).
Results or Findings: Significant differences in all morphological features were observed between metastatic and non-metastatic LNs. Metastatic LNs showed significantly lower iodine concentration (IC) and normalized iodine concentration (NIC) in the arterial phase, along with higher effective atomic number (Zeff), normalized Zeff in the venous phase, and slope of the spectral Hounsfield unit curve (λHu) in both phases. A positive correlation was identified between λHu values of LNs and primary tumors in both arterial and venous phases within the metastatic group. The model based solely on morphological features achieved an AUC of 0.695. In contrast, the multivariate model incorporating DLSCT parameters significantly improved diagnostic performance, yielding an AUC of 0.901.The DeLong test and DCA comfirmed that quantitative multiparameter model provided superior predictive performance and greater clinical benefit compared to the morphological assessment alone.
Conclusion: Quantitative parameters derived from DLSCT demonstrate superior diagnostic efficacy in differentiating metastatic from non-metastatic LNs in CRC.
Limitations: Our findings indicate that the utilization of DLSCT-derived parameters provides significant value in differentiating lymph node metastasis in colorectal cancer patients by enabling the accurate assessment of tissue composition. The combination n of DLSCT multiple parameters can enhance the accuracy of LN assessment.
Funding for this study: This work was supported by Guangzhou Basic and Applied Basic Research Foundation (Grant No. 2023A03J0245), National Nature Science of Foundation of China (Grant No.82202259), and Youth Talent Project of The Second Affiliated Hospital of Guangzhou University of Chinese Medicine (Grant No. ZY2022YL05).

Advancing Preoperative Staging in Colorectal Cancer: Dual-Energy CT and Explainable AI Define Novel Risk-Stratifying Imaging Habitats (6 min)

LIHAO XIAO; Shanghai / China

Author Block: S. Xiang[1], L. XIAO[2]; [1]Chongqing/CN, [2]Shanghai/CN
Purpose: To develop and validate a machine learning (ML) model integrating dual-energy CT (DECT) features for the preoperative prediction of lymph node metastasis (LNM) in colorectal cancer, and to rigorously assess its incremental value and clinical utility.
Methods or Background: This retrospective study enrolled 210 colorectal cancer patients with preoperative DECT. They were randomly divided into training (n=168) and validation (n=42) cohorts. Using clinical, conventional CT, and DECT features, five nested models were built with five machine learning algorithms (including XGBoost) and rigorously evaluated. Validation performance was assessed by the AUC with 1000-bootstrapping and compared using the DeLong test. Clinical utility and interpretability were examined by decision curve analysis, reclassification, and SHAP analysis, while imaging phenotypes were identified via unsupervised clustering.
Results or Findings: The optimal XGBoost model, combining clinical data with lymph node features from both conventional and DECT imaging, achieved an AUC of 0.8882 (95% CI: 0.7780–0.9760) in the validation set. The addition of DECT features significantly improved predictive performance over a model with only conventional CT features (P=0.0153). DCA demonstrated a clear net benefit across a wide range of threshold probabilities (9%–86%). SHAP analysis identified a DECT-derived feature (arterial phase 100KeV CT value) as the single most important predictor. Furthermore, unsupervised clustering revealed three distinct "imaging habitats" that strongly correlated with LNM risk (30.2% vs. 42.1% vs. 82.4%).
Conclusion: An explainable ML model incorporating DECT features accurately predicts LNM in colorectal cancer and demonstrates clear clinical utility. DECT provides significant incremental diagnostic value over conventional imaging. This robustly validated approach, along with the novel concept of "imaging habitats," shows high potential for improving personalized risk stratification and guiding clinical decision-making.
Limitations: Small sample.
Funding for this study: No funding was received by this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Written informed consent obtained from all participants.

Cost-effectiveness analysis of dedicated MR imaging vs. surgical staging in patients with colorectal peritoneal metastases (6 min)

Max Lahaye; Amsterdam / Netherlands

Author Block: L. Van der Snee, A. Kramer, N. Kok, A. Aalbers, M. Lopez, V. Retel, M. Lahaye; Amsterdam/NL
Purpose: In patients with colorectal peritoneal metastases (PM-CRC), cytoreductive surgery with hyperthermic intraperitoneal chemotherapy (CRS-HIPEC) is potentially life-prolonging but carries substantial morbidity. Standard staging with computed tomography (CT) and diagnostic laparoscopy often results in preventable surgical procedures. The randomized multicenter DISCO trial demonstrated that adding diffusion-weighted magnetic resonance imaging (DW-MRI) reduces such procedures. This study evaluated the cost-effectiveness of additional DW-MRI in the Netherlands.
Methods or Background: A decision-analytic cohort model combined a decision tree of diagnostic strategies with a Markov model simulating survival. Patients were staged with either standard care (CT ± laparoscopy) or additional DW-MRI. Model inputs were derived from 149 Dutch patients randomized in DISCO (DW-MRI n=74, 49.7%; standard care n=75, 50.3%). Outcomes included short-term metrics (staging laparoscopies, CRS-HIPEC rates, diagnostic costs) and long-term outcomes (quality-adjusted life years [QALYs], total costs). Deterministic and probabilistic sensitivity analyses tested robustness.
Results or Findings: DW-MRI markedly reduced staging laparoscopies and lowered diagnostic costs, saving €2087 per patient. Over a lifetime horizon, DW-MRI yielded a gain of 0.162 QALYs and total cost savings of €455 compared with standard care. Both deterministic and probabilistic analyses confirmed cost-effectiveness. National implementation could generate annual diagnostic savings of ~€2.8 million.
Conclusion: Adding DW-MRI to the staging work-up for PM-CRC is a cost-effective strategy that reduces unnecessary surgical procedures and patient burden. In the Dutch healthcare setting, DW-MRI implementation would improve patient selection for CRS-HIPEC and result in significant cost savings.
Limitations: This analysis was based on Dutch trial data, and results may not fully generalize to healthcare systems with different surgical practices, cost structures, or MRI expertise.
Funding for this study: This study was investigator-initiated and sponsored by ZonMw. This study was approved by the Medical Ethics Committee of the Netherlands Cancer Institute (13 September 2019; NL70045.031.19) and registered in the ClinicalTrials.gov registry of the U.S.
National Library of Medicine (NCT04231175), and the study protocol was published in BMC Cancer (PMID: 33902498).

Correlation of FDG Uptake with Serum Tumor Markers in Gynecologic and Gastrointestinal Malignancies (6 min)

Farook Abubacker Sulaiman; Chennai / India

Author Block: F. Abubacker Sulaiman, S. Zainamb Begum, R. Praveenkumar, M. Nivitha, J. Lydia, A. Raashid Ibrahim; Chennai/IN
Purpose: To evaluate the correlation between ^18F-FDG uptake parameters on PET/CT and serum tumor markers in patients with gynecologic and gastrointestinal malignancies, and to assess their combined prognostic and diagnostic utility in disease characterization.
Methods or Background: A prospective study was conducted on 80 patients—40 with gynecologic (ovarian, endometrial, cervical) and 40 with gastrointestinal (colorectal, gastric, pancreatic) cancers—who underwent baseline ^18F-FDG PET/CT and serum tumor marker analysis (CA-125, CEA, and CA 19-9). Quantitative PET parameters including SUVmax, SUVmean, metabolic tumor volume (MTV), and total lesion glycolysis (TLG) were recorded. Correlations between imaging and biochemical markers were analyzed using Pearson's correlation coefficient and regression modeling. Diagnostic and prognostic significance were assessed against histopathologic grade and clinical stage.
Results or Findings: A strong positive correlation was observed between SUVmax and CA-125 in ovarian and endometrial carcinomas ($r = 0.76$, $p < 0.001$), and between SUVmax and CEA in colorectal cancer ($r = 0.71$, $p < 0.001$). Elevated TLG values correlated with advanced FIGO and TNM stages. Combined FDG and tumor marker evaluation improved detection of metastatic disease by 19% and provided better prognostic stratification for recurrence risk. Patients with discordantly high CA-125 or CEA and low FDG uptake demonstrated low-grade or mucinous histology, reflecting reduced glycolytic activity.
Conclusion: FDG uptake shows significant correlation with serum tumor markers in gynecologic and GI malignancies, supporting their complementary role in staging, prognosis, and treatment monitoring.
Limitations: Single-center study with modest sample size and absence of longitudinal follow-up. Multicentric validation is recommended to standardize combined metabolic–biochemical assessment.
Funding for this study: No external funding was received for this study.

Hypoxia-related functional MRI monitoring hypoxia rhythm in colorectal cancer for imaging-guided chemotherapy (6 min)

Yaqiong Wang; Shanghai / China

Author Block: Y. Wang[1], G. Miao[1], Y. Wang[1], C. Fu[2], W-R. Wei-Ren Liu[1], L. Liu[1]; [1]Shanghai/CN, [2]Shenzhen/CN
Purpose: Neoadjuvant chemotherapy is a standard approach for treating colorectal cancer, yet a significant proportion of patients exhibit resistance due to tumor hypoxia. This study aimed to evaluate the potential of intravoxel incoherent motion diffusion-weighted imaging (IVIM-DWI) and blood oxygenation level-dependent MRI (BOLD-MRI) techniques to non-invasively monitor tumor hypoxia dynamics and guide the timing of chemotherapy.
Methods or Background: Tumor-bearing mice were randomly assigned to control, unguided chemotherapy, and BOLD MRI-guided chemotherapy groups, with 5-fluorouracil administered according to either fixed schedules or BOLD-MRI-monitored hypoxia rhythms ($T2^* < 20$ ms or lower than last day).
Results or Findings: MRI-guided group achieving the lowest tumor-to-weight ratio (1.76 vs 2.20 in unguided and 5.59 in control). $T2^*$ values exhibited strong positive correlation with HIF-1α expression ($r = 0.6806$, $p = 0.0436$) and CD31 ($r = 0.7053$, $p = 0.0338$), and a very strong negative correlation with vascular maturity index (VMI) ($r = -0.8618$, $p = 0.0028$).
Conclusion: By identifying optimal oxygenation phases, BOLD-MRI can guide the timing of chemotherapy to align with periods of improved perfusion, demonstrating superior tumor suppression and stable IVIM value trends in the guided group. Therefore, hypoxia-related functional MRI provides a promising imaging-based framework for optimizing chemotherapy timing and evaluating therapeutic response in colorectal cancer.
Limitations: Not applicable.
Funding for this study: This work was supported by the National Natural Science Foundation of China (Grant No. 82371920), Shanghai Sailing Program (Grant No. 23YF1441700).

SA 16a - Rectal cancer: where do we stand and where do we go?

Categories: Oncologic Imaging, GI Tract, Evidence-Based Imaging, Artificial Intelligence, President's Choice
ETC Level: LEVEL II+III
Date: March 6, 2026 | 16:00 - 17:30 CET
CME Credits: 1.5

Moderator:
Sofia Gourtsoyianni; Athens / Greece

Chairperson's introduction (3 min)
Sofia Gourtsoyianni; Athens / Greece

Where do we stand? Primary rectal cancer staging (18 min)
Svetlana Balyasnikova; London / United Kingdom

1. To discuss the role of imaging in early rectal cancers.
2. To learn about sphincter complex anatomy in relation to low rectal cancers.
3. To become familiar with extra TNM prognostic imaging markers such as EMVI and mesorectal fascia involvement.

Where do we stand? Restaging (18 min)
Inês Santiago; Parede / Portugal

1. To outline the key criteria for high-quality MR imaging and recognise common pitfalls in image interpretation following neoadjuvant therapy.
2. To explore the role of MRI in assessing rectal cancer response, focusing on its influence on curative surgical planning and patient selection for organ preservation strategies.
3. To identify MR imaging features indicative of a clinical complete response.

Where do we go? Functional imaging techniques and DWI (18 min)
Doenja Marina Johanna Lambregts; Amsterdam / Netherlands

1. To understand how DWI and other functional imaging may guide decision-making in the clinical management of rectal cancer.
2. To know emerging trends and future developments in functional imaging, including MRI and DWI technology advances.
3. To be familiar with the key limitations and challenges of these techniques.

Where do we go? Use of radiomics and AI (18 min)
Damiano Caruso; Rome / Italy

1. To understand the principles of radiomics and artificial intelligence (AI) in the context of rectal cancer imaging, including the workflow from image acquisition to data extraction and model development.
2. To evaluate the current and emerging applications of radiomics and AI in rectal cancer for diagnosis, staging, treatment response assessment, and outcome prediction.
3. To identify the main challenges and future directions for the clinical integration of radiomics and AI, including validation strategies, regulatory considerations, and multidisciplinary collaboration.

Panel discussion: Enhanced structured reporting or not? (15 min)

SA 16b - Prostate MRI scoring systems: what is new and what we still need?

Categories: Oncologic Imaging, Genitourinary, President's Choice

ETC Level: LEVEL II+III

Date: March 6, 2026 | 16:00 - 17:30 CET

CME Credits: 1.5

This session reviews the various scores recently published to enhance the quality of prostate MRI reports. Their primary goal is to reduce subjective assessments of acquisition quality, active surveillance progression, or the likelihood of recurrence after treatment by offering clear scores based on validated, universally understood objective criteria. Using these scores improves the quality of prostate MRIs and strengthens the role of the radiologist and imaging in cancer management.

Moderator:

Philippe Puech; Lille / France

Chairperson's introduction (5 min)

Philippe Puech; Lille / France

Active surveillance (PRECISE) (15 min)

Imaging the lymphatic system (15 min)
Claus Christian Pieper; Bonn / Germany

1. To learn the current techniques and modalities available for imaging the lymphatic system.
2. To appreciate the clinical indications and diagnostic value of lymphatic imaging in various pathologies.
3. To understand the anatomy and physiology of the lymphatic system as visualised through imaging.

Lymphatic embolisation (15 min)
Geert Maleux; Tienen / Belgium

1. To learn the procedural steps and materials used in lymphatic embolisation.
2. To appreciate the role of embolisation in the management of lymphatic leaks and disorders.
3. To understand patient selection, outcomes, and potential complications associated with this intervention.

Chronic venous insufficiency and varicose vein treatment (15 min)
Miltiadis Krokidis; Athens / Greece

1. To learn about modern interventional treatments for chronic venous insufficiency and varicose veins.
2. To appreciate the clinical impact and quality-of-life improvements following treatment.
3. To understand the pathophysiology and progression of chronic venous disorders.

Interventional solutions for venous disease in pregnancy and postpartum (15 min)
Maria Tsitskari; Nicosia / Greece

1. To learn the safe and effective interventional approaches for managing venous disease during pregnancy and postpartum.
2. To appreciate the unique physiological challenges and considerations in this patient population.
3. To understand indications, risks, and outcomes of venous interventions in pregnant and postpartum patients.

Panel discussion: What specific areas need more evidence to guide practice? (20 min)

SF 16b - Advances in multiple sclerosis (MS): exploring the new McDonald criteria and emerging imaging biomarkers

Categories: Neuro, Paediatric, Education, President's Choice
ETC Level: LEVEL II

The 2024 McDonald criteria: key updates and clinical implications (18 min)
Alejandro Rovira Cañellas; Barcelona / Spain

1. Toidentify and describe the major revisions in the 2024 McDonald criteria.
2. Toapply the updated criteria to real-world clinical scenarios.
3. Toassess the clinical implications for early diagnosis and treatment decisions.

The 2024 McDonald criteria in paediatric MS: special considerations and challenges (18 min)
Amarnath Chellathurai; Chennai / India

1. To highlight paediatric-focused updates in the 2024 update of the McDonald's criteria.
2. To discuss persistent and emerging diagnostic challenges in paediatric MS.
3. To address current barriers and future needs in imaging of paediatric MS.

Optic nerve imaging in MS: role, timing and techniques (18 min)
Emanuele Pravatà; Chieti / Italy

1. To describe the rationale behind and the emerging demands for MRI of the anterior visual pathways in multiple sclerosis and related diseases.
2. To outline the anatomical basis, technical challenges, and current capabilities of MRI techniques.
3. Tosummarise current knowledge regarding disease distribution patterns along the anterior optic pathways, in both acute and asymptomatic conditions.

MRI biomarkers for monitoring disease progression: are they ready for routine use? (18 min)
Yukio Miki; Osaka / Japan

1. To review conventional MRI-based biomarkers used for disease monitoring in MS, including T2-lesion volume, contrast-enhancing lesions, and brain atrophy.
2. To review advanced MRI-based biomarkers for monitoring disease progression in MS, including magnetisation transfer imaging, diffusion metrics, and myelin-related imaging.
3. To discuss the readiness of MRI biomarkers for monitoringdisease progression in MS.

Panel discussion: New criteria: impact on radiological practice (13 min)

Case review (25 min)
Harriet Thoeny; Bern / Switzerland

1. To become familiar with typical prostate cancer in the peripheral zone.
2. To know the imaging findings of transition zone tumours.
3. To know the most frequent differential diagnoses.

ESR Education 17 - The radiologist's role in medical education: sharing knowledge without losing authority

Categories: Professional Issues, Education
ETC Level: LEVEL II+III
Date: March 7, 2026 | 08:00 - 09:00 CET
CME Credits: 1

Moderator:
Amelie Lutz; Kreuzlingen / Switzerland

Chairperson's introduction (5 min)
Amelie Lutz; Kreuzlingen / Switzerland

Empowering through imaging: why all referrers benefit from radiology literacy? (10 min)
Boris Brkljačić; Zagreb / Croatia

1. To understand the evolving role of radiologists in medical education and interdisciplinary teaching.
2. To recognise how radiologists support non-radiologists in selecting appropriate imaging tests and interpreting results accurately.
3. To explore practical strategies to enhance radiology literacy and foster effective collaboration across specialities.

Walking the line: sharing imaging expertise without undermining our speciality (10 min)
Liesbeth Peters-Bax; Nijmegen / Netherlands

1. To explore how radiologists can share imaging expertise while contributing to the education of other healthcare professionals.
2. To understand the importance of balancing interdisciplinary collaboration with preserving the unique identity of the radiology speciality.
3. To identify strategies for positioning radiologists as the leading authorities in imaging interpretation.

Radiology education as a catalyst for multidisciplinary collaboration (10 min)
Regina G.H. Beets-Tan; Amsterdam / Netherlands

1. To learn how radiology education strengthens teamwork and improves patient care.
2. To recognise the impact of radiologist-led training in enhancing communication, diagnostic efficiency and clinical accuracy.
3. To understand how integrating imaging education into multidisciplinary teams can strengthen the radiologist's role as a leader in healthcare delivery.
4. To discuss whether and how integrating diagnostic biomarkers (integrated diagnosis) would impact radiologists' role and education.

Panel discussion: How do we share knowledge without losing visibility, authority or leadership? (25 min)

How 17 - How we perform image-guided abdominal interventions in everyday radiological practice

Categories: Emergency Imaging, GI Tract, Interventional Radiology, Abdominal Viscera, President's Choice
ETC Level: LEVEL I+II
Date: March 7, 2026 | 08:00 - 09:00 CET
CME Credits: 1

Moderator:
Christoph D. Becker; Geneva / Switzerland

Chairperson's introduction (2 min)
Christoph D. Becker; Geneva / Switzerland

Percutaneous liver biopsy (15 min)
Hannah Lambie; Leeds / United Kingdom

1. To become familiar with the indications and results of percutaneous liver biopsy.
2. To learn about the different biopsy systems (coaxial systems, end-cut versus side notch).
3. To understand tips and tricks for choosing the best image guidance (US/CT) and optimising the technique of needle placement.

Percutaneous abscess drainage (15 min)
Viktors Linovs; Riga / Latvia

1. To become familiar with the indications and results of percutaneous abscess drainage.
2. To understand tips and tricks for optimising the technique and choosing the right drainage size.
3. To learn about appropriate follow-up for drain removal and strategies for long-term salvage.

Percutaneous cholecystostomy (15 min)
Miltiadis Krokidis; Athens / Greece

1. To understand the clinical indications, contraindications, and patient selection criteria for percutaneous cholecystostomy, particularly in acute cholecystitis and critically ill patients unfit for surgery.
2. To become familiar with the imaging guidance methods and technical steps of the procedure, including transhepatic versus transperitoneal approaches, catheter types, and imaging modalities used.
3. To learn about post-procedural management principles and complications, and discuss the role of percutaneous cholecystostomy as a bridge to surgery versus definitive therapy.

Open forum discussion (13 min)

OF 17 - Towards regulatory-ready AI in radiology: integrating new approach methods and virtual clinical trials

Categories: General Radiology, Physics in Medical Imaging, Imaging Informatics, Education, Artificial Intelligence
ETC Level: LEVEL I+II
Date: March 7, 2026 | 08:00 - 09:00 CET
CME Credits: 1

Moderator:

Chairperson's introduction (5 min)
Federica Zanca; Leuven / Belgium

Scientific validity and standardisation of new approach methods (NAMs) and virtual clinical trials (VCTs) in AI radiology (12 min)
Ehsan Samei; Durham / United States

1. To understand how R&I are advancing the scientific foundations of NAMs and VCTs for AI applications in radiology.
2. To review scientific frameworks for simulation reproducibility, interoperability, and benchmarking, and how they inform regulatory-science principles.
3. To connect these developments to ongoing European and global initiatives aiming at establishing reliable, ethically sound, and regulation-ready approaches for AI validation in medical imaging.

The industry perspective: how SMEs use virtual trial to generate regulatory-grade evidence for AI (12 min)
Bruno Virieux; Saint-Étienne / France

1. To explore how innovators use synthetic and virtual data to train and validate AI tools in imaging.
2. To understand how NAMs and VCTs can address data scarcity, bias, and patient privacy challenges.
3. To identify opportunities and barriers to integrating NAM-based and virtual evidence into regulatory submissions.

The regulatory viewpoint: accepting simulation-based evidence for AI in radiology (14 min)
Richard Holborow; Newport / United Kingdom

1. To review the evolving US/EU regulatory framework for AI-based medical imaging devices.
2. To discuss how simulation-based validation can support conformity assessment and clinical evaluation.
3. To outline pathways for recognition of virtual evidence in European regulatory practice.

Open forum discussion

SESSION RECOMMENDED BY ESR EUROSAFE IMAGING

Moderators:
Valeria Panebianco; Rome / Italy
Diana Adliene; Kaunas / Lithuania

Chairpersons' introduction (5 min)
Valeria Panebianco; Rome / Italy
Diana Adliene; Kaunas / Lithuania

Setting the scene: foetal doses and associated risks in diagnostic imaging and beyond (11 min)
Agnieszka Kuchcinska; Warsaw / Poland

1. To evaluate the risks from ionising radiation to the foetus, and what are the international recommendations concerning risk assessment.
2. To be aware of the order of magnitude of foetal doses in different diagnostic and therapeutic procedures.
3. To understand how to communicate and support pregnant patients who need diagnosis or treatment with ionising radiation.

Behind the optimisation: foetal dose-management in radiology procedures (11 min)
Natalia Saltybaeva; Baar / Switzerland

1. To understand how we can optimise medical imaging for pregnant patients to minimise foetal dose by modifying acquisition parameters.
2. To be aware of the type and accuracy of the methods and tools available for foetal dose estimation.
3. To understand and act according to local regulations concerning unintended exposure while considering the spirit of the international recommendation on this topic.

Clinical indications and existing guidelines for imaging pregnant patients (11 min)
Charis Bourgioti; Athens / Greece

1. To remind of the clinical scenarios justifying imaging in pregnant patients.
2. To enumerate current guidelines for the safe use of X-ray, CT, MRI, and ultrasound when required during pregnancy.
3. To learn about low-dose CT and non-contrast MRI advancements for safer imaging.

Focus on renal stone imaging in emergency (11 min)
Sudhir Kumar Kale; Bengaluru / India

1. To detail current indications requiring urgent imaging evaluation during pregnancy.
2. To learn how to evaluate ultrasound, low-dose CT, and MRI for safe stone diagnosis of stone migration during pregnancy.
3. To explore dual-energy CT and advanced ultrasound for improved renal stone detection with minimal radiation.

Panel discussion: Evidence vs. perception - are we too conservative in imaging pregnant patients? (11 min)

RC 1701 - Small bowel obstruction: let’s stop wandering!

Categories: Emergency Imaging, Evidence-Based Imaging, Contrast Media, Abdominal Viscera, President's Choice

Standardised protocols and diagnostic approach using CT (15 min)
Damian John Michael Tolan; Leeds / United Kingdom

1. To define key CT acquisition parameters and oral contrast strategies.
2. To describe a structured CT reporting approach.
3. To discuss the possible role of MRI and ultrasound.

Adhesive-related small bowel obstruction: diagnostic criteria for identifying severe cases (15 min)
Marc Zins; Paris / France

1. To recognise early signs of bowel ischemia and closed-loop obstruction.
2. To assess the predictive value of specific CT findings (e.g. decreased enhancement, mesenteric congestion).
3. To guide urgent surgical decision-making based on imaging.

When it’s not an adhesive band: looking beyond the obvious (15 min)
Luis Guimaraes; Porto / Portugal

1. To identify less common causes of small bowel obstruction: neoplasms, internal hernias, endometriosis, and inflammatory diseases.
2. To review imaging strategies for tricky and subtle cases.
3. To propose diagnostic algorithms based on clinical and imaging clues.

Panel discussion: CT as the decision tool: how far can we go? (12 min)

RC 1702 - Breast imaging in 2026

Categories: Imaging Methods, Breast, Contrast Media

The role of tomosynthesis in a world of contrast imaging (15 min)
Sophia Zackrisson; Malmö / Sweden

1. To understand the fundamental differences between contrast-enhanced imaging and tomosynthesis by exploring how each technique works and what their individual roles in breast imaging are.
2. To evaluate the complementary roles of contrast-enhanced imaging and tomosynthesis in clinical practice and how they may be combined.
3. To assess future potential and technological advancements for both imaging techniques.

Contrast-enhanced mammography (CEM) vs MRI: are they comparable across all indications? (15 min)
Paola Clauser; Vienna / Austria

1. To identify the specific clinical indications for which CEM and MRI are used in breast imaging.
2. To evaluate diagnostic accuracy in various clinical scenarios, explore each technique's advantages and limitations.
3. To explore patient preferences and experiences with CEM and MRI, considering factors such as comfort, accessibility, and cost.

AI in clinical practice: what's working now? (15 min)
Nisha Sharma; Leeds / United Kingdom

1. To identify and describe how diagnostic AI technologies are currently being used in breast imaging, in both the screening and symptomatic settings.
2. To explore the challenges and best practices for integrating AI into existing clinical systems and workflows.
3. To discuss the practical considerations for breast imagers, such as training of staff, adoption barriers, and the future potential of AI in breast imaging.

Panel discussion: What will breast imaging look like in 2030? (10 min)

RC 1703 - Structural heart disease: measurements, reporting and complications

Surgical and transcatheter aortic valve implantation (15 min)
Ricardo P. J. Budde; Rotterdam / Netherlands

1. To describe the technique of surgical and transcatheter aortic valve implantation procedures.
2. To describe the role of CT imaging in planning and post-procedural evaluation of valve interventions.
3. To recognise the most important CT imaging findings of complications after valve interventions and surgery.

Atrioventricular valve repair and replacement (15 min)
Giuseppe Muscogiuri; Rome / Italy

1. To demonstrate the complex anatomy of the mitral annulus.
2. To describe potential strategies for mitral valve repair and replacement.
3. To understand the relevance of CT-based measurements for mitral valve interventions.

Atrial cardiomyopathy: preinterventional imaging (15 min)
Carl Guillaume Glessgen; Geneva / Switzerland

1. To define atrial cardiomyopathy and identify its pathological hallmarks.
2. To summarise the aims of pre-AF ablation imaging.
3. To differentiate procedural planning markers from prognostic features.

Q&A (10 min)

RC 1707 - Different faces of endometriosis: a diagnostic challenge

Imaging strategy according to clinical context (15 min)
Ludovico Muzii; Rome / Italy

1. To learn about endometriosis and fertility sparing from a gynaecologist's perspective.
2. To understand the imaging strategy in endometriosis patients with chronic pain.
3. To understand what the surgeon needs to know before surgery and the surgical landmarks of interest.

Adnexal endometriosis: value of the combination of different techniques (15 min)
Susan Freeman; Cambridge / United Kingdom

1. To understand the role of ultrasound in managing patients with endometriosis.
2. To understand the role of MRI in managing patients with endometriosis.
3. To learn about the imaging features of malignant transformation of endometriosis.

Deep endometriosis: how I read an MRI so as not to miss any location? (15 min)
Miriam Dolciami; Rome / Italy

1. To understand the role of MRI in diagnosing deep endometriosis.
2. To learn about the diagnostic accuracy and pitfalls of MRI
3. To understand the clinical implications of imaging.

Panel discussion: How to use the new imaging guidelines in clinical practice? (10 min)

RC 1708 - Sinonasal and dental imaging

Surgically relevant sinonasal anatomy: how do I analyse and structure my report? (15 min)
Philip Touska; London / United Kingdom

1. To understand the complex anatomy of the sinonasal region, including critical surgical landmarks and common anatomical variants relevant to endoscopic sinus surgery.
2. To learn a structured and standardised approach to analysing sinonasal CT scans using checklists or mnemonics (e.g., CLOSE) to ensure all surgically important areas are assessed and reported.
3. To develop skills to produce clear, clinically relevant, and structured radiology reports that enhance communication with ENT surgeons and improve surgical planning and patient outcomes.

Imaging complicated acute sinonasal and dental infections (15 min)
Jussi Hirvonen; Turku / Finland

1. To recognise the imaging features of complicated acute sinonasal infections, including extension beyond the sinuses and involvement of adjacent structures on CT and MRI.
2. To understand the role of imaging in differentiating sinonasal infections from dental infections and identifying potential complications such as abscess formation or osteomyelitis.
3. To develop a diagnostic checklist of not-to-be-missed findings to guide timely and appropriate management of complicated sinonasal and dental infections.

How I report odontogenic tumours: pearls and pitfalls (15 min)
Ingrid Rozylo-Kalinowska; Lublin / Poland

1. To understand the typical imaging characteristics of odontogenic tumours (e.g., ameloblastomas, keratocystic odontogenic tumours) on CBCT, CT and MRI.
2. To learn to use advanced MRI techniques, including contrast enhancement and diffusion-weighted imaging (DWI), to differentiate odontogenic tumours based on signal intensity patterns, wall thickness, and internal architecture.
3. To develop a systematic approach to interpreting imaging findings to accurately distinguish between benign and potentially aggressive tumours, aiding diagnosis and treatment planning.

Panel discussion: Let’s talk anatomy: reporting that matters in the operating theatre (10 min)

RC 1711 - Miscellaneous diseases of the CNS: navigating diagnostic challenges

Categories: Emergency Imaging, Neuro

Brain infections in disguise: radiologic pitfalls and pearls in complex hosts (16 min)
Ana Ramos Gonzalez; Madrid / Spain

1. To learn to recognise typical and atypical imaging patterns of brain infections in immunocompromised and clinically complex patients.
2. To understand common diagnostic pitfalls and how the appropriate choice of imaging technique and timing can help avoid misinterpreting infectious findings.
3. To gain practical strategies to improve diagnostic accuracy and support clinical decision-making in this increasingly diverse and challenging population.

Decoding non-multiple sclerosis central nervous system demyelinating disorders (16 min)
Majda M. Thurnher; Vienna / Austria

1. To develop a solid approach to identifying CNS demyelination beyond classic multiple sclerosis, using appropriate imaging protocols and updated diagnostic strategies.
2. To learn how to differentiate key patterns in inflammatory and autoimmune demyelinating conditions, including recognising newer radiological features.
3. To understand when to consider alternative diagnoses and how radiological interpretation can guide early classification and influence patient management.

Toxins in the brain: essential insights for radiologists on creating clinically useful reports (16 min)
Leandro Tavares Lucato; São Paulo / Brazil

1. To become familiar with the imaging presentations of toxic and metabolic brain disorders, and learn to recognise patterns suggestive of specific underlying etiologies.
2. To understand when to consider a toxic-metabolic process and how to incorporate it meaningfully into your differential diagnosis.
3. To learn how to tailor your report to highlight findings that support clinical suspicion, inform prognosis, and prompt appropriate follow-up.

Q&A (10 min)

RC 1712 - Imaging of congenital cardiothoracic anomalies

Categories: Paediatric, Chest, Cardiac
ETC Level: LEVEL II+III
Date: March 7, 2026 | 08:00 - 09:00 CET

Chairperson's introduction (5 min)
Marek Kardos; Bratislava / Slovakia

Imaging of congenital lung anomalies (15 min)
Georgia Papaioannou; Athens / Greece

1. To learn about the most common congenital lung anomalies.
2. To list the typical imaging features that outline the diagnosis from fetal life to childhood, affect treatment choices and differentiate from other entities.
3. To clarify the imaging approach during diagnosis and follow-up of these lesions.

Congenital anomalies of the pulmonary arteries and veins (15 min)
Charlotte de Lange; Gothenburg / Sweden

1. To learn about the most common anomalies in the pulmonary arteries and veins.
2. To describe the typical anomalies according to age and time point of presentation.
3. To discuss the choice of imaging in a pre- and post-operative situation.

Vascular rings and slings (15 min)
Maria Navallas Irujo; Barcelona / Spain

1. To illustrate the most common and relevant anomalies.
2. To discuss the role of different imaging techniques in the diagnosis of these lesions.
3. To share simple imaging tips and tricks to facilitate accurate diagnosis.

Panel discussion: Can MRI replace CT in imaging of congenital cardiothoracic anomalies? (10 min)

RC 1713 - Clinical testing processes for artificial intelligence applications in radiology: from procurement to validation and quality control

Categories: Physics in Medical Imaging, Imaging Informatics, Medico-legal, Multidisciplinary, Artificial Intelligence

Brenda Byrne; Dublin / Ireland

Optimising AI application procurement: key considerations for integration and compliance in radiology workflows (15 min)
Maciej Bobowicz; Gdańsk / Poland

1. To identify essential technical, clinical, and regulatory criteria for evaluating AI solutions during the procurement process.
2. To understand the legal, ethical, and compliance considerations involved in AI procurement, including data privacy, cybersecurity, and adherence to local and international standards (e.g., Conformité Européenne (European CE mark), Food and Drug Administration (FDA), General Data Protection Regulation (GDPR)).
3. To assess strategies for effectively integrating AI applications into existing radiology workflows, ensuring compatibility with PACS/RIS systems, user experience optimisation, and clinician acceptance.

Clinical validation of AI applications in radiology (15 min)
Teemu Mäkelä; Helsinki / Finland

1. To understand the key phases of clinical validation for radiology AI applications.
2. To identify critical success factors and common pitfalls in designing and executing clinical validation processes.
3. To evaluate the role of stakeholders (medical physicists, radiologists, radiographers, IT support, clinicians, data scientists, and regulatory bodies) in shaping validation strategy, and how validation outcomes inform procurement decisions and quality assurance processes.

Ensuring quality and safety in AI-driven radiology systems (15 min)
Merel Huisman; Nijmegen / Netherlands

1. To describe the main principles and frameworks for assessing the quality and safety of AI systems in radiology, including performance monitoring, error analysis, and compliance with clinical standards.
2. To recognise potential risks and failure modes in the deployment of AI tools within radiological workflows, and explore strategies for mitigating harm through continuous validation and human-AI collaboration.
3. To apply best practices for post-deployment surveillance, auditing, and quality assurance, ensuring AI applications maintain clinical effectiveness and safety across diverse patient populations and imaging environments.

Panel discussion: How could we test AI applications before implementing them into clinical practice, taking into account the size and resources of the hospital/department? (10 min)

RC 1715 - Acute aortic syndromes: state-of-the-art imaging and treatment

Meta-Analysis of AI-Assisted Detection of Liver Lesions in Multiphasic CT (6 min)
Yousef Ahmed Sliem; Giza / Egypt

Author Block: Y. A. Sliem, M. A. Shaaban; 6th of October City/EG
Purpose: Perform a meta-analysis evaluating the diagnostic accuracy of AI-assisted multiphasic CT for detection and characterization of liver lesions and to compare AI performance with conventional interpretation.
Methods or Background: Background:Early and accurate detection of hepatic lesions,including primary hepatocellular carcinoma and metastases,is critical for patient prognosis and treatment planning.Multiphasic CT is a standard imaging modality; however;radiologist interpretations can be subjective and time-intensive,with potential for missed small or subtle lesions. Artificial intelligence(AI),particularly convolutional neural networks (CNNs), has been increasingly applied to medical imaging for automated lesion detection and characterization.

Methods: A systematic literature search was conducted in PubMed, Embase, and Scopus from January 2015 to June 2025 for studies evaluating AI-assisted detection of liver lesions on multiphasic CT. Inclusion criteria were original studies reporting sensitivity and specificity, comparison with radiologists, and histopathology or follow-up as the reference standard.Data were extracted independently by two reviewers.Pooled sensitivity,specificity,positive predictive value(PPV), negative predictive value(NPV),and diagnostic odds ratios(DOR)were calculated using random-effects model.Heterogeneity was assessed with I^2 statistics,and publication bias was evaluated using funnel plots.
Results or Findings: Thirteen studies(n=3,400 patients)met inclusion criteria. Pooled sensitivity and specificity of AI-assisted detection were 93%(95% CI: 90–95%)and 91%(95% CI: 88–94%),respectively.PPV and NPV were 90% and 94%.The diagnostic odds ratio was 145(95% CI: 110–180).AI outperformed radiologists in small lesion detection(<1 cm)with an odds ratio of 2.1($p<0.01$).Interobserver agreement increased with AI assistance(Cohen's kappa from 0.73 to 0.88).Subgroup analyses showed consistent performance across primary and metastatic lesions and various CT protocols. Moderate heterogeneity was observed($I^2=45\%$).
Conclusion: AI-assisted multiphasic CT demonstrates high diagnostic accuracy for liver lesion detection and can enhance radiologist performance, particularly for small lesions. Integration of AI into clinical workflow may improve early diagnosis,reduce variability,and optimize patient management.
Limitations: Future research should focus on prospective multicenter validation and cost-effectiveness analyses.
Funding for this study: None
Has your study been approved by an ethics committee? Not applicable

Short MRI Surveillance (SMS) for hepatocellular carcinoma screening: preliminary results of the prospective multicentre SMS-HCC study (6 min)
Céline Van De Braak; Rotterdam / Netherlands

Author Block: C. Van De Braak, F. Willemssen, R. De Man, A. Van Der Lugt, D. Bos, R. S. Dwarkasing, .. SMS Consortium; Rotterdam/NL
Purpose: Current guidelines recommend biannual ultrasound (US) screening for high-risk patients for developing hepatocellular carcinoma (HCC), however it has limited sensitivity for early-stage detection of 47%. Our aim is to validate a Short MRI Surveillance (SMS)-protocol for HCC screening, and compare this to US in a prospective multicentre study. Here, we present our preliminary results.
Methods or Background: From November 2023, patients included from the current HCC surveillance programme underwent paired US-MRI screening. The abbreviated MRI (aMRI) was performed on 1.5/3.0-T systems from different vendors, using dedicated 8-16 channel range body coil. The SMS-protocol consisted of T1W in-out phase, T2W with fat saturation, and DWI. One radiologist evaluated both US and aMRI images, while two additional radiologists solely evaluated aMRI images. Statistical analyses included inter-rater reliability- and sensitivity/specificity analysis.
Results or Findings: For final analyses, 82 participants were included. The most common indication was hepatitis B (53.7%), and cirrhosis (32.9%). Based on US, a total of 20 lesions were found in 11 patients, whereas aMRI detected 132 lesions in 29 patients. Most findings were benign, except for two lesions that were noted on SMS, but undetected on US, and proved to be ≥ LIRADS-3 on subsequent contrast-enhanced MRI, i.e. the golden standard. There was substantial agreement between the readers (Gwet's AC1: 0.70). There was no difference in sensitivity/specificity between US and SMS for detection of suspicious lesions (0.50/0.99, and 0.50/1.00, respectively).
Conclusion: Our preliminary results provide a proof of principle that aMRI can be a potential screening modality for HCC surveillance. At this timepoint, with the low number of events, no difference between the sensitivity/specificity of US and SMS could be established. Ongoing enrolment and follow-up are expected to provide more insight.
Limitations: Preliminary findings due to ongoing inclusions
Funding for this study: Funding was provided by a grant of the Dutch Cancer Society (KWF, grant number: 2021-2/13803)
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was approved by the institutional review board, and written informed consent was obtained from all participants.

Abbreviated MRI for Hepatocellular Carcinoma Screening: A meta-analysis and Cost-effectiveness (6 min)

Lulu Jia; Lanzhou / China

Author Block: L. Jia, J. Lei; Lanzhou/CN
Purpose: While ultrasound has low sensitivity for hepatocellular carcinoma(HCC) screening in high-risk patients, this is particularly pronounced in the growing population with non-viral liver disease (e.g., MASH/NAFLD). This meta-analysis aimed to evaluate the diagnostic accuracy and cost-effectiveness of abbreviated MRI (AMRI) specifically in this subpopulation, and to compare the performance of different AMRI protocols.
Methods or Background: PubMed, Embase, Cochrane Library, and Web of Science databases were searched for studies published from inception to March 2025. A pre-specified subgroup analysis was performed for studies focusing on patients with non-viral etiologies of liver disease. Additionally, we directly compared the diagnostic accuracy of hepatobiliary phase AMRI (HBP-AMRI) versus non-contrast AMRI (NC-AMRI) protocols. qualitatively compared the cost-effectiveness of AMRI protocol with ultrasound in HCC screening.
Results or Findings: 17 studies (including 3290 high-risk patients) characterized the accuracy of AMRI for surveillance of HCC. The pooled sensitivity and specificity were 88% (95% CI: 84,91) and 95% (95% CI: 92,96). Six studies directly compared diagnostic accuracy of AMRI and ultrasound monitoring end-to-end, the sensitivity of ultrasound was significantly lower at 39% (95% CI: 23,57) than the sensitivity of AMRI at 82% (95% CI: 0.74,0.88, $p < 0.001$). Hepatobiliary phase contrast-enhanced AMRI (HBP-AMRI) had higher sensitivity than non-contrast AMRI (NC-AMRI) (91% [95% CI: 87, 95] vs 86% [95% CI: 82, 90], p □0.001),also higher than contrast enhanced AMRI (CE-AMRI) (91% [95% CI: 87, 95] vs 90% [95% CI: 86, 95], p □0.001). Most studies found semi-annual abbreviated MRI cost-saving versus ultrasound.
Conclusion: Abbreviated MRI demonstrates high performance in HCC screening for patients with both viral and non-viral liver disease and is cost-effective or cost-saving.

A Multicenter Multinational Retrospective Study of the 1-Year Natural History of LI-RADS 3 Observations in Patients with Cirrhosis (6 min)

Luigi Asmundo; Milan / Italy

Author Block: L. Asmundo[1], N. Mercaldo[2], A. J. Herold[3], F. Vernuccio[4], D. V. Sahani[2], M. Renzulli[5], G. Brancatelli[4], A. Vanzulli[1], O. A. Catalano[2]; [1]Milan/IT, [2]Boston, MA/US, [3]Vienna/AT, [4]Palermo/IT, [5]Bologna/IT
Purpose: To assess the 1-year natural history of LI-RADS 3 observations on contrast-enhanced MRI in cirrhotic patients across multiple international centers, and to identify clinical and imaging predictors of progression using multivariable and machine learning models.
Methods or Background: This retrospective study included 347 cirrhotic patients with 540 LI-RADS 3 observations from six centers across three countries, each with 12-month MRI follow-up. Observations were reassessed using LI-RADS v2018 criteria. Generalized linear mixed-effects models and machine learning (LASSO, random forest) evaluated predictors of progression. Area under the curve (AUC) analysis assessed the predictive performance of clinical and imaging variables.
Results or Findings: Within one year, 27% of LI-RADS 3 observations progressed: 13% to LI-RADS 4 and 14% to LI-RADS 5. Independent predictors of progression included lesion size (OR: 1.12, 95% CI: 1.01–1.24), Child-Pugh Class C (OR: 8.36, 95% CI: 1.01–69.27), and alcohol-related liver disease (OR: 0.24, 95% CI: 0.06–0.94). Enhancing capsule and untreated HCV were significant in univariable analysis. Imaging features improved predictive accuracy, increasing AUC from 0.65 to 0.72 ($p = 0.01$). A lesion size cut-off of 9.5 mm was associated with increased progression risk.
Conclusion: One in four LI-RADS 3 observations progress within one year. Lesion size, liver function, and etiology are key predictors. Integration of imaging features enhances risk stratification and supports more personalized follow-up strategies for indeterminate liver lesions.
Limitations: The potential selection bias and variability in imaging protocols across centers. Follow-up was limited to contrast-enhanced MRI within 12 months, excluding some patients. Reliance on imaging rather than histopathology may have caused misclassification. Ancillary features were applied in LI-RADS categorization but not independently analyzed to reduce inter-reader variability.
Funding for this study: This research received no external funding.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Institutional review board approval was obtained and informed consent was waived due to the retrospective design. Patient-identifiable information remained secure and encrypted on site servers.

Routes to hepatocellular carcinoma diagnosis: A UK-based multicentre service evaluation (6 min)

Aiman Aslam; London / United Kingdom

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: A. Aslam[1], J. Cowen[2], T. Parry[1], E. J. Wigmore[3], N. Abimanue[2], A. Gangi-Burton[4], A. Aravinthan[4], J. Franklin[5]; [1]London/UK, [2]Portsmouth/UK, [3]Manchester/UK, [4]Nottingham/UK, [5]Bournemouth/UK
Purpose: Six-monthly surveillance for patients with hepatitis B or cirrhosis aims to detect hepatocellular carcinoma (HCC) at an earlier, and more treatable, stage. This UK-based multi-centre service evaluation described the proportion, demographics, and staging of HCC patients diagnosed through surveillance, symptomatically, or incidentally.
Methods or Background: This retrospective service evaluation was conducted by the Radiology Academic Network for Trainees (RADIANT). Consecutive patients with a first diagnosis of HCC from 1st January 2020 across 14 centres were included. Data were collected from electronic patient records and Radiology Information Systems, and presented using descriptive statistics.
Results or Findings: A total of 723 patients were included (79% [570/723] male, median 71 years [IQR 64-77]). Only 28% (201/723) were diagnosed with HCC through surveillance, whilst 48% (346/723) were diagnosed through symptomatic presentation and 24% (176/723) incidentally. Although 51 % (369/723) of patients had known cirrhosis pre-diagnosis, only 36% (257/723) had been enrolled in a local surveillance programme. A further 20% of patients (143/723) were confirmed to have cirrhosis at diagnosis. Surveillance-diagnosed patients were younger (median 67 years [IQR 61-74]) compared to symptomatic (median 72 years [IQR 65-79]) or incidental (median 73 years [IQR 65-79]) groups, and also had a greater proportion of BCLC 0/A HCC (55%, 110/201), compared to symptomatic (26%, 91/346) or incidental (35%, 62/176) groups. Patients diagnosed symptomatically had highest proportions of ascites, vascular invasion, metastases, and lowest 3-, 6-, and 12-month survival.
Conclusion: In the UK, most patients with HCC are diagnosed outside of surveillance. Surveillance-diagnosed patients are identified at earlier stages of disease, with lower mortality rate, reinforcing the need to improve how we identify high-risk patients, enrol and maintain these patients in surveillance, and deliver surveillance itself.
Limitations: Retrospective design.

Adherence to ultrasound surveillance for hepatocellular carcinoma: A UK-based multicentre service evaluation (6 min)

Aiman Aslam; London / United Kingdom

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: E. J. Wigmore[1], N. Abimanue[2], T. Parry[3], A. Aslam[3], J. Cowen[2], A. Gangi-Burton[4], A. Aravinthan[4], J. Franklin[5]; [1]Manchester/UK, [2]Portsmouth/UK, [3]London/UK, [4]Nottingham/UK, [5]Bournemouth/UK
Purpose: Hepatocellular carcinoma (HCC) prognosis is suboptimal, typically due to late-stage diagnosis. Although six-monthly ultrasound surveillance (USS) is recommended for high-risk patients, absence of a centralised national programme results in inconsistent implementation. This United Kingdom (UK) multicentre service evaluation assessed provider adherence and patient compliance with HCC USS.
Methods or Background: The Radiology Academic Network for Trainees (RADIANT) retrospectively identified consecutive adult patients receiving ≥1 HCC USS in 2021 using the Radiology Information System of 17 participating centres. Records from 2022 were reviewed to assess adherence to six-monthly USS. Provider adherence was defined by scan requests; patient compliance by attendance. Data were presented using descriptive statistics and risk differences with chi-squared confidence intervals.
Results or Findings: A total of 1713 patients (58% [993/1713] male; median age 62 years [IQR 54-70]) were included, with 2285 HCC USS requested, of which 88% (2018/2285) were attended. Provider full (2/2 USS), partial (1/2 USS) and non-adherence was 49% (839/1713), 35% (607/1713) and 16% (267/1713) respectively. Of the 84% (1446) of patients for whom ≥1 USS had been requested, full, partial and non-compliance rates were 83% (1199/1446), 11% (160/1446), and 6% (87/1446) respectively. The absolute risk of none relative to full compliance for patients with alcohol history relative to those without was 3% (95% CI 0, 6) higher. For patients with ≥2 comorbidities relative to those without, the absolute risk of none relative to full compliance was 2% (95% CI -1, 4) lower.
Conclusion: UK surveillance delivery is suboptimal, due to deficits in provider adherence and patient compliance. National investment in HCC surveillance infrastructure, including tracking and recall systems, is needed, as well as targeted interventions to promote patient compliance.
Limitations: Retrospective. Patients eligible for USS but not scanned in 2021 were not captured.

Enhanced CT Characteristics of P53-mutated Hepatocellular Carcinoma (6 min)

Lulu Jia; Lanzhou / China

Author Block: L. Jia, J. Lei; Lanzhou/CN
Purpose: P53-mutated hepatocellular carcinoma (HCC) is a highly aggressive subtype with profound implications for prognosis and treatment planning. However, non-invasive preoperative identification remains challenging. The purpose of this study was to assess the diagnostic utility of enhanced CT imaging characteristics for P53-mutated HCC and to elucidate their imaging characteristics.
Methods or Background: Patients with surgically resected HCC in a university hospital between January 2020 and December 2023 were retrospectively evaluated. Two radiologists independently evaluated CT imaging features and assessed inter-reader agreement.The Mann-Whitney test, □2 test, and logistic regression analysis were used to compare the enhanced CT characteristics, clinical features, and pathologic results. Using area under the curve, sensitivity and specificity to assess model performance.
Results or Findings: A total of 194 patients (mean age, 56 ± 10 years; 151 men) were included. P53 mutations were significantly associated with several aggressive pathological features (p-values ranging from <0.001 to 0.016). On enhanced CT, the presence of intratumoral arteries ($p < 0.001$) and an arterial phase hypovascular component ($p < 0.001$) were strong predictors of mutation. Multivariate analysis confirmed these as independent predictors, with high odds ratios of 9.4 (95% CI: 3.3, 26.8) and 10.6 (95% CI: 4.1, 27.6), respectively. The logistic regression model integrating these two features demonstrated excellent diagnostic performance, with an AUC of 0.82 (95% CI: 0.76, 0.89), a sensitivity of 71%, and a specificity of 79%.
Conclusion: Our study identifies two specific enhanced CT features—intratumoral arteries and an arterial phase hypovascular component—that are independently associated with P53 mutations in HCC. The model enables noninvasive, preoperative detection of this aggressive HCC subtype to guide risk stratification and personalize treatment.
Limitations: None

Ethics committee - additional information: This study was approved by the institutional review boards of all participating centers, and the requirement for obtaining informed consent from patients was waived.

Gadoxetic Acid-Enhanced MRI Features Correlated with Transcriptomic Subtypes of Hepatocellular Carcinoma (6 min)

Daeun Choi; Seoul / Korea, Republic of

Author Block: D. Choi[1], H. Rhee[1], Y. N. Park[1], H. G. Woo[2], T. Chung[1], J-h. Choi[2], J. E. Yoo[1]; [1]Seoul/KR, [2]Suwon/KR
Purpose: To identify gadoxetic acid-enhanced MRI findings associated with transcriptomic subtypes of hepatocellular carcinoma (HCC).
Methods or Background: We retrospectively enrolled treatment-naïve patients with pathologically confirmed HCC who underwent surgery between January 2008 and December 2019. Eligible patients had preoperative gadoxetic acid–enhanced MRI within 3 months of surgery and available RNA sequencing data. In cases with multiple tumors, only the largest lesion was analyzed. Transcriptomic subtypes were classified according to Montironi, Hoshida, and Chiang frameworks. Two radiologists independently evaluated major, ancillary, and LR-M LI-RADS features, as well as prognostic imaging findings on gadoxetic acid–enhanced MRI.
Results or Findings: This study included 89 HCCs from 89 patients (median age, 55 years; interquartile range, 49–64 years; 68 men). By Montironi's classification, 36 tumors (40%) were inflamed and 53 (60%) non-inflamed. Hoshida's system identified S1 (n=26, 29%), S2 (n=16, 18%), S3 (n=38, 43%), and unclassified (n=9, 10%) tumors. Chiang's framework grouped them into CTNNB1 (n=17, 19%), proliferation (n=32, 36%), interferon (n=8, 9%), polysomy 7 (n=15, 17%), unannotated (n=8, 9%), and unclassified (n=9, 10%). In the proliferation subtype, marked HBP hypointensity was positively correlated (OR 4.214, P=0.005). For Hoshida S1, peritumoral HBP hypointensity (OR 5.715, P=0.028) and transitional-phase targetoid appearance (OR 18.118, P=0.037) were positive correlates, while capsule presence was negative (OR 0.276, P=0.037). In CTNNB1, marked HBP hypointensity was negatively correlated (OR 0.137, P =0.001) and intratumoral fat was positive (OR 3.980, P=0.040). For the inflamed subtype, capsule presence (OR 0.243, P=0.007) and substantial necrosis (OR 0.062, P=0.019) were negative correlates, with no other significant associations.
Conclusion: Ancillary, LR-M features, and prognostic imaging features on gadoxetic acid-enhanced MRI were significantly associated with established transcriptomic subtypes of HCC.
Limitations: Limitations include the single-center, retrospective design, lack of validation, and small sample size.

Diagnostic sensitivity for small hepatic metastases: Half-dose ultra-high-resolution photon-counting CT versus full-dose EID-CT in prospective intraindividual comparison (6 min)

Ping Hou; Zhengzhou / China

Author Block: P. Hou; Zhengzhou/CN
Purpose: To prospectively compare half-dose ultrahigh-resolution (UHR) photon-counting CT (PCCT) with full-dose standard-resolution energy-integrating detector CT (EID-CT) for detecting small liver metastases.
Methods or Background: Fifty patients with confirmed or suspected liver metastases underwent paired contrast-enhanced abdominal scans: standard-dose EID-CT (SD-SR) followed by half-dose UHR-PCCT (120×0.2-mm collimation), as LD-UHR. Four blinded radiologists independently analyzed all scans, marking lesions, rating confidence (5-point scale), and assessing image quality. Lesion detection sensitivity, inter-/intrareader reproducibility (intraclass correlation coefficient [ICC]), and measurement accuracy were compared using McNemar tests, paired t test, and mixed-effects models.
Results or Findings: Consensus sensitivity for all lesions was comparable between PCCT and EID-CT (87.3% [144/165] vs 91.1% [163/179], P=0.13). PCCT demonstrated higher reader confidence (mean score: 4.5±0.3 vs 4.2±0.7, P<0.05) and superior intrareader reproducibility (ICC>0.90 vs. 0.75-0.85 for EID-CT). Notably, for lesions <0.5 cm, sensitivity showed a modest reduction with PCCT (68.2% [45/66] vs 75.8% [50/66], P<0.001), though still maintaining diagnostic acceptability for subcentimeter lesions .Radiation dose was reduced by 52% with PCCT (3.1 vs 6.5 mSv, P<0.001). Multivariable analysis confirmed PCCT's independent association with improved measurement precision (odds ratio:1.42, P=0.02).
Conclusion: Half-dose UHR-PCCT achieves diagnostic sensitivity equivalent to full-dose EID-CT for liver metastases >0.5 cm while reducing radiation exposure by half, offering a viable low-dose strategy for longitudinal oncologic surveillance without compromising detection efficacy for clinically actionable lesions.
Limitations: Not applicable.

RPS 1702 - Predicting response and recurrence in breast cancer

Categories: Imaging Methods, Oncologic Imaging, Breast
Date: March 7, 2026 | 08:00 - 09:00 CET
CME Credits: 1

Moderator:
Nuala Healy; Dublin / Ireland

Early Monitoring of NAC in Breast Cancer Using CEUS: A Systematic Review and Meta-Analysis of Predictive Accuracy for pCR (6 min)
Filipe Ramos Barra; Brasilia / Brazil

Author Block: F. Ramos Barra[1], V. A. Ohannesian[2], P. Q. Monteiro[3], M. S. Dias[4]; [1]Brasilia/BR, [2]São Paulo/BR, [3]Salvador/BR, [4]Goiania/BR
Purpose: This systematic review and meta-analysis aimed to evaluate the diagnostic accuracy of early, mid-treatment Contrast-Enhanced Ultrasound (CEUS) for predicting pathological Complete Response (pCR) in patients with primary, non-metastatic breast cancer undergoing Neoadjuvant Chemotherapy (NAC).
Methods or Background: Following PRISMA guidelines, we systematically searched PubMed, Embase, and Web of Science for studies assessing the predictive accuracy of CEUS after one or more cycles of NAC. The reference standard for pCR varied across studies (absence of invasive cancer or Miller-Payne Grade ≥4). A potential source of heterogeneity was addressed by selecting the best performing CEUS parameter from each study for analysis.
Results or Findings: Seven eligible studies, comprising 979 patients, were included in the bivariate meta-analysis. The overall diagnostic accuracy of early CEUS for predicting pCR was high, demonstrated by an Area Under the Summary Receiver Operating Characteristic Curve (AUROC) of 0.90 (95% CI: 0.87–0.93) and a Diagnostic Odds Ratio (DOR) of 25 (95% CI: 13, 48). The pooled sensitivity and specificity were 0.83 (95% CI: 0.74, 0.89) and 0.84 (95% CI: 0.76, 0.90), respectively, with low heterogeneity (I2=8.4%). Subgroup analysis indicated that assessment after 2nd or 3rd cycles offered slightly higher sensitivity (0.86; 95% CI: 0.76–0.96 versus 0.80; 95% CI: 0.68-0.92) than assessment at the end of the 1st cycle.
Conclusion: Early monitoring of NAC response in breast cancer using CEUS demonstrates high diagnostic accuracy for predicting pCR. This non-invasive tool is valuable for guiding mid-treatment decisions and tailoring subsequent therapeutic strategies for patients.
Limitations: Limitations included the variability in the pathological complete response definition used across studies (absence of invasive cancer or Miller-Payne Grade ≥4) and the methodological choice to utilize the best-performing CEUS parameter from each study to synthesize the findings.

The Role of Pre-treatment Contrast-Enhanced Mammography Findings in Predicting Response to Neoadjuvant Chemotherapy in Breast Cancer (6 min)
Özlem Ezmeci; Trabzon / Turkey

Author Block: Ö. Ezmeci, S. Kul; Trabzon/TR
Purpose: Pathological complete response (pCR) after neoadjuvant chemotherapy (NAC) has gained importance as a favorable prognostic indicator in breast cancer (BC). Pretreatment imaging biomarkers may predict tumors likely to achieve pCR and support personalized NAC planning. This study investigated the role of pretreatment contrast-enhanced mammography (CEM) findings in predicting the NAC response in BC.
Methods or Background: This retrospective, ethics-approved single-center study (2021–2024) included BC patients treated with NAC who had pretreatment CEM and surgical pathology. Patients who did not complete NAC, did not undergo surgery or lacked histopathological results were excluded. Pre-treatment CEM images were evaluated for breast density, background enhancement (BPE), lesion size, shape, margin, internal enhancement, conspicuity, and presence of calcifications using BI-RADS lexicon. Tumor contrast-to-noise ratio (CNR) was calculated from early-phase recombined images using the formula: (mean tumor SI – mean background SI) / standard deviation of background SI). Tumor enhancement kinetics were assessed by visually comparing early and delayed phase images. Imaging parameters were correlated with response status. Chi-square and Mann–Whitney U tests were used ($p<0.05$).
Results or Findings: In 15 (26%) of the 58 cases pCR was achieved. The relationship between pre-treatment CEM parameters and the presence of pCR was documented in Table 1. Tumor visibility and CNR values were significantly higher in patients with pCR ($p<0.049$) (Fig 1). pCR rates were 0%, 24%, and 43% in tumors with type 1, 2, and 3 enhancement kinetics, respectively ($p=0.025$) (Fig 2). Other CEM parameters showed no correlation with pCR.
Conclusion: This study suggests that CEM-derived tumor enhancement intensity and kinetics may serve as markers in predicting NAC response. Previous radiomics-based studies also support these findings (2-4).
Limitations: Small cohort and lack of inter-reader analysis.
Funding for this study: No funding was received.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Approved by the Ethics Committee of Karadeniz Technical University, Faculty of Medicine (approval no: 2024/280, year 2025)

Refining CEM Protocols to Predict pCR in Breast Cancer: Early, Delayed, or Both? (6 min)

Chiara Bellini; Scandicci / Italy

Author Block: C. Bellini[1], G. Bicchierai[1], F. Amato[2], C. Maiello[1], F. Di Naro[1], D. De Benedetto[1], S. Vidali[1], V. Miele[1], J. Nori[1]; [1]Florence/IT, [2]Agrigento/IT
Purpose: To evaluate which contrast-enhanced mammography (CEM) acquisition protocol—early, delayed, or combined—is most accurate in assessing pathological complete response (pCR) after neoadjuvant chemotherapy (NAC) in breast cancer.
Methods or Background: This retrospective study included 202 women who underwent CEM after NAC and before surgery, with both early and delayed acquisitions. Pathological tumor status (ypT) at surgery was the gold standard, with pCR defined as ypT0 or ypTis. Two breast radiologists reviewed images in consensus. Early, delayed, and combined image sets were assessed in randomized sessions. Radiologic response was categorized per RECIST criteria and then dichotomized as complete response vs residual disease. Sensitivity, specificity, predictive values, accuracy, and ROC-AUCs were calculated and compared.
Results or Findings: Sensitivity was higher for combined (86.6%) and delayed (85.7%) acquisitions than for early images (68.1%), whereas specificity was superior in early acquisitions (63.9%). Accuracy was 66.3% for early, 71.3% for delayed, and 69.8% for combined CEM. NPV improved from early (58.2%) to delayed (71.2%) and combined acquisitions (70.4%). ROC curve comparisons showed no statistically significant differences between protocols. Delayed acquisitions reclassified 57.9% of early false negatives as true positives and corrected 13.3% of early false positives but converted 28.3% of early true negatives into false positives. A relevant proportion of false positives in both protocols corresponded to residual in situ carcinoma at histology.
Conclusion: Delayed acquisitions improve sensitivity and reduce false negatives in NAC response assessment with CEM, although at the cost of decreased specificity due to overestimation of residual disease, particularly in cases with in situ carcinoma.
The combined protocol enhances overall performance but does not significantly differ from early or delayed acquisitions alone.
Limitations: Limitations include the retrospective, single-center design, consensus readings without interobserver analysis, absence of comparison with MRI.

Diagnostic Accuracy of Contrast-Enhanced Mammography in Evaluating Breast Cancer Response to Neoadjuvant Therapy: A Systematic Review and Meta-Analysis (6 min)

Roberto Maroncelli; Rome / Italy

Author Block: G. Barcaroli, F. Galati, F. Shakki Katouli, R. Maroncelli, F. Cicciarelli, M. Pasculli, F. Pediconi, C. Catalano; Rome/IT
Purpose: Neoadjuvant therapy (NAT) in breast cancer enables tumor downstaging and response evaluation. Although magnetic resonance imaging (MRI) is the gold standard, its limitations have prompted growing interest in alternatives such as contrast-enhanced mammography (CEM).
Methods or Background: This review was conducted according to PRISMA guidelines. We evaluated CEM accuracy in predicting pathological complete response after NAT, using surgery as reference standard. A comprehensive search was conducted in PubMed/Medline, Embase, Cochrane, and Web of Science. Two reviewers screened studies, extracted data, and evaluated risk of bias with QUADAS-2 tool. A bivariate random-effects model estimated diagnostic odds ratio (DOR), sensitivity, specificity, and likelihood ratios. Summary receiver operating characteristic (sROC) curves were generated, and heterogeneity was quantified using Higgins' I^2. Publication bias was assessed via Deek's funnel plot.
Results or Findings: 13 studies, including 582 patients, met inclusion criteria. The pooled analysis showed a DOR of 8.60 (95%,CI:3.29–22.52) with substantial heterogeneity (I^2=70.06%). Pooled sensitivity and specificity were 72% (95%,CI:63%–79%) and 83% (95%,CI:68%–92%), respectively, with an sROC AUC of 0.82 (95%,CI:0.78–0.85). Excluding the study contributing most to heterogeneity improved the DOR to 9.76 (95%,CI:6.00–15.89) and reduced I^2 to 0.00%.
Conclusion: CEM demonstrates good diagnostic accuracy for assessing NAT response, performing comparably to MRI.
Limitations: Retrospective study, limited number of studies included

MRI-Based Evaluation for Predicting Pathological Response and Monitoring Reactive Angioma Evolution in Triple-Negative Breast Cancer Undergoing Neoadjuvant Chemoimmunotherapy (6 min)

Luyi Lin; Shanghai / China

Author Block: L. Lin, J. Zheng, C. You, Y. Gu; Shanghai/CN
Purpose: Neoadjuvant chemotherapy combined with anti-programmed cell death protein-1 (PD-1) immunomodulators (NACI) has been proven to improve outcomes in triple-negative breast cancer (TNBC). However, the role of MRI in predicting therapeutic response remains underexplored. This study aims to investigate the utility of MRI for early response prediction and longitudinal assessment of reactive angiomatous changes in TNBC patients undergoing NACI therapy.
Methods or Background: This secondary analysis pooled data from the CamRelief and NeoTENNIS RCTs, among others, investigating NACI at our center (2020-2023). We analyzed baseline clinicopathological characteristics, MRI features (including BI-RADS descriptors and whole-tumor ADC histogram metrics), and response outcomes. Independent predictors of pathological complete response (pCR) were identified via univariate and multivariate logistic regression to develop a prognostic model. Longitudinal evolution of reactive angiomas during NACI was assessed with non-parametric and chi-square tests.
Results or Findings: A total of 61 TNBC patients undergoing NACI were enrolled. Univariate analysis identified four independent predictors of pCR. While elevated Ki-67 index ($p<0.001$) and CD8-T cell infiltration ($p=0.004$) reflected baseline pathological predictors, type III kinetic curves ($p=0.004$) and reduced median_ADC value ($p=0.021$) of MRI provided unique insights with pCR. Moreover, the combined multi-dimensional model achieved a high prediction accuracy, got AUC of 0.89. Serial MRI monitoring identified transient reactive changes characterized by multiple small masses emerging (mean 8.82±0.67mm) during NACI unrelated to response, peaking at post-cycle-2 MRI, followed by progressive regression. One was histopathologically confirmed as benign reactive angiomatous remodeling.
Conclusion: MRI played a dual role in managing NACI for TNBC. An integrative model of MRI biomarkers and clinicopathology superiorly predicted pCR, whereas reactive angiomatous remodeling was transient.
Limitations: Small sample size and and paucity of quantitative features on MRI.
Funding for this study: Special Research Fund for Clinical Studies of Innovative Drugs after Market Launch (WKZX2024CX103301)
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the Ethics Committee of the Institutional Review Board (IRB) of our institution. All patients provided written informed consent before enrollment.

Predicting pathologic complete response before neoadjuvant therapy: pre-treatment breast MRI-derived radiomics with radiologic-pathologic integration (6 min)

Cennet Yanardağ; Ankara / Turkey

Author Block: C. Yanardağ, M. G. Akpınar, G. Durhan, F. Demirkazık; Ankara/TR
Purpose: This study evaluates whether pre-treatment breast Magnetic Resonance Imaging (MRI)-derived radiomic features, alone and combined with radiologic and pathologic variables, can predict pathologic complete response (pCR) before neoadjuvant therapy (NAT) in breast cancer.
Methods or Background: We retrospectively included 154 patients who underwent pre-treatment breast MRI, received NAT, and subsequently had surgery at our center (2016-2024). Patients were split 70/30 into training (n=109) and test (n=45) sets. Pathologic variables (estrogen receptor, progesterone receptor, HER2 status, and histologic grade) were obtained from pre-treatment biopsies. Radiologic variables included tumor size, distribution, shape, and axillary lymph-node status. Variables showed balanced distributions between training and test sets ($p>0.05$). Tumors were manually volumetrically segmented on early post-contrast fat-suppressed T1-weighted images with syngo.via. We extracted 1,691 radiomic features, retained 652 after applying an intraclass correlation coefficient threshold of 0.90 (one reader, repeated segmentations, 38-case subset). Radiomic features underwent elastic-net selection in the training set with cross-validation, yielding nine features. Pure radiomic, radiologic, and pathologic, as well as combined (radiomics-radiologic, radiomics-pathologic, and radiomics-radiologic-pathologic) models were developed using a Support Vector Machine (SVM). The area under the curve (AUC), accuracy, sensitivity, and specificity were calculated for both sets.
Results or Findings: A total of 42.9% had pCR. Test-set AUCs: radiomics 0.563; radiologic 0.558; pathologic 0.704; radiomics+radiologic 0.557; radiomics+pathologic 0.662; radiomics-radiologic-pathologic 0.607. The pathologic model had the highest AUC. Specificities: radiomics 0.846; radiologic 0.807; pathologic 0.692; radiomics+radiologic 0.846; radiomics+pathologic 0.539; radiomics-radiologic-pathologic 0.654. Radiomics-only and radiomics+radiologic models showed higher specificity.
Conclusion: Radiomics alone offered modest discrimination, but adding pathologic variables improved performance. Radiomic models have higher specificity, useful for ruling out pCR. Combining radiologic and pathologic findings before treatment can help with risk stratification and customizing therapy prior to NAT.
Limitations: A modest sample size, retrospective, single-center design.
Funding for this study: No funding was received for this study.

Tumor to breast ratio as radiological tool to predict breast-conserving surgery vs mastectomy in patients with pathologic partial response after neoadjuvant systemic treatment: a retrospective study (6 min)

Eliana Tallamona; Gela / Italy

Author Block: E. Tallamona[1], R. Gioco[2], C. Giuseppe[2], P. Francesco[2]; [1]Gela/IT, [2]Misterbianco/IT
Purpose: This study aims to identify radiological features along with clinical and pathological predictors that influence the choice of mastectomy in non-metastatic breast cancer patients who demonstrate a pathological partial response (pPR) after neoadjuvant systemic therapy (NACT), despite presenting a favorable tumor-to-breast ratio that could allow breast-conserving surgery (BCS). The goal is to better understand factors that lead to over-treatment and to prove how radiologists could help to reach a more evidence-based surgical approach.
Methods or Background: This retrospective single-center study included 165 female patients treated with NACT followed by surgery between 2021 and 2023 at Humanitas Istituto Clinico Catanese in Catania. Only patients with residual cancer burden class I or II were included. Patients with RCB III, metastatic disease, BRCA mutations, or male gender were excluded. For a subgroup of 26 patients, a tumor-to-breast volume ratio was calculated using mammographic measurements before and after NACT to determine suitability for BCS. Statistical analysis was performed to identify correlations between radiological measurement, clinical characteristics and surgical choice (BCS vs mastectomy).
Results or Findings: Among 165 patients with partial pathological response (pPR), 43% underwent BCS and 57% underwent mastectomy. Mastectomy was more frequently performed in younger and premenopausal patients, those with multifocal or larger tumors, and higher clinical staging at diagnosis. In the subgroup with a post-NACT favorable tumor-to-breast ratio, 38.5% still underwent mastectomy.
Conclusion: Despite partial tumor response and anatomical feasibility, many patients undergo mastectomy due to factors beyond tumor biology. A multidisciplinary, patient-centered approach, integrating predictive tools like tumor-to-breast ratio analysis and shared decision-making, may promote a more conservative and personalized surgical strategy leading to reduce unnecessary mastectomies and enhance patient outcomes and satisfaction
Limitations: Main limitation include the single-center design and limited sample size
Funding for this study: No funding was required for this study

Digital twins for breast cancer surgery (6 min)

Rafaela Timóteo; Lisbon / Portugal

Author Block: R. Timóteo, A. Laborde, Y. Forghani, N. Loução, A. Cardoso, M. Correia, J. Santinha, T. Marques, P. Gouveia; Lisboa/PT
Purpose: Breast cancer (BC) is the second most common cancer worldwide, and breast conservative surgery (BCS) is its primary treatment. Accurate tumor localization is essential to achieve negative margins and reduce recurrence, yet current methods are invasive and often imprecise, leading to re-excision. Digital twins (DTs) are emerging in healthcare as dynamic virtual replicas of patients, integrating both anatomy and physiology, and serving as a powerful tool for treatment, decision-making, and outcome prediction. By providing a non-invasive and precise approach to tumor localization, DTs may enhance surgical accuracy, reduce re-excision rates, and ultimately improve patient outcomes.
Methods or Background: Four breast cancer patients proposed for BCS were selected between January and September 2025. Patient-specific DTs were built from annotated supine breast MRI and automatically aligned to the patient in real-time with a 3D surface scanning system in the operating room (OR). DTs were visualized through an Augmented Reality (AR) interface that was co-designed with breast surgeons to ensure suitability for the OR environment. Tumor marking with AR was compared to carbon tattoo marking and intraoperative findings.
Results or Findings: Results reveal a high degree of tumor localization accuracy in most surgeries, with fast setup time and tumor marking. Usability and workload questionnaires highlighted our system's excellent user experience.
Conclusion: Integrating DTs in AR environments represents the next era of breast cancer surgery, offering surgeons a new paradigm for interacting with patient-specific data, enhancing their performance in the OR, and leading to better surgical outcomes.
Limitations: Future work should consider a clinical study with a larger patient cohort, accuracy measurement through rate of positive margins, non-rigid registration of DTs with volumetric correction, and biomechanical simulation capabilities.
Funding for this study: This research is part of the Health for Portugal (HfP), funded by Agendas Mobilizadoras para a 5 Inovação Empresarial - Plano de Recuperação e Resiliências Português (PRR). A special thanks to the Breast Unit at Champalimaud Clinical Center for their collaboration, and to all of those who participated in this study, to contribute to the evolution of health technologies and consequent patient care.

Local Recurrence After Treatment of Pure Ductal Carcinoma In Situ: A Radiological Retrospective Study (6 min)

Andrea Gaia Azzarito; Pescara / Italy

Author Block: A. G. Azzarito, M. C. Torrione, A. Delli Pizzi, M. F. Savina, L. Di Pietrantonio, A. Di Credico, A. Figorilli, M. Muzi, M. Caulo; Chieti/IT
Purpose: To evaluate the local recurrence rate of pure ductal carcinoma in situ (DCIS) after surgery, with particular focus on the impact of adjuvant radiotherapy and clinicopathological factors, in order to explore the potential for more personalized management strategies.
Methods or Background: We retrospectively analyzed 403 patients with histologically confirmed pure DCIS treated with breast-conserving surgery or mastectomy between 2014 and 2023. Imaging and pathological variables were assessed. Recurrence rates were correlated with tumor grade, radiotherapy, and other clinicopathological parameters. Statistical analyses included Kaplan–Meier survival estimates and multivariate Cox regression.
Results or Findings: Among 417 lesions, 21 ipsilateral recurrences (5%) were observed, of which 57% were non-invasive and 38% invasive. Recurrences occurred predominantly in patients not treated with adjuvant radiotherapy (52%) and in those with breast-conserving surgery. All recurrent tumors were estrogen receptor–positive, yet none received endocrine therapy. Tumor grade and size were not significantly associated with recurrence. No distant metastases or disease-related deaths were recorded.
Conclusion: Recurrence after treatment for pure DCIS is relatively uncommon and often non-invasive. Traditional prognostic markers such as tumor grade and size did not predict recurrence. These findings support a more individualized approach to treatment, where selected patients may avoid overtreatment. Further studies incorporating molecular profiling are warranted to refine risk stratification.
Limitations: This study is limited by its retrospective design and by the relatively short follow-up in some patients, which may not capture late recurrences. Moreover, the absence of molecular or genomic profiling restricts the ability to refine risk stratification.

Navigating the CT Wave: Multicentric Chest Imaging Trends Before, During, and After COVID-19 pandemic (6 min)
Thiago Viana Miranda Lima; Lucerne / Switzerland

Author Block: T. Viana Miranda Lima, N. Saltybaeva, T. Gassenmaier, L. Ebner, J. E. Roos; Lucerne/CH
Purpose: The COVID-19 pandemic has significantly impacted healthcare practices worldwide, including the use of CT in chest examinations. This study is aimed to analyse the trends in CT chest examinations before, during, and after the COVID-19 pandemic.
Methods or Background: Data was retrospectively collected from 10 public hospitals over a period pre-pandemic years (2019 until February 2020), through the pandemic (March 2020- April 2023) (as defined by the World Health Organisation) and post-pandemic (May 2023- December 2024). Patient exposure information from more than 240 000 CT examinations was collected and analysed using a commercial dose management system. Statistical analysis was performed with descriptive and inferential statistics employed to compare the number of CT chest examinations and patient radiation exposure across different periods.
Results or Findings: The results indicate a increase in CT chest examinations during the pandemic, which reached a plateau and remained stable post-pandemic (p-value < 0.001). Importantly, the average radiation exposure per patient has decreased with the evolution of technology. There was also a shift between protocols used during the pandemic with the move towards more dedicated procedures.
Conclusion: These findings highlight the sustained demand for CT chest examinations and the effective management of patient radiation exposure during and after the pandemic. The study underscores those possible practices obtained during the pandemic became the normal after the end of the pandemic.
Limitations: This study has few limitations: firstly, the data are derived from DICOM data, which, while ensuring reproducibility and objectivity, may not capture all clinical nuances for example a patient being imaged on the wrong protocol. Secondly, the analysis of radiation exposure was conducted primarily to demonstrate overall trends in dose levels rather than to thoroughly investigate or attribute the main factors underlying the observed changes.
Funding for this study: None

Deep Learning-based analysis of HRCT images for outcome prediction in pulmonary fibrosis: the added value over clinico-functional assessment in a prospective longitudinal study (6 min)
Federico Villone; Roma / Italy

Author Block: F. Villone, L. Calandriello, G. Cicchetti, R. D'Abronzo, F. Scrocca, F. Del Prete, G. Sgalla, L. Natale, A. R. Larici; Roma/IT
Purpose: Prognostic assessment in interstitial lung disease (ILD) is challenging, due to unpredictable behaviour and scarcity of validated progression markers. Clinico-functional progression criteria are limited by subjectivity and variability, while radiological progression relies on visual assessment, affected by inter-observer variability. Artificial intelligence(AI) on high-resolution Computed Tomography(HRCT) has emerged as a reliable tool for ILD assessment.
This study evaluated deep-learning HRCT analysis with commercially available software in assessing progression and mortality in a real-life prospective ILD patients cohort.
Methods or Background: HRCT scans from ILD patients (idiopathic pulmonary fibrosis [IPF] and non-IPF ILDs) at baseline and after 12±4 months were analyzed using AVIEW software (Coreline Soft). Correlation among baseline AI variables and baseline forced vital capacity (FVC) categories(≥80%; 79-50%; ≤49%) and between AI changes and FVC decline categories(≥10%; 5-9%; ≤4%) were assessed. Multivariate logistic regression tested correlation of AI variables with all-cause mortality and functional progression. Integration of quantitative data into clinico-functional models to predict mortality was evaluated with C-index.
Results or Findings: 148 HRCT scans from 74 ILD patients were assessed (mean age 73.3±7.8 yrs; male 61.3%;IPF 68.8%). Thirty-nine patients(52.7%) progressed and twenty-four(32.4%) died. At baseline, most AI variables inversely correlate with the FVC categories; changes in the quantitative measurements correlates with the categorial FVC decline, showing responsiveness. At multivariate analysis, 19 variables at baseline were independently predictive of mortality; at follow-up, changes in 5 variables predicted mortality, with the best predictor being Δ% of consolidation(HR 4.01, 95%CI 1.69-10.13, p=0.003). Incorporating AI variables into clinico-functional models improved mortality prediction at baseline (C-index 0.707 vs 0.57; p=0.012) and follow-up(0.866 vs 0.763; p=0.005).
Conclusion: Deep-learning-based HRCT measurements and longitudinal changes predict progression and mortality in fibrotic ILD. Composite AI clinico-functional models may allow more precise prognostic assessment .
Limitations: Single-center study

Microradiological Characterization and Novel Growth Pattern Insights of Ultra-Early-Stage Lung Squamous Cell Carcinoma (6 min)

Heng Zhang; Dazhou / China

Author Block: H. ZHANG[1], L. Xu[2]; [1]Joondalup/CN, [2]Dazhou/CN
Purpose: To delineate the microradiological features of ultra-early-stage lung squamous cell carcinoma (UESLSCC) and investigate hypotheses on growth dynamics, vascular supply, and early morphological evolution between central- and peripheral-type lesions.
Methods or Background: A retrospective study included 38 patients with pathologically confirmed UESLSCC identified via opportunistic screening or health examinations. Pre-diagnostic thin-section CT was reviewed, with microradiological post-processing (MPR, CPR, MIP, VB) to enhance visualization. Lesions were classified by anatomical location (central- vs peripheral-type). Recognition intervals, morphological subtypes, microradiological signs (tail sign, microvascular convergence), and relationships with bronchovascular structures were evaluated by experienced thoracic radiologists. The study was approved by the institutional ethics committee, and informed consent was waived due to its retrospective design.
Results or Findings: Central-type lesions had significantly shorter recognition intervals than peripheral-type ($P < 0.05$), plausibly due to earlier respiratory symptoms, earlier bronchoscopy, and/or larger lesion volumes. We hypothesize that central lesions—supported by richer bronchial arterial flow and larger airway caliber—proliferate and present earlier, whereas peripheral lesions—reliant on pulmonary circulation in narrower distal airways—grow more slowly. Morphologically, wall-type and luminal-type patterns predominated in central lesions, while non-specific alveolar-type and pleural-type patterns were more common peripherally, suggesting an alveolar origin. Peripheral lesions frequently arose near bronchial bifurcations and showed tail signs, indicating bidirectional growth along adjacent bronchioles. Microradiological post-processing significantly improved detection and characterization of ultra-early lesions, especially subtle bronchovascular relationships.
Conclusion: Ultra-early–stage lung squamous cell carcinoma predominantly originates from the bronchial wall. Microradiological imaging is pivotal for detecting and characterizing these lesions, revealing distinct vascular supply patterns and growth dynamics between central and peripheral types. These findings propose new pathophysiological hypotheses and provide a foundation for early screening, near-pathological preoperative diagnosis, and tailored management of UESLSCC.
Limitations: Single-center, retrospective design, a small opportunistically screened cohort.

High-Pitch Low-Dose Chest CT with Calcium-Aware Reconstruction for Coronary Artery Calcium Scoring: Accuracy and Dose Reduction (6 min)

He Zhang; Xuzhou / China

Author Block: H. Zhang, Y. Meng; Xuzhou/CN
Purpose: To evaluate the accuracy, radiation dose, and clinical feasibility of a high-pitch low-dose chest CT (Sa36LDCT) protocol with calcium-aware reconstruction for coronary artery calcium scoring (CACS).
Methods or Background: This prospective study included 90 patients underwent both standard CAC scans and Sa36LDCT. CACS was quantified as Agatston score, calcium volume, and equivalent mass. Risk stratification was assessed using Agatston categories. Agreement between protocols was evaluated using ICC, Bland–Altman analysis, and weighted kappa. Subgroup analyses were performed according to heart rate (≤75 vs >75 bpm). Radiation dose and subjective image quality were compared.
Results or Findings: CAC metrics showed no significant difference between protocols, with excellent agreement (ICC=0.983-0.996). Subgroup analysis revealed that heart rate didn't significantly influence CAC quantification or risk classification with Agatston score ICC values of 0.98 for ≤75 bpm and 0.99 for >75 bpm, demonstrating accuracy in both subgroups. Radiation dose reduction was consistently observed across both subgroups, with Sa36LDCT reducing effective radiation dose by 62% (0.74 vs 0.28 mSv, P<0.001). Risk stratification showed near-perfect consistency across heart rate subgroups.
Conclusion: High-pitch Sa36LDCT provides accurate CACS equivalent to standard CACS with radiation dose reduction and preserved image quality. The protocol's robustness across heart rate subgroups supports its clinical use as a safe and practical one-stop approach for combined pulmonary and cardiovascular screening.
Limitations: First, it was conducted at a single center with a relatively limited sample size. Second, calcium-aware Sa36 reconstruction kernel is manufacturer-specific, and our results may not be directly applicable to scanners from other vendors or reconstruction algorithms with different technical implementations. Third, we did not specifically investigate the influence of BMI on calcium quantification.
Funding for this study: We acknowledge financial support from the Jiangsu Traditional Chinese Medicine Science and Technology Development Plan Project (MS2021100), and the Key Research and Development Program of Xuzhou Science and Technology Bureau (KC20159).

Regional ventilation imaging in normal and bronchoconstricted in vivo rabbit lungs using spectral Xe-enhanced CT (6 min)

Emma Verelst; Brussels / Belgium

Author Block: E. Verelst[1], S. Bayat[2], S. Verbanck[1], G. Van Gompel[1], J. De Mey[1], N. Buls[1]; [1]Brussels/BE, [2]Grenoble/FR
Purpose: To investigate regional ventilation in healthy and pathological in vivo rabbit lungs using Xenon (Xe)-enhanced spectral CT-based ventilation maps.
Methods or Background: Six anesthetized rabbits [2.6 ± 0.2 (SD) kg] were mechanically ventilated. Dynamic multi-breath imaging was performed during Xe washout using a clinical DECT (Revolution, GE Healthcare) before and after the administration 40 mg/mL Methacholine (MCh) to induce bronchoconstriction (post-MCh). Xe concentration (Xeconc) was monitored using a mass spectrometer (LR6000, Logan Research). The dynamic DECT data was decomposed into Xe densities images. Ventilation maps were generated depicting specific ventilation (sV), quantified as the time constant (min-1) of a fitted mono-exponential model, following image registration. Agreement between global sV derived from ventilation maps (sV_image) and mass spectrometry data (sV_ms) was assessed. Ventilation defect fraction (VDF) was computed as voxels with sV below 25% of the mean and compared between baseline and post-MCh. Regional ventilation was evaluated by comparing the mean sV within the VD-area (sV_VDF) compared to the non-VD area (sV_non-VDF).
Results or Findings: The ventilation maps revealed differences in ventilation distribution between baseline and post-MCh conditions. VDF increased from 22.6% ± 10.6% at baseline, to 37.2% ± 9.8% post-MCh, p = 0.003. At baseline and post-MCh, sV_VDF (6.6 ± 9.92 min-1, 5.27 ± 8.38 min-1) was reduced compared to sV_non-VDF (0.29 ± 0.09 min-1, 0.22 ± 0.03 min-1), p < 0.001. Lastly, a strong agreement was found between global sV_image and sV_ms at baseline (3.0 min-1 ± [-0.77 min-1, 6.7 min-1]) and post-MCh (3.8 min-1 ± [-1.15 min-1, 8.8 min-1]).
Conclusion: This study shows the potential of dynamic Xe-enhanced spectral CT-imaging for quantitative studies of ventilation defects, supporting its utility for regional assessments of pulmonary function.
Limitations: This study was an in vivo animal study.
Funding for this study: Flemish Research Foundation (FWO) personal grant, number: 1SH1Z24N.

Quantitative CT of Lung Parenchyma and Airways in Primary Ciliary Dyskinesia (6 min)

Oliver Weinheimer; Heidelberg / Germany

Author Block: O. Weinheimer[1], S. Riepenhausen[2], R. Tenardi-Wenge[2], M. A. Mall[3], H-U. Kauczor[1], H. Omran[2], M. O. Wielpütz[4], J. Raidt[2]; [1]Heidelberg/DE, [2]Muenster/DE, [3]Berlin/DE, [4]Greifswald/DE
Purpose: Primary Ciliary Dyskinesia (PCD) is a rare genetic disorder where tiny hair-like structures called cilia don't work properly. Various quantitative CT (QCT) techniques have been proven to deliver useful and objective biomarkers describing lung parenchyma and airways. This study explores which QCT biomarkers best characterize lung and airway abnormalities in PCD.
Methods or Background: A total of 148 inspiratory CT scans from 106 genetically confirmed PCD subjects (55 female, mean age 29.2 ± 17.7 years), collected from multiple medical centers, were automatically analyzed using YACTA software. 59 CT scans from 35 individuals with situs inversus were mirrored to enable standard YACTA evaluation. Quantitative CT parameters of the airways and lung parenchyma were assessed on a six-lobe basis.
Results or Findings: Mirroring the CT scans allowed for the inclusion of all situs inversus subjects in the analysis. Airway wall percentage (AWP) was significantly higher in the lower lobes compared to the upper lobes (60.54% vs 55.89%, p<2.2e-16). Similarly, the bronchiectasis index (BEI) was elevated in the lower lobes (1.64 vs 0.45, p<2.2e-16). Mean lung density (MLD) and the 75th percentile of the lung histogram were also higher in the lower lobes (–729.39 HU vs –763.45 HU, p=1.95e-11 and –854.42 HU vs –892.74 HU, p=3.79e-10). The values in the right middle lobe and lingula were comparable to those in the lower lobes. AWP, BEI and MLD showed a moderate correlation with subject age (R=-0.57, p=8.91e-14 and R=0.27, p<0.001 and R=-0.47, p=2.85e-09).
Conclusion: QCT showed significant changes in airway and lung parenchyma paramaters predominantly in the lower lobes, differing from the typical pattern seen in cystic fibrosis, where changes are distributed across all lobes. QCT may be a valuable tool for PCD research.
Limitations: Retrospective study, no uniform CT protocol.

Computed Tomography Pulmonary Angiography biomarkers of peripheral vascular disease in patients treated for chronic thromboembolic pulmonary hypertension: prognostic evaluation (6 min)

Emanuele Muscogiuri; Leuven / Belgium

Author Block: E. Muscogiuri, F. De Keyzer, W. De Wever, L. Hardy, G. Aerts, R. Quarck, M. Delcroix, T. Verbelen, L. Godinas; Leuven/BE
Purpose: Chronic Thromboembolic Pulmonary Hypertension (CTEPH) is a rare form of pulmonary hypertension, with pulmonary endarterectomy (PEA) being the treatment for suitable candidates. This study investigates the prognostic value of quantitative imaging biomarkers from Computed Tomography Pulmonary Angiography (CTPA) in patients undergoing PEA.
Methods or Background: We retrospectively enrolled CTEPH patients who underwent CTPA within 6 months pre-PEA, and right heart catheterization (RHC) pre- and post-PEA. CTPA scans were analyzed with a dedicated software (Aview, Coreline Soft, Inc) to extract BV5 and BV10 (representing total blood volume of pulmonary vessels with cross-sectional areas <5mm2 and <10mm2, respectively), also indexing them on total blood (TBV) and lung volume (respectively BV5/TBV, BV10/TBV; ρBV5, ρBV10). Significant associations (p<0.05) with RHC parameters, including their percentage change (Δ%), were evaluated using Spearman's rank correlation.
Results or Findings: Thirty-three patients (16 men, mean age 60.2 years) were included. Pre-operatively, BV5/TBV and BV10 negatively correlated with cardiac output (CO) and cardiac index (CI). Post-operative analysis revealed a negative correlation between BV5/TBV and the RHC parameters mean pulmonary artery pressure (mPAP), right atrial pressure (RAP), and pulmonary artery wedge pressure (PAWP), with r=-0.39, -0.43, -0.55 respectively. A negative correlation was also observed between ρBV5 and both post-operative pulmonary vascular resistance (PVR) and percentage change (Δ%) in PVR (r=-0.38 for both), highlighting the association between increased peripheral involvement and a reduced improvement of vascular resistance.
Conclusion: CTPA-derived quantitative biomarkers show that a lesser involvement of the peripheral vasculature results in a better post-PEA outcome. The extent of peripheral disease, quantified with CTPA, correlates with greater reductions in pulmonary pressures and vascular resistances, and improved cardiac function post-PEA, supporting the prognostic value of these quantitative imaging metrics.
Limitations: Small study population with possible selection bias.

The clinical value of low-dose CT in evaluating emphysema for predicting the growth of lung nodules (6 min)

Yajie Wang; Zhengzhou / China

Author Block: Y. Wang, S. W. Yue; Zhengzhou/CN
Purpose: To investigate the clinical value of low-dose CT (LDCT)-based diagnosis of emphysema, its subtypes, and severity in predicting pulmonary nodule growth.
Methods or Background: We retrospectively collected data from 947 patients diagnosed with pulmonary nodules by LDCT who underwent subsequent follow-up. Two radiologists independently performed visual assessments of the presence of emphysema, its subtypes (centrilobular emphysema, CLE; paraseptal emphysema, PSE), and severity. For non-calcified nodules with a volume ≥30 mm^3, evaluations included volume, type, location, mean CT attenuation, and imaging features such as vacuole sign, lobulation, spiculation, pleural indentation, and vascular convergence. Patients were classified into growth and stable groups based on whether the maximum nodule volume increased (≥25%) or new nodules (>30 mm^3) developed. Kaplan-Meier analysis and Cox proportional hazards models were applied to evaluate associations between the presence, subtype, severity of emphysema, and pulmonary nodule growth.
Results or Findings: In the nodule growth group, there were 458 cases (48.4%), and 562 patients (59.3%) had emphysema. Multivariate Cox regression analysis identified emphysema (particularly PSE), age, nodule volume, mean CT attenuation, and the presence of vacuole sign as independent predictors of nodule growth ($P<0.05$).
Conclusion: Visual assessment of emphysema, particularly PSE, is an independent risk factor for pulmonary nodule growth and provides an important basis for more precise risk stratification and management of pulmonary nodules.
Limitations: First, as a single-center retrospective study, it may introduce selection bias. Second, there is a lack of pathological confirmation of the nodules. Furthermore, visual assessment of emphysema has subjective variability. Finally, the growth risk assessment of the baseline largest nodule was based on previous studies, but it may not be the optimal indicator.

Deep learning motion reduction algorithm: Its efficacy of improving image clarity in CT pulmonary angiogram (6 min)

Kai Zheong Lim; Melbourne / Australia

Author Block: K. Z. Lim, E. Yang, B. Jong, K. K-P. Lau; Melbourne/AU
Purpose: Deep-learning motion correction algorithm (DLMCA) (CLEAR MOTION, Canon Medical Systems) works by creating a 4D motion vector-map from raw CT data to compensate for coronary artery movement during reconstruction and corrects motion artifacts without increasing radiation dose. Reducing motion/pulsation artifacts in CT pulmonary angiography (CTPA) is essential in evaluating pulmonary arteries (PA) and the adjacent ascending aorta (Ao) and aortic root (Ar). We aimed to investigate the efficacy of DLMCA in CTPA in image quality (IQ) improvement.
Methods or Background: All adult consecutive CTPAs over 3-month period in a specialist cardiac-lung hospital were included. Images of each CTPA were reconstructed with standard deep-learning image-reconstruction (SDLIM) and DLMCA. Two radiologists independently and randomly assessed the image quality using Likert 5-point scale of PA, Ao and Ar. Interobserver agreement with Kappa score was determined. Objective IQ using signal-to-noise (SNR) and contrast-to-noise ratio (CNR) were calculated. Quantitatively, the degrees of motion artifact (the width of double-shadow) at PA and Ao were assessed. Statistical analysis with paired t-test and Wilcoxon signed-rank test was undertaken (p-value <0.05 as significant).
Results or Findings: 100 CTPAs (44% male, mean age of 65.5 years) were included. There was substantial to excellent interobserver agreement with kappa-score of 0.73 for SDLIM and 0.81 for DLMCA. Significant improvement in subjective image clarity with all three structures and significant reduction of double shadow sign of ascending aorta (mean 1.9mm difference, $p<0.0001$) and pulmonary trunk (mean 1.2mm difference, $p<0.0001$) were achieved. However, mean SNR and CNR for both aorta and pulmonary trunk were reduced with DLMCA ($p<0.0001$).
Conclusion: DLMCA has benefit of reducing motion artifact of PA, Ao and Ar in CTPA, and therefore, improving image clarity, despite some degradation of SNR and CNR.
Limitations: Single centre retrospective study.
Funding for this study: None.

Performance of contrast photon-counting CT in differentiating osteoblastic metastases from bone islands (6 min)
Yuhan Zhou; Zhengzhou / China

Author Block: Y. Zhou, Y. Guo, Z. Wang, L. Lei, X. Guo; Zhengzhou/CN
Purpose: This study aims to investigate the diagnostic value of contrast-enhanced photon-counting CT (PCCT) in differentiating between bone islands and osteoblastic metastases, with the goal of enhancing clinical diagnostic accuracy.
Methods or Background: This prospective study enrolled patients undergoing spectral contrast-enhanced CT between February and May 2025 who were diagnosed with either bone islands or osteoblastic metastases. Based on clinical data and pathological confirmation, 80 cases of bone islands and 80 cases of osteoblastic metastases were included. ROIs were delineated at the lesion sites, and spectral post-processing (SPP) datasets were reconstructed to obtain conventional mixed-energy CT images (CI), virtual monoenergetic images (VMI, 40-150 keV at 10 keV intervals), iodine density maps (ID), and spectral curves. A multiparametric spectral model combining iodine density and VMI (ID-VMI40-150 keV) was established. For each ROI, conventional CT values (CIHU), iodine density values (ID value), and the slope of the spectral curve (λHU) were measured. ROC curves were generated, and the AUC and cutoff values were calculated to compare the diagnostic performance of each spectral parameter.
Results or Findings: Compared with arterial phase CT values (AUC: 0.854; cutoff: 0.69), venous phase CT values (AUC: 0.861; cutoff: 0.702), arterial iodine density (AUC: 0881; cutoff: 0.792), and virtual monoenergetic images at 40 keV (AUC: 0.901; cutoff: 0.735), 50 keV (AUC: 0.899; cutoff: 0.634), and 60 keV (AUC: 0.883; cutoff: 0.725), the spectral multiparametric model ID-VMI60 keV demonstrated the highest diagnostic performance for distinguishing bone islands from osteoblastic metastases (AUC: 0.952; cutoff: 0.934; sensitivity: 97.4%; specificity: 100%).
Conclusion: Contrast PCCT ID-VMI60 keV combined models enhanced the differential diagnosis between BIs and OBMs compared to conventional CT parameters and individual VMI parameters and did not require the use of iodine contrast agents.
Limitations: Not applicable.

Assessment of Trabecular Microstructure using Photon-Counting CT: Influence of Dose, Spatial Resolution and Reconstruction Algorithm (6 min)
Jaime Andres Pena; Kiel / Germany

Author Block: J. A. Pena[1], F. Thomsen[2], T. Damm[1], M. Frölich[3], S. O. Schönberg[3], C-C. Glüer[1], J-B. Hövener[1], M. Kachelrieß[4], S. Sawall[4]; [1]Kiel/DE, [2]Minden/DE, [3]Mannheim/DE, [4]Heidelberg/DE
Purpose: To evaluate the feasibility and accuracy of photon-counting computed tomography (PCCT) for assessing trabecular microstructure in human vertebrae at clinically realistic dose levels, while investigating the effects of radiation dose, spatial resolution, and reconstruction method.
Methods or Background: Seven excised human vertebrae were imaged with a PCCT system (Naeotom Alpha) in ultra-high-resolution mode. To reproduce clinically relevant intersection lengths, the vertebrae were placed inside a semi-anthropomorphic thorax phantom and scanned at 120 kV and dose levels between 6-20 mGy (CTDI32cm). Additional scans were performed without the phantom for high-dose reference measurements. Data were reconstructed with filtered backprojection (FBP) and quantum iterative reconstruction (QIR3) using three kernels of increasing resolution (Br56, Br76, Br89) and 0.2 mm slice thickness. Bone mineral density (BMD), bone volume fraction (BV/TV), trabecular separation (Tb.Sp), and trabecular thickness (Tb.Th) were quantified within standardized volumes of interest. Agreement with high-dose reference scans was evaluated using Wilcoxon signed-rank tests, Bland-Altman analysis, and Lin's concordance correlation coefficient (rccc).
Results or Findings: BMD and BV/TV were comparable between FBP and QIR3 with no significant differences. Sharper kernels increased noise, particularly for FBP, which compromised microstructural accuracy. Br56 resolution was insufficient to resolve trabecular microstructure. Bland-Altman and rccc analyses showed Br76 with QIR3 achieving the best agreement to the high-dose reference. For Br76, rccc ranged between 0.66-0.94 for Tb.Sp across dose levels, compared with 0.05-0.58 for Br89. Similar trends were observed for other parameters.
Conclusion: PCCT enables reliable estimation of vertebral trabecular microstructure at diagnostic dose levels and clinically relevant intersection lengths. Br76 with QIR3 was the most robust setting across dose levels and offered a good balance between noise suppression and microstructural fidelity.
Limitations: Small sample size of cadaveric vertebrae.

Gantry-based Cone-beam CT of the thoracolumbar spine: A phantom comparison with Photon-Counting CT and Energy-Integrating CT (6 min)

Carina Obermüller; Zurich / Switzerland

Author Block: U. Bach, C. Obermüller, D. Cester, F. Ensle; Zürich/CH
Purpose: This study aimed to evaluate the performance of a novel gantry-based, multi-scan CBCT system for spinal imaging with complete anatomic coverage and compare it to energy integrating (EI)CT and photon counting (PC)CT using dose-matched protocols.
Methods or Background: An anthropomorphic torso phantom was used to simulate human anatomy. Gantry-based CBCT scans of the thoracolumbar spine were performed using different presets (low-dose, enhanced, best quality), while EICT and PCCT scans followed dose-matched clinical protocols. Qualitative image analysis was assessed by three blinded readers using a 4-point Likert scale, and quantitative analysis was conducted using global noise level (GNL) measurements.
Results or Findings: CBCT achieved diagnostic-quality imaging for the thoracic and lumbar spine, particularly with "best" and "enhanced" presets. Subjective image quality was highest for PCCT, followed by EICT and CBCT. CBCT demonstrated lower GNL than EICT, nearing PCCT levels. However, high radiation doses (5 mGy) were required for CBCT imaging of the upper thoracic spine (Th1–Th6) due to anatomical complexity, while low doses (0,5 mGy) sufficed for the lower thoracolumbar spine (Th7–S1).
Conclusion: Gantry-based CBCT generated diagnostic-quality images of large spinal regions at relatively low radiation doses, although the upper thoracic spine (above Th6) required higher doses. The overall subjective image quality remained below EICT and PCCT.
Limitations: Limitations of this study include its reliance on a single-sized phantom, which does not fully capture the complexity and variability of human anatomy and physiology. Although the phantom imitates the diverse tissue composition of the human body, it lacks pathological conditions such as fractures, and the dynamic factors present in clinical settings, including motion artifacts.

Optimising CT metal artefact reduction: quantitative evaluation of acquisition and reconstruction strategies across nine orthopaedic alloys (6 min)

Marvin A. Spurek; Cologne / Germany

Author Block: M. A. Spurek, J. P. Janssen, S. Skornitzke, N. Große Hokamp; Cologne/DE
Purpose: CT evaluation in patients with orthopaedic implants is often complicated by metal artefacts. Although methods such as iterative reconstruction and orthopaedic metal artefact reduction (O-MAR) have shown promising results, evidence on interaction effects with alloy density, acquisition parameters, and with each other, remains limited. This study aimed to systematically assess both main and interaction effects on metal artefact reduction.
Methods or Background: Cylindrical rods of nine implant alloys were scanned using a CT7500 and IQon (Philips) at 100/120/140 kVp and 2/5/10 CTDIvol. Conventional and iterative model reconstructions (IMR) were generated with and without O-MAR. Artefacts were assessed across 20 cross-sections using an objective quantitative approach based on Fourier analysis. Mixed-effects regression was used to quantify the independent and combined effects of physical alloy density, kVp, CTDIvol, reconstruction method, and O-MAR on metal artefacts.
Results or Findings: Artefact levels increased with higher alloy density. O-MAR, IMR, higher kVp, and higher CTDIvol substantially reduced artefacts, with O-MAR exerting the strongest and IMR the second-strongest effect. The artefact-increasing effect of alloy density was particularly reduced by O-MAR and higher kVp, while the interaction effects with both IMR and CTDIvol were small. Combining O-MAR and IMR with higher kVp yielded a small additional artefact reduction, whereas the artefact-reducing effect of higher CTDIvol was diminished by the combined use of O-MAR and IMR.
Conclusion: On standard scanners, O-MAR is the most, and IMR the second-most, effective tool for reducing metal artefacts, and both should be routinely applied. Higher kVp provides additional benefit, particularly in dense alloys, whereas increasing CTDIvol yields little extra improvement and should not be prioritised considering patient radiation exposure. These findings provide practical guidance for optimising CT protocols in patients with orthopaedic implants.
Limitations: Results should be verified in vivo.
Funding for this study: No funding was received for this study.

Leveraging iterative metal artifact reduction with cinematic volume rendering technique for enhanced CT assessment of hip replacements: a visual and diagnostic leap forward (6 min)

Xing Liu; Zhengzhou / China

Author Block: X. Liu, J. Li; Zhengzhou/CN
Purpose: To explore the potential of combining the iterative metal artifact reduction (iMAR) algorithm with cinematic volume rendering technique (cVRT) in photon-counting CT for assessing hip replacements.
Methods or Background: A retrospective study was conducted on 120 patients who underwent hip arthroplasty exams using the photon-counting CT scanner (NAEOTOM Alpha). Reconstruction of CT images employing conventional methods, volume rendering (VR), and cVRT, both with and without iMAR. Measurements of CT numbers and standard deviations (SDs) in regions of interest (ROIs) were obtained. Objective image quality and subjective scores were assessed using established scales. Statistical analyses included paired T tests, Mann-Whitney U tests, and Kappa tests.
Results or Findings: Compared with the non-iMAR group, the iMAR group showed significantly decreased and increased CT numbers in hyperattenuating and hypoattenuating areas, respectively, as well as lowered artifact and image noise ($p<.001$). Qualitatively, the iMAR group showed superiority to the non-iMAR group in both image quality and diagnostic confidence, with scores increases of 2.70 and 2.88 points, respectively ($P<0.05$). iMAR combined with cVRT received the highest subjective score ($P<0.05$) among the four series of post-processing images, followed by iMAR with VR images($P<0.05$), cVRT and VR images in the non-iMAR group both received the lowest scores.
Conclusion: The iMAR algorithm in photon-counting CT effectively reduces artifacts and image noise, enhancing both image quality and diagnostic confidence in post-hip metal replacement assessments. When combined with cVRT, it provides a more intuitive visualization of metal implant stability and the relationship between implants and adjacent tissues.
Limitations: We focused exclusively on patients undergoing unilateral total hip replacement surgery, without differentiation by metal type or specific surgical approaches, leaving the effects of these variables on artifacts unexplored

Photon-Counting CT Virtual Noncalcium Technique for Osteoporosis Diagnosis: A Quantitative CT-Based Validation Study (6 min)

Yao Jun Jiang; Zhengzhou / China

Author Block: Y. J. Jiang, Y. Wu, J. Gao; Zhengzhou/CN
Purpose: This study aimed to evaluate the clinical utility of photon-counting CT (PCCT) virtual noncalcium (VNCa) technology in diagnosing osteoporosis, using quantitative CT (QCT)-measured bone mineral density (BMD) as the reference standard.
Methods or Background: In this cross-sectional study, retrospective data from 445 patients were analyzed. All participants underwent PCCT scans encompassing the L1–L3 vertebral levels, with concurrent QCT BMD measurements obtained using dedicated software. Pearson correlation analysis was performed to assess the relationship between decalcified density and BMD. Multivariable linear regression was used to derive a predictive equation for BMD.
Results or Findings: A calcium ratio of 1.57 was established for decalcified density measurement. Multivariable linear regression revealed a significant model ($F = 749.2$, $p < 0.0001$), with calcium density ($\beta = 24.68$, $p < 0.0001$) as a significant positive predictor of BMD, while age ($\beta = -0.4297$, $p < 0.0001$) and BMI ($\beta = -0.4354$, $p = 0.0341$) were negative predictors. Sex ($\beta = -0.4139$, $p = 0.792$) did not significantly influence BMD. The regression equation was:
BMD = 24.68 × Decalcified Density - 0.4297 × Age - 0.4139 × Sex - 0.4354 × BMI + 6.556. The area under the ROC curve (AUC) for decalcified density in diagnosing osteoporosis was 0.9917 (95% CI: 0.9856–0.9997, $p < 0.0001$). At a decalcified density threshold of <4.685 mg/cm³, sensitivity and specificity were 97.61% and 96.3%, respectively.
Conclusion: Dual-energy CT VNCa technology can serve as an effective alternative for quantifying bone mineral content in osteoporosis diagnosis.
Limitations: The cross-sectional design cannot assess the relationship between dynamic changes in calcium density and the evolution of BMD. manufacturers.

A preliminary study of automated segmentation and quantification of human knee trabecular bone in vivo using photon-counting CT (6 min)

Kaicheng Wen; Shenyang / China

Author Block: K. Wen[1], Y. Zhu[1], g. fan[1], B. Zhang[1], Y. Ling[2], X. Liang[2], B. Li[1], H. Li[1], K. Zhang[1]; [1]Shenyang/CN, [2]Shanghai/CN
Purpose: To explore the feasibility of evaluating knee trabecular microstructure in vivo using photon-counting CT (PCCT) with automated segmentation and quantitative analysis.
Methods or Background: Changes of knee trabecular microstructure are associated with the onset and progression of bone diseases such as osteoporosis and osteoarthritis. High-resolution peripheral quantitative CT (HR-pQCT) has been used to quantify trabecular microstructure in vivo, but is limited by a relatively small field of view. PCCT enables superior spatial resolution and dose efficiency for whole-body imaging. Seven volunteers (age range 30-69 years) were recruited in this preliminary study for PCCT scans (P10, Neusoft Medical Systems; 104µm @2%MTF and 120 kV) of both knees. Images were reconstructed with a 1024 matrix and slice thickness of 274 µm. Subchondral trabecular bone of femoral and tibial condyle was automatically segmented using a ResUNet-based framework. Trabecular parameters, including bone volume fraction (BV/TV), trabecular thickness (Tb.Th), trabecular separation (Tb.Sp), trabecular number (Tb.N), and synthetic images (SMI), were computed via the NeuSpace platform (Neusoft Medical Systems) and compared with values previously reported in cadaveric PCCT studies.
Results or Findings: The automated pipeline successfully segmented and quantified in vivo subchondral trabecular microstructure. Compared to cadaveric literature of knee PCCT, our in vivo cohort exhibited a 65% higher bone volume fraction (BV/TV: 48.90±8.74 % vs. 29.61±11.06 %), 74% thicker trabeculae (Tb.Th: 0.75±0.08 mm vs. 0.43±0.09 mm), and more plate-like structure (SMI: 0.68±0.26 vs. 1.64±0.74).
Conclusion: This study provides preliminary subchondral trabecular evidence in vivo using PCCT, and demonstrates the feasibility of automated segmentation and quantitative analysis with NeuSpace, suggesting potential applications for osteoporosis and osteoarthritis assessment.
Limitations: This is a preliminary study with a small sample size. Larger-scale studies are needed to confirm the clinical value.
Funding for this study: No funding was received for this study.

Impact of motion artifacts on registration accuracy in dynamic CT images of the wrist joint: a multivendor phantom study (6 min)

Hanne Vries; Nijmegen / Netherlands

Author Block: H. Vries[1], B. van der Heijden[1], S. Hummelink[1], J. G. G. Dobbe[2], I. Sechopoulos[1], G. J. Streekstra[2]; [1]Nijmegen/NL, [2]Amsterdam/NL

Purpose: To assess how motion artifacts influence registration accuracy across acquisition and reconstruction protocols of different CT systems in 4D CT images of a rotating wrist phantom.

Methods or Background: A rotating wrist phantom with three 3D-printed bones (scaphoid, lunate, capitate) was scanned on four CT systems (two vendors; single- and dual-source). One static 3D scan and multiple axial 4D scans were acquired at different phantom rotation speeds, each lasting 10s. Single-source covered 0.5–3 cycles, and dual-source 1–6 cycles (one cycle represents radial–ulnar–radial; 0.5 cycle represents radial–ulnar). Dose dependence was evaluated on two systems (80 kV/40 mA and 120 kV/100 mA). Images were reconstructed in full and partial modes, segmented, and registered using point-to-image registration. Registration accuracy was calculated as translation and rotation errors of the scaphoid and capitate relative to the lunate, referenced to the static scan, and reported as median with interquartile range per wrist cycle.

Results or Findings: Registration accuracy was unaffected by dose. For one cycle, the errors of the best single-source system were 0.29(0.21–0.36) mm and 1.37(0.82–2.18) degrees for full and 0.21(0.16–0.25) mm and 0.70(0.52–0.95) degrees for partial reconstructions for the capitate; the dual-source system showed the highest accuracy (errors of 0.14(0.12 – 0.17) mm and 0.48(0.39 – 0.62) degrees). For all systems with partial reconstructions, the translation errors remained below the voxel size (0.28mm) for ≤one cycle per 10s.

Conclusion: Dynamic 4DCT of the wrist has shown promise, but the impact of motion artifacts on bone-to-bone measurements needs to be understood. Partial reconstructions kept registration errors below the pixel size for wrist rotations up to one cycle per 10s, while dual-source scans reached similar accuracy at higher speeds.

Limitations: Limited to a phantom with 3D-printed bones and not yet validated in clinical setting.

Diagnostic Performance of Standard versus SWI- and Neuromelanin-Sensitive Imaging-Reconstructed Susceptibility Map–Weighted Imaging in Early Parkinson's Disease (6 min)
Seon Lee; Seoul / Korea, Republic of

Author Block: S. Lee, J. Youn, E. Y. Kim, B. Sohn; Seoul/KR
Purpose: Susceptibility map-weighted imaging (SMwI) provides a reliable marker for the loss of nigral hyperintensity in Parkinson's disease (PD), yet requires a dedicated high-resolution oblique-coronal acquisition. To improve feasibility and broader applicability, we investigated whether SMwI reconstructed from existing sequences—susceptibility-weighted imaging (SWI) and neuromelanin-sensitive imaging (NM)—could approximate the diagnostic performance of standard SMwI in differentiating early PD from disease controls (DC). Diagnostic performance was further evaluated with reference to 18F-FP-CIT PET as an independent standard.
Methods or Background: We retrospectively reviewed 187 early PD and 43 DC subjects imaged at Samsung Medical Center between 2021 and 2022. Source data for SMwI, SWI, and NM were acquired perpendicular to the midbrain, along the anterior commissure–posterior commissure plane, and perpendicular to the fourth ventricle, respectively, with resolutions of 0.5×0.5×1 mm^3, 0.5×0.5×2 mm^3, and 0.7×0.7×1.2 mm^3. Standard SMwI, SWI-driven SMwI, and NM-driven SMwI were reconstructed in MATLAB. Two blinded neuroradiologists evaluated nigral hyperintensity, and diagnostic accuracy was assessed relative to both clinical diagnosis and PET.
Results or Findings: Standard SMwI demonstrated the highest accuracy against clinical diagnosis, significantly outperforming reconstructed alternatives, with the largest disparity observed for NM-driven SMwI. In both lesion- and patient-level analyses referenced to PET, standard SMwI consistently exceeded NM-driven SMwI, whereas its performance was not statistically distinguishable from SWI-driven reconstructions. These differences appear attributable to variations in spatial resolution, slice thickness, and acquisition geometry.
Conclusion: Standard SMwI outperformed reconstructed methods against clinical diagnosis, but SWI-driven SMwI showed comparable accuracy to the standard with PET, indicating its potential as a practical alternative when standard acquisition is not feasible.
Limitations: Because the compared methods varied simultaneously in in-plane resolution, slice thickness, and acquisition plane, the independent contribution of each factor could not be isolated.
Funding for this study: No funding was received for this study.

Substantia Nigra and Neuromelanin Volume Changes in Association with Motor Symptoms in Parkinson's Disease Using Semi-Automated Neuromelanin Quantification (6 min)
Arturs Silovs; Riga / Latvia

Author Block: A. Silovs, N. Zdanovskis, G. K. Skuburs, S. Umbrasko, A. Sevcenko, J. Mednieks, A. Platkājis, J. Skilters, S. Bartusevica; Riga/LV
Purpose: Parkinson's disease (PD) is characterised by progressive dopaminergic neuronal loss in the substantia nigra pars compacta. Neuromelanin-sensitive MRI (NM-MRI) allows in vivo assessment of this degeneration. We aimed to evaluate substantia nigra neuromelanin volume changes in PD patients and their association with motor symptoms using semi-automated volumetric analysis.
Methods or Background: This prospective case-control study enrolled 23 PD patients, mean age 64.9 ± 12.3 years; 23 controls, mean age 50.8 ± 11.1 years. High-resolution 3T NM-MRI was acquired using a T1-weighted spin-echo sequence. Semi-automated segmentation (Mango v3.5.1) with intracranial volume correction (FreeSurfer 7.3) was performed. Clinical severity was assessed with the Unified Parkinson's Disease Rating Scale (UPDRS) and Hoehn & Yahr (H&Y) staging.
Results or Findings: Corrected substantia nigra volume was significantly reduced in PD patients (0.0276 ± 0.0058 mm^3) compared with controls (0.0337 ± 0.0102 mm^3), representing an 18% reduction ($p = 0.014$, t-test; $p = 0.039$, Mann–Whitney U). ROC analysis demonstrated moderate diagnostic performance (AUC = 0.700; sensitivity = 68.4%; specificity = 74.1%). Progressive reduction was observed across disease stages: H&Y stage 1 (0.0285 ± 0.0054 mm^3) and stage 2 (0.0279 ± 0.0064 mm^3), both significantly lower than controls ($p < 0.05$). No significant correlation was found between corrected volumes and UPDRS-III motor scores. Semi-automated segmentation showed excellent agreement with manual measurements (ICC = 0.945).
Conclusion: Semi-automated NM-MRI reliably detects substantia nigra volume loss in early-stage PD with moderate diagnostic accuracy. While not strongly correlated with UPDRS-III, corrected NM volume reflects disease staging and may serve as a supportive biomarker for PD diagnosis and monitoring.
Limitations: The main limitation is age mismatch between groups (mean difference 14 years), representing a potential confounder. Additional limitations include modest sample size and cross-sectional design.
Funding for this study: This research was funded by the Latvian Council of Science, project No. lzp-2022/1-0100

Resting-State brain connectivity in Parkinson's disease: a randomized controlled trial following the Quadrato Motor Training (6 min)

Flora De Rosa; Caserta / Italy

Author Block: F. De Rosa[1], R. Franciosi[2], D. Vo[1], G. Greco[1], M. Fusina[1], C. C. Quattrocchi[1]; [1]Trento/IT, [2]Rovereto (TN)/IT
Purpose: To evaluate the effects of Quadrato Motor Training (QMT) on resting-state FC in PD patients.
Methods or Background: Parkinson's disease (PD) is characterized by motor and cognitive impairments, associated with alterations in functional connectivity (FC) across brain networks. Motor interventions with cognitive engagement may foster neuroplasticity and compensatory mechanisms.
Results or Findings: Out of 50 randomized PD patients, 48 completed the trial (QMT n=23, control n=25). Independent component analysis identified 11 major resting-state networks (RSNs).
Control group showed significant FC decrease ($p<0.01$ FDR-corrected) across multiple RSNs including default mode (Tmax=5.03, L frontal pole), dorsal attention (Tmax=5.03, R occipital cortex), executive control (Tmax=3.72, paracingulate gyrus), sensorimotor (Tmax=4.80, precuneus; Tmax=4.38, R postcentral gyrus) and cerebellar networks (Tmax=4.89, L Crus II).
QMT group exhibited increased FC in the right frontoparietal network (T=3.99, R angular gyrus) and in the sensorimotor II network (T=3.62, R postcentral gyrus), with no significant reductions in any RSN.
Between-group comparisons (ΔFC): QMT preserved connectivity in the left postcentral gyrus (T=4.41), supplementary motor area (T=3.72), and cerebellar Crus II (T=3.83), while controls showed significant decline.
Conclusion: By combining motor and cognitive stimulation,QMT may prevent FC decline and enhance connectivity within key motor and cognitive networks in PD. Brain functional connectivity measures are suitable to measure the effect of rehabilitation strategies in PD.
Limitations: The study was limited to 4 weeks; pre- and post-intervention assessments of motor and cognitive functions (beyond fMRI) were not included; control groups: only a sham motor control was used, without an active cognitive control group.
Funding for this study: Brain functional connectivity (FC) emerged as a sensitive marker to capture the neural effects of rehabilitation strategies in Parkinson's disease (PD). Resting-state fMRI revealed that controls (sham exercise) exhibited a widespread decline in FC across default mode, executive, dorsal attention, sensorimotor, and cerebellar networks, confirming the progressive disconnection typical of PD.
QMT group: showed preserved or increased FC, with significant gains in the right frontoparietal and sensorimotor networks.
Between-group comparison: highlighted that QMT protected connectivity in regions critical for motor control and compensation, including the supplementary motor area and cerebellar Crus II, which were selectively impaired in controls.
These findings demonstrate that resting-state FC is not only suitable but highly informative to assess the impact of motor-cognitive rehabilitation in PD. The ability of QMT to enhance or stabilize FC in key brain networks supports its potential role as a neuroplastic and neuroprotective intervention, measurable with functional imaging biomarkers.

Five-Year MRI Visibility of MRgFUS Thalamotomy in Essential Tremor and Parkinson's Disease (6 min)

Giovanni Di Cerbo; Maddaloni / Italy

Author Block: G. Di Cerbo, G. Saltarelli, A. Innocenzi, C. De Felici, S. Di Terlizzi, A. Catalucci, F. Bruno, E. Di Cesare, A. Splendiani; L'Aquila/IT
Purpose: To evaluate long-term clinical and radiological outcomes of unilateral MR-guided focused ultrasound (MRgFUS) Vim thalamotomy for essential tremor over five years, assessing durability of tremor control and lesion evolution on MRI.
Methods or Background: Retrospective single-centre cohort of 28 right-handed, medication-refractory essential tremor patients who underwent unilateral (left) Vim MRgFUS thalamotomy between February 2018 and December 2019 (San Salvatore Hospital, L'Aquila). Clinical evaluations used the Fahn–Tolosa–Marin Tremor Rating Scale (FTM-TRS) at baseline, 24 h, 1 month, 1, 2, and 5 years. Brain MRI (T1, T2, FLAIR, DWI, SWI, DTI) was acquired at the same time points. Lesion presence and volume were assessed on all sequences, and whole-brain volumetry was performed with dedicated software. DTI tractography reconstructed the dentato-rubro-thalamic tract (DRTT) in the treated hemisphere using ROIs in the dentate nucleus, red nucleus, and Vim.
Results or Findings: Tremor severity improved and remained stable (FTM-TRS 5.1 ± 0.79 baseline vs 1.3 ± 0.61 at 5 years; −74.5%). Recurrence occurred in 2 patients. No adverse events at 5-year follow-up. MRI showed progressive lesion shrinkage. At 5 years, lesions were visible in 56% on fluid-sensitive sequences, 73% on T1-weighted, and 100% on SWI. No lesion was visible on DWI after 6 months. Only the treated thalamus showed significant long-term volume reduction (7.36 ± 0.79 mL at 1 year vs 7.15 ± 0.71 mL at 5 years; $p = 0.001$).
Conclusion: MRgFUS thalamotomy provides sustained tremor control with a favorable safety profile and durable imaging signatures of thalamic ablation.
Limitations: The main limitation is the small sample size, which may reduce statistical power.
Funding for this study: This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Neuromelanin-sensitive MRI for locus coeruleus imaging in parkinson's disease and multiple system atrophy (6 min)

Yiqing Yang; Shanghai / China

Author Block: Y. Yang, H. Lyu, Y. Lu; Shanghai/CN
Purpose: The locus coeruleus (LC), brain's principal noradrenergic nucleus, contributes to cognitive and non-motor symptoms in Parkinson's disease (PD), yet its role in multiple system atrophy (MSA) and its subtypes—cerebellar (MSA-C) and parkinsonian (MSA-P)—remains unclear. This study quantified LC relative contrast ratios (rCR) on neuromelanin-sensitive MRI (NM-MRI), compared LC integrity among PD, MSA subtypes, and healthy controls (HC), and examined associations with motor, autonomic, cognitive, and sleep functions.
Methods or Background: A total of 147 participants (42 PD, 82 MSA, 23 HC) underwent 2D NM-MRI. LC signal intensity was normalized to pontine white matter (rCR-LC-Pons). Group differences were assessed using Kruskal–Wallis with Bonferroni correction; clinical associations were examined via Spearman correlations and age-, sex-, and education-adjusted GLMs. Receiver operating characteristic (ROC) analyses evaluated the diagnostic performance of rCR-LC-Pons across groups.
Results or Findings: rCR-LC-Pons showed strong group differences ($p < 0.001$), indicating a progressive LC signal decline from HC to PD to MSA and MSA subtypes. rCR-LC-Pons correlated negatively with disease duration in both PD and MSA, reflecting ongoing neuro degeneration. Adjusted models showed rCR-LC-Pons 5.44 units lower in MSA than PD at matched duration, independent of age or sex. Diagnostic accuracy was high for distinguishing MSA from HC (AUC = 0.93) and PD from HC (AUC = 0.82). In PD, LC integrity predicted cognitive performance (MoCA: $\beta = 0.46$, $p < 0.01$; $R^2 \approx 0.20$), supporting its value as a marker of cognitive vulnerability and disease stratification.
Conclusion: NM-MRI reliably detects LC degeneration across PD and MSA spectra. Pons-referenced normalization provides superior discrimination, and LC integrity partly explains cognitive variance in PD, supporting its utility as a clinical imaging biomarker.
Limitations: Cross-sectional design and modest model fits limit causal inference; longitudinal and multimodal validation is needed.

Cortical susceptibility mapping in Parkinson's Disease reveals spatial iron accumulation and its molecular basis (6 min)

Jianmei Qin; Hangzhou / China

Author Block: J. Qin, M. Zhang; Hangzhou/CN
Purpose: Parkinson's disease (PD) is increasingly recognized to involve cortical regions. Quantitative susceptibility mapping (QSM), a marker of iron accumulation, may sensitively capture such changes. We sought to characterize whole-brain susceptibility alterations in PD and evaluate their structural and molecular correlates.
Methods or Background: We studied 355 PD patients and 206 healthy controls with 3T MRI, including QSM and T1-weighted imaging. Cortical QSM values were extracted using Desikan–Killiany parcellation with multiscale vessel filter to minimize venous contamination, while cortical thickness and subcortical volumes were derived from FreeSurfer. Group comparisons used general linear models adjusting for age, sex, and intracranial volume. Spatial correlations were tested against ENIGMA PD cortical atrophy maps (3092 PD patients and 1262 healthy controls), intrinsic functional networks, cytoarchitectonic classes, and neurotransmitter receptor distributions, with spin-test spatial null models. Regional gene expression from the Allen Human Brain Atlas was analyzed using partial least squares (PLS), followed by gene set enrichment analysis to identify underlying biological pathways.
Results or Findings: QSM revealed widespread cortical and subcortical susceptibility increases, already evident in early-stage PD, while morphometric measures showed limited changes. Cortical QSM abnormalities show strong spatially overlapped with ENIGMA PD atrophy patterns, and were centered in frontoparietal and association cortices. This susceptibility abnormalities pattern correlated with serotonin (5-HT6, 5-HT2A), dopamine transporters, and cholinergic systems. PLS analysis revealed gene expression profiles associated with cortical QSM alterations, highlighting pathways related to mitochondrial dysfunction, impaired synaptic signaling, and immune–glial processes.
Conclusion: QSM detects early cortical iron-related abnormalities in PD, aligning with large-scale atrophy patterns and linking to neurotransmitter and molecular pathways. These findings support cortical susceptibility as a potential biomarker and implicate neuronal vulnerability in disease mechanisms.
Limitations: Longitudinal imaging and multi-cohort replication will be needed to validate and extend these findings.
Funding for this study: This work was supported by the National Natural Science Foundation of China (Grant Nos. 82271935, 82171888, 82202091, 82001767 and 82302132), the China Postdoctoral Science Foundation (Grant Nos. 2023M733085), and the 13th Five-year Plan for National Key Research and Development Program of China (Grant No. 2016YFC1306600).

Predictive value of perivascular space network and choroid plexus for levodopa responsiveness in Parkinson's disease (6 min)

Zekai Chen; Shenzhen / China

Author Block: Z. Chen, S. Huang, Y. Liang, D. Cai, X. Zhou, W. He, J. Xia; Shenzhen/CN
Purpose: Inter-individual variability in levodopa responsiveness complicates personalized treatment of Parkinson's disease (PD). Previous studies have suggested that magnetic resonance imaging (MRI)-based indices of the perivascular space (PVS) and choroid plexus (CP) volume may be related to levodopa responsiveness. This study integrated multiple MRI indices, including CP volume, free water (FW) fraction, PVS volume fraction (PVSVF), and diffusion tensor imaging along the PVS (DTI-ALPS), to investigate their associations with levodopa responsiveness.
Methods or Background: This retrospective study included 100 participants with PD (median age, 63.5 years; 53% females) who underwent 3T MRI between March 2023 and December 2024 and were grouped into good (n=54) and poor (n=46) responders based on the results of an acute levodopa challenge test. CP volume, FW fraction, PVSVF, and DTI-ALPS index were calculated. The Mann–Whitney U test and binary logistic regression were used for analysis.
Results or Findings: Participants in the poor responder group had a higher CP volume ($p = 0.048$) and FW fraction ($p < 0.01$) than those in the good responder group. Higher CP volume (odds ratio [OR], 0.986; $p = 0.038$) and FW fraction (odds ratio [OR], 0.883; $p < 0.01$) were significantly associated with poor levodopa responsiveness, while higher PVS volume fraction, higher PVSVF-BG, higher PVSVF-WM and lower DTI-ALPS were not.
Conclusion: Higher CP volume and FW fraction were independently associated with poor levodopa responsiveness. CP volume and FW fraction measurements may be valuable imaging biomarkers for predicting levodopa responsiveness.
Limitations: Glymphatic and choroid plexus metrics were indirect or structural, not fully capturing function or regional variations. Future work should employ direct imaging tracers, dynamic techniques, and spatially refined analyses for validation.

Integrating Neuroimaging Transcriptomics and Single-Cell Sequencing Reveals Cortical Vulnerability and Novel Therapeutic Targets in Amyotrophic Lateral Sclerosis (6 min)

Jixin Luan; Beijing / China

Author Block: J. Luan, S. Liu, F. Liu; Jinan/CN
Purpose: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease characterized by cortical thinning and surface area reduction, though its molecular basis remains poorly understood. This study combined multi-level data to explore regional vulnerability in ALS.
Methods or Background: We analyzed T1-MRI from 73 ALS patients and 70 healthy controls to assess cortical surface area (SA) and thickness (TH). Two-sample Mendelian randomization (MR) evaluated causal effects of structural phenotypes on ALS risk. Regional gene expression from the Allen Human Brain Atlas was integrated via partial least squares regression and differential expression analysis to identify SA- and TH-associated genes. Functional annotation, cell-type enrichment, and summary-data-based MR (SMR) incorporating eQTL/mQTL were performed. Candidate genes were validated using single-cell RNA sequencing and cell-cell communication analysis.
Results or Findings: ALS patients exhibited reduced SA in the left precentral gyrus and decreased TH in the left frontal pole. MR analysis confirmed a causal influence of reduced SA in the paracentral lobule and diminished TH in the frontal pole regions on ALS risk. Integrated imaging-transcriptomic analysis identified 215 SA-intersect and 979 TH-intersect genes, which were enriched in synaptic processes, neuroactive ligand-receptor interactions, and glycosphingolipid metabolism. SA-intersect genes were primarily expressed in oligodendrocytes (ODC), while TH-intersect genes showed expression in astrocytes (ASC). SMR nominated myelin-associated MOBP and ZNHIT3 as potential causal genes. Single-cell analyses confirmed downregulation of MOBP in ODC and reduced expression of ZNHIT3 in ASC. Cell-cell communication analysis revealed enhanced signaling involving neuregulin (NRG) and pleiotrophin (PTN) pathways in ALS.
Conclusion: We demonstrate a causal influence of cortical structural changes on ALS risk, implicate synaptic and glial dysregulation in regional vulnerability, and nominate MOBP and ZNHIT3 as potential therapeutic targets.
Limitations: Limited sample size, cross-sectional design, and regional focus constrain causal and generalizable conclusions.
Funding for this study: This work was supported by Natural Science Foundation of Shandong Province (2601010520249H).

Microstructure and gene expression influence gyrification in Amyotrophic Lateral Sclerosis (6 min)

Xiaoping Yi; Chongqing / China

Author Block: X. Yi[1], B. T. Chen[2]; [1]Chongqing/CN, [2]Duarte, CA/US
Purpose: Beyond well-established gray and white matter pathology, alterations in cortical gyrification have recently been observed in Amyotrophic lateral sclerosis (ALS) , yet their clinical relevance and molecular underpinnings remain to be understood. We aimed to perform an in-depth investigation of the cortical gyrification changes and their microstructural and transcriptional correlates in symptomatic patients with ALS.
Methods or Background: Here, we investigated this premise by examining its microstructural and transcriptional basis in 60 patients with ALS (median age = 55, range = 25-72 years) and 60 matched controls (median age = 56, range = 27-72 years) using structural and diffusion MRI.
Results or Findings: Patients exhibited a significant reduction in local gyrification index (LGI) within bilateral precentral and postcentral gyri, left middle frontal gyrus, and left superior parietal lobule. This was accompanied by reduced fractional anisotropy (FA) in the white matter tracts, primarily involving the corticospinal tract and corpus callosum. Higher LGI and FA values were associated with better motor function as measured by the ALS Functional Rating Scale-Revised, and LGI also showed positive associations with global cognitive status. A mediation analysis indicated that FA partially accounted for the relationship between LGI and functional disability, suggesting that disrupted white matter pathways contribute to the clinical impact of gyrification changes. Regions of reduced LGI showed spatial convergence with cortical expression of ALS-related genes such as TARDBP and C9orf72, enriched for biological processes related to protein aggregation, axon guidance, and synaptic signaling.
Conclusion: These findings suggest that cortical gyrification abnormalities in ALS are closely linked to white matter degeneration, functional impairment, and genetic vulnerability, thereby offering an integrative window into the multiscale pathology of ALS.
Limitations: The sample size was relatively small, and this was a cross-sectional study.

Understanding Mammography Care for People with Dementia-Related Cognitive Disorders (6 min)
Stephanie Frei; Le Vaud / Switzerland

Author Block: S. Frei, M. Champendal, R. Freund, C. S. D. Reis; Lausanne/CH
Purpose: The care of individuals with cognitive impairment related to dementia (CI) in the context of mammography remains insufficiently documented, despite its potential impact on examination quality. This study aimed to identify facilitators and barriers influencing the performance of mammography examinations in this context.
Methods or Background: A cross-sectional design was applied using a questionnaire developed in French, translated into German, and disseminated via professional radiography bodies. The survey covered four domains: sociodemographic characteristics, training, professional practices, structural environment. Data were analysed using descriptive and differential statistics (test exact de Fisher), supplemented by qualitative thematic analysis for open-ended questions. As no sensitive data were collected, ethics approval was not required.
Results or Findings: A total of 243 radiographers (233 females,10 males) responded. Only 2.8%(n=7) reported having received specific training on dementia-related care, while 82.3%(n=200) expressed a need for such preparation. Formal procedures were rare (1.6%,n=4), with 17.6%(n=43) of participants indicating adaptations as allocation of extra time to perform the examination. Implementation of facilitators varied according to experience and education but the presence of caregivers was highlighted. Structural limitations were also evident: over half of respondents (51.8%,n=126) reported working in departments with inadequate floors, raising concerns about accessibility and mobility of this population. Statistical significant differences ($p<0.05$) were identified according to the type of institution.
Conclusion: Findings demonstrate that recommended strategies to adapt mammography examinations for people with CI are inconsistently applied within practice. The absence of training, protocols, and supportive environments represents a barrier to provide adequate care. Targeted professional development, explicit procedural guidelines, and organisational adjustments are required to optimise patient management and ensure examination quality.
Limitations: Conducted in several languages

Assessing image acquisition in Contrast-enhanced mammography: dosimetric, temporal and qualitative evaluation (6 min)
Eleonora Di Paola; Corbetta / Italy

Author Block: F. E. El Archa, E. Di Paola, V. Magni, S. Marziali, M. Zanardo, F. Sardanelli; Milan/IT
Purpose: Since technical variability in contrast-enhanced mammography (CEM) may compromise diagnostic performance, the aim of this study was to retrospectively evaluate adherence to acquisition protocols and image quality.
Methods or Background: A retrospective analysis was conducted on 122 CEM examinations performed at the Radiology department of IRCCS Policlinico San Donato between January 2019 and August 2020, using a dedicated digital mammography system (Senographe Pristina, GE Healthcare). Three domains were assessed: dosimetric parameters (kVp, mAs, compressed breast thickness); temporal data (acquisition times, overall examination duration); and qualitative criteria derived from the PGMI system, including pectoral muscle visualisation, nipple profile alignment, posterior nipple line (PNL) consistency, inclusion of the inframammary fold, pectoral muscle shape, and the presence of artefacts or excluded tissue. Descriptive statistics were applied.
Results or Findings: Median kVp was 34 (IQR 34–34), median mAs 40.6 (IQR 32.3–49.1), and mean compressed breast thickness 5.5 ± 1.3 cm. The recommended 10-minute post-contrast window was consistently respected, with a mean examination duration of 1:22 minutes (maximum 4:13).
Qualitative analysis showed frequent deviations from positioning standards. The pectoral muscle was absent in 106/122 (87%) CC-right views and in 103/122 (84%) CC-left views. Nipple profile was inadequate in 22/122 (18%) CC views and 43/122 (35%) MLO views. PNL discrepancies >1 cm occurred in 81% patients. The inframammary fold was included in 101/122 (83%) MLO-right views and in 99/122 (81%) MLO-left views, but perfectly visualised in only 3/122 (2%) and 5/122 (4%) cases, respectively. Exclusion of glandular tissue occurred in 115/122 (94%) cases.
Conclusion: CEM examinations demonstrated marked heterogeneity in image acquisition, with frequent failure to meet positioning criteria.
These findings highlight the urgent need for standardised acquisition protocols and quality assurance frameworks to optimise clinical implementation of CEM.
Limitations: Single-centre retrospective study.

Breast screening attendance amongst culturally and linguistically diverse women in Ireland (6 min)

Clare Rainey; Cork / Ireland

Author Block: C. Power, M. F. Mcentee, C. Rainey, J. ONeill, L. McLaughlin, P. C. Murphy, A. England; Cork/IE
Purpose: To identify the gap in breast screening services in Ireland for this population of women, promoting inclusiveness in breast cancer services.
Methods or Background: Cultural and linguistic diversity is increasing worldwide with a significant increase in migration. Access of breast cancer services for cultural and linguistically diverse women in Ireland may impose challenges, due to many factors including lack of education, language, social and cultural factors. Breast cancer is one of the most common cancers diagnosed in women worldwide, however screening rates vary amongst populations with cultural and linguistically diverse women having lower screening rates when compared with the general population of women.

Using a qualitative approach, this study aims to explore the personal perspectives of cultural and linguistically diverse women in accessing breast cancer services in Ireland, through 1:1 face-to-face online interviews.
Results or Findings: Five themes and two subthemes emerged throughout discussion which included, barriers and facilitators to accessing care, reflection on previous experience in home country, knowledge and awareness of breast cancer/breast health, knowledge and awareness of screening/health care provision in Ireland for breast cancer and breast health, and recommendations/ healthcare strategies to improve services for the culturally and linguistically diverse population.
Conclusion: Culturally and linguistically diverse women's access to breast cancer screening and services in Ireland is influenced by a variety of factors, some favourable and others unfavourable. Raising education and awareness for culturally and linguistically diverse women around breast health and breast cancer services may lead to increased screening rates and improved outcomes for these women.
Limitations: This study included only those who were proficient in English, thus might not be representative of all seeking asylum.
Funding for this study: None

AI in action: a European radiography survey on Endometriosis diagnostic protocols (6 min)

Martina Haber; Zejtun / Malta

Author Block: M. Haber, M. Montebello, K. Borg Grima; Msida/MT
Purpose: Endometriosis is a chronic, gynaecological condition that affects approximately 10% of females worldwide, with an average diagnostic delay of 6-12 years. While, AI shows promise in aiding diagnosis, a gap exists regarding its practical applications and the radiography professionals' perceptions on its use. The study aims to compare imaging protocols for endometriosis used within Europe in MRI and gynaecological ultrasound. It will assess radiographers' knowledge and awareness of AI-based diagnostic tools.
Methods or Background: This study comprises a phase of an ongoing PhD study. An online survey will be distributed through the European Federation of Radiographer Societies (EFRS). The survey is targeted at radiographers working in MRI or gynaecological ultrasound. Its objective is to gather insights into the current medical imaging procedures and protocols used in diagnosing Endometriosis, while collecting information on the awareness and use of AI-based tools in clinical practice.
Results or Findings: A systematic review of 116 articles conducted in February 2025 highlighted a need for further research on the use of AI in the diagnosis of Endometriosis. The results of this survey will reveal region-specific practices, variations in imaging protocols, and the perceived value for the adoption of AI-based diagnostic tools within the radiography community.
Conclusion: The findings from this survey will provide an overview of radiography practices and the perceived utility of AI in Endometriosis diagnosis. The results could inform the standardisation of imaging protocols used in MRI and gynaecological ultrasound to diagnose this pathology. Data collected can provide information to professional bodies and educational institutions on the integration of AI-based tools.
Limitations: Limitations of the study relate to the use of an online survey which may limit responses while introducing a response bias, since self-reported data reflects participants' perceptions and practices.
Funding for this study: No funding was received for this study.

Ethics committee - additional information: The study was approved by the University of Malta Research Ethics committee (reference number: FHS-2025-00146).

Evaluation of Postpartum Abdominal Diastasis in Vaginal Births vs. Cesarean Sections Using Ultrasound (6 min)

Magda Miranda Silva; Lousã / Portugal

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: M. M. Silva[1], A. F. C. L. Abrantes[2], L. P. V. Ribeiro[3], S. I. Rodrigues[1], R. P. P. Almeida[4], R. Van Hauwaert[4], A. Onofre de Carvalho[1], R. Lopes[5], S. Tavares[5]; [1]Faro/PT, [2]Évora/PT, [3]Lagoa/PT, [4]São Brás de Alportel/PT, [5]Lisboa/PT
Purpose: This study aims to assess the prevalence of rectus abdominis diastasis in nulliparous postpartum women, identifying associated factors and differences between vaginal delivery and cesarean section, reinforcing the role of ultrasound as a diagnostic and monitoring
method.
Methods or Background: A quantitative descriptive correlational design, was applied to a convenience sample of 50 women (25 vaginal, 25 cesarean), aged 18–40 years, with 37–42 weeks of gestation. Diastasis was assessed by ultrasound at three standardized points: ½ supraumbilical (>1.5
cm), ¼ supraumbilical (>2.6 cm), and ½ infraumbilical (>1.8 cm). Total diastasis was defined when all three points were positive, and classified as severe if any exceeded 2.5 cm.
Results or Findings: No statistically significant associations were observed between the type of delivery or the percentile of the newborn and abdominal diastasis, although a moderate negative correlation was observed between higher percentiles and diastasis in the supraumbilical
region in eutocic deliveries (rs=-0.45, p=0.02). Pre-delivery body mass index (BMI) was found to be a significant variable, showing a moderate negative correlation with supraumbilical diastasis (rs=-0.390, p=0.01), especially in eutocic deliveries. Pre-pregnancy physical activity did not show significant influence. Diastasis prevalence was highest in supra- and infraumbilical regions, with lower incidence at the umbilicus.
Conclusion: Postpartum abdominal diastasis was common, especially supra- and infraumbilically. Pre-pregnancy BMI emerged as the main factor influencing its extent, while delivery type, neonatal percentile, and exercise showed limited impact. These findings highlight theimportance of standardized ultrasound protocols for early detection, follow-up, and guidance of preventive and therapeutic strategies in abdominal wall recovery after childbirth.
Limitations: The sample size.
Funding for this study: I did not receive any funding for this research.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: In accordance with ethical standards, this study obtained ensured privacy, and received approval from the institutional ethics committee (CEUAlg Pn° 90 /2024).

Improving Early Pregnancy Outcomes: Predictive Tools for Threatened Miscarriage (6 min)

Lara Sammut; Madliena / Malta

Author Block: L. Sammut; Msida/MT
Purpose: To investigate the prevalence, risk factors, and predictive markers of threatened miscarriage (TM) through a structured three-part research design in a national state hospital.
Methods or Background: The study comprised three components:

- A retrospective cohort of 711 women presenting with first-trimester bleeding.

- A scoping review of 128 studies evaluating ultrasound and biochemical predictors.

- A prospective case-control study of 118 TM cases and 59 controls, using ultrasound, biochemical, clinical, and demographic data, analysed through logistic regression and random forest modelling.
Results or Findings: - Retrospective cohort: 33.9% of TM cases progressed to live births beyond 22 weeks. Advanced maternal age (≥35 years) increased miscarriage risk. Neonates following TM had lower birthweights (female: 3008g vs 3239g; male: 3085g vs 3346g, $P < 0.001$) and shorter gestational ages (female: 38.1 vs 39.0 weeks; male: 38.0 vs 38.6 weeks, $P < 0.05$).

- Scoping review: Intrauterine haematoma, yolk sac abnormalities, and fetal heart rate deviations emerged as strong ultrasound predictors. Combined with biochemical markers (e.g., beta-hCG), predictive value improved, but heterogeneity limited generalisability.

- Prospective case-control: Key predictors included progesterone, trophoblast thickness, mean gestational sac diameter, cervical length, sFlt-1:PlGF ratio, and maternal age. Logistic regression and random forest models performed strongly (AUC 0.85 and 0.968; accuracies 82.7% and 93.1%).
Conclusion: TM significantly affects perinatal outcomes. Integrated ultrasound, biochemical, and clinical markers can reliably predict miscarriage risk. These findings support the development of structured early pregnancy pathways to improve care delivery.
Limitations: Single-centre recruitment, and limited sample sizes for some analyses may affect generalisability.
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Ethical approval was obtained from the hospital's Data Protection Officer (DPO) and Chief Executive Officer (CEO) and the University of Malta Research Ethics Committee (UREC).

Radiofrequency Echographic Multispectrometry (REMS) as a Tool for Osteoporosis Screening in Primary Care (6 min)

Rute Santos; Coimbra / Portugal

Author Block: R. Santos, A. I. Saraiva Vieira; Coimbra/PT
Purpose: Radiofrequency echographic multispectrometry (REMS) has emerged as a promising, non-ionising, portable, and accessible alternative for osteoporosis diagnosis, with potential for use in primary healthcare. This study aimed to evaluate the effectiveness of REMS in detecting osteoporosis in this setting.
Methods or Background: Bone mineral density (BMD) was assessed in 86 participants through 172 REMS scans of the lumbar spine and femur, conducted in two Portuguese primary healthcare units (Guarda region).
Results or Findings: In the lumbar spine, 51.2% of participants were classified with osteopenia and 31.4% with osteoporosis. In the femur, 43.0% had osteopenia and 34.9% osteoporosis. These findings reveal a high prevalence of bone fragility. REMS-derived BMD showed good concordance with clinical diagnosis, supporting its reliability for early detection.
Conclusion: REMS-based bone densitometry, performed by radiographers in primary healthcare, represents a feasible and innovative alternative for the early and effective detection of osteoporosis and osteopenia.
Limitations: This study is limited by its small, exclusively Caucasian sample, which may reduce the generalisability of the results. The use of self-reported questionnaires for fracture history and lifestyle factors introduces potential recall bias. Moreover, the absence of DXA comparison and clinical confirmation of osteoporosis/osteopenia constrains the robustness of the findings. Finally, the lack of frailty and body composition analysis restricted a more comprehensive assessment of fracture risk.

Hand bone densitometry: a more sensitive standard for the early bone damage in rheumatoid arthritis (6 min)

Meghana Avinash Deshmukh; Pune / India

Author Block: M. A. Deshmukh, P. C. P. Joshi, J. D' Souza; Pune/IN
Purpose: To determine the role of dual-energy X ray absorptiometry (DEXA) compared with plain radiography in early rheumatoid arthritis of hand who have active disease.
Methods or Background: This study included 69 patients with suspicion of rheumatoid arthritis underwent DEXA scans of both hands, performed according to a standardised procedure for each site. For whole hand DEXA, all hand bones distal from the wrist joint were included in the measurement, the hand is put flat on a table and fingers extended.
Plain radiographs were also performed of both hands and the joint damage score was calculated by van der Heijde modification of the Sharp method. Final diagnosis was made on RA Factor test. Diagnostic accuracy was evaluated via sensitivity and specificity.
Results or Findings: In this cross-sectional study of 69 patients with suspected early rheumatoid arthritis of the hand dual-energy X-ray absorptiometry (DEXA) and plain radiography were used to assess BMD loss. DEXA identified BMD loss in 49 out of 69 patients (71.0%). Plain radiography detected BMD loss in only 12 patients (17.4%). All patients who were positive on X-ray were also detected as positive by DEXA, indicating 100% agreement in radiographically confirmed cases. Additionally, DEXA identified 37 patients with BMD loss not detected by X-ray, who came out to be positive for rheumatoid arthritis.
Conclusion: This study underscores the superior sensitivity of hand DEXA over conventional hand radiographic joint damage scoring in detecting early bone damage in patients with rheumatoid arthritis. Traditional radiography, it often fails to identify subtle, preclinical changes in bone mineral density that precede visible erosions. The enhanced sensitivity of hand DEXA not only facilitates timely diagnosis but also enables more accurate monitoring of disease activity and treatment response.
Limitations: Loss to followup.
Funding for this study: No funding.

Fetal MRI: Challenges and Strategies for Optimal Patient Management (6 min)

Alket Collaku; Tirana / Albania

Author Block: A. Collaku[1], E. Dybeli[2], Z. Mulla[1], F. Goga[1]; [1]Tirana/AL, [2]Elbasan/AL
Purpose: To discuss the main challenges of fetal MRI and propose practical approaches for handling different patients, with focus on maternal comfort, technical optimization, and safety.
Methods or Background: Technical and patient-related factors influencing fetal MRI were reviewed. Special attention was given to motion artifacts, sequence selection, maternal positioning, and safety considerations. Strategies were evaluated across different gestational ages and maternal conditions, including obesity, claustrophobia, and multiple gestations.
Results or Findings: Fetal MRI provides high diagnostic value when ultrasound findings are inconclusive, especially in central nervous system, thoracic, and abdominal evaluation. However, challenges include fetal/maternal motion, maternal discomfort, and safety limitations. Optimal results are achieved between 20–28 weeks of gestation, when fetal size and mobility allow better image quality. Later stages require protocol adaptation with ultrafast sequences and repeated acquisitions. Maternal positioning with left lateral tilt reduces vena cava compression and improves tolerance. Wider bore scanners and effective patient communication are essential for obese and anxious patients. Gadolinium should be avoided, while SAR and acoustic noise must be carefully monitored.
Conclusion: Fetal MRI is a safe and effective diagnostic tool when protocols are tailored to gestational age and maternal condition. Success relies on balancing technical parameters with patient-centered care, ensuring both image quality and maternal-fetal safety.
Limitations: No

A combined diagnostic model to evaluate the outcome of neoadjuvant chemotherapy for pancreatic ductal adenocarcinoma (6 min)
Alexandra Zharikova; Moscow / Russia

Author Block: E. V. Kondratyev, A. Zharikova, I. Gruzdev, A. Ustalov, S. A. Shmeleva, V. Egorov, E. P. Yasakova, P. V. Markov, D. V. Kalinin; Moscow/RU
Purpose: To develop and compare diagnostic models, including a combined model, so as to predict the patologic responce to neoadjuvant chemotherapy (NAC) for pancreatic ductal adenocarcinoma (PDAC).
Methods or Background: 59 patients with histologically confirmed PDAC and preoperative computed tomography (CT) were included in the study.
Patients were divided into two groups depending on the grade of histological response of the tumour based on Tumour Regression Score (TRS) criteria. The first group had a favourable response (TRS 0, 1 ,2), the second - unfavourable response (TRS 3).
A radiologist with 6 years of experience, segmented the region of interest (lesion) for radiomics structure analysis in the arterial and venous CT phases before and after NAC. The extracted texture features were divided into 3 groups (pre-NAC, post-NAC, combined model) and analysed using machine learning techniques.
Results or Findings: The AdaBoost ensemble model (pre-NAC) - ROC AUC (0,831), PR-AUC (0,874) и F1 Score (80%), accuracy (77%), precision (88%), specificity (85,7%) and the Optimized Random Forest (post-NAC) - ROC AUC (0,870), PR-AUC (0,941), F1 Score (85,7%), accuracy (83,3%), precision (90%), recall/sensitivity (81,8%) are the best models for recognising tumours with an unfavourable response, if the high accuracy is priority.
Gradient Boosting is the best fitting model both pre- and post-NAC, when focusing on ROC AUC(0.896) and PR-AUC (0.95).
Comparing the results of the pre- and post-NAC models, the latter were more efficient.
Conclusion: Machine learning models, specifically Optimized Random Forest and Gradient Boosting, trained on texture features from post-NAC CT scans demonstrated high accuracy in detecting non-responders with an unfavorable prognosis.
Limitations: A relatively small sample size and the absence of an external validation group, which complicates the wider application of our model.
Funding for this study: It was not required.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Extract from the minutes № 003-2025 of the meeting of the Scientific Research Ethics Committee of the Federal State Budgetary Institution “A.V. Vishnevsky National Medical Research Center of Surgery” of the Ministry of Health of the Russian Federation dated March 21, 2025.

Dual-energy CT extracellular volume fraction to predict tumor collagen ratio and to assess response to neoadjuvant chemotherapy in pancreatic ductal adenocarcinoma (6 min)
Shuai Ming; Hefei / China

Author Block: S. Ming, W. Wei; Hefei/CN
Purpose: To investigate the value of dual-energy computed tomography (DECT)-derived extracellular volume fraction (ECV) for predicting tumor collagen ratio and assessing the response to neoadjuvant chemotherapy (NAC) in pancreatic ductal adenocarcinoma (PDAC).
Methods or Background: This retrospective study enrolled 176 patients with pathologically confirmed PDAC (64 resected, 112 unresectable) who underwent DECT. The ECV fraction based on iodine concentration (ECV_IC) was calculated. Histological collagen ratio was measured from surgical specimens using Masson's trichrome staining and digital image analysis. For unresectable patients, chemotherapy response was evaluated according to RECIST 1.1. Univariate and multivariate analyses were performed to identify predictors of collagen ratio and treatment response. Receiver operating characteristic (ROC) curves were used to evaluate predictive performance.
Results or Findings: ECV_IC showed a strong positive correlation with the histological collagen ratio ($r = 0.618$, $p < 0.001$) and was an independent predictor of high collagen ratio (HR = 1.420, p = 0.009). In the unresectable cohort, ECV_IC was also an independent predictor of poor response to NAT (HR = 1.259, p = 0.023). ROC analysis demonstrated that ECV_IC could discriminate between responders and non-responders with area under the curve (AUC) of 0.83 (sensitivity 81.0%, specificity 70.4%) at a cutoff value of 31.8%, significantly outperforming venous-phase iodine concentration (IC_VP; AUC = 0.73, P = 0.026).
Conclusion: DECT-derived ECV_IC is a promising non-invasive biomarker for predicting tumor collagen ratio and assessing response to NAC in PDAC, with potential to guide personalized treatment strategies.
Limitations: First, its retrospective and single-center nature introduces potential selection bias. Second, the chemotherapy regimens were not completely standardized, which might have influenced the response assessment. Third, the evaluation of treatment response was based on RECIST 1.1 criteria rather than pathological confirmation, which remains the gold standard.
Funding for this study: This study warted by the following projects:the National Natural Science Foundation of China (NSFC, No.82271991);Joint Fund for Medical Artificial Intelligence of USTC (No.MAI2023C006);Level A Funding Project for Reserve Candidates of Academic and Technical Leaders in Anhui Province (No.2022H279).

Imaging Pancreatic Cancer with Photon-Counting CT: image quality, dose reduction and clinical impact (6 min)

Ludovica Lofino; Milan / Italy

Author Block: L. Lofino, A. Ammirabile, R. Levi, C. Bonifacio, A. Laghi; Rozzano/IT
Purpose: To compare quantitative and qualitative image quality parameters and radiation dose between photon-counting CT (PCCT) and energy-integrating detector CT (EIDCT) for the detection of pancreatic cancer.
Methods or Background: In this IRB-approved prospective study, 32 patients pancreatic cancer underwent multiphase CT (16 PCCT, 16 EIDCT). Patients were matched by age and BMI. Arterial and 5-minute delayed venous phase imaging were retrieved and analyzed. Contrast-to-noise ratio (CNR) was calculated as follows: (pancreatic parenchyma HU - pancreatic cancer HU) / noise, where noise was considered as the standard deviation of subcutaneous fat attenuation. Three radiologists with 7, 10 and 22 years of experience independently evaluated tumor conspicuity and overall image quality on a 5-point scale. Dose-length product (DLP) was retrieved for all examinations.
Statistical analysis included t-tests, ANOVA and inter-reader agreement.
Results or Findings: PCCT demonstrated significantly higher tumor CNR than EIDCT in both arterial (5.3 ± 0.8 vs 4.0 ± 1.1, P<0.01) and delayed venous phases (4.9 ± 1.0 vs 2.3 ± 0.6, P<0.01). Image quality scores were consistently higher with PCCT for overall image quality (arterial: 4.5 ± 0.4 vs 3.3 ± 1.2; venous: 4.2 ± 0.8 vs 3.0 ± 1.1) and tumor conspicuity (all P<0.03). DLP was significantly lower for PCCT compared with EIDCT (1,050 ± 120 vs 2,350 ± 750 mGy·cm, P<0.01). Inter-reader agreement was strong both for PCCT and for EIDCT. Of note, in 2 patients imaged with both modalities, PCCT showed a clearer tumor delination which allowed for downstaging.
Conclusion: In our population, PCCT has shown higher objective and subjective image quality with reduced radiation dose compared to EIDCT. Enhanced delineation of pancreatic cancer and surrounding structures may improve staging and increase the cohort of potentially operable patients.
Limitations: Small sample size, single center.
Funding for this study: This study was funded by ANTHEM foundation.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Ethics committee reviewed and approved the study protocol.

From Scan to Surgery: Comparison of CT-based vascular status with intraoperative findings in pancreatic cancer (6 min)

Nabila Gala Nacul Mora; Muenster / Germany

Author Block: N. G. Nacul Mora[1], A. Andreou[2], B. Strücker[2], S. Katou[2], H. Morgül[2], F. Becker[2], A. Pascher[2], M. Köhler[1], G. H. Pöhler[1]; [1]Muenster/DE, [2]Münster/DE
Purpose: To compare NCCN radiological vessel contact grading and binary surgical infiltration assessment in pancreatic cancer with surgical and histological finding as reference.
Methods or Background: Single-center, retrospective cohort study including 103 patients (mean age 68 years, male 61%) with CT-based diagnosis of pancreatic carcinoma (2012 - 2023) undergoing primary resection. CT-tumor-vessel contact was blindly classified following NCCN criteria by two abdominal radiologists. By discrepancies, the statement of the radiologist with longer experience was chosen. Radiological infiltration was defined as any-contact / no-contact and compared to surgical and histological findings using McNemar-test, Spearman-correlation, sensitivity (how well CT detects actual infiltration) and specificity (how well CT rules out infiltration when there's none). Subgroup analysis of CT interval to operation ≤4 weeks (n=83) vs. >4 weeks (n=20) was compared using ROC-Analysis.
Results or Findings: Vessel infiltration was radiologically assessed higher (radiological 51%, surgical 39%, p= 0.041): arterial infiltration was comparable (radiological 7%, surgical 5%, p= 0.625), but venous infiltration was radiologically higher (radiological 44%, surgical 34%, p= 0.019), with 83.5% overall agreement but systematic radiological overestimation of venous involvement. Radiological artery infiltration sensitivity was 99% and specificity 98%, venous infiltration sensitivity was 88% and specificity 81%. CT ≤4 weeks subgroup showed enhanced correlations (arterial AUC: 0.731, venous AUC: 0.888).
69% of patients had R0 resection status, 28% R1 status. The histological finding of R0 patients did not show arterial invasion. There was a significant difference in venous infiltration between surgical and histological invasion ($p < 0.001$).
Conclusion: The interdisciplinary study reveals the complexity of vascular status in NCCN-based grading, resulting in radiological overestimation of venous infiltration, which may lead to over-recommendation for neoadjuvant therapy in interdisciplinary tumor boards. A CT-surgery interval ≤4 weeks should be prioritized.
Limitations: Small cohort, single-centre Study
Funding for this study: No funding.

The role of FDG-PET based systemic surveillance in re-staging of borderline resectable pancreatic cancer after neo-adjuvant treatment: a multicenter study (6 min)

Dong Ho Lee; Seoul / Korea, Republic of

Author Block: S. Han[1], D. H. Lee[2]; [1]SEOUL/KR, [2]Seoul/KR
Purpose: To retrospectively evaluate the clinical significance of PET based systemic surveillance for distant metastasis in borderline resectable pancreatic cancer (BRPC) patients who are undergoing FOLFIRINOX based neoadjuvant chemotherapy (NAC).
Methods or Background: 161 patients who underwent FOLFIRINOX based NAC for BRPC from two institutes during January 2013 to December 2019 were retrospectively reviewed. All of the patients underwent an initial PET scan to confirm local disease. Image review including pre- and post-NAC images was done by 2 radiologists in consensus based on the NCCN 2020 guideline. Clinical information were obtained from patients records. Risk factor analysis for metastasis development was performed.
Results or Findings: Among the 161 patients who underwent NAC, 22.4% (36/161) converted to palliative setting due to local progression (14.3%, 23/161) or distant metastasis (8.1%, 13/161). The remaining 84.6% (125/161) proceeded to preoperative evaluation with (n=70) or without (n=55) PET evaluation. Among the patients with preoperative PET scan, distant metastasis was detected in 7.1% (5/70) of the patients. Among them, one liver metastasis (20%, 1/5) in one patient was only found on PET scan. Overall, 11.8% (19/161) patients developed metastasis during NAC. Among them, 2 cases of metastasis were only detected in the PET scan (2/19, 10.5%). Regarding the risk factors, the increment of CA 19-9 level during treatment (OR 4.43 [1.62-12.05], p=0.004) and present of major vein invasion before NAC (OR 5.70 [1.27-25.62], p=0.02) was associated with development of metastasis during NAC.
Conclusion: Considerable proportion of patients undergoing NAC for BRPC develop distant metastasis during treatment, especially for patients with increased CA 19-9 during the NAC or patients with initial major vein invasion. Systemic PET can aid in detection before undergoing curative resection.
Limitations: This is a retrospective study with heterogenous patient group.
Funding for this study: N/A

Baseline tumor stiffness measurement by MR elastography predicts survival in pancreatic ductal adenocarcinoma (6 min)

Simone Poli; Bern / Switzerland

Author Block: S. Poli[1], A. Wenning[2], P. Lombardo[2], V. C. Obermann[2], A. T. Huber[1]; [1]Lucerne/CH, [2]Bern/CH
Purpose: Investigate the association between baseline tumor stiffness measured by magnetic resonance elastography (MRE) and survival in pancreatic ductal adenocarcinoma (PDAC). We hypothesized that patients with an MRE “ring sign” (high stiffness in the periphery but low in the center, indicating necrosis) or homogeneously high-stiffness have worse survival than those with homogeneous lower stiffness.
Methods or Background: 55 patients with newly diagnosed PDAC (Jan-21 to April-23, ethics approval Bern, registry-ID:NCT03469726) underwent baseline fasting (≥6 hours) multiparametric-MRI and 3D-MRE (3T Magnetom Prisma, Siemens) for cancer staging and stiffness assessment, and exclusion of liver metastasis. 3D-MRE was performed with a pneumatic driver (Resoundant, 40Hz, 40A), and a spin-echo 3D-MRE sequence (10 slices, 3.5 mm, end-expiration), providing pancreatic coverage. Kaplan-Meier curves and Cox-proportional hazard models were used to compare mortality.
Results or Findings: During follow-up, unresectable PDAC showed poorest survival, confirming its adverse prognosis (0% 3-years survival). Patients with homogeneous stiffness <13.3 kPa demonstrated significantly better outcomes (39% 3-year survival). In contrast, high tumor stiffness (hazard ratio, HR[95%CI] = 2.3[1.2,4.3]; p=<.05) and the presence of the MRE ring sign (HR[95%CI] = 2.1 [1.1,4.0]; p=<.05) were independently associated with increased 3-year mortality (26% and 0% survival, respectively). Resected patients with a ring sign had a prognosis comparable to that of patients with unresectable disease. As tumor necrosis has been histologically linked to aggressive PDAC, our findings support MRE-derived stiffness as a promising, noninvasive survival imaging biomarker.
Conclusion: A single baseline measurement of tumor stiffness by MRE is predictive of patient survival in newly diagnosed PDAC. MRE may serve as a valuable imaging biomarker for risk stratification in PDAC and could be incorporated into standard clinical MRI.
Limitations: The limitation of the study is the relatively small, single-center patient cohort, which may limit generalizability.
Funding for this study: SNF-project:REPORT-IT(#10003604)
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This was a local, single-center sub-study of the DIA-PANC multi-center study (registry ID NCT03469726). The registry was approved by the Bern cantonal ethics committee, and the study was carried out in accordance with the principles of the Declaration of Helsinki.

Dual-Energy CT as a Non-Invasive Alternative to Perfusion CT for Functional Assessment of Pancreatic Ductal Adenocarcinoma (6 min)

Shuai Ming; Hefei / China

Author Block: S. Ming, P. Cheng, M. Li, W. Wei; Hefei/CN
Purpose: To evaluate the correlations between dual-energy CT (DECT) parameters, such as iodine concentration, and perfusion CT parameters in patients with Pancreatic Ductal Adenocarcinoma (PDAC).
Methods or Background: This single-center, IRB-approved study obtained written informed consent from all participants. Twenty-two patients with PDAC underwent concurrent dynamic perfusion CT and multiphase DECT examinations on a single-source, fast-kV-switching DECT scanner in a one-stop session. DECT images were analyzed using the Protocols General module of the GE AW 4.7 workstation's GSI Viewer software to obtain iodine concentration (IC) and normalized iodine concentration (NIC). Perfusion CT data were processed using the CT Perfusion 4.0 software to generate blood volume (BV), blood flow (BF), permeability surface (PS), time to peak (TTP), and mean transit time (MTT) maps. Pearson correlation analysis between the iodine parameters and perfusion parameters was computed. A p-value < 0.05 was considered significant.
Results or Findings: The mean IC and NIC values were 8.28±4.02 mg/mL and 0.20±0.11 in the portal phase, and 9.96±4.32 mg/mL and 0.32±0.16 in the delayed phase, respectively. The mean BF, BV, PS, TTP, and MTT values were 31.36 ml/100g•min, 4.48 ml/100g, 23.03 ml/100g•min, 28.80 s, and 10.52 s, respectively. The IC in the portal phase was significantly correlated with BF and BV (r=0.989, p<0.001; r=0.920, p=0.009). The NIC in the portal phase was significantly correlated with BF and BV (r=0.976, p=0.001; r=0.903, p=0.014). Both IC and NIC in the delayed phase were significantly correlated with BF (r=0.918, p=0.010; r=0.905, p=0.013).
Conclusion: In PDAC lesions, DECT-derived IC and NIC are strongly correlated with perfusion parameters BF and BV. This suggests that DECT has the potential to serve as a non-invasive alternative for evaluating both morphological and functional perfusion changes.
Limitations: This study has several limitations.
Funding for this study: This study warted by the following projects:the National Natural Science Foundation of China (NSFC, No.82271991);Joint Fund for Medical Artificial Intelligence of USTC (No.MAI2023C006);Level A Funding Project for Reserve Candidates of Academic and Technical Leaders in Anhui Province (No.2022H279).

Multi-frequency magnetic resonance elastography for predicting pancreatic cancer aggressiveness and patient survival (6 min)

Qi Wang; Beijing / China

Author Block: Q. Wang, L. Zhu, J. Liu, M. Dai; Beijing/CN
Purpose: To compare the stiffness and fluidity in the central part and peripheral part of pancreatic cancer using multi-frequency magnetic resonance elastography (MF-MRE), to correlate the MF-MRE parameters with clinicopathological factors that indicates tumor aggressiveness, and to identify risk factors for patient survival.
Methods or Background: MF-MRE was performed in 97 pancreatic cancer patients before treatment. High-resolution shear wave speed (SWS) and loss angle (φ) maps were generated, representing tissue stiffness and fluidity. SWS and φ were measured in the central part, the peripheral part and covering the entire pancreatic lesion, respectively. Pearson's and Spearman's correlation analysis were performed to evaluate the relationship between MRE parameters and tumor stage; grade; vascular and perineural invasion, regional lymphadenopathy and distant metastasis. Kaplan-Meier and Cox proportional hazards models were used to identify prognostic factors in patients with and without R0 resection (n=48 and 30, respectively).
Results or Findings: Fluidity in the peripheral part of the tumor was higher compared to the central part (1.23±0.25 vs. 0.96±0.20 rad, p□0.001), whereas stiffness of the tumor didn't show regional difference (p=0.064). In all patients, tumors with higher stiffness had more frequent regional lymphadenopathy (p=0.038), and tumors with higher fluidity in the peripheral part had more frequent vascular invasion, regional lymphadenopathy and distant metastasis (p=0.037, 0.007, and 0.027, respectively). Fluidity in the peripheral part of the tumor was positively correlated with tumor stage (rho=0.26; p=0.010). For patients with R0 resection, patients with higher fluidity in the peripheral part of the tumor (φ□1.17 rad) had shorter disease-free survival (12.1 vs. 19.4 months, p=0.022).
Conclusion: MF-MRE may help to predict pancreatic cancer aggressiveness and patient survival.
Limitations: Not applicable.
Funding for this study: Funding was provided by National Natural Science Foundation of China (grant number: 82371950).

US 17 - What should a radiologist know? Vascular ultrasound from head to toe

Categories: General Radiology, Head and Neck, Vascular, Abdominal Viscera, Multidisciplinary

ETC Level: LEVEL II+III

Date: March 7, 2026 | 08:00 - 09:00 CET

CME Credits: 1

The session provides an overview of current methods, trends, and future innovations in the field of vascular ultrasound. It will provide a comprehensive insight into the technical methods, which will then be deepened using ultrasound of the carotid artery, liver transplants, and dialysis access.

Moderators:

Dirk-André Clevert; Munich / Germany

Vito Cantisani; Rome / Italy

Chairpersons' introduction (4 min)

Dirk-André Clevert; Munich / Germany

Vito Cantisani; Rome / Italy

ST 21 - EDiR: Evolving for the Future (What's changing. What stays the same)

Categories: Professional Issues, Education

Date: March 7, 2026 | 08:30 - 09:00 CET

A short interview with Prof. Laura Oleaga, EDiR Scientific Director, explaining how the EDiR is evolving to meet today's training and clinical practice realities. The discussion highlights what is being updated, what remains unchanged in terms of standards and quality assurance, and what candidates and radiology departments can expect in the coming months.

Moderator:

Mélisande Rouger; Bilbao / Spain

Interview (30 min)

Laura Oleaga Zufiria; Barcelona / Spain

CUBE 19 - Flow diverters in action: intra- and extra-saccular devices and the role of coatings

Categories: Neuro, Interventional Radiology
ETC Level: LEVEL I
Date: March 7, 2026 | 09:00 - 09:30 CET
CME Credits: 0.5

Moderator:
Hans Henkes; Stuttgart / Germany

Chairperson's introduction (2 min)
Hans Henkes; Stuttgart / Germany

Flow diverters in action: intra- and extra-saccular devices and the role of coatings (28 min)
Ali Khanafer; Stuttgart / Germany

1. To learn about the differences between intra- and extra-saccular flow diverter devices and their indications.
2. To appreciate the role of device coatings in reducing thrombogenicity and optimising procedural safety.
3. To understand patient selection, procedural planning, and strategies for complication management in flow diverter therapy.

BS 18a - Intervertebral disc pathology: herniations, bulges and modic changes

Categories: Musculoskeletal, President's Choice
ETC Level: LEVEL I+II

Basic anatomy and biomechanics of intervertebral discs (10 min)
Katariina Luoma; HHelsinki / Finland

1. To present the intervertebral disc structure: nucleus pulposus, annulus fibrosus, endplates.
2. To explain the role in spinal stability and motion.

Types of disc pathology: definitions and imaging features (10 min)
Filip M. Vanhoenacker; Mechelen / Belgium

1. To differentiate between disc bulge vs herniation on MRI.
2. To present T2-weighted MRI findings between disc protrusion vs extrusion vs sequestration.
3. To correlate clinical relevance with symptoms.

Modic changes: what they mean and why they matter (10 min)
Gustav Andreisek; Münsterlingen / Switzerland

1. To present type 1: edema/inflammation (T2 hyperintense, T1 hypointense).
2. To present type 2: fatty degeneration (T1 hyperintense, T2 isointense).
3. To present type 3: sclerosis (T1 and T2 hypointense).
4. To correlate with degenerative disc dis

Case-based learning: real MRI examples - reporting tips for young radiologists (25 min)
Thomas Le Corroller; Marseille / France

1. To discuss interactively common findings.
2. To recognise pitfalls and mimics such as infections and tumours.
3. To present standardised terminology such as Fardon and Milette classification.
4. To recommend when further imaging or intervention is needed.

BS 18b - Radiography as a whole: connection competencies of the three branches

Categories: Oncologic Imaging, Radiographers, Nuclear Medicine

Date: March 7, 2026 | 09:30 - 10:30 CET

CME Credits: 1

This session highlights the integrative potential of radiography by connecting competencies across diagnostic imaging, therapy, and nuclear medicine. With a focus on cutting-edge technologies such as MRI-Linac, theranostics, proton therapy, and PET-MRI, it showcases how radiographers can bridge disciplines to enhance patient care and innovation.

Moderator:

Early Coronary CT Angiography for Non-Culprit Plaque Characterization After Primary PCI: Preliminary Results from the CT-STEMI Study (8 min)
Ludovica Blasi; Torino / Italy

Author Block: L. Blasi[1], E. Puglisi[1], T. D'Angelo[2], M. Olivieri[3], M. Moretti[1], D. Verna[1], R. Aroasio[1], R. Faletti[4], M. Gatti[1]; [1]Turin/IT, [2]Messina/IT, [3]Chieti/IT, [4]Candiolo/IT
Purpose: To assess burden and morphological characteristics of non-culprit plaques in STEMI patients undergoing early coronary CT angiography (CCTA) following PCI.
Methods or Background: 67 consecutive patients (mean age 62.5 ± 9.9 years; 52 men) were enrolled in the multicenter CT-STEMI study (NCT05941585). Coronary CT angiography was performed at a median of 9 days after the infarction [IQR 4]. All 16 coronary segments were evaluated per patient for the presence of stents, plaques, stenosis severity (scale 0–5), vulnerable plaque features (positive remodeling, low attenuation, spotty calcification, napkin-ring sign), Segment Involvement Score (SIS) and Segment Stenosis Score (SSS).
Results or Findings: Among 1072 segments analyzed, plaques were present in 33.2%, with 81.5% showing <50% stenosis, 12.9% moderate (50–69%), and 23 residual severe lesions (≥70% or occluded) in 15 patients, including 3 in proximal locations. A total of 148 segments contained stents. Overall, 173 plaques showed at least one high-risk feature: 105 with positive remodeling, 170 with low attenuation, 34 with spotty calcification, and 10 with napkin-ring sign. A single high-risk plaque (defined as having ≥2 features) was found in 17 patients (25.4%), while 30 patients (44.8%) had two or more. In proximal segments alone, 46 high-risk plaques were observed. The mean SIS was 5.3±2.6 and the mean SSS was 10.0±5.7.
Conclusion: Early CCTA in STEMI patients reveals a significant residual atherosclerotic burden, predominantly composed of plaques with mild to moderate stenosis. However, a notable number of severe and morphologically high-risk lesions, especially in proximal segments, were also detected. These findings, once correlated with clinical outcomes, may support more targeted therapeutic strategies.
Limitations: Limitations include small sample size, preliminary nature of the data, variable CT timing post-MI and segment-based analysis.
Funding for this study: This research was supported by a grant from the Italian Ministry of Health under the “Ricerca Finalizzata 2021 – Giovani Ricercatori” program, project number GR-2021-12372092. The funding was allocated to the project titled “Cardiac Computed Tomography for Comprehensive Risk Stratification of Arrhythmic, Atherothrombotic, and Heart Failure Events Following Reperfused ST-Segment Elevation Myocardial Infarction”. The funder had no role in the design, data collection, analysis, or interpretation of this study

IKF-035/ABC-HCC: A Phase IIIb, randomized, multicenter, open-label trial of Atezolizumab plus Bevacizumab versus transarterial Chemoembolization (TACE) in intermediate-stage HepatoCellular Carcinoma (8 min)

Roman Klöckner; Lübeck / Germany

Author Block: R. Klöckner[1], F. Foerster[2], V. Vilgrain[3], T. Vogl[4], A. M. Ierardi[5], M. Reig[6], J. Bruix[6], P. R. Galle[2], *. For the ABC-HCC Investigators[7]; [1]Lübeck/DE, [2]Mainz/DE, [3]Clichy/FR, [4]Frankfurt/DE, [5]Milan/IT, [6]Barcelona/ES, [7]Frankfurt am Main/DE
Purpose: Transarterial chemoembolization (TACE) is standard of care (soc) for intermediate stage (BCLC B) HCC. IMbrave150 trial demonstrated that combining the anti-PD-L1 antibody atezolizumab and anti-VEGF antibody bevacizumab (atezo/bev) significantly improves overall survival compared to sorafenib as first-line treatment of advanced/intermediate stage HCC failing/unsuited for TACE. It remains unknown if atezo/bev is more efficacious than TACE in patients who would be treated with TACE per soc.
Methods or Background: Several trials assess the benefit of combining systemic therapy with TACE. In contrast, ABC-HCC, an international phase 3b, randomized, multicenter, open-label, investigator-initiated trial directly compares atezo/bev vs. TACE in intermediate stage HCC or HCC indicated for TACE according to treating physicians. In total, 320 patients with confirmed HCC (not amenable to curative surgery/ablation transplantation, no extrahepatic spread, no macrovascular invasion except Vp1/2, ECOG ≤1, Child-Pugh A/B7) are randomized (1:1) to receive atezo/bev (Arm A) or TACE (Arm B) for max 24 months. Imaging (CT/MRI, Q8W) determines the primary endpoint time to failure of treatment strategy (TTFS). Here, we report on the first of two interim analyses (IA) at 33% information time (85 events) assessing efficacy and futility.
Results or Findings: At data cut-off (13-Jun-2025), 194 patients were randomized at 54 centers in seven countries. Of these, 168 patients were included in the IA (A:87; B:81) and 100 events were observed for TTFS (A:44; B:56). Median TTFS was 14.6 months (A) vs. 9.5 months (B) with a HR of 0.55 (95% CI [0.36-0.83]).
Conclusion: The results provide first signals suggesting a superiority of atezo/bev compared to TACE in intermediate stage HCC. Therefore, the trial progresses to the second IA at 66% information time (169 events).
Limitations: The presented interim analysis was performed after the occurrence of only 33% of planned events.
Funding for this study: Funding for this study was provided by the legal sponsor IKF – The Frankfurt Institute of Clinical Cancer Research.
Additionally, the study is financially supported by F. Hoffmann-La Roche Ltd.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study is approved in CTIS (EU CT No.: 2024-512953-26-00).
Written informed consent was obtained from all participants.
This abstract reports on original research.

Prospective Multicentre Study investigating the management of patients with Malignant Ureteric Obstruction (OPTIMISE MUO) interim analysis of a multi-centre prospective observational study (8 min)

Oliver Llewellyn; Edinburgh / United Kingdom

Author Block: O. Llewellyn[1], J. Blackmur[1], J. Aning[2], M. Bagkeris[3], T. Barrett[4], N. Shaida[4], A. Laird[1], U. Collaborative[1], B. Oncology[1]; [1]Edinburgh/UK, [2]Bristol/UK, [3]London/UK, [4]Cambridge/UK
Purpose: Unlike other oncology emergencies such as metastatic spinal cord compression, no standardised care pathway exists for malignant ureteric obstruction (MUO) and there is geographical variation in management approach. This study aims to understand the rationale for management choices made by clinicians in patients with MUO and lay the groundwork for further work.
Methods or Background: National UK-wide multicentre observational prospective research study using national Interventional Radiology and Urology stakeholder networks (UNITE & BAUS). This is an HRA approved, RCR funded research study.
MUO patients will be identified by research teams from referrals (in and out of hours) and multidisciplinary team meetings. Pseudonymised data will be recorded using the REDCap platform. Data about reason for referral will be captured and patients will be followed up for 1 year at 3 month timepoints to capture survival, further treatment, and hospital re-admissions and re-interventions.
Results or Findings: We will present an interim analysis of this work which follows on from extensive previous multi-centre work (INSITE MUO) demonstrating an overall survival benefit for intervening (nephrostomy or ureteric stent) in advanced cancer involving the abdomen and causing malignant ureteric obstruction ($p = 0.049$). We suspect there are confounding factors influencing this finding and this study will allow us to present data addressing this.
Conclusion: Intervention (nephrostomy or ureteric stent) in MUO in advanced cancer appears to have a protective effect on overall survival. We will present interim findings of the OPTIMISE MUO study addressing reasons for this.
Limitations: Observational nature of methodology.
Funding for this study: Royal College of Radiologists, Kodak fellowship
Has your study been approved by an ethics committee? Not applicable

Chairperson's introduction (4 min)
Andrea Rossi; Genoa / Italy

Why neuroradiology is the ultimate subspecialty choice (18 min)
Rui Duarte Armindo; Lisboa / Portugal

1. To understand the unique intellectual and diagnostic challenges that make neuroradiology a fulfilling career choice.
2. To recognise the opportunities for growth and interdisciplinary collaboration within neuroradiology.
3. To analyse cases within neuroradiology that illustrate the satisfaction of a career in neuroradiology.

From pixels to prognosis: how diagnostic neuroradiology impacts lives? (18 min)
Alejandro Rovira Cañellas; Barcelona / Spain

1. To demonstrate how timely and precise neuroradiologic interpretation informs clinical decision-making and alters prognosis.
2. To present real-world cases in which diagnostic imaging was key to the patient's diagnosis, treatment, or outcome.
3. To define the evolving role of neuroradiologists as key contributors to multidisciplinary, patient-centred care.

From pixels to prognosis: how interventional neuroradiology impacts lives? (18 min)
Frédéric Clarençon; Paris / France

1. To illustrate how key interventional neuroradiology techniques (e.g. stroke thrombectomy, aneurysm coiling) translate imaging into immediate and long-term patient outcomes.
2. To demonstrate how interventional neuroradiology made a life-saving difference.
3. To formulate the evolving therapeutic role of (interventional) neuroradiologists in acute and elective settings.

The future is now: scientific developments driving neuroradiology (18 min)
Marion Smits; Rotterdam / Netherlands

1. To name current and emerging technologies shaping the field of neuroradiology (e.g., AI, radiomics, ultra-high-field MRI, molecular imaging).
2. To understand how research and innovation in neuroradiology translate into clinical practice.
3. To inspire engagement in scientific discovery and technological adoption among young radiologists.

Panel discussion: Why is neuroradiology so wonderful? (14 min)

ESR Undergraduate 18 - Back to the basics: classic signs in radiology

From basic concepts to dynamic DRLs: evolution and clinical impact (18 min)
Jenia Vassileva; Vienna / Austria

1. To explain the core concept of DRLs.
2. To outline the limitations of static approaches and define the term "dynamic DRLs".
3. To analyse the clinical impact of implementing DRLs on optimisation.

Expanding DRLs beyond traditional modalities (e.g., hybrid imaging, imaging in RT) (18 min)
Habib Zaidi; Geneva / Switzerland

1. To define the role of DRLs in hybrid imaging and radiotherapy imaging.
2. To identify challenges in establishing DRLs in hybrid imaging and radiotherapy imaging.
3. To review current approaches for DRL development in hybrid imaging and radiotherapy imaging.

Challenges in setting paediatric DRLs (18 min)
Claudio Granata; Trieste / Italy

1. To identify the specific characteristics of paediatric patients that make establishing DRLs more complex compared to adults.
2. To explain the challenges associated with patient grouping for paediatric DRLs.
3. To describe the practical difficulties in collecting data for paediatric examinations across diverse institutions and equipment.

Harnessing big data and AI for DRLs: advancing establishment, application, and training (18 min)
John Damilakis; Iraklion / Greece

1. To appreciate the role of AI in the establishment and use of DRLs.
2. To understand the potential applications of AI in DRLs, including education and training.
3. To learn how AI can assist in dose estimation and radiation protection optimisation.

Panel discussion: Adult and paediatric DRLs: what can we expect in the years to come? (15 min)

Head and neck anatomy simplified (28 min)
Berit Verbist; Leiden / Netherlands

1. To give an overview of key regions: the nasal cavity, paranasal sinuses, oral cavity, oropharynx, larynx, hypopharynx, and skull base.
2. To highlight the normal anatomy through CT and MRI examples.
3. To describe common anatomical variations: what to know and when to worry.

Emergencies in head and neck imaging (28 min)
Jussi Hirvonen; Turku / Finland

1. To identify critical conditions: deep neck infections, traumatic injuries, and airway obstructions.
2. To describe a practical approach: what to report urgently and how to prioritise findings.
3. To illustrate real-world case discussions with interactive audience participation.

TNM, node-RADS, and iENE (28 min)
Caterina Giannitto; Milan / Italy

1. To give an overview of the TNM staging system for head and neck cancers, with practical imaging examples.
2. To introduce node-RADS for lymph node evaluation, including criteria, applications, and pitfalls, and to understand iENE (extranodal extension), how to identify it and its impact on staging and treatment.
3. To illustrate staging in real-world scenarios.

How 18 - How we overcome imaging challenges in the thoracic outlet

Brachial plexus (15 min)
Amelie Lutz; Kreuzlingen / Switzerland

1. To learn how to tailor MRI sequences and how to mitigate artefacts for brachial plexus imaging.
2. To review key anatomic landmarks on imaging and how to reliably identify the different plexus components.
3. To become familiar with the most common brachial plexus pathologies and how to differentiate them from mimics using a case-based approach.

Vascular thoracic outlet syndrome (TOS) (15 min)
Maija Radzina; Riga / Latvia

1. To learn how to perform and interpret positional imaging studies, US, CT, and MRI for TOS evaluation.
2. To understand how to choose imaging protocols tailored to neurogenic versus vascular TOS.
3. To become familiar with imaging abnormalities and their clinical presentation to improve diagnostic confidence using a case-based approach.

Lung apex pathologies (15 min)
Julien Cohen; Geneve / Switzerland

1. To understand protocol modifications for optimised lung apex visualisation on CT and MRI scans.
2. To learn about the imaging appearance of the most common benign and malignant lesions found in the lung apices.
3. To understand the management strategies for incidental findings in the lung apex.

Open forum discussion (13 min)

HW Ui 18 - Interventional ultrasound: biopsy and fine needle aspiration (FNA) techniques in the head and neck

IAEA - Enhancing quality and safety in medical imaging: an IAEA global perspective

Categories: Physics in Medical Imaging, EuroSafe Imaging/Radiation Protection, Evidence-Based Imaging, Education, Artificial Intelligence, President's Choice

ETC Level: LEVEL II

Date: March 7, 2026 | 09:30 - 11:00 CET

CME Credits: 1.5

SESSION RECOMMENDED BY ESR EUROSAFE IMAGING

This session will explore the momentum toward achieving the highest quality, safest, most efficient, and most appropriate uses of medical imaging worldwide, across the entire clinical imaging pathway and within diverse country contexts. Topics will cover imaging appropriateness; the role of EuroSafe in strengthening quality and safety across borders; the updated IAEA global data on medical imaging access and its efforts to improve imaging sustainability, including technology transfer and capacity building; and the evolving role of AI in clinical imaging and research.

Moderators:

Mauro Carrara; Vienna / Austria

Boris Brkljačić; Zagreb / Croatia

Chairpersons' introduction (5 min)

Mauro Carrara; Vienna / Austria

Boris Brkljačić; Zagreb / Croatia

ESR EuroSafe Imaging: strengthening quality and safety across borders in cooperation with IAEA (15 min)

Boris Brkljačić; Zagreb / Croatia

1. To describe the key components of the EuroSafe Imaging initiative and its alignment with IAEA quality and safety frameworks.
2. To evaluate cross-border strategies that enhance radiation protection, appropriateness, and harmonisation of clinical practice.
3. To identify opportunities for strengthening collaborative actions that support global imaging safety culture.

On-the-ground implementation of clinical imaging protocols and standardised reporting: achieving diagnostic objectives worldwide (9 min)

Dina Husseiny Salama; Cairo / Egypt

1. To explain the fundamental elements of clinical imaging protocols and their role in achieving diagnostic accuracy.
2. To assess barriers and enablers to implementing standardised imaging protocols and structured reporting across diverse healthcare settings.
3. To apply strategies for improving protocol adherence and reporting consistency to enhance global diagnostic quality.

Medical imaging quality quest: importance of quality management (9 min)

Virginia Tsapaki; Vienna / Austria

1. To define essential components of quality management systems in diagnostic imaging departments.
2. To analyse the impact of quality assurance and quality control programmes on patient safety and image optimisation.
3. To integrate evidence-based quality management approaches into clinical workflows to ensure continuous performance improvement.

Global imaging resources: how much is available? Technology transfer to low- and middle-income countries and capacity building (9 min)

Miriam Mikhail-Lette; Vienna / Austria

1. To summarise current global disparities in imaging equipment availability using updated IAEA data.
2. To discuss mechanisms through which technology transfer and training initiatives strengthen imaging capacity in LMICs.
3. To formulate approaches to sustainable capacity building that support long-term system resilience and equitable access.

The patient's perspective in modern medical imaging: justification insights from a cancer survivor and radiation expert (9 min)

Steve Ebdon-Jackson; Reading / United Kingdom

1. To learn what matters to a patient.
2. To appreciate that the scope of justification is comprehensive.
3. To understand that patient needs vary.

The evolving role of AI in clinical imaging workflow, the patient pathway, and coordinated research (9 min)

Enrique Estrada Lobato; Vienna / Austria

1. To describe current and emerging AI applications that support image acquisition, interpretation, and workflow optimisation.
2. To critically appraise how AI integration can enhance quality, safety, and efficiency across the patient imaging pathway.
3. To identify areas where coordinated international research can accelerate safe and ethical AI adoption in medical imaging.

WHA resolution on strengthening medical imaging capacity (10 min)

Diana Isabel Paez; Vienna / Austria

1. To explain the key commitments and global health priorities outlined in the WHA resolution on medical imaging.
2. To assess the implications of the resolution for national imaging strategies, regulatory frameworks, and resource allocation.
3. To propose pathways for Member States and partners to operationalise the resolution, ensuring sustainable improvements in imaging access and quality.

Panel discussion (15 min)

IF 18 - From snapshots to a story: AI in follow-up imaging after oncologic treatment

Categories: Oncologic Imaging, Evidence-Based Imaging, Imaging Informatics, Artificial Intelligence, President's Choice

ETC Level: ALL LEVELS

Date: March 7, 2026 | 09:30 - 11:00 CET

CME Credits: 1.5

Regular follow-up imaging is a cornerstone of oncologic care, enabling the monitoring of disease progression and treatment response. In radiology, this process involves the structured acquisition of comparable imaging studies over time - these individual exams are complete in their meaning based on their temporal relationship to one another. This session explores how AI already helps radiologists by enhancing and optimising oncologic follow-up imaging and how it can facilitate a more holistic assessment of oncological patients.

Moderator:
Melvin D'Anastasi; Mosta / Malta

Chairperson's introduction (5 min)
Melvin D'Anastasi; Mosta / Malta

The groundwork: segmentation and lesion detection (20 min)
Luis Marti-Bonmati; Valencia / Spain

The next steps: lesion characterisation - typification (20 min)
Georg Langs; Vienna / Austria

The future: evolution of oncologic follow-up imaging assessments (20 min)
Jacob Sosna; Jerusalem / Israel

Panel discussion: When will AI automate manual work in oncologic imaging? (25 min)

MS 18 - Female pelvic pain: from symptom to diagnosis

Categories: Imaging Methods, Emergency Imaging, Oncologic Imaging, Paediatric, Genitourinary, Multidisciplinary
ETC Level: LEVEL II
Date: March 7, 2026 | 09:30 - 11:00 CET
CME Credits: 1.5

Moderator:
Andrea Grace Rockall; London / United Kingdom

Chairperson's introduction (3 min)
Andrea Grace Rockall; London / United Kingdom

Acute pelvic pain: diagnosis and imaging (22 min)
Catriona Stalder; Beaconsfield / United Kingdom
Siham Sudderuddin; London / United Kingdom

1. To learn the typical clinical presentations and differential diagnoses in acute female pelvic pain.
2. To understand the appropriate key diagnostic and imaging tests in acute pain.
3. To appreciate the key imaging features on ultrasound, CT and MRI.

Chronic pelvic pain: diagnosis and imaging (22 min)
Nishat Bharwani; Surbiton / United Kingdom
Tariq Miskry; London / United Kingdom

1. To learn the typical clinical presentations and differential diagnoses in chronic female pelvic pain.
2. To learn appropriate diagnostic and imaging tests for chronic pelvic pain.
3. To understand the important considerations in the report to allow optimal treatment planning.

Multidisciplinary case discussion (43 min)
Andrea Grace Rockall; London / United Kingdom
Siham Sudderuddin; London / United Kingdom
Nishat Bharwani; Surbiton / United Kingdom

PA 18 - Emotional intelligence and empathy (part 1): theory

Evidence of impact of emotional intelligence and empathy on patients and professionals (20 min)
Jonathan Mcnulty; Dublin / Ireland

1. To explore the evidence on the patient-centred benefits linked to emotional intelligence (EI) and empathy.
2. To consider how EI and empathy improve satisfaction, trust, and cooperation.
3. To describe how EI and empathy support clinician well-being, resilience, reduce burnout, and enhance communication, teamwork and professional satisfaction.

Its value from a patient's perspective (15 min)
Caroline Justich; Vienna / Austria
Erik Briers; Hasselt / Belgium

1. To understand how emotional intelligence applied by medical professionals improves communication for various groups of patients.
2. To explore real patients' life examples to facilitate shared decision making.
3. To learn about the ESR Patient Advisory Group (PAG) and ESR-endorsed initiatives to support the implementation of emotional intelligence in communication.

Its value from a professional's perspective (15 min)
Dominique-Gérard Carrie; Balma / France

1. To understand how radiology professionals perceive value EI and empathy in their practice.
2. To reflect on professional experiences where empathy shaped clinical decision-making and patient rapport.
3. To recognise common challenges and benefits associated with empathic care.

Enhancing our emotional intelligence and empathy (15 min)
Stuart J. Mackay; Liverpool / United Kingdom

1. To explore the evidence on developing EI and empathy in education and training programmes.
2. To identify strategies and tools for developing EI and empathy in the curriculum and among radiology professionals.
3. To explore approaches to enhance self-awareness, emotional regulation, and empathic communication.

Panel discussion: Valuing EI and empathy: let's make a difference together!

Combined Pancreatic Attenuation and Pancreas-to-Spleen Ratio on Non-Contrast CT Improve Diabetes Risk Stratification over Single Biomarkers: A Retrospective Analysis (6 min)

Christian Booz; Frankfurt / Germany

Author Block: C. Booz, A-I. Nica, I. Yel, V. Koch, L. D. Grünewald, P. Reschke, J. Gotta, K. Eichler, T. J. Vogl; Frankfurt/DE
Purpose: Non-invasive imaging biomarkers derived from routine CT may assist in the early identification of individuals at risk for diabetes mellitus (DM). While both decreased pancreatic attenuation and a reduced pancreas-to-spleen attenuation ratio (PSR) have been associated with dysglycemia, it remains unclear whether a combination of both parameters yields additional diagnostic benefit. This study aimed to evaluate the added value of combining pancreatic attenuation and PSR for risk stratification of DM.
Methods or Background: We retrospectively analyzed non-contrast abdominal CT scans from 5624 patients (51% male; mean age 52 ± 10 years). Patients were categorized into normoglycemic (n=2900), prediabetic (n=1569), and diabetic (n=1155) groups based on clinical and laboratory data. Mean pancreatic attenuation (HU) was measured in head, body, and tail regions and compared to splenic attenuation to calculate PSR. ROC curve analyses and multivariate logistic regression were used to evaluate diagnostic performance for identifying diabetic status using individual and combined CT parameters.
Results or Findings: Pancreatic attenuation decreased progressively from normoglycemic (43 HU) to prediabetic (36 HU) to diabetic patients (32 HU) (all $p < 0.001$). PSR showed stronger correlation with HbA1c ($r = –0.90$) than pancreatic HU alone ($r = –0.76$). The AUC for PSR alone was 0.88, outperforming pancreatic HU (AUC: 0.79). However, combining both parameters slightly improved diagnostic accuracy (AUC: 0.92; $p = 0.01$ vs. PSR alone). In multivariate models, the combined approach remained an independent predictor of diabetes, offering both improved sensitivity and specificity.
Conclusion: Although PSR is a superior single CT-derived biomarker for assessing diabetes risk, combination of PSR and pancreatic attenuation provides a small but statistically significant improvement in diagnostic performance. This supports usage of combined attenuation-based metrics for more precise opportunistic screening in routine CT.
Limitations: Single-center study; retrospective study design

Alterations of the pancreas in type 1 diabetes - from prior to diagnosis to long-standing disease (6 min)

Nathalia Missima; Uppsala / Sweden

Author Block: N. Missima, H. Hill, C-S. Aioanei, P. Liss, D. Espes; Uppsala/SE
Purpose: In type 1 diabetes (T1D), the loss of insulin-producing beta-cells is the hallmark pathophysiological alteration. However, volumetric and functional abnormalities of the exocrine pancreas are also observed. These changes may result from the loss of insulin's anabolic effects or reflect an underexplored aspect of T1D. Imaging techniques have enabled a better characterization of pancreatic morphology throughout T1D progression. This study examines exocrine pancreatic alterations at various stages of T1D using CT scans, including assessments conducted prior to diagnosis.
Methods or Background: The study utilized retrospective abdominal CT scans and clinical data collected from Uppsala University Hospital,
including 150 T1D subjects, with 15 examined before diagnosis, and 61 age- and gender-matched non-diabetic controls. Volume segmentation and 3D reconstruction assessed the exocrine pancreas, and pancreas volume index (PVI) calculations were standardized using body weight, BMI, and body surface area (BSA). Descriptive and laboratory data were obtained from electronic medical records.
Results or Findings: Pancreas volume was significantly reduced in T1D patients. The reduction was more pronounced in patients diagnosed before the age of 20. No significant volume difference was noted in patients before their T1D diagnosis compared to controls, however, a reduction was observed post-diagnosis. Pancreas volume correlated negatively with disease duration and HbA1c levels and correlated positively with body surface area and plasma amylase levels.
Conclusion: Pancreas volume reduction is a consistent feature in T1D, correlating with both disease duration and markers of metabolic control. These findings support the potential of using imaging techniques as a non-invasive method for monitoring T1D progression.
Limitations: Lack of standardization, absence of relevant laboratory measurements (e.g. amylase, C-peptide) in the original clinical evaluations. Variability in imaging protocols. Many T1D patients and control subjects with native CT scans were excluded due to segmentation challenges.
Funding for this study: Research grants from SciLife Lab, Barndiabetesfonden, Diabetesfonden, Familjen Ernfors fond, EXODIAB and Göran Gustafssons Stiftelse.

Diffusion-Weighted Imaging of the Healthy Pancreas: Association Between Subcutaneous Adipose Tissue Thickness and Pancreatic ADC Values (6 min)

Mehmet Ali Arıkan; Istanbul / Turkey

Author Block: H. ATASOY, S. Kaya, M. A. Arıkan, A. H. H. Yardımcı, M. Karagülle, C. C. Arıkan; Istanbul/TR
Purpose: To evaluate the relationship between abdominal subcutaneous adipose tissue thickness and pancreatic apparent diffusion coefficient (ADC) values in healthy individuals, using diffusion-weighted imaging (DWI).
Methods or Background: A total of 100 abdominal MRI scans (69 females, 31 males; mean age 42.8 ± 12.0 years) performed on a 1.5T scanner were retrospectively reviewed. ADC values were measured in the head-neck, body, and tail of the pancreas with free-hand regions of interest encompassing the entire visible segment. Subcutaneous adipose tissue thickness was measured at the umbilical level. Two radiologists independently performed measurements, with interobserver agreement assessed by intraclass correlation coefficients (ICC). Correlations between ADC values, adipose thickness, age, and gender were analyzed using Pearson correlation and Mann–Whitney U tests.
Results or Findings: No significant differences in ADC values were observed among pancreatic segments or between genders, and no correlation with age was found ($p > 0.05$ for all). Subcutaneous adipose tissue thickness showed a significant inverse correlation with ADC values across all pancreatic segments (head-neck $r = -0.296$, $p = 0.003$; body $r = -0.302$, $p = 0.002$; tail $r = -0.310$, $p = 0.002$). Interobserver agreement was excellent (ICC range: 0.810–0.862).
Conclusion: Pancreatic ADC values appear stable across age and gender but decrease significantly with increasing subcutaneous adipose tissue thickness. This novel finding identifies adipose thickness as a potential confounding factor in pancreatic DWI interpretation and may improve the reliability of pancreatic imaging in clinical and research settings.
Limitations: This study has no limitations.
Funding for this study: No funding was received for this study.

CT-Based Pancreatic Biomarkers for Risk Stratification of Diabetes Mellitus: A Retrospective Analysis in A Huge Patient Cohort (6 min)

Christian Booz; Frankfurt / Germany

Author Block: C. Booz, A-I. Nica, I. Yel, V. Koch, L. D. Grünewald, P. Reschke, J. Gotta, K. Eichler, T. J. Vogl; Frankfurt/DE
Purpose: Non-invasive imaging biomarkers may aid in early detection of individuals at risk for diabetes mellitus (DM). While decreased pancreatic attenuation on non-contrast CT has been associated with metabolic disorders, recent evidence suggests that the pancreas-to-spleen attenuation ratio (PSR) may offer improved diagnostic performance by minimizing inter-individual and technical variability. This study aimed to compare the diagnostic value of pancreatic attenuation versus PSR in assessing diabetes risk.
Methods or Background: In this retrospective study, non-contrast abdominal CT scans from 5634 patients (52% male, mean age 53 ± 8 years) were analyzed. Patients were categorized into normoglycemic (n=2902), prediabetic (n=1572), and diabetic groups (n=1160) based on clinical and laboratory data. Mean pancreatic attenuation (HU) was measured at three anatomical regions and compared with splenic attenuation to derive the PSR. Diagnostic performance was evaluated using ROC curve analysis and multivariate logistic regression.
Results or Findings: Mean pancreatic attenuation was significantly lower in diabetic patients (HU:31) compared to prediabetic (HU:37) and normoglycemic controls (HU:44) (all comparisons, $p < 0.001$). PSR showed a stronger inverse correlation with HbA1c ($r = -0.89$ vs -0.75) and yielded a higher diagnostic accuracy for identifying diabetes (AUC: 0.88) compared to pancreatic attenuation alone (AUC: 0.79) ($p<.001$). Optimal cut-off values for pancreatic attenuation and PSR were 35 HU and 0.85, respectively. In multivariate analysis, the PSR remained an independent predictor of diabetic status, outperforming absolute pancreatic HU values.
Conclusion: PSR is a more robust and reliable CT-based biomarker for assessing diabetes risk than pancreatic attenuation alone. Its relative nature reduces scanner- and patient-related variability, making it a preferable parameter for opportunistic screening in routine CT.
Limitations: Single-center study; retrospective study design
Funding for this study: No funding

Topographical classification of postoperative pancreatic fistula: a radiological proposal for a novel, prospective classification system (6 min)

Benedetta De Franciscis; Milano / Italy

Author Block: B. De Franciscis, D. Palumbo, A. Campisi, D. Tamburrino, S. Partelli, S. Crippa, M. Falconi, F. De Cobelli; Milano/IT
Purpose: Postoperative pancreatic fistula (POPF) remains the major cause of morbidity/mortality after pancreaticoduodenectomy (PD). The 2016 revision of the International Study Group for Pancreatic Surgery defines only grade B and grade C POPF as clinically relevant: grade B requires non surgical interventions, whereas grade C involves organ failure, reoperation or death. However, such classification is burdened by significant limitations, the main one being its retrospective nature. Radiological tools able to early stratify POPF severity and, more generally, morbidity burden after PD remain limited.
Methods or Background: We retrospectively analyzed 809 patients who underwent PD (01/2015–12/2023) and subsequent postoperative CT. 309 patients suffered from clinically relevant (CR)-POPF. Radiological variables (anastomotic defect/dehiscence, fluid collections, perianastomotic air bubbles, HU values of pancreatic remnant) were considered. A scoring system was derived from significant radiologic features. Model performance was assessed using area under the ROC curve (AUC).
Results or Findings: Among 309 CR-POPF patients, 259 were grade B and 50 grade C. Mortality was 44 % in grade C versus 0.4 % in grade B. Univariate analysis revealed that the presence of i) posterior anastomotic defect [2 points], ii) intra-abdominal fluid collections [1 point1], iii) perianastomotic air [2 points] and iv) lower pancreatic attenuation on CT [2 points] was associated with grade C POPF ($p < 0.05$). A postoperative CT score achieved AUC 0.74; a cut-off ≥ 4 provided 84 % sensitivity and 73 % specificity. Also, the score strongly predicted morbidity (in terms of Clavien-Dindo grading) and mortality (AUC: 0.68).
Conclusion: Several early CT findings differentiate grade C from grade B POPF. A simple CT-based score offers good discrimination. Prospective validation is necessary to establish these tools for early risk stratification and timely intervention.
Limitations: Retrospective Single Center

Iodine concentration in photon counting computed tomography: correlation with tumor grade and Ki-67 in pancreatic NEN (6 min)

Marwin-Jonathan Sähn; Minden / Germany

Author Block: M-J. Sähn, S. Waltermann, J. Ottemöller, R. I. Danebrock, J. H. Niehoff, B. Gerdes, J. Borggrefe, N. Begum, A. S. Surov; Minden/DE
Purpose: Iodine concentration (IC) derived from dual energy computed tomography was recently explored as a potential biomarker for pancreatic NEN grade and Ki-67. With methodologies exhibiting significant variability, outcomes in recent publicatiobns were ambigous - ranging from, at best, weak correlation to strong predictive performance in complex multivariate analyses.
This study revisits the issue and aims to provide evidence for tumor characterisation using PCCT derived iodine concentration in pancreatic NEN.
Methods or Background: IC in neuroendocrine pancreatic primaries were analyzed in venous phase pre treatment regarding correlation with histopathological tumor grade and Ki-67. Pancreatic NEN IC was normalized vs. aortic IC (NIC), as well as relative to unaffected pancreatic tissue (RIC).
Correlations were analyzed using Spearman correlation, mean concentrations were analyzed using Mann-Whitney-U-test.
Results or Findings: Iodine concentration in P-NEN compared to normal pancreatic tissue (RIC) exhibited a strong correlation with tumor grade ($\rho = 0.54$, $p = 0{,}021$) and Ki-67 ($\rho = 0.54$, $p = 0.021$). Mean RIC were higher in high grade tumors ($p = 0.028$). NIC exhibited weak, non statistically significant correlation with tumor grade ($\rho = 0.328$, $p = 0.183$) and Ki-67 ($\rho = 0.302$, $p = 0.224$). Mean NIC did not diverge significantly in low grade vs. high grade pancreatic NET.
Conclusion: PCCT derived IC and especially RIC is a promising biomarker for tumor grade and Ki-67 prediction with strong, statistically significant correlations in untreated pancreatic NEN. The method is non-invasive, requires little to no additional resources and may support early, valid therapeutic decisions.
Limitations: Retrospective analysis

Meta-Analysis of Diffusion-Weighted MRI in Characterizing Pancreatic Tumors (6 min)

Yousef Ahmed Sliem; Giza / Egypt

Author Block: Y. A. Sliem, M. A. Shaaban; 6th of October City/EG
Purpose: To conduct a meta-analysis evaluating the diagnostic accuracy of ADC measurements from DWI MRI for differentiation of pancreatic adenocarcinoma, neuroendocrine tumors, and benign lesions.
Methods or Background: Background: Differentiating pancreatic adenocarcinoma from neuroendocrine tumors and benign lesions remains challenging with conventional imaging. Diffusion-weighted MRI (DWI) measures water molecule mobility in tissues, providing ADC values that reflect tissue cellularity and structural integrity. Multiple studies have investigated the diagnostic utility of DWI in pancreatic tumors, but results vary.
Methods: A literature search in PubMed, Embase, and Cochrane databases from 2010 to 2025 identified studies reporting ADC values with histopathologic confirmation. Data extraction included mean ADC, standard deviation, sensitivity, specificity, and ROC-AUC. Pooled estimates were calculated using a random-effects model. Heterogeneity was assessed with I^2 statistics. Meta-regression explored ADC cutoff variations.
Results or Findings: Eleven studies (n=980 patients) were included. Pooled sensitivity and specificity for differentiating adenocarcinoma from neuroendocrine tumors were 91% (95% CI: 87–94%) and 89% (95% CI: 85–92%), respectively. Mean ADC was significantly lower in adenocarcinomas compared to neuroendocrine tumors (1.06 ± 0.12 vs $1.38 \pm 0.15 \times 10^{-3}$ mm²/s, $p<0.001$). The ROC-AUC pooled estimate was 0.92 (95% CI: 0.88–0.95). Subgroup analysis indicated higher diagnostic performance in 3T MRI studies compared to 1.5T.
Conclusion: ADC values from DWI MRI reliably differentiate pancreatic adenocarcinoma from neuroendocrine tumors. Incorporation into clinical imaging protocols can improve noninvasive characterization and guide management.
Limitations: Future studies should standardize imaging parameters and explore integration with radiomics.

Automated Bone Mineral Density from Routine Staging CT as a Predictor of Progression-Free Survival in Resected Pancreatic Cancer under Adjuvant Chemotherapy (6 min)

Lukas Endrös; Munich / Germany

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: L. Endrös[1], J. H. W. Bodden[2], F. Jungmann[2], R. L. Walter[2], M. Eiber[2], J. S. Kirschke[2], R. Braren[1], L. Steinhelfer[2]; [1]Hamburg/DE, [2]Munich/DE
Purpose: To evaluate whether automated, opportunistic analysis of volumetric bone mineral density (BMD) from routine staging CT predicts progression-free survival (PFS) in resected pancreatic ductal adenocarcinoma (PDAC) under adjuvant chemotherapy, and to compare its prognostic value with CA 19-9, as established biomarkers such as CA 19-9 have known limitations.
Methods or Background: We retrospectively analyzed 112 patients with resected PDAC who received gemcitabine-based or FOLFIRINOX chemotherapy. Vertebral BMD was quantified preoperatively and after completion of adjuvant therapy using SpineQ (BoneScreen), a CE-certified AI tool providing absolute volumetric BMD values (mg/cm³). Associations with PFS were tested using univariate and multivariate Cox regression models.
Results or Findings: During adjuvant chemotherapy, mean BMD declined from 97.6 ± 42.5 to 73.7 ± 34.1 mg/cm³. In univariate Cox regression, relative BMD change, follow-up BMD, and baseline CA 19-9 were significantly associated with PFS, whereas CA 19-9 change was not. In multivariate analysis, only relative BMD change remained predictive (HR 0.947, $p < 0.0001$). Each 1% decline in BMD corresponded to an approximately 5% higher risk of progression. Follow-up BMD and baseline CA 19-9 lost significance in the adjusted model.
Conclusion: Automated CT-based volumetric BMD analysis provides robust, independent prognostic information in resected PDAC and outperforms CA 19-9 for predicting PFS. Opportunistic skeletal assessment from routine staging CT enables longitudinal monitoring and individualized risk stratification without additional imaging or patient burden.
Limitations: This was a retrospective single-center study with a moderate sample size. Validation in larger, prospective, multicenter cohorts is required before clinical implementation.
Funding for this study: No funding was provided for this study.

Volume and location of extrapancreatic necrosis in predicating the severity and clinical outcomes of acute necrotizing pancreatitis (6 min)

Gaowu Yan; Suining / China

Author Block: G. Yan, Y. Li; Suining/CN
Purpose: To explore the value of extrapancreatic necrosis volume (EPNV) and location in predicting the severity and clinical outcomes of acute necrotizing pancreatitis (ANP), and compare its diagnostic performances with some current scoring systems.
Methods or Background: Patients diagnosed with ANP from three hospitals were included. All underwent upper abdominal CT scans within one week of ANP onset. Data of the clinical severity, modified CT severity index (MCTSI), CT severity index (CTSI), extrapancreatic inflammation on CT score (EPIC), bedside index for severity in acute pancreatitis (BISAP), and C-reactive protein (CRP) levels were collected. Clinical outcomes included multiple organ failure (MOF), infection, therapeutic procedures, intensive care unit (ICU) admission, and death. Correlations between the EPN location and the ANP severity/clinical outcomes were assessed. Diagnostic performances of the various scoring systems were compared.
Results or Findings: 128 ANP patients were enrolled. EPN (lesser sac, left anterior pararenal space, left paracolic gutter) showed weak correlations with ANP severity and clinical outcomes ($P < 0.05$). The AUCs of EPNV for predicting ANP severity, MOF, infection, therapeutic procedures, ICU admission, and death were 0.908, 0.899, 0.887, 0.891, 0.878, and 0.893, respectively ($P < 0.05$). Its diagnostic performance in predicting these indicators was higher than or similar to that of MCTSI, CTSI, EPIC, BISAP, and CRP levels.
Conclusion: EPN located in the lesser sac, left anterior pararenal space, and left paracolic gutter may have a certain correlation with severe ANP, MOF, infection, therapeutic procedures, ICU admission, and death in ANP patients. The EPNV may have high diagnostic performances in predicting ANP severity and clinical outcomes, which are higher or similar to that of some current commonly used clinical, radiological, and laboratory scoring systems.
Limitations: This study is a retrospective and may have some selection bias.
Funding for this study: None

Less Dose, More Signal: Clinical Evaluation of Photon-Counting Detector CT in Pancreatic Patients (6 min)

Bettina Katalin Budai; Heidelberg / Germany

Author Block: A. I. Vigh, S. Nettesheim, T. Ojejinmi, M. Benke, Á. Szücs, A. Szijártó, P. Maurovich-Horvat, B. K. Budai, I. Dudás; Budapest/HU
Purpose: To compare radiation dose and image quality between photon-counting detector CT (PCD-CT) and energy-integrating detector CT (EID-CT) in patients with pancreatic disease who underwent abdominopelvic venous phase imaging.
Methods or Background: We retrospectively identified patients scanned with both PCD-CT and EID-CT between February 2022 and August 2023. Only patients without significant body-size change (L3 axial slice area difference <15%) were included, yielding 58 matched pairs. Radiation dose was compared using CTDIvol. Agreement in body size between scans was assessed using concordance correlation coefficients (CCC) and Bland–Altman analysis. Linear regression models tested the interaction between modality and body size. In a subset of 32 patients with identical venous phase protocols (3.0 mm slice thickness), signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR, muscle–fat) were measured at the L3 level.
Results or Findings: The mean time interval between scans was 116 ± 99 days, with a body-size difference of 4.3 ± 3.3 cm². Body size agreement was excellent (CCC = 0.968, LoA: –10.0 to 11.3 cm²). CTDIvol was significantly lower for PCD-CT than EID-CT (paired $p < 0.0001$), independent of body size (interaction $p = 0.291$). In protocol-matched cases, muscle SNR was significantly higher for PCD-CT ($p < 0.0001$), while muscle–fat CNR was not significantly different ($p = 0.875$).
Conclusion: PCD-CT provides substantial radiation dose reduction compared with EID-CT without compromising body-size comparability. In addition, PCD-CT improves muscle SNR, although CNR between muscle and fat remains unchanged. These results support the potential of PCD-CT to enhance dose efficiency and image quality in abdominopelvic imaging of pancreatic disease.
Limitations: This was a single-center study with a retrospective study design. Only venous phase 3.0 slice thickness scans were investigated.
Funding for this study: No funding was received for this study.

An Explainable AI Workflow Integrating Automated Volumetric Body Composition Analysis for Predicting Pathological Grading of Gastroenteropancreatic Neuroendocrine Neoplasms: A Multicenter Cohort Study (6 min)

Chenxi Lyu; Wuhan / China

Author Block: C. Lyu, W. Qu, J. Li, Z. Li; Wuhan/CN
Purpose: To develop a non-invasive predictive model by integrating auto-segmented abdominal CT-based volumetric body composition with machine learning to preoperatively distinguish low-grade from high-grade Gastroenteropancreatic Neuroendocrine Neoplasms(GEP-NENs).
Methods or Background: This multicenter analysis enrolled 633 GEP-NENs patients from three institutions. Patients were divided into: Training set (n=403) and internal validation (n=174) (7:3 ratio from Hospital 1); test set (n=56 from 2 other hospitals). An nnUNetv2-based automatic segmentation algorithm of abdominal fat tissue and skeletal muscle on arterial-phase CT was applied. Visceral fat index, subcutaneous fat index, intermuscular fat index and skeletal muscle index were calculated. Features with a p-value < 0.05 were selected using univariate logistic regression and included in the prediction model built with extreme gradient boosting algorithm. Receiver operating characteristic curves and decision curve analysis were performed to evaluate the utility of the model. SHapley Additive explanation was conducted to enhance the model interpretability and visualization.
Results or Findings: The automatic segmentation achieved a Dice coefficient of 0.90. For pathological grading, a model built with body composition parameters achieved an AUC of 0.863 in the training set, 0.750 in the validation set, and 0.717 in the test set. SHAP analysis revealed that the relative intermuscular adipose tissue(rIMAT) contributed most among the body composition parameters to the model decision-making. And rIMAT levels were higher in P53-mutant and CK19-positive cases compared to negative cases.
Conclusion: Auto-segmented abdominal body composition combined with machine learning-based model could provide an assisted, non-invasive tool for prediction of pathological grade in GEP-NENs.
Limitations: First,changes in CT scanning protocols are inevitable. Second, retrospective and observational designs may be prone to have selection bias.
Funding for this study: National Natural Science Foundation of China (NSFC) [grants number 82202127, 82071889 and 62131009].

Patient-Derived Predictors of Peak Pancreatic Enhancement in CT Perfusion (6 min)

Mischa Woisetschlager; Linköping / Sweden

Author Block: B. Kataria, I. Khudair, W. C. Bartholomä, P. Sandström, B. Björnsson, M. Woisetschlager; Linköping/SE
Purpose: For accurate diagnosis, optimal contrast timing is crucial in pancreatic CT imaging. To standardize scan timing, fixed protocols or bolus-tracking techniques are used. However, these methods often fail to account for individual physiological differences, potentially compromising image quality. The purpose of this study was to identify patient-specific parameters in order to individualize scan timing.
Methods or Background: Data from 16 patients who underwent a CT perfusion and a 4-phase abdominal examination at the same time point were used to evaluate the relationship between patient-specific parameters and contrast enhancement timing across three specific time intervals:
t1: Time to aortic threshold >100 HU
t2: Time from aortic threshold to maximum pancreatic enhancement
t3: Total time from injection start to peak pancreatic enhancement
Correlation analyses were performed between the three time intervals and variables including height, cardiac volume, lean body mass (LBM), and fat-related metrics.
Results or Findings: At time t1, significant correlations were observed for height ($r = 0.550$, $p = 0.027$) and cardiac volume ($r = 0.595$, $p = 0.015$); and at time t3 for LBM ($r = 0.501$, $p = 0.048$) and cardiac volume ($r = 0.528$, $p = 0.036$). No significant associations were observed at time t2. Strong inter-parameter relationships were noted between height and cardiac volume ($r = 0.758$, $p=0.0007$), and between cardiac volume and LBM ($r = 0.812$, $p=0.0001$).
Conclusion: Cardiac volume and LBM are easily accessible promising predictors of contrast timing in abdominal CT and may enable individualized timing, thus improving diagnostic accuracy in patients with diverse body compositions. Further research is warranted to validate these findings and to support clinical implementation.
Limitations: Small sample size

When AI Joins the Table: Evaluating Large Language Model Performance in Sarcoma Tumor Board Decisions (6 min)
Reza Dehdab; Nehren / Germany

Author Block: R. Dehdab, F. K. E. Mankertz, N. Maalouf, S. Afat, C. Deinzer; Tübingen/DE
Purpose: Multidisciplinary tumor boards (MDTs) are critical for the personalized management of soft tissue sarcomas (STS), but they are limited by time, cost, and resource demands. With recent advances in large language models (LLMs) like ChatGPT, there is growing interest in evaluating their potential role in augmenting MDT workflows. This study aimed to assess the clinical performance of ChatGPT-4o in real-world STS cases using predefined evaluation criteria, comparing its treatment suggestions with expert MDT decisions.
Methods or Background: We retrospectively analyzed 152 sarcoma cases presented to a single-center MDT between July 2023 and April 2024; 13 cases were used for prompt development and excluded. ChatGPT-4o generated guideline-based treatment suggestions from anonymized tumor board registration letters. Two blinded experts independently scored outputs using a five-domain framework: diagnostics, therapeutics, sequencing, chemotherapy, and contextualization. Scores were normalized to 1.0. Descriptive statistics and non-parametric ANOVA with post hoc tests assessed performance, including subgroup analysis by sarcoma subtype.
Results or Findings: The final cohort included 138 sarcoma cases (median age: 66; 51% male). The most common subtypes were leiomyosarcoma (n=22), dedifferentiated liposarcoma (n=16), and myxofibrosarcoma (n=15). The median normalized score was 0.857 (IQR: 0.75–1.0), significantly below the maximum achievable score ($p < 0.05$). Clinical contextualization scored highest ($p < 0.05$ vs. other criteria). No significant performance differences were observed across sarcoma subtypes ($p = 0.138$).
Conclusion: ChatGPT-4o showed high but imperfect concordance with sarcoma tumor board decisions, performing best in individualized reasoning. While overall appropriate, gaps in sequencing and chemotherapy selection highlight the need for further refinement before clinical use.
Limitations: Limitations include prompt development on a limited internal case set, reliance on internal expert consensus without external validation, and the absence of testing across different model temperature settings.
Funding for this study: No funding was received for the conduct of this study.

LLMs Software Performance Evaluation for Prostate mpMRI Reports Interpretation (6 min)
Benedetta Masci; Rome / Italy

Author Block: B. Masci[1], L. Nardoni[1], M. Polici[1], M. Zerunian[1], G. Argento[1], D. Caruso[1], M. Francone[1], A. Laghi[2]; [1]Rome/IT, [2]Milan/IT
Purpose: To evaluate a large language model(LLM)-based software for simplifying prostate multiparametric MRI(mpMRI) reports, focusing on clinical accuracy and communication clarity.Special attention was given to correct identification of key diagnostic elements, including PIRADS category and appropriate diagnostic work-up.
Methods or Background: This prospective single-center study analyzed 40 prostate mpMRI reports(January–May 2025) using a custom LLM-based software designed to process clinical data quickly and improve patient understanding.Reports were created by multiple board-certified radiologists to reduce bias and then simplified by the LLM tool.
Two radiologists(Reader1,R1;Reader2,R2) independently evaluated each AI-generated report in six domains:clarity,completeness,capacity of identifying patient-relevant information,accuracy,communicative safety and overall satisfaction,with a 5-point Likert scale.Interpretative errors and correct identification of PIRADS-based diagnostic pathway were also assessed.Statistical analysis included Wilcoxon signed-rank test and inter-reader agreement was assessed.
Results or Findings: Both radiologists evaluated all reports across the domains. Language clarity of LLM-generated reports was moderate (R1: 3.35±0.98; R2: 3.08±0.80;$p<0.05$).Completeness showed greater variability (R1: 3.85±1.14; R2: 3.58±0.87;$p<0.05$). Capacity of identifying patient-relevant information was rated 3.25±0.81 (R1) and 3.13 ± 0.65 (R2;$p=0.1970$). Clinical accuracy scored 3.73±1.09 (R1) vs 3.45±0.82 (R2;$p<0.05$).Communicative safety was 3.58±0.98 for R1 and 3.23±0.83 for R2 ($p<0.05$); finally,overall satisfaction was moderate for both readers, with a mean score of 3.43±0.93 for R1 and 3.08±0.76 for R2, ($p<0.05$).Inter-reader agreement was moderate-to-good(ICC 0.65–0.78).Errors occurred in 35% of reports, mostly minor; 77.5% preserved correct PI-RADS-based diagnostic pathways.These findings highlight the potential to enhance patient communication but support maintaining radiologist oversight.
Conclusion: A tailored LLM-based software showed encouraging performances in simplifying prostate mpMRI reports, with moderate inter-reader agreement. This tool may improve communication and patient empowerment in complex diagnostic settings such as prostate mpMRI, helping reduce communication gaps in imaging workflows.
Limitations: Single software evaluation; no patients' assessments of the AI generated reports

Democratizing Radiomics: Comparing Expert, “Vibe Coding” (LLM-Generated), and Ai-Assisted Pipelines For Clinical Prediction (6 min)

Pietro Paolo Azzaro; Rome / Italy

Author Block: P. P. Azzaro, G. Avesani, R. Chianura, M. Dolciami, B. Gui, E. Sala; Rome/IT
Purpose: Evaluate the performance and usability of three approaches for building radiomics machine-learning (ML) pipelines: an expert-crafted pipeline, a semi-automated AutoML tool (CLIMB), and a pipeline generated by a large language model (ChatGPT-o3).
Methods or Background: Radiomic and clinical data from 94 patients with ovarian cancer (1,702 features from the primary mass and metastatic sites) were used to predict BRCA status. The expert pipeline, implemented in Python with PyRadiomics and scikit-learn, employed SHAP-based feature selection and grid-search hyperparameter tuning. The LLM pipeline was created via iterative prompting of ChatGPT-o3 by a radiologist with good radiomics/ML knowledge but limited coding experience. CLIMB was attempted but could not execute because the feature matrix exceeded token capacity. Both working pipelines evaluated four classifiers—Random Forest, Support Vector Machine, Logistic Regression, and XGBoost—within a SMOTE-based workflow to address class imbalance. Five-fold cross-validation generated fold-wise accuracy and precision.
Results or Findings: Mean accuracy across classifiers was 0.76 ± 0.03 for the expert pipeline and 0.73 ± 0.04 for the ChatGPT pipeline; the difference was not statistically significant ($p = 0.27$). The best individual model in both pipelines was XGBoost (expert 0.78; ChatGPT 0.75). CLIMB yielded no executable model due to input-size limitations. Development effort differed: the expert pipeline required about four programmer-hours and ~220 lines of bespoke code, whereas the ChatGPT pipeline required roughly ten hours of dialog-driven corrections but only ~110 lines. The expert code offered maximal transparency and tunability; the ChatGPT code was functional yet less flexible and relied on the prompt history for reproducibility.
Conclusion: LLM assistance enabled a non-programmer to build a radiomics pipeline with accuracy comparable to an expert benchmark.
Limitations: Single-dataset design, non-deterministic LLM behavior, assessment of only one LLM and one AutoML tool, and no prospective clinical evaluation.

A major potential of LLMs: determining skeletal biological age in breast cancer to predict vertebral compression fractures (6 min)

Chengxin Wan; Chongqing / China

Author Block: C. Wan, Z. Zhang, L. Kong, J. Hao, L. Fajin; Chongqing/CN
Purpose: To determine whether an unsupervised large language model (LLM)–inferred skeletal biological age gap (BAG: LLM bone age minus chronological age) from routine CT–based reports predicts incident vertebral compression fractures (VCF) in women with breast cancer and improves risk stratification beyond conventional metrics.
Methods or Background: We retrospectively included 528 consecutive, newly diagnosed, surgically treated breast cancer patients (2018–2024; 46–76 years). Baseline assessments comprised thoracolumbar CT (T12–L2), quantitative CT volumetric BMD, dual-energy X-ray absorptiometry T-scores, bone-metabolism labs and lifestyle data; patients with baseline VCF or bone metastasis were excluded. All variables were transcribed into a structured Chinese radiology/clinic report. A domain-adapted LLM performed prompt-based, label-free inference of skeletal bone age from the textual report (including CT-derived metrics); BAG (years) was computed. The primary endpoint was first low-energy VCF within 3 years. Cox and Fine–Gray models estimated hazard ratios (HR) per 1-year BAG, adjusting for age, body mass index and Hounsfield units. Discrimination was compared against Hounsfield units, DXA and FRAX using C-index, time-dependent AUC and net reclassification improvement (NRI).
Results or Findings: Fifty-four VCFs occurred (3-year cumulative incidence 10.2%). Each 1-year increase in BAG was associated with 6% higher VCF risk (HR 1.06; 95% confidence interval 1.02–1.11; P=0.002). Adding BAG to a base model (age, body mass index, Hounsfield units) improved 3-year C-index from 0.66 to 0.73 (Δ0.07; P<0.001), increased time-AUC by 0.06 and yielded an NRI of 0.15. Results were consistent in competing-risk analysis, bootstrap validation and endocrine-therapy strata.
Conclusion: Unsupervised LLM-inferred skeletal BAG from routine CT reports independently predicts VCF in breast cancer and meaningfully enhances discrimination beyond density-based metrics, supporting targeted post-operative fracture prevention.
Limitations: Single-center, retrospective design; external validation pending; potential residual confounding.

Multidisciplinary Management of B3 Breast Lesions: A Comparative Performance Analysis of General and Custom-Trained LLM Models (6 min)

Gianmarco Della Pepa; Milan / Italy

Author Block: G. Della Pepa, G. Irmici, M. Cao, C. De Berardinis, E. D'Ascoli, L. Corradini, G. Rossini, C. Depretto, G. P. Scaperrotta; Milan/IT
Purpose: To retrospectively compare GPT-4o, a general-purpose large language model (LLM), and a custom-trained GPT adapted to breast imaging practice, in supporting clinical decision-making for B3 breast lesions. The goal was to assess concordance with multidisciplinary team (MDT) decisions and evaluate clinical utility.
Methods or Background: Clinical, imaging, and histopathological data of consecutive biopsy-confirmed B3 breast lesions discussed at the institutional MDT between February and July 2024 were anonymized and standardized for text-only input.
Two LLMs were tested: GPT-4o and a custom GPT trained using retrospective institutional cases, internal MDT protocols, and international guidelines and consensus.
Each case was submitted to both models using a two-step prompt: generation of management options, followed by a single best recommendation with rationale. Three breast radiologists reviewed outputs and rated option accuracy and recommendation appropriateness (1–5 scale). Concordance with MDT decision was recorded.
Results or Findings: Forty-nine cases were included. Both models generated accurate management options (mean scores: GPT-4o 4.6/5; custom GPT 4.9/5). Appropriateness of the final recommendation was lower for GPT-4o (3.8/5) compared to the custom GPT (4.5/5). Concordance with MDT decisions was 65.3% (32/49) for GPT-4o and 83.7% (41/49) for the custom GPT. Weighted Kappa values were 0.41 and 0.68, respectively. McNemar's test confirmed a significant difference in concordance (p=0.03); Wilcoxon signed-rank test confirmed the difference in appropriateness (p=0.002). Inter-reader agreement was substantial (Fleiss' Kappa 0.72).
Conclusion: Both models showed high accuracy in understanding complex cases. While GPT-4o aligned only moderately with MDT decisions, the custom GPT demonstrated improved concordance and appropriateness. Carefully trained LLMs may provide valuable decision support in challenging scenarios, particularly when MDT expertise is not readily available.
Limitations: Single-institution pilot with a small sample size. Broader validation and training on larger, more diverse datasets are needed.

Potential value of the commercialised large language models for cancer staging based on head and neck MRI reports (6 min)

Qiyong Hemis Ai; Hong Kong / Hong Kong SAR China

Author Block: Q. H. Ai, H. H. Leung, H. M. Kwok, K. F. Hung, L. M. Wong, T. Y. So, A. D. King, K. T. Bae; Hong Kong/HK
Purpose: MRI is routinely used for staging head and neck cancer (HNC), which is a vital step for disease management. However, T and N category criteria for HNC staging are complex and require specialized expertise, and so in many institutions only descriptive MRI reports without formal staging are available. This study aimed to evaluate the potential of commercialized large language models (LLMs) in staging HNC based on the descriptive MRI reports for oral cavity cancer (OCC) by comparing the accuracies of LLMs for T and N categorization and overall stage with that of human experts.
Methods or Background: Descriptive contents in 70 eligible MRI reports were retrospectively input to three commercialised LLMs (ChatGPT5.0, ChatGPT4.0 and DeepSeekV3), respectively. The T- and N- categorisation, and overall stage were extracted from the outputs for further analysis. Accuracies of the LLMs for HNC staging were assessed by the gold standard (confirmed by other two senior head and neck radiologists), and compared using McNamar test.
Results or Findings: The LLMs staged all cases based on the 8th edition of the AJCC cancer staging manual. The ChatGPT5.0, ChatGPT4.0 and DeepseekV3 achieved an accuracy of 74.3%, 72.8%, and 57.1%, respectively for T-categorisation; 85.7%, 82.8%, and 61.4%, respectively for N-categorisation; and 75.7%, 72.8%, and 52.8%, respectively for overall stage. Compared with DeepseekV3, ChatGPT5.0 and ChatGPT4.0 showed higher accuracies for T- and N-categorisation, and overall stage (all $p<0.05$). No differences in accuracies for T- and N- categorization and overall stage between ChatGPT5.0 and ChatGPT4.0 (all $p>0.05$).
Conclusion: Results suggested that the current commercialised LLMs may not be able to assist HNC staging based on descriptive MRI reports for OCC.
Limitations: Small sample size;
Only tested the LLMs using OCC MRI reports

Turning Reports into Labels: LLM-Driven Extraction of Tumor Progression in Lung Cancer Patients using Radiological Reports (6 min)

Sina Warmer; Essen / Germany

Author Block: S. Warmer, Y. Wen, C. Bojahr, L. Umutlu, J. Haubold, J. Kohnke, K. A. Borys, F. Nensa, R. Hosch; Essen/DE
Purpose: Radiology reports routinely describe tumor response, yet this information remains embedded in unstructured text, limiting its clinical structured availability. Therefore, this study investigates whether a large language model (LLM) can accurately classify tumor progression, regression, or stability from free-text radiological reports using a zero-shot approach.
Methods or Background: 223 radiology reports were randomly selected from a retrospective cohort of 100 lung cancer patients (female=41, 65±9.72 years, NSCLC=96, SCLC=4) who underwent CT or PET/CT imaging between 2003 and 2021. The dataset consisted of thoracic CT scans (44%), PET/CT whole-body scans (34%), and abdominal CT scans (22%). Clinical experts independently annotated reports to indicate whether they showed progression, regression, or stability. A general-purpose, open-source LLM (Qwen3-235B) was prompted in a zero-shot setting to classify each report. Performance was evaluated for two tasks: binary classification (progression vs. no progression) and multiclass classification (progression, regression, stability, non-classifiable). Performance was measured using accuracy and F1 score.
Results or Findings: In the binary classification task, the model achieved 80% accuracy with an F1 score of 0.71 and strong agreement with expert labels. In the multiclass setting, accuracy was 0.74, with per-class F1 scores of 0.74 for progression, 0.9 for regression, and 0.71 for stability. The model achieved 70% accuracy on non-classifiable cases. These results were achieved without fine-tuning, relying solely on zero-shot prompting, which underscores the potential of open-source LLMs for clinical information extraction.
Conclusion: This study demonstrates the potential of zero-shot LLMs to extract structured tumor responses directly from free-text radiology reports. Such models offer a scalable, training-free solution to support longitudinal therapy monitoring and improve access to critical clinical information written in radiological reports.
Limitations: The limitations of the study are the need for further evaluations of different llms and prompting strategies.
Funding for this study: No funding was provided for this study.

Privacy-Preserving LLMs for Structured Lymphoma Progression Reporting: Llama 3.3 vs Llama 4 (6 min)

Philipp Prucker; Munich / Germany

Author Block: P. Prucker; Munich/DE
Purpose: To evaluate the ability of privacy preserving locally deployed large language models (LLMs) to generate structured lymphoma progression reports from cross-sectional imaging narratives and compare the performance of Llama-3.3-70B-Instruct and Llama-4-Scout-17B-16E-Instruct.
Methods or Background: This was a single-centre, retrospective study of 65 adult lymphoma patients (July 2023–July 2024). Models were run on-premises (Ollama/Open-WebUI, temperature = 0; HTTPS within firewall) to extract nodal/extranodal involvement, assign the Lugano stage and treatment response, and populate a fixed template (three iterations). Two radiologists assessed the outputs, and the following metrics were included: accuracy, precision, recall, F1 score and specificity, with 95% confidence intervals (CIs); inter-rater agreement was assessed using the kappa statistic (κ).
Results or Findings: Both LLMs produced complete and correctly structured reports for all cases. Llama-4 outperformed Llama-3.3 in terms of extraction, with nodal accuracy of 0.99 versus 0.97 ($p = 0.001$) and extranodal accuracy of 0.99 versus 0.99 ($p = 0.013$). For reasoning tasks, the difference increased: Lugano stage: 0.85 vs 0.60 ($p < 0.001$); treatment response: 0.88 vs 0.65 ($p < 0.001$). No hallucinated new disease sites occurred. The highest relative error rates arose in the assessment of the post-treatment response; the extraction errors were mainly omissions. Inter-rater agreement was excellent ($\kappa \approx 0.90–0.93$).
Conclusion: Privacy-preserving LLMs can reliably structure lymphoma information from radiology reports. Llama-4 shows superior performance, particularly with regard to staging and response. While LLMs excel at data extraction, they remain less robust for complex clinical inference, making a human-in-the-loop workflow necessary.
Limitations: This was a single-centre, adult cohort over a short interval. The reports were in German and only two open-source models were tested. There was no evaluation of alternative prompting, RAG or multimodal inputs. Generalisation to rarer subtypes and broader settings requires validation.
Funding for this study: None.

Predicting IDH Mutation and 1p/19q Codeletion Status in Non-enhancement and Hypo-enhancement Adult-type Diffuse Glioma Using Large Language Models (6 min)

Zhi Liu; Chongqing / China

Author Block: Z. Liu; Chongqing/CN
Purpose: To investigate the effectiveness of integrating LLMs with image-to-text technology to predict IDH mutation and 1p/19q codeletion status in non-enhancement and hypo-enhancement adult-type diffuse glioma.
Methods or Background: The MRI (T2WI/T2-FLAIR/CE-T1WI/ADC) and CT images of non-enhancement or hypo-enhancement adult-type diffuse glioma confirmed by pathology in four tertiary hospitals from July 2016 to May 2024 were retrospectively collected. The intra-LLM and inter-LLM agreement of two large language models (LLMs), ChatGPT 3.5 and ChatGPT 4.0, were evaluated in terms of their ability to predict IDH mutation and 1p/19q codeletion status using predefined prior knowledge. Four deployment strategies were assessed: human-LLM interaction, image-to-text-LLM, end-to-end CNN model, and locally fine-tuned natural language models. Performance was compared using accuracy, precision, recall, and F1-score.
Results or Findings: A total of 39120 images from 873 patients were evaluated. GPT 4.0 had higher intra-LLM agreement and better diagnostic performance compared to GPT 3.5. The human-LLM interaction strategy with senior readers using GPT 4.0 demonstrated the best performance, with an accuracy of 0.9011 for IDH mutation classification and 0.8743 for 1p/19q codeletion classification. The locally constructed NLP model fine-tuned on PubMedBERT performed the worst, while the end-to-end CNN strategy exhibited superior performance but with no significant difference compared to the human-LLM interaction strategy with senior readers using GPT 4.0. Predefined prior knowledge prompting strategies improved the performance of both LLMs.
Conclusion: LLMs, integrated with image-to-text techniques, enhance predictive accuracy for IDH mutation and 1p/19q codeletion status in non-enhancement and hypo-enhancement adult-type diffuse glioma.
Limitations: Diagnostic tasks relied on standardized reports, potentially limiting evaluation of LLMs' complex analytics. Incorporating human experts introduced variability, affecting reproducibility. High data dependence restricts applicability to non-standardized reports or diverse clinical settings.
Funding for this study: No.

Large Language Models in Medical Data Structuring: A Case Study on Neuro-Oncological Cohorts (6 min)

Robert Hahnfeldt; Mönchengladbach / Germany

Author Block: R. Hahnfeldt, M. Schönfeld, T. Schömig, J. P. Janssen, S. Lennartz, D. Maintz, M. Schlamann, K. R. Laukamp, J. Kottlors; Cologne/DE
Purpose: Primary brain tumors form a heterogeneous group of neoplasm. Standardized follow-up protocols lead to growing institutional MRI datasets that reflect local epidemiology and offer a basis for clinical research. Large language models (LLMs) offer a novel approach by enabling automated structuring and real-time summarization of clinical cohorts. This study evaluated LLM use for automated analysis of a neuro-oncological database, including estimation of entity distributions, follow-up frequencies, and progression patterns.
Methods or Background: A total of 248 patients with intracranial neoplasms treated between 2014 and 2023 at a neuro-oncological center were included, with 165 glioblastoma patients. An anonymized institutional database was processed using Claude Sonnet 3.5 to autonomously generate descriptive statistics and cohort-specific estimates of follow-up intervals and progression rates. Model outputs were cross-validated using conventional statistical techniques.
Results or Findings: Patients underwent an average of 11 MRI examinations during their disease course. In glioblastoma cases, the shortest intervals between imaging and clinical progression were observed (mean: 348 days for imaging; 533 days for clinical symptoms). The LLM successfully extracted these patterns and predicted progression timelines that plausible matched manual statistical analysis results.
Conclusion: LLM-based cohort analysis enables reliable, automated extraction of key metrics from routine clinical data. The high concordance with classical statistics underscores the potential of these models to support longitudinal data analysis, resource planning, and individualized follow-up strategies in neuro-oncology.
Limitations: Potential bias due to incomplete or inconsistent documentation in the past
The use of Claude Sonnet 3.5 for statistical analyses is not yet established and validated.
Funding for this study: This study was conducted with project funding from the Else Kröner-Fresenius-Stiftung (Grant-Number: 2023_EKEA.77)

Symptom-Only Localization of Brainstem Ischemia: LLM vs Neurologists in 109 DWI-Positive Cases (6 min)

Nedim Beste; Cologne / Germany

Author Block: N. Beste[1], T. Dratsch[1], J. Kottlors[1], P. Floßdorf[1], A-M. Konitsioti[1], L. Volz[1], D. Pinto Dos Santos[2], M. Schönfeld[1]; [1]Köln/DE, [2]Mainz/DE
Purpose: To evaluate the diagnostic accuracy of large language models (LLMs) in localizing brainstem ischemic lesions based solely on neurological symptoms, compared with experienced neurologists.
Methods or Background: We retrospectively included 109 patients with diffusion-weighted imaging (DWI)-confirmed acute brainstem ischemia. Clinical symptoms were provided to three neurologists and five LLMs (GPT-5, GPT-4, GPT-4.1, GPT-4o, o3, o3 pro), which were tasked to predict lesion site (midbrain, pons, medulla) and laterality (left/right). Accuracy, Cohen's κ, region-specific performance, and correlations with symptom count were analyzed.
Results or Findings: GPT-4 and GPT-4o achieved the highest overall accuracy (56.0%), outperforming GPT-5 (48.6%), GPT-4.1 (41.3%), GPT-o3 (34.9%), GPT-o3 pro (10.1%), and all neurologists (32.1–36.7%). Cohen's κ was highest for GPT-4o (κ = 0.29). LLMs performed best in pontine strokes (GPT-4: 74.0%, GPT-4o: 68.8%), while performance in midbrain and medulla lesions was substantially lower. A weak but significant correlation between number of symptoms and prediction accuracy was found for GPT-4 ($r = 0.28$, $p < 0.01$), GPT-5 ($r = 0.26$, $p < 0.01$), and one neurologist ($r = 0.29$, $p < 0.01$).
Conclusion: GPT-4 and GPT-4o outperformed neurologists in localizing brainstem lesions based on clinical symptoms alone, while GPT-5 also exceeded human performance but remained less accurate than GPT-4/4o. Accuracy was modest overall, especially outside pontine strokes.
Limitations: Retrospective design, small cohort size, absence of multimodal input, high percentage of pontine strokes and lack of external validation limit generalizability. Prospective studies with integrated imaging and reasoning-augmented models are needed.
Funding for this study: 1. GPT-4 and GPT-4o reached the highest overall accuracy (56.0%), surpassing GPT-5 (48.6%), other LLMs (41.3–10.1%), and all neurologists (32.1–36.7%) in localizing brainstem lesions based on clinical symptoms alone .
2. Agreement with imaging (Cohen's κ) was highest for GPT-4o (κ = 0.29).
3. Performance was best in pontine strokes (GPT-4: 74.0%, GPT-4o: 68.8%), but substantially lower in midbrain and medulla lesions.
4. Weak yet significant correlations between number of symptoms and accuracy were found for GPT-4 ($r = 0.28$), GPT-5 ($r = 0.26$), and one neurologist ($r = 0.29$).

Demographic bias in large language models for CT organ assignment: a multicentre diagnostic accuracy study (6 min)

Mor Saban; Tel Aviv / Israel

Author Block: M. Saban[1], Y. Alon[1], O. Luxenburg[2], C. Singer[3], M. Hierath[4], A. Karoussou-Schreiner[5], B. Brkljačić[6], J. Sosna[2]; [1]Tel Aviv/IL, [2]Jerusalem/IL, [3]Ramat Gan/IL, [4]Vienna/AT, [5]Luxembourg/LU, [6]Zagreb/HR
Purpose: To determine whether large language models (LLMs) exhibit sex- and age-related performance differences when recommending organs for CT and CT angiography (CTA) referrals, compared with clinicians and the ESR iGuide reference standard.
Methods or Background: In this retrospective multicentre diagnostic accuracy study, 5 308 referrals (4 396 CT, 912 CTA) from seven European countries (2022–2023) were analysed. Organs suggested by GPT-4 and Claude-3 Haiku were compared with ESR iGuide recommendations and independent radiologist assessments. Accuracy, precision, recall, F1 score and Cohen's kappa were calculated with bootstrap 95 % confidence intervals. Subgroup analyses contrasted male versus female and <65 versus ≥65 years. Differences between modalities and subgroups were assessed with permutation and χ^2 tests (significance $p < 0.05$).
Results or Findings: Clinicians demonstrated consistently high performance across all strata, achieving a kappa of 0.80 for CT and 0.72 for CTA, with no significant differences observed based on sex or age. Large language models (LLMs) displayed comparable performance for CT, with GPT-4 attaining a kappa of 0.68 and Claude-3 recording a kappa of 0.71. However, performance for CTA declined, resulting in kappa values of 0.56 for GPT-4 and 0.59 for Claude-3 ($p < 0.001$). Both models exhibited significant variations in accuracy related to sex: for CT, the accuracy was 6–8% higher for males, whereas for CTA, it was 4–6% higher for females ($p < 0.01$). Furthermore, LLMs favored younger patients in both modalities, with F1 scores being 5–7% higher in the population under 65 years ($p < 0.05$).
Conclusion: LLMs approach expert performance in CT organ assignment but display clinically relevant demographic biases and reduced robustness in CTA. Mitigation strategies and hybrid human-AI workflows are required before clinical deployment.
Limitations: The study's retrospective design may limit generalisability.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the Tel Aviv University institutional review board (TAU-0306-CTAI-2024).

ChexFract: Fracture-Focused Vision–Language Models for Chest Radiography (6 min)

Ekaterina Petrash; Moscow / Russia

Author Block: N. Nechaev, E. Przhezdzetskaya, D. Umerenkov, V. Gombolevskiy, E. Petrash, D. Dylov; Moscow/RU
Purpose: State-of-the-art vision–language models (VLMs) often miss or underspecify fractures—rare yet clinically critical findings on chest radiographs. We aimed to (i) build a fracture-focused dataset for report generation and (ii) train specialized VLMs that produce precise, structured fracture descriptions, improving clinical utility over general-purpose systems.
Methods or Background: We curated ChexFract, a public set of 18,710 CXR–text pairs with standardized, template-based fracture mentions. Fracture sentences were extracted from original reports and normalized to a schema capturing presence, location, side, stage (acute/healed/other), and implants. As the language backbone we used Phi-3.5 Vision Instruct. We compared two domain visual encoders—Rad-DINO (MAIRA-2) and CheXagent—by training lightweight projection heads and fine-tuning end-to-end for free-text generation. To score model outputs, we parsed generated text to the same schema and computed standard classification metrics against ground truth.
Results or Findings: Fracture-specialized VLMs consistently outperformed general baselines. With the MAIRA-2 encoder, end-to-end fine-tuning achieved ROC-AUC 0.715 and F1 0.629; with the CheXagent encoder, fine-tuned models reached ROC-AUC 0.697 and F1 0.591. General baselines were lower (e.g., MAIRA-2 baseline ROC-AUC 0.518, F1 0.085; CheXagent baseline ROC-AUC 0.604, F1 0.376). Stratified analyses by fracture type and anatomical site (ribs, clavicle, shoulder, spine, sternum, scapula, sternal wires/other) showed complementary strengths across encoders and informed selection for trauma-focused reporting workflows.
Conclusion: ChexFract enables accurate, structured fracture reporting directly from chest radiographs by focusing learning on clinically salient trauma findings. Specialized VLMs trained on ChexFract markedly improve detection and description quality versus general models, with best configurations achieving ROC-AUC ≈0.71 and F1 ≈0.63.
Limitations: Relabeling used an LLM-assisted protocol and may inherit parsing/bias artifacts; external, multi-center validation is pending. Prospective workflow impact, safety, and hallucination controls require clinical studies.
Funding for this study: No external funding was received; the work was conducted as part of the authors' institutional duties.

Ultrasound Assessment of Therapeutic Water-based Exercise in a Frail Population - A Randomized Controlled Trial (6 min)
Rebeca Mirón Mombiela; Herlev / Denmark

Author Block: J. S. Cárdenas Herran[1], J. Vucetic[1], M. Inglés[1], C. Borras[1], R. Mirón Mombiela[2]; [1]Valencia/ES, [2]Herlev/DK
Purpose: Frailty, an age-related functional capacity loss, constitutes a significant health concern. High-impact exercises are effective in improving frailty, while the effect of therapeutic water-based exercise remains poorly studied. We aimed to investigate the impact of a therapeutic water-based exercise program on ultrasound parameters related to frailty and functional capacity in older adults.
Methods or Background: This was a randomized controlled trial set in a tertiary-care hospital and a private swimming pool. Thirty-five older adults, median age 72 (+/-10), were divided into two groups: i) therapeutic water-based exercise group (WEG) (n=19) and ii) control group (CG) (n=16). WEG underwent a twelve-week water-based exercise intervention supervised by a physiotherapist. CG did not receive any intervention. Frailty status, quantitative muscle ultrasound parameters, and functional outcomes were assessed before and after the intervention. Possible differences between quantitative variables were determined using a two-way ANOVA model with interaction. Minimum detectable change (MDC) between the quantitative variables was also determined.
Results or Findings: Frailty status, sex, physical function, and comorbidities were homogeneously distributed. There was a statistically significant effect on the ultrasound variables: Echo-Intensity ($p = 0.013$), Muscle-Thickness ($p = 0.011$), and Subcutaneous-Fat-Thickness ($p = 0.010$) with respect to treatment and time. We also observed differences in the values of Echo-Intensity in the treatment group after the intervention exceeded the MDC values, thus demonstrating a change that can be attributed to the intervention.
Conclusion: A therapeutic water-based exercise program improves parameters related to frailty and physical condition in older adults, likely by enhancing muscle quality or Echo-Intensity as measured by ultrasound. This suggests that ultrasound can be used as a tool to measure the effect of exercise-based treatments in frail older adults.
Limitations: The study was not double-blind, and the sample size was small.
Funding for this study: Not Applicable.

Association between spinal deformity and pulmonary function in patients with interstitial lung disease (6 min)
Angela Ventura; Verona / Italy

Author Block: L. Pinali, A. Fassio, A. Ventura, L. Carobene, C. Micheletto, D. Gatti, M. Rossini, G. Puppini, S. Baltieri; Verona/IT
Purpose: Vertebral fractures and spinal deformities are common in patients with interstitial lung disease (ILD). We aimed to explore impact of vertebral damage on pulmonary restriction evaluating the association between the Spinal Deformity Index (SDI) and lung volumes in patients with ILD.
Methods or Background: This retrospective study included 200 patients with ILD: 76 idiopathic pulmonary fibrosis (IPF), 65 systemic sclerosis-associated ILD (SSc-ILD), 31 idiopathic inflammatory myopathy-associated ILD (IIM-ILD) and 28 other ILDs. SDI was assessed on multiplanar reconstructions of CT thoracic examinations. Pulmonary function tests included percent predicted forced vital capacity (ppFVC), total lung capacity (ppTLC), absolute FVC and TLC volumes. Multivariable linear regression models were used to evaluate the association between SDI and lung function parameters, adjusted for age, sex, ILD subtype and presence of diffuse idiopathic skeletal hyperostosis or osteoarthritis (DISH/OA).
Results or Findings: In adjusted models, higher SDI was significantly associated with lower ppFVC (2.9% per SDI unit, $p<0.01$) and ppTLC (2.7%, $p<0.01$). These associations persisted across ILD subtypes. SDI was inversely associated with absolute lung volumes: each unit increase in SDI corresponded to a 95.64 ml reduction in FVC ($P = 0.02$) and 199.46 ml in TLC ($p<0.05$ for both). No significant relationship was observed between SDI and ppDLCO.
Conclusion: Spinal deformity, as quantified by SDI, is independently associated with reduced lung volumes in ILD patients, irrespective of ILD subtype. Spinal integrity assessment may be a valuable addition to the interpretation of restrictive ventilatory defects, especially in elderly and osteoporotic populations.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study.

Intravenous Contrast Effects on Opportunistic Osteoporosis Assessment: Impact on Absolute Values, T-Scores, and Classifications in Single- and Dual-Energy CT (6 min)

Simon Bernatz; Frankfurt am Main / Germany

Author Block: S. Bernatz, J. Gotta, V. Koch, S. Mahmoudi, R. Hammerstingl, T. Vogl, L. D. Grünewald; Frankfurt/DE
Purpose: This study evaluates the effect of contrast agents on Hounsfield measurements, T-scores, and Z-scores, assessing their impact on diagnostic accuracy to reduce misclassification and optimize CT-based BMD assessment.
Methods or Background: A retrospective analysis of 597 patients (median age:66 years, 157 females, 440 males) was performed using dual-energy CT (DECT) scans of the abdomen and chest. All patients underwent non-contrast, arterial, and venous phase CT. Automated segmentation (nnU-Net) delineated L1 and L1-L4 trabecular bone, validated by two radiologists. T-scores were calculated according to DEXA-equivalent guidelines.
Results or Findings: Based on non-contrast CT, 35% were diagnosed with osteoporosis, 46% with osteopenia, and 18% had normal bone status. Median T-score was -2.0 (L1) and -2.1 (L1-L4)($p<0.001$). Contrast agents significantly altered BMD values, with median changes of 22.9% (arterial) and 20.1%(venous). The most pronounced changes occurred in patients under 50 years (+99% at L1, $p<0.001$). In older females, 21% were misclassified as osteopenic instead of osteoporotic ($p<0.001$).
Conclusion: Contrast agents significantly affect BMD measurements, leading to diagnostic misclassification. This effect should be considered when using CT for osteoporosis diagnosis and treatment planning.
Limitations: It was conducted at a single center, which may limit generalizability across different scanners. Slice thickness was not assessed, despite its known influence on body composition parameters. Bone density was evaluated using T-scores derived from routine CT rather than quantitative CT, while pragmatic and clinically familiar, this approach may lack the precision of QCT. The cohort was imbalanced, with a predominance of male patients and relatively few individuals under 50 years, reflecting the underlying clinical population but restricting subgroup analyses. Finally, only cases with complete agreement between two readers were included; although this ensured high-quality ground truth, a consensus process or third reviewer would have been more robust.

Bone health assessment in patients with prostate cancer: the role of REMS technology (6 min)

Manuela Montatore; Barletta / Italy

Author Block: M. Montatore[1], S. Casciaro[2], F. R. Contaldo[2], F. Conversano[2], F. A. Lombardi[2], M. Muratore[2], P. Pisani[2], C. Stomaci[2], G. Guglielmi[1]; [1]Foggia/IT, [2]Lecce/IT
Purpose: Prostate cancer (PCa) represents one of the most prevalent malignancies among men, and its management often leads to significant complications, particularly concerning bone health. The interaction between prostate cancer and osteoporosis is multifaceted, involving both the disease itself and the therapies employed in its treatment (such as Androgen Deprivation Therapy (ADT)), which accelerates bone loss and increases fracture risk. Given the intricate relationship between PCa, its treatments, and bone health, proactive monitoring and management of osteoporosis in these patients are essential. This study aims to evaluate the impact of PCa and ADT on bone mineral density (BMD) using the non-ionizing REMS (Radiofrequency Echographic Multi-Spectrometry), the ultrasound-based method for diagnosing osteoporosis and predicting fracture risk on spine and femur
Methods or Background: A cohort of 51 Caucasian men with PCa and a healthy control group matchedfor gender, ethnicity, age, and body mass index (BMI), underwent REMS scans on the femoral neck (FN). A t-test to evaluate the differences in the measured BMD values between the two groups was conducted.
Results or Findings: In subjects with PCa and healthy controls, the mean ± standard deviation for age, weight, height, and BMI were73.5±7.3years, 25.3 ± 2.9 kg/m2) and (73.4 ± 7.2 years, 25.3 ± 3.1 kg/m², respectively. Patients with PCa had a significantly reduced BMD, T- and Z-score at the femoral neck compared to the healthy control group, table 1. BMD percentage difference: -3.4% g/cm2
Conclusion: The obtained significant decrease in FN BMD in PCa patients, as measured by REMS, underlines the disease's negative impact on bone health. The accuracy and precision of REMS allows it to early detect a bone damage for better management of PCa patients, especially those at higher risk due to ADT.
Limitations: No limitation were identified

Dual-parameter optimized ultra-low-dose CT for lumbar bone mineral density assessment: a prospective validation of radiation reduction and diagnostic accuracy (6 min)

Mengqiang Xiao; Zhuhai / China

Author Block: M. Xiao[1], R. Xu[2], J. Chen[1]; [1]Zhuhai/CN, [2]Guangzhou/CN
Purpose: To validate a dual-parameter optimized ultra-low-dose CT (ULD-CT) protocol for quantitative lumbar bone mineral density (BMD) assessment, with comparison to standard-dose CT (SD-CT) in radiation exposure, image quality, and diagnostic accuracy.
Methods or Background: In this prospective study, 245 patients undergoing lumbar surgery received paired SD-CT (120 kV/250 mAs) and ULD-CT (100 kV/30 mAs). Dose metrics (CTDIvol, DLP, effective dose), objective image quality (noise, SNR, CNR), subjective quality (5-point Likert scale), and volumetric BMD (vBMD) were compared. Bone status was classified as normal, osteopenia, or osteoporosis using American College of Radiology criteria. Diagnostic accuracy was evaluated with ROC analysis.
Results or Findings: ULD-CT achieved a 92.5% radiation reduction versus SD-CT (ED: 0.88 vs. 11.68 mSv; CTDIvol: 1.93 vs. 25.66 mGy; both $P < 0.001$). Although objective and subjective quality were lower ($P = 0.001–0.01$), diagnostic acceptability was preserved (scores ≥3; interobserver ICC = 0.73). ULD-CT slightly overestimated BMD, but subgroup analyses by age, sex, and osteoporosis status showed no significant differences (all $P > 0.05$). ROC analysis demonstrated excellent performance (AUC: 0.986–0.996), with sensitivity 94.7–100% and specificity 95.7–98.0%.
Conclusion: The dual-parameter ULD-CT protocol markedly reduces radiation dose while maintaining diagnostic accuracy and acceptable image quality for lumbar BMD evaluation. This technique represents a safe, effective option for osteoporosis screening and longitudinal monitoring.
Limitations: Single-center prospective study.
Funding for this study: None.

Machine learning for the prediction of fragility fractures by bone and body composition parameters: the OsteoLaus 10 years populational cohort (6 min)

Colin Vendrami; Lausanne / Switzerland

Author Block: C. Vendrami, G. Gatineau, E. Shevroja, E. Gonzalez Rodriguez, O. Lamy, D. Hans; Lausanne/CH
Purpose: Recent reviews have highlighted the potential value of machine learning (ML) in improving fragility fracture prediction. We aim to analyse the prediction of fragility fractures using regional and total body dual X-ray absorptiometry (DXA) assessments using a ML pipeline.
Methods or Background: A total of 1475 Swiss postmenopausal women (mean age 63.3±7.1 years, body mass index 25.4±4.3kg/m2) were followed for 10 years between 2010 and 2022. Parameters of bone health (from regional hip and spine DXA: 34 variables) and body composition (total body DXA: 65 variables) were assessed by DXA scans at baseline. Vertebral fractures were screened with lateral DXA during follow-up. Other risk factors (15 variables) and fragility fractures were collected from questionnaires at baseline and during follow up, respectively. All datasets were split for training (85%) and testing (15%) with a balanced fragility fractures proportion. Eight ML models were trained with hyperparameters tunning through 5-fold cross-validation to maximize the area under the curve (AUC).
Results or Findings: Using different combination of variables in the final complete case analysis, a total of 590 to 957 participants with 115-221 fragility fractures were included. The combination of all 114 variables in the same dataset (n=590) achieved the best AUC in both the training set (1.00-0.70) and test set (0.79-0.64). Logistic regression demonstrated the best balance in performance metrics: AUC 0.78, specificity 0.82, and sensitivity 0.71. ML models tend toward higher sensitivity and lower specificity.
Conclusion: These findings emphasize the combination of DXA-derived bone and body composition parameters for fragility fracture prediction. Logistic regression produced the most promising results. ML models remain at interest for further analysis in combination with image based analysis.
Limitations: Further studies including comparisons with FRAX®, larger sample sizes and external validation are needed.
Funding for this study: This study was funded by the Swiss National Science Foundation (SNSF 32473B_156978 and 320030_188886).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The OsteoLaus study received approval from the Institutional Ethics Committee of the University of Lausanne, and all participants signed informed consent (reference 215/09).

Prospective assessment of bone mineral density in spectral localizer radiographs from photon counting detector CT: A prospective in-vivo study (6 min)

Lukas Jakob Moser; Zürich / Switzerland

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: L. J. Moser[1], K. Klambauer[1], V. Mergen[1], M. Eberhard[1], T. Nowak[2], B. Schmidt[2], T. Flohr[2], O. Distler[3], H. Alkadhi[1]; [1]Zürich/CH, [2]Forchheim/DE, [3]Zurich/CH
Purpose: To determine in a prospective patient study the accuracy of areal bone mineral density (aBMD) measurements with spectral localizer radiographs obtained with a clinical photon-counting detector (PCD)-CT scanner in comparison with dual-energy x-ray absorptiometry (DXA).
Methods or Background: In this IRB-approved, prospective study, 41 patients (15 females, 26 males; mean age 61.3 years, age range 35 - 78 years) underwent PCD-CT of the abdomen with a spectral localizer radiograph (tube voltage 140 kVp, tube current 30 mA) and DXA within a median of 45 days. Areal bone mineral density (aBMD) values were derived for lumbar vertebrae L1 - L4 from both methods and were compared with linear regression, Pearson correlation, intraclass correlation coefficients (ICCs), and Bland-Altman plots. T-scores were calculated on a patient level and were compared between methods.
Results or Findings: DXA and spectral localizer radiographs showed strong correlation in aBMD measurements ($R = 0.97$, $p < 0.001$) and patient level T-scores ($R = 0.99$, $p < 0.001$). There was a strong agreement between aBMD from both methods (ICC, 0.96 (95% CI [0.94, 0.97])). Bland-Altman analysis revealed a very small mean difference in aBMD between methods (mean absolute error 0.019 g/cm2) with narrow limits of agreement (-0.083 g/cm2 to 0.121 g/cm2). Similarly, there were small differences in regard to the T-score (mean absolute error 0.156) with narrow limits of agreement (-0.422 to 0.734) between methods. ICCs indicated an excellent agreement between T-scores from DXA and spectral localizer radiographs (ICC, 0.98 (95% CI [0.95, 0.99])).
Conclusion: Our prospective patient study indicates that spectral localizer radiographs obtained with a clinical PCD-CT system enable accurate quantification of the lumbar bone areal mineral density.
Limitations: The limitations of this study are as follows: Small sample size. Manual segmentation process. Prototype software.
Funding for this study: No funding was received for this study.

Longitudinal Changes of Muscle and Bone Marrow Fat Fraction over 5 years Postpartum in Premenopausal Women with Prior Gestational Diabetes (6 min)

Yannick Stohldreier; Munich / Germany

Author Block: Y. Stohldreier, U. Ferrari, S. Schläger, O. Dietrich, H. Hermann, E. Pappa, J. Seißler, A. Gersing, N. Hesse; Munich/DE
Purpose: This study investigates the longitudinal associations between transient insulin resistance during gestational diabetes mellitus (GDM), a prediabetic state, and the composition of vertebral bone marrow (VBM) and paraspinal muscles assessed using quantitative magnetic resonance imaging (MRI).
Methods or Background: We included 78 premenopausal women, 46 with a history of GDM (GDM group) and 32 healthy controls (HC) after normoglycemic pregnancy. At the 5-year-follow-up the glucose metabolism remained pathologic (pGM) in 10 women, based on oral glucose tolerance testing. 3T MRI including quantitative spine imaging was acquired at 1 year and 5 years postpartum, from which proton density fat fraction (PDFF) maps were calculated and autochthone muscles (AM), psoas, and VBM of the thoracic (T9-12) and lumbar (L1-L4) spine were assessed.
Results or Findings: At 1-year-follow-up, all women with prior GDM showed a significantly higher PDFF in the VBM (p=0.03) and AM (p=0.04) compared with controls, suggesting increased fat content and reduced quality. At 5-year-follow-up, no significant group differences were observed, indicating a potential reversal of the previous composition alterations. In contrast, after 5 years, the pGM group exhibited higher PDFF values in the PM and AM (both p=0.01), but not in VBM at 5-year-follow-up (p>0.05). Elevated muscle PDFF was associated with significantly increased odds of pGM at 5-year-follow-up after adjusting for age (PDFF AM OR 1.26 [95% CI 1.05, 1.56], p=0.02; PDFF psoas OR 1.49 [95% CI 1.07, 2.24], p=0.03).
Conclusion: Vertebral bone marrow fat fraction was elevated 1 year after GDM and normalized after 5 years postpartum, while persistent impairment of glucose metabolism was associated with increased PDFF, suggesting reduced skeletal muscle quality 5 years postpartum. Therefore, muscle PDFF may be a useful biomarker for monitoring muscle health in patients with metabolic diseases.
Limitations: Retrospective monocentric study.
Funding for this study: This work was funded by the Munich Clinician Scientist Program (MCSP) of the University of Munich (LMU; grant number ACS-10), LMU Klinikum, the German Center for Diabetes Research (DZD), and the Helmholtz Zentrum München
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the local institutional review board (Ethics Commission of the Medical Faculty, Ludwig-Maximilians Universität München) and all study participants provided written informed consent prior to their participation in the study, which was conducted in accordance with the declaration of Helsinki.

Assessment of bone microarchitecture and its correlation with trabecular fracture predictor using ImageView (6 min)

Nagore Castro; Barcelona / Spain

Author Block: N. Castro, J. Catala March; Barcelona/ES
Purpose: This preliminary study evaluates ImgView, a novel software for high-resolution CT (HR-CT) analysis, in quantifying bone microarchitecture and predicting trabecular fracture risk. The relationship between microarchitectural parameters and predicted fracture risk is assessed in skeletal regions affected by morphological alterations or metabolic bone disease.
Methods or Background: Ten healthy subjects underwent 5G Cone Beam CT (CBCT) imaging. Scans were analysed using ImgView (RAR SRL, Italy) and ImageJ software to obtain bone volume fraction (BV/TV), trabecular thickness (Tb.Th), and trabecular spacing (Tb.Sp). ImgView automatically segments cortical and trabecular bone within a 9.5 mm distal radial ROI, computing densitometric and morphometric indices including bone mineral density, cortical thickness and porosity, and detailed trabecular parameters. A subtool predicts fracture risk by applying a uniform 1000N force to the reconstructed bone structure.

Statistical analysis used paired t-tests, Bland–Altman plots, and linear regression to evaluate bone parameters against fracture prediction.
Results or Findings: No significant differences were found for BV/TV between methods ($p > 0.05$). In contrast, minor differences were identified for Tb.Th ($p=0.034$) and Tb.Sp ($p=0=0.028$), Bland-Altman analysis confirmed these remained within acceptable clinical limits. Regression analysis demonstrated strong, significant correlations: BV/TV with fracture prediction ($p=0.002$; $R^2=0.764$), and Tb.Sp with fracture prediction ($p=0.001$; $R^2=0.787$). Tb.Th showed a weaker, marginally significant association ($p=0.05$; $R^2=0.444$).
Conclusion: This study confirms that favourable bone microarchitecture, with greater bone volume and thickness, correlates with lower fracture risk, while increased intertrabecular spacing indicates higher risk. Despite data variability, this study validates ImgView's indicators for fracture risk assessment. ImgView offers automated metrics to enhance diagnostic accuracy by detecting subtle trabecular changes in suspected osteoporosis, enabling radiologists to target high-risk fracture areas. This tool represents a significant advancement in objective bone health assessment, promising improved patient outcomes.
Limitations: Sample size.

Opportunistic screening of lumbar vertebrae in CT using TotalSegmentator to prevent osteoporotic vertebral fractures (6 min)

Magdalena Seng; Basel / Switzerland

Author Block: M. Seng, J. Wasserthal, M. Bach, D. Harder, M. Obmann, C. Meier, E. M. Merkle, H-C. Breit, M. Segeroth; Basel/CH
Purpose: Osteoporotic vertebral fractures impair quality of life but are preventable. Routine CT examinations offer an opportunity for early risk stratification. This study assessed quantitative metrics of vertebral and paraspinal tissue extracted by TotalSegmentator to identify predictors of osteoporotic vertebral fractures.
Methods or Background: 3299 lumbar spine CT datasets were retrospectively identified in our PACS (2020-2025). 1469 were excluded using large language models (contrast agent, bone metastasis, severe artefacts, hematological diseases, high impact trauma) and 370 due to incompatible imaging parameters (image type, bone kernel, slice thickness). Automated segmentation of vertebrae and paraspinal tissue was performed using TotalSegmentator. Quantitative measures included mean attenuation values and volumes. Vertebral heights of L1 to L4 were assessed on three coronal slices, with fractures defined by a height reduction of >20%. Associations were assessed with logistic regression and ROC analyses.
Results or Findings: Automated vertebral segmentation was successful in 1185 of 1460 cases. The mean attenuation of the non-fractured lumbar vertebrae was lower in patients with an osteoporotic fracture (85.08 (CI: 81.25 - 89.17) n=612) compared to patients without any fracture (125.75 (CI: 120.50 - 131.13) n=573, $p < 0.001$). Attenuation alone showed an AUC of 0.70 (95% CI: 0.67–0.73) with an optimal cut-off at 90 Hounsfield units (sensitivity 0.71, specificity 0.59).
Volume and attenuation of the iliopsoas and autochthon muscles differed significantly between groups ($p < 0.001$), whereas subcutaneous and visceral fat did not. A combined logistic model (AUC 0.77 (95% CI: 0.71–0.82)) rendered the attenuation of the non-fractured vertebrae as most relevant followed by the attenuation of L1, L3, L2 and L4.
Conclusion: Vertebral attenuation, below 90 HU, is a robust predictor of osteoporotic fractures. Opportunistic CT-based screening could support early identification and timely intervention in patients at risk.
Limitations: None.
Funding for this study: None.

Ethics committee - additional information: The requirement for informed consent was waived as this was a retrospective study.

Novel and Compact Digital Tomosynthesis DXA Device for Bone Mineral Density (6 min)

Karen Knapp; Newton Abbot / United Kingdom

Author Block: J. Hu[1], J. Chen[1], S. Wells[2], V. Soloviev[2], S. Coulson[2], S. Phillips[2], J. Evans[1], A. Forbes-Brown[1], K. Knapp[1]; [1]Exeter/UK, [2]Oxford/UK
Purpose: Bone mineral density (BMD) measurement is central to the diagnosis and management of osteoporosis [1]. Dual-energy X-ray absorptiometry (DXA) remains the most widely used clinical tool, but is limited by large, immobile scanners restricted to specialist centres, reducing accessibility [2] and two-dimensional (2D), low-resolution measurements of areal BMD (aBMD) that do not capture the true volumetric density of local bone variation [3].
Methods or Background: We present early feasibility results from an ongoing collaboration with Adaptix Ltd. to develop a digital tomosynthesis–based DXA (DT-DXA) system. It employs a compact x-ray source that can sequentially fire X-rays from an array of positions with a short source–detector distance, enabling portable deployment and three-dimensional tomographic capability with areal or volumetric BMD (vBMD) as an add-on to extremity orthopaedic imaging. DT-DXA can use synthetic 2D to calculate aBMD with the potential advantage of being able to exclude slices containing only soft tissue from the calculation.
3D-printed trabecular bone phantoms [4] and 30 surgically replaced human femoral heads, representing a broad spectrum of densities and microarchitectures, were used to compare DT-DXA performance against iDXA (GELunar) and microCT and to evaluate its accuracy and robustness across clinically relevant bone conditions.
Results or Findings: DT-DXA aBMD and vBMD results were benchmarked against GE iDXA. Phantom and femoral head studies showed close agreement.
Conclusion: DT-DXA offers BMD measurement in a compact, mobile platform. These results highlight its potential for offering point-of-care access to bone density assessment, with the potential to expedite diagnosis and treatment of osteoporosis.
Limitations: In vivo patient imaging has not yet been performed. The radiation dose of DT-DXA was higher than the iDXA, but far lower than medical CT, with scope for further optimisation.
Funding for this study: UK Research and Innovation

Reproducibility of DXA BMD measurements: effect of soft-tissue thickness and acquisition mode (6 min)

Francesco Cicchetti; Milan / Italy

Author Block: F. Cicchetti, G. De Padova, L. Macrì, M. Costa, K. Caringal, D. Albano, A. Zagarella, C. Messina; Milan/IT
Purpose: To evaluate how acquisition mode and simulated soft-tissue thickness affect the stability of dual-energy X-ray absorptiometry (DXA) measurements.
Methods or Background: DXA scans were performed with Stratos DR densitometer (DMS, France), software version 5.3.3.3. Three acquisition modes (Fast, Normal, Precision) were tested under four simulated adipose tissue thicknesses (0, 1, 3, 6 cm, applied with pork rind). Each condition had 25 repeated acquisitions, totalling 300 measurements. Data were analyzed with two-way ANOVA and Tukey's HSD test ($p < 0.05$).
Results or Findings: ANOVA demonstrated a highly significant effect of tissue thickness ($F = 27.0$, $p < 0.0001$), while acquisition mode alone was not significant ($F = 0.72$, $p = 0.49$). A significant thickness × mode interaction was observed ($F = 3.26$, $p = 0.004$). Post-hoc analysis revealed that at the same thickness no differences were observed between Fast, Normal, and Precision modes. Within modes, Normal and Precision showed significant changes between 0 cm and 1 cm ($p \leq 0.04$), and between 1 cm and thicker layers ($p \approx 0.001$–0.002). The Fast mode showed significance only between 0 cm and 1 cm ($p = 0.0002$). Although the 0 cm vs 6 cm comparison was not statistically significant ($p = 0.53$), reproducibility indices indicated a reduction in measurement precision from ~98.5% at 0 cm to ~94% at 6 cm, suggesting a relevant downward trend.
Conclusion: Simulated soft tissue thickness is the main determinant of DXA measurement variability. Although the three acquisition modes provide comparable results under the same thickness, Normal and Precision modes are more sensitive to minimal increments in tissue layers, whereas the Fast mode appears less sensitive but more variable.
Limitations: The limitations of the study are the phantom design and use of simulated soft tissue.
Funding for this study: No funding was received for this study.

HR-pQCT versus DXA for longitudinal monitoring of patients with osteogenesis imperfecta: results at 1-year follow-up (6 min)

Silvia Gazzotti; Bologna / Italy

Author Block: S. Gazzotti[1], G. Fraterrigo[1], E. Schileo[1], R. Sassi[1], M. P. Aparisi Gomez[2], A. Moroni[1], L. Sangiorgi[1], F. Taddei[1], A. Bazzocchi[1]; [1]Bologna/IT, [2]Auckland/NZ
Purpose: Osteogenesis imperfecta (OI) is a rare genetic disease characterised by frequent fractures. Affected patients undergo periodic dual-energy X-ray absorptiometry (DXA), but this has limitations. High-resolution peripheral quantitative computed tomography (HR-pQCT) is an alternative low-dose technique providing information on volumetric density and microstructure, but there are scarce data on its use for follow-up. The aim of this work is to compare the performance of DXA and HR-pQCT in the longitudinal monitoring of OI.
Methods or Background: This preliminary analysis includes 19 adult patients (median age: 35.5 years) with OI type I who underwent DXA scans at lumbar spine, hip, total body, and forearm and HR-pQCT at distal radius and tibia at baseline and at 1-year follow-up.
Results or Findings: Median Z-scores at the femoral neck and lumbar spine were -1.3 and -1.9 at baseline versus -1.4 and -1.9 at 1-year, respectively. No significant changes in DXA-areal bone mineral density (aBMD) could be detected in 1-year at central sites. HR-pQCT parameters overall showed minimal variations (median change: +1.5% to -6.4% at radius; +1.75% to -0.4% at tibia). DXA-aBMD at ultradistal radius was correlated with total volumetric BMD by HR-pQCT at radius both at baseline (Spearman's rho = 0.70; $p < 0.05$) and at 1-year (Spearman's rho = 0.88; $p < 0.001$). However, when the respective longitudinal changes were directly compared, the results were not statistically significant.
Conclusion: While data indicate some site-specific agreement between DXA and HR-pQCT, the two modalities are likely to play a differential role in the longitudinal monitoring of OI. A 1-year time frame may be too short to observe significant changes in measured parameters, which could have important implications for selecting the most appropriate interval for follow-up in clinical practice.
Limitations: Ongoing study, small sample size.
Funding for this study: No funding was received for this study.

Real-World Diagnostic Accuracy of 4D-CT Angiography for the Detection and Localization of Cerebrovascular Arteriovenous Shunts: a 15-year Cohort Study (6 min)
Frederick Jan Anton Meijer; Nijmegen / Netherlands

Author Block: F. J. A. Meijer, O. Van Hulst, S. Pegge, H. D. Boogaarts; Nijmegen/NL
Purpose: The aim of this study was to evaluate the indications for four-dimensional computed tomography angiography (4D-CTA), and to assess its diagnostic accuracy for detecting and localizing cerebrovascular arteriovenous shunting, in a real-world clinical setting.
Methods or Background: A single-center retrospective cohort study was performed, where all patients who underwent 4D-CTA in the period January 2010 and January 2025 were retrieved. Demographic and clinical parameters including age, sex, and presenting symptoms were obtained from the medical records. The indications and results of angiographic studies (shunt presence, type, location, and classification) were retrieved from the study reports. Diagnostic accuracy of 4D-CTA for the detection of AV-shunting was evaluated in a subgroup of patients who underwent digital subtraction angiography (DSA) within 6 months of 4D-CTA, with unchanged clinical status.
Results or Findings: Among 366 patients, the most common indications for 4D-CTA were pulsatile tinnitus (37%) and the diagnostic work-up of cerebral hemorrhage (19%). In the subgroup of patient who also underwent DSA (n=71), 4D-CTA demonstrated a sensitivity of 96.2%, positive predictive value of 98.0%, specificity of 94.7%, and negative predictive value of 90.0% for the detection of AV-shunting. 4D-CTA demonstrated high accuracy (98%) in distinguishing between arteriovenous malformations (AVM) and dural arteriovenous fistulas (AVF).
Conclusion: 4D-CTA exhibits high sensitivity and specificity for the detection of cerebrovascular arteriovenous shunting, and high accuracy to differentiate between AVM or AVF, supporting its potential role as a first-line imaging modality prior to invasive DSA.
Limitations: The lack of confirmatory DSA following negative 4D-CTA examinations may have introduced a selection bias, as a majority of patients with positive findings on 4D-CTA underwent subsequent DSA.

The generalizability of our findings may be constrained to tertiary neurovascular centers, where referred populations often differ from broader clinical cohorts.

Automated Assessment Pipeline for Aneurysm Rupture Risk: Automatic Segmentation, Classification, and External Testing (6 min)
Fei Yao; Wenzhou / China

Author Block: F. YAO, D. Zhu, Y. Yang; Wenzhou/CN
Purpose: Current research on intracerebral aneurysms (IAs) rupture risk assessment mainly focuses on deep learning and radiomics models, both of which rely on accurate segmentation of aneurysm regions. This study aims to create a robust, fully automated segmentation network for multi-center use and compare deep learning and radiomics models for rupture prediction.
Methods or Background: The study utilized data from the MIRACLE cohort, applying the DGIS method for automatic aneurysm segmentation. Five machine learning (ML) and deep learning models were developed for rupture prediction. The models were trained on 593 aneurysms and validated on 75 aneurysms from four hospitals. Model performance was evaluated using AUC, accuracy, sensitivity, specificity, and F1 score, along with SHAP analysis for feature importance and Grad-CAM for interpretability.
Results or Findings: The DGIS segmentation method achieved high accuracy, with Dice coefficients of 0.98 in the source domain and 0.75 in the target domain. The DRE deep learning model outperformed other models, achieving an AUC of 0.995 in training and 0.851 in external testing, surpassing radiomics AdaBoost (AUC, 0.983 and 0.634) and SVM (AUC, 0.712 and 0.656). SHAP analysis revealed key rupture risk features, and Grad-CAM highlighted the model's focus on the aneurysm region.
Conclusion: This study presents an automated, generalizable approach for IA rupture risk analysis, offering an efficient and clinically applicable method for aneurysm detection and rupture prediction across multi-center datasets.
Limitations: First, the study primarily focused on a single type of aneurysm (middle cerebral artery aneurysms), which may limit the generalizability of the findings to other types of aneurysms. Even though the attention regions of the model can be visualized, fully understanding the internal workings of the model is still challenging.
Funding for this study: This study has received funding by the Key Laboratory of Novel Nuclide Technologies on Precision Diagnosis and Treatment & clinical Transformation of Wenzhou (Grant No. 2023HZSY0012), the Discipline Cluster of Oncology, Wenzhou Medical University, China (Grant No. z1-2023008), the Summit Advancement Disciplines of Zhejiang Province (Wenzhou Medical University – Pharmaceutics).

SEMAR + Subtraction CTA: A Quantitative Solution for Metal Artifacts in Intracranial Aneurysm Follow-up (6 min)

Yihan Zhao; Kunming / China

Author Block: Y. ZHAO; Kunming City, Yunnan Province,China/CN
Purpose: To quantitatively evaluate the effectiveness of combining Single-Energy Metal Artifact Reduction (SEMAR) with subtraction techniques in CTA for patients with intracranial aneurysm implants (coils/clips), using DSA as a reference standard.
Methods or Background: In this retrospective study, 80 post-operative CTA scans were analyzed. Conventional images, SEMAR-alone, and SEMAR+Subtraction images were generated. Artifact index (AI), CNR, and vessel measurements were quantified. Two radiologists performed blinded subjective analysis. DSA (available for 46 patients) served as the gold standard.
Results or Findings: SEMAR+Subtraction significantly reduced AI and improved CNR 2.3-fold compared to conventional CTA (12.4±3.1 vs 5.2±1.8, $p<0.001$), with better performance in coils than clips. Vessel diameter measurements showed excellent agreement with DSA (ICC=0.88). Sensitivity for detecting residual aneurysm increased to 94%. Subjective vessel sharpness improved by 47%.
Conclusion: The combination of SEMAR and subtraction CTA significantly reduces metal artifacts, improves quantitative and subjective image quality, and enhances diagnostic confidence, providing a reliable non-invasive alternative to DSA for postoperative monitoring.
Limitations: Retrospective design. The subtraction technique requires good patient cooperation to minimize motion between scans. Sample size for clip cases was relatively small.

Deep learning assistance improves clinician performance in detecting cerebral aneurysms on MRA (6 min)

Gucheol Jung; Seoul / Korea, Republic of

Author Block: G. Jung, J. Y. Lee, H. Kim, S-M. Gho, Y. Yim, J-B. Lee, T-K. Nam, C-Y. Park, K-Y. Park; Seoul/KR
Purpose: Reliable detection of intracranial aneurysms on MRA requires substantial expertise, yet diagnostic variability among physicians remains a challenge. As clinical use of MRA expands, there is a growing demand for consistent and accurate aneurysm detection. This study aimed to assess interobserver variability in detection performance across physicians with different levels of experience and to explore the potential role of artificial intelligence as a decision-support tool.
Methods or Background: TOF-MRA studies with and without intracranial aneurysms were retrospectively collected. An inexperienced physician and a neurology resident with one year of training independently reviewed the images and marked suspected aneurysms. Their findings were compared with reference annotations provided by two board-certified neuroradiologists. After a washout period, the same readers reinterpreted the MRAs with the assistance of deep learning–based software. Diagnostic accuracy and interpretation time were compared between readings with and without AI support.
Results or Findings: A total of 642 patients were included, among whom 321 patients had 398 aneurysms (up to five per patient). Without AI assistance, the inexperienced physician required an average of 85 seconds per case, achieving a sensitivity of 63.6% (253/398) and an accuracy of 74.5%. The neurology resident required 33 seconds per case, with a sensitivity of 60.0% and an accuracy of 66.8%. With AI support, the inexperienced physician improved to 42 seconds per case, with a sensitivity of 83.4% and an accuracy of 80.2%. The resident improved to 29 seconds per case, with a sensitivity of 85.9% and an accuracy of 86.1%.
Conclusion: Deep learning–based AI assistance improved sensitivity and accuracy of intracranial aneurysm detection on MRA while reducing interpretation time.
Limitations: As the study is ongoing, the findings represent a preliminary analysis of the available data.

Clinical verification of deep learning enabled CTA-based intracranial aneurysm auxiliary diagnostic systems: dual-center clinical trial (6 min)

Dawei Wang; Beijing / China

Author Block: D. Wang, S. Wang, C. Xia; Beijing/CN
Purpose: Mounting evidence indicates that early treatment of the aneurysm and aggressive prevention and management of complications can both improve patients' clinical outcomes. This study intends to verity the effectiveness of a CT-angiography-based auxiliary triage and evaluation system for intracranial aneurysms via a clinical trial.
Methods or Background: A dual-center, retrospective, single-arm target-value design was used to evaluate the triage performance of a deep learning-based intelligent system (InferRead CTA Stroke. A total of 485 subjects were enrolled from two centers. Of these, 481 subjects completed the trial: 321 from Center 1 and 160 from Center 2. Reference standard was established by three experienced cerebrovascular imaging experts who were independent of the AI system. Primary endpoints are aneurysm triage sensitivity and specificity both over 80%. Secondary endpoint is saved time by the AI system compared to the hospital's routine imaging-report turnaround time.
Results or Findings: The system achieved a triage sensitivity of 88.14 % (95 % CI: 82.44 %–92.50 %) and specificity of 88.16 % (95 % CI: 83.98 %–91.57 %). Because the lower bound of the confidence interval exceeded the pre-specified targets of 80% (sensitivity, $p = 0.0068 < 0.01$; specificity, $p = 0.0004 < 0.001$), the system can be considered effective in identifying positive cases and ruling out negative cases. Median software reading time was 843s, which was 3 545s faster than the hospital's routine reporting time ($p < 0.0001$). In terms of mean time consumption, the system increased diagnostic efficiency by 94%. Thus, the software is expected to significantly improve reading efficiency.
Conclusion: The validated AI auxiliary diagnostic system is effective in identifying aneurysm cases in a more efficient way, exhibiting great potential to improve the clinical workflow for early detection of intracranial aneurysm.
Limitations: N/A

Preoperative high-resolution vessel wall MRI of unruptured intracranial aneurysms: correlation of bleb enhancement with wall inflammation and instability (6 min)

Alessandro Brancasi; Rome / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: A. Brancasi, D. Parisi, A. Perna, G. Marziali, R. Di Bonaventura, M. Galeazzi, R. Russo, A. Albanese, S. Gaudino; Rome/IT
Purpose: This study investigates the diagnostic value of high-resolution preoperative MRI for unruptured intracranial aneurysms and the association between wall bleb enhancement and aneurysm instability.
Methods or Background: Intracranial aneurysm rupture is life-threatening, yet non-invasive risk assessment remains difficult. Blebs—focal protrusions of the aneurysmal sac—are considered markers of instability, though their predictive value is inconsistent. High-resolution vessel wall imaging (VWI) with post-contrast black-blood sequences suppresses intraluminal flow and depicts wall thickening and enhancement as indicators of inflammation and remodeling. Although enhancement has been linked to unstable phenotypes, its association with blebs remains uncertain. We conducted a prospective single-center study of 30 patients scheduled for surgery for unruptured aneurysms. All patients underwent preoperative 3T MRI (GE, 48-channel coil) with Gadovist, including 3D TOF and pre- and post-contrast black-blood sequences. Imaging findings were compared with intraoperative appearance, and wall tissue was collected for histopathology in nine cases.
Results or Findings: Of 30 aneurysms, 22 (73.3%) had at least one bleb confirmed by imaging and surgery. Contrast enhancement was significantly associated with blebs (73% vs. 25%; P = 0.0492). Blebs were classified as red, yellow, or white. Enhancement was most frequent in white blebs (77%), followed by red (63%) and yellow (60%), with no link between morphology and inflammation. In all histological samples, wall enhancement matched inflammatory infiltration.
Conclusion: High-resolution VWI with black-blood sequences is a valuable tool for preoperative aneurysm assessment. Bleb wall enhancement correlates with histological inflammation, supporting its role as a non-invasive biomarker of wall instability and a tool for rupture risk stratification.
Limitations: No limitations were identified.

Quantitative angiographic parameters associated with symptomatic radiation induced changes in supratentorial brain arteriovenous malformations after radiosurgery (6 min)

Wei Lun Kao; Taipei / Taiwan, Chinese Taipei

Author Block: W. L. KAO[1], Y-S. Hu[2], C-J. Lin[1], J-K. Loo[2], H-C. Yang[1], C-C. Lee[1], H-J. Chiou[1], F-C. Chang[1], K-D. Liu[1]; [1]Taipei/TW, [2]New Taipei/TW
Purpose: Radiation-induced changes (RICs) may cause neurological deficits in patients with brain arteriovenous malformations (BAVMs) after radiosurgery. The present study investigated quantitative angiographic parameters contributing to symptomatic RICs.
Methods or Background: A total of 131 patients with supratentorial BAVMs who had not received prior treatment and underwent radiosurgery between 2011 and 2020 were included. Patients completed ≥ 24 months of MRI and clinical follow-up. MRIs and angiograms taken before radiosurgery were analyzed for morphological characteristics and quantitative angiographic parameters. Symptomatic RICs were defined as neurological symptoms attributed to RICs. The vein-artery (VA) ratio was defined as the sum of all draining vein diameters divided by the sum of all supplying artery diameters. The modified cerebral circulation time (mCCT) was defined as the interval between the bolus arrival time of the ipsilateral cavernous internal carotid artery and the parietal vein. Logistic regression models were used to evaluate associations between these parameters and symptomatic RICs.
Results or Findings: Symptomatic RICs developed in 27 (20.6%) of 131 patients. Nine patients with symptomatic RICs were hospitalized. Multivariable analysis revealed that a lower VA ratio and shorter mCCT were independently associated with symptomatic RICs. Furthermore, the quantitative angiographic model exhibited a higher performance in association with symptomatic RICs than the angioarchitectural model did.
Conclusion: A lower VA ratio and shorter mCCT were quantitative angiographic parameters of venous outflow impairment and high blood flow of BAVMs, respectively. These parameters may quantify the hemodynamic effect that contributes to symptomatic RICs development in patients with BAVMs after radiosurgery.
Limitations: Our single-center, retrospective study may have overestimated symptomatic RIC rates due to follow-up bias and excluded certain BAVM cases, limiting generalizability to other patient groups and treatments.
Funding for this study: Funding was provided by Taiwan's Ministry of Science and Technology (grant number: MOST 112-2314-B-A49-064- to C.J.L. and MOST 113-2314-B-A49-051- to C.J.L.) and Melissa Lee Cancer Foundation.

After the review by Human Research Protection Center, the implementation of the study was approved.

Evaluation of cerebral perfusion patterns in patients with chronic internal carotid artery occlusion for EC-IC bypass surgery selection (6 min)

Tatiana Nemirovskaya; Kazan / Russia

Author Block: T. Nemirovskaya[1], A. Nemirovskiy[2]; [1]Kazan, Moscow/RU, [2]Kazan/RU
Purpose: Extracranial-intracranial bypass (ECIC) surgery may be useful for internal carotid artery (ICA) chronic occlusion. Most cases are secondary to atherosclerosis, however other mechanisms exist, e.g. post-radiotherapy damage, vasculopathy, developmental anomalies. We use CT-perfusion (CTP) as key modality for revascularization candidates selection. Purpose of study was assessment of perfusion patterns in unilateral, bilateral atherosclerotic and moya-moya disease/syndrome ICA occlusion.
Methods or Background: Retrospective assessment of pre-operation CTP-maps of 271 patients, later underwent ECIC in our Neurosurgery department, was performed. All underwent CTP according to standard institutional protocol. Perfusion maps: cerebral blood flow (CBF), cerebral blood volume (CBV), mean transit time (MTT). Six regions of interest were manually outlined bilaterally in main supply areas. Mean hemispheric values and mean ICA-area values were calcualted with interhemispheric ratios assessment.
Results or Findings: A total 271 patients with chronic unilateral (234) and bilateral (27) ICA occlusion and moya-moya disease (10) were selected for ECIC surgery. Candidates criteria were ipsilateral MTT elevation, CBF reduction, increased CBV. Unilateral occlusion group CBF was 34.785 ml/100g/min, interhemispheric asymmetry 76.59% , ICA areas asymmetry 65.159% . No significant difference of interhemispheric CBF in bilateral occlusion group, 37.612 and 35.933ml/100 g/min and symmetry 104.67%, were observed, however anterior-posterior asymmetry was detected. Moya-moya group demonstrated highest CBF, 49.251 and 57.913ml/100 g/min, with asymmetry 81,806%. P-value <0.0001. The highest MTT values were observed in unilateral occlusion group (P = 0.05). CBV values were high and not significantly differed. We established perfusion patterns for each group with highest interhemispheric asymmetry in unilateral occlusion, anterior-posterior pattern in bilateral occlusion and asymmetric increased values in moya-moya group.
Conclusion: Specific CTP patterns depending on different aetiology of chronic ICA occlusion should be considered surgical treatment candidates evaluation.
Limitations: Retrospective assessment of CT perfusion maps

Berlin EMMA Score (BE-EMMA): Branch-enhanced grading of middle meningeal artery embolization in chronic subdural hematoma (6 min)

Leonard Fetscher; Berlin / Germany

Author Block: L. Fetscher[1], E. Siebert[1], C. Csapo-Schmidt[1], N. Mahmoudi[1], O. Reihani[1], D. Kupka[2], M. P. Wattjes[1], J. Nawabi[1]; [1]Berlin/DE, [2]Falun/SE
Purpose: Endovascular treatment of chronic subdural hematoma (cSDH) by middle meningeal artery embolization (MMAE) is rapidly expanding, yet treatment success remains difficult to predict. Existing grading tools on angiographic imaging neglect branch anatomy, dominance, and collateral supply. We therefore developed the BE-EMMA Score, a branch enhanced, angiographic grading system, intended to improve reliability and enable prognostic correlation.
Methods or Background: We retrospectively reviewed 50 MMAEs in 38 patients with cSDH (Charité, 2023-2024). Initial inter-rater testing of a preliminary version of the BE-EMMA Score (capturing branch dominance, occlusion, and collaterals) in 19 cases was followed by refinement in consensus with four interventional (neuro-)radiologists. The refined scoring system integrates pre-, intra- and post-embolization parameters: (i) branch-specific occlusion grade (0-3; grade 4 = proximal stasis without distal penetration, liquid agents only), (ii) branch dominance (F/f = frontal, P/p = posterior), (iii) aplasia or surgical interruption, (iv) main trunk diameter (D/d for ≥/<1.5 mm), and (v) collateral status (C+ = relevant supply, C− = hazardous collaterals prohibiting embolization).
Evaluation of inter-rater reliability (four inter-raters) and correlation with treatment outcome is ongoing in a final dataset of 50 MMAE-cases.
Results or Findings: Using the preliminary version, near-complete occlusion (grade ≥2) was achieved in 84% of divisions; full bilateral occlusion in 53%; relevant collaterals (C+) in ~20%. Inter-rater agreement was strong (κ = 0.84 overall; occlusion κ = 0.88; collaterals κ = 0.85).
Conclusion: The BE-EMMA Score provides an accurate, imaging based, reproductible, and anatomically detailed evaluation of MMAE. By integrating multiple anatomical and procedural dimensions, it extends beyond descriptive reporting toward a standardized framework that may facilitate future correlation with treatment success and clinical outcome.
Limitations: Broader validation is needed to confirm prognostic value and clarify potential use in clinical decision-making.
Funding for this study: Future prospective research including validation of the BE-EMMA Score is funded by the ESMINT Pilot Research Grant. Development of the score itself was not funded.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Ethics approval for the retrospective study of MMAE cases (2022–2024) was granted by the institutional review board of Charité – Universitätsmedizin Berlin (EA4/181/24).

Birth-Related Subdural Hemorrhage in Asymptomatic Newborns: Magnetic Resonance Imaging Prevalence and Evolution of Intracranial and Intraspinal Localization (6 min)

Liala Mirella Fattacciu; Sassari / Italy

Author Block: D. Turilli, L. Piscopo, A. Dessì, C. Pinna, L. M. Fattacciu, E. Solinas, I. Conti, S. Masala, M. Scaglione; Sassari/IT
Purpose: Neonatal birth-related intracranial subdural hemorrhages (SDHs) represent a form of bleeding inside the skull that occurs in newborns. This condition includes the extravasation of blood both in the encephalic parenchyma and in the extra-axial spaces. Recent studies have shown that SDH and particularly post-traumatic birth-related hemorrhages represent a frequent occurrence, but they are often asymptomatic. The gold standard for the diagnosis and follow-up of patients with SDH is multiparametric Magnetic Resonance Imaging. The aim of this study is to describe our experience by reporting several cases of SDH with different distribution and Central Nervous System involvement by the MRI of this pathology in infants up to 30 days of age.
Methods or Background: We analyzed the age and sex of the patients included in this study, the localization of SDH in different CNS areas, and their frequency using distribution plots and pie charts.
Results or Findings: About the analysis of the SDH locations in the 32 patients, the most common location was the cerebellum (31/32, 96.9%), followed by parietal and occipital lobes (19/32, 59.4%; 18/32, 56.2%, respectively), falx cerebri (11/32, 34.4%), tentorium cerebelli (10/32, 31.2%), temporal lobes (6/32, 18.7%), and finally cervical and dorsal spine in the same patients (4/32, 12.5%). According to SDH locations, the patients were divided into supratentorial, infratentorial, both, and Spinal Canal.
Conclusion: Our study confirmed the literature data regarding the neonatal birth-related SDH high frequency, but also allowed us to focus our attention on the rarest spinal SDH localizations with the same benign evolution.
Limitations: The small sample object of the study.
Funding for this study: This research received no external funding.

Radiological Management Of Reversible Cerebral Vasoconstriction Syndrome (RCVS) In France: A Multicenter Survey (6 min)

Vincent L'Allinec; Angers / France

Author Block: V. L'ALLINEC; Angers/FR
Purpose: Reversible Cerebral Vasoconstriction Syndrome (RCVS) is characterized by thunderclap headaches and reversible segmental cerebral arterial narrowing. In the absence of guidelines, radiological management remains heterogeneous. This study aimed to evaluate diagnostic and follow-up imaging practices across French hospitals.
Methods or Background: A multicenter cross-sectional survey was conducted between February and May 2024 in 25 French neuroradiology centers. A self-administered online questionnaire explored initial imaging strategies, CT and MRI protocols, confirmatory and long-term follow-up imaging, and the role of invasive techniques. Responses were analyzed descriptively.
Results or Findings: Twenty centers (80%) responded, mostly university hospitals. CT was the preferred first-line modality (85%), mainly to exclude aneurysmal subarachnoid hemorrhage. MRI was used in all centers at some stage, with a common protocol including DWI, FLAIR, SWI, and TOF-MRA. Practices diverged beyond this: CTA coverage varied (head and neck vs intracranial only), advanced MRI sequences such as vessel wall imaging (40%) and ASL (15%) were inconsistently used. After positive initial imaging, 40% of centers did not perform confirmatory exams, while 75% repeated imaging after negative but clinically suspicious cases. Long-term follow-up was performed by 90% of centers, most often at 3 months, to confirm reversibility. No center reported invasive endovascular treatments.
Conclusion: This first national survey highlights consensus on initial non-invasive imaging but substantial heterogeneity in subsequent diagnostic and follow-up pathways. Such variability reflects the low incidence of RCVS and the absence of formal guidelines. These findings emphasize the need for national recommendations and collaborative prospective studies.
Limitations: Declared practices may differ from real-world management. The predominance of university hospitals may limit generalizability, and descriptive design precludes outcome comparisons. Rapidly evolving imaging technologies could also impact practices
Funding for this study: Investigator-initiated study with no external funding.

Optimal Timing of Dual-Energy CT to predict Hemorrhagic Complications following Endovascular Thrombectomy in Acute Ischemic Stroke (6 min)

Sangil Suh; Seoul / Korea, Republic of

Author Block: K. Lee, S. Suh; Seoul/KR
Purpose: Iodine extravasation on dual-energy CT (DECT) predicts hemorrhagic complications after endovascular thrombectomy (EVT), but most studies have relied on quantitative iodine concentration, leaving optimal timing unclear. We aimed to compare DECT predictive value at different time points using simple region of interest (ROI).
Methods or Background: We retrospectively analyzed 307 patients undergoing EVT for anterior circulation stroke and subsequent DECT. Maximal ROI within the EVT area and contralateral reference were measured to calculate ROI ratio. Any hemorrhage (hemorrhagic infarction, parenchymal hematoma [PH], subarachnoid hemorrhage) was confirmed by follow-up MRI within 24 hours. We assessed ROI predictive performance across DECT time points using AUC, sensitivity, specificity, chi-square tests, and logistic regression.
Results or Findings: Mean age was 70.3 years, 56.7% were male, and 48.5% had cardioembolic stroke. Successful reperfusion (mTICI ≥2b) was achieved in 85.7%. Any hemorrhage occurred in 51.5% (PH in 19.2%). DECT was performed at ≤1 hour (n=92), 1–2 hours (n=29), 2–3 hours (n=132), and >3 hours (n=55) post EVT. DECT ≤1 hour better predicted any hemorrhage than >1 hour (AUC 0.884 vs. 0.812, p=0.040) and ≤2 hours better than >2 hours (0.877 vs. 0.805, p=0.046). DECT ≤1 hour tended to better predict hemorrhage than 2–3 hours, though not statistically significant (0.884 vs. 0.847, p=0.214). Among patients without apparent hemorrhage on hemorrhage map, DECT ≤3 hours better predicted any hemorrhage and PH than >3 hours (all p<0.001). Higher ROI ratio independently predicted any hemorrhage (OR 1.61, 95% CI 1.33–1.93) and PH (1.12, 1.04–1.20).
Conclusion: DECT within 1 hour after EVT provided the best prediction of hemorrhagic complications. If early DECT is not feasible, scanning within 3 hours is acceptable, whereas DECT beyond 3 hours offers limited predictive value.
Limitations: Uneven patient distribution by time period

Persistent Dizziness After EDAS Surgery in Adult Moyamoya Disease Patients: Identifying Risk Factors (6 min)

Baobao Li; Beijing / China

Author Block: B. Li[1], Y. Liu[1], X. Du[1], Z. Hong-Tao[1], R. Xie[1], M. Lu[2], X. Zhao[1], J. Cai[1]; [1]Beijing/CN, [2]Tianjin/CN
Purpose: This study aims to examine the determinants associated with persistent dizziness (RD) in adult patients diagnosed with Moyamoya disease (MMD) following successful Encephalo-Duro-Arterial-Synangiosis (EDAS) surgery.
Methods or Background: In patients with dizziness as the initial symptom of MMD, post-surgery dizziness improvement is noted, but mechanisms remain unclear. This study included 78 adults with MMD who initially experienced dizziness. We recorded patient characteristics, comorbidities, and DHI scores. CVR was assessed pre- and post-EDAS surgery with breath-modulated BOLD-fMRI. DSC-MRI measured TTP, MTT, CBV, and CBF in middle cerebral artery (MCA) regions. White matter was evaluated with LA-score MRI. Patients were categorized into RD and non-RD groups based on dizziness within 3 months post-surgery. We then assessed the impact of CVR, perfusion, and white matter on RD in MMD patients.
Results or Findings: In the RD group, pre- and post-surgical CVR was markedly lower than in the non-RD group, accompanied by elevated DHI and LA scores, with statistically significant differences ($P < 0.05$). Decreased CVR in MCA territory, along with increased DHI and LA scores, were identified as risk factors for early RD post-indirect surgery in adults with MMD. Multivariate logistic regression confirmed CVR, DHI, and LA scores as independent RD risk factors. ROC analysis revealed AUCs of 0.705 for CVR, 0.720 for LA score, and 0.782 for DHI score. Combined, these indicators achieved an AUC of 0.821, indicating high diagnostic accuracy (sensitivity 68.93%, specificity 89.54%).
Conclusion: Reduced CVR in MCA region, along with increased DHI and LA scores, predict short-term residual dizziness in adult MMD patients post-EDAS surgery. The combined assessment of CVR, DHI, and LA scores provides superior predictive value for RD.
Limitations: The study was conducted at a single medical center, which may limit the generalizability.

Clinical value of 5.0T magnetic resonance TOF-MRA in assessing Suzuki classification and the dilatation of hemorrhage related vascular in patients with moyamoya disease (6 min)

Liu Chang; Hefei / China

Author Block: L. Chang; Hefei/CN
Purpose: Explore the effect of 5.0T Mr time-of-fight magnetic angiography to evaluate the application value of resonance angiography (TOF-MRA) in the staging of moyamoya disease (MMD) and the evaluation of bleeding related vessels.
Methods or Background: The data of 22 patients with MMD who underwent 5.0T magnetic resonance TOF-MRA and computed tomography angiography
(CTA) were retrospectively analyzed. Two radiologists performed Suzuki staging, moyamoya vessel (MMV), anterior choroidal artery (AChA), and posterior communicating artery on 5.0T magnetic resonance TOF-MRA and CTA.The display ability of posterior communicating artery (pcoma) was evaluated, and the presence or absence of expansion of AChA and pcoma was graded according to the unilateral cerebral hemisphere.
Results or Findings: A total of 39 cerebral hemispheres were included in the study (5 cases of unilateral MMD, 17 cases of bilateral MMD). The ability of 5.0T TOF-MRA to evaluate Suzuki staging was equivalent to that of CTA ($z = -1.032$, $P > 0.05$), and the display ability of MMV, AChA and pcoma was better than that of CTA ($P < 0.05$). The evaluation ability of 5.0T magnetic resonance TOF-MRA for AChA and pcoma expansion grading was equivalent to that of CTA ($P < 0.05$).
Conclusion: 5.0T magnetic resonance TOF-MRA sequence is superior to CTA in displaying MMD bleeding related vessels, and Suzuki staging and vasodilation grading evaluation are equivalent. It can be used as the preferred imaging method for follow-up review of MMD patients, and has high clinical application value.
Limitations: Its superior sensitivity in detecting MMV and perforator morphology enhances preoperative planning and post□interventional surveillance. Future integration with hemodynamic mapping may refine risk stratification and guide personalized therapeutic strategies,
positioning 5.0T TOF-MRA as a first-line imaging tool for MMD management.

Glucometabolic Dysregulation Drives White Matter Hyperintensity Progression in Cerebral Small Vessel Disease: Longitudinal Evidence from the UK Biobank and Mendelian Randomization Analysis (6 min)
Xu Han; Shanghai / China

Author Block: X. Han[1], X. Yu[2], Y. Zhou[1]; [1]shanghai/CN, [2]Shanghai/CN
Purpose: To develop a prediction model for WMH progression and to investigate whether glucometabolic dysregulation causally influences WMH progression via microstructural damage.
Methods or Background: The study analyzed data from UK Biobank participants of European descent with serial brain MRI scans. Participants took part in both imaging visit and with a diagnosis of CSVD were included in the study. For machine learning, a total of 8 key features were identified from Akaike information criterion, including age, body mass index, cystatin C, glucose, fractional anisotropy, mean diffusivity, intracellular volume fraction, and isotropic volume fraction. For Mendelian Randomization, 4 glucose indexes including fasting plasma glucose, 2-hour plasma glucose after an oral glucose tolerance test, HbA1c, fasting insulin, and 75 diffusion MRI (dMRI)-derived microstructural metrics were applied. Machine learning models were constructed to predict WMH progression, while structural equation modeling tested mediation pathways. Bidirectional two-sample Mendelian Randomization was employed to establish causal relationships between glucose metabolism indices and white matter microstructure using genome-wide association study data.
Results or Findings: Of 1616 participants included, 902 had WMH increase and 714 had WMH. Seven algorithms were employed to develop WMH prediction models, with logistic regression and support vector machine (SVM) demonstrating optimal performance. Structural equation modeling (SEM) revealed that glucose partially mediates WMH progression through ISOVF. Mendelian randomization (MR) analyses indicated that genetic susceptibility to hemoglobin A1c (HbA1c) significantly altered free water content in the left cerebral peduncle, right hippocampal gyrus, left anterior thalamic radiation, and left corticospinal tract.
Conclusion: Glucometabolic dysregulation contributed to WMH progression via microstructural damage.
Limitations: our study population was predominantly of European cohort from UK Biobank, which may limit the generalizability of the findings to other ethnic groups.

CTA-Based Radiomics and Deep Learning Combined with Clinical Imaging Features for Predicting Two-Year Ischaemic Stroke Risk in Asymptomatic Carotid Plaque Patients (6 min)
Guihan Lin; Lishui / China

Author Block: G. Lin, W. Chen, M. Chen, J. Ji; Lishui/CN
Purpose: To evaluate the predictive value of CTA-based radiomics (Rad) and deep learning (DL), combined with clinical and imaging features, for two-year ischemic stroke risk in patients with asymptomatic carotid plaque.
Methods or Background: We retrospectively studied 528 asymptomatic patients who underwent CTA. Patients were randomly allocated to training (n = 370) and validation (n = 158) cohorts and followed for two years. Plaque regions of interest were manually segmented. Radiomics features were extracted with PyRadiomics and DL features from convolutional neural networks. In the training set, feature reduction used t-tests, Pearson correlation, and least absolute shrinkage and selection operator (LASSO) regression. Rad, DL, and fusion deep learning radiomics (DLR) models were developed and evaluated by receiver operating characteristic analysis. Clinical imaging predictors were screened by logistic regression and integrated with the optimal model.
Results or Findings: Hypertension, plaque ulceration, and plaque length were independent predictors (all $P < 0.05$). After selection, 12 Rad, 9 DL, and 16 DLR features remained. The DLR model achieved the highest AUCs in the training and validation cohorts (0.853 and 0.840) and was chosen as optimal. The combined model, which integrates DLR scores with independent clinical imaging predictors, further improved discrimination, achieving AUCs of 0.918 and 0.911 in the training and validation cohorts, respectively.
Conclusion: A combined model integrating CTA-based Rad, DL, and clinical imaging predictors accurately stratifies two-year ischemic stroke risk in asymptomatic carotid plaque patients and may support personalized risk management.
Limitations: The retrospective nature of this study may introduce inherent bias.
Funding for this study: This work was supported by the National Key Research and Development Program of China (2024YFC2417600) and the Zhejiang Medicine and Health Science and Technology Project (2025KY495, 2024KY568).

Carotid Plaque Dynamic Contrast-enhanced MRI Normalised Signal Intensity as a Simple Surrogate for Neovascularisation: A Reproducible Alternative to Kinetic Modelling of Gadolinium Contrast Agents (6 min)

Nicola Giannotti; Sydney / Australia

Author Block: T. R. Readford[1], G. Martínez Rodríguez[2], S. Patel[1], M. Ugander[3], P. Kench[1], N. Giannotti[1]; [1]Sydney/AU, [2]Santiago/CL, [3]Solna/SE
Purpose: Dynamic contrast-enhanced MRI (DCE-MRI) can non-invasively characterise carotid atherosclerotic plaque vulnerability by quantifying measures related to arterial wall neovascularisation and endothelial permeability, which are linked to stroke risk. However, quantitative perfusion metrics such as Ktrans and Kep require complex kinetic modelling and generate disagreement regarding optimal methodology, hindering clinical interpretation.

The purpose of this study was to assess the reproducibility of a simple method for carotid plaque DCE quantification using signal intensity in the vessel wall normalised to skeletal muscle signal intensity, as an accessible surrogate marker of neovascularisation.
Methods or Background: This was a sub-study of the CAPRI trial, which had a neutral outcome for the effect of colchicine versus placebo on carotid atherosclerotic plaque volume after six months. All participants underwent T1-weighted black-blood DCE-MRI of the carotid arteries at baseline and six months, with images acquired every 10 seconds over 210 seconds following intravenous administration of 0.1 mmol/kg gadoteric acid. Plaque core and remote unaffected vessel wall were manually delineated in the same slice. Signal intensities were normalized to skeletal muscle signal intensity from the same slice and timepoint.
Results or Findings: Among included patients (n=28, median [interquartile range] age 72 [64–74] years, 36% female), normalised peak signal intensity of the plaque core was greater than the remote vessel wall at both baseline (3.5 [2.3–4.1] vs 2.1 [1.7–2.5], $p<0.001$) and six months (3.2 [2.5–4.4] vs 2.0 [1.7–2.5], $p<0.001$; but compared to baseline: $p\geq0.81$ for both, mean±SD differences 0.7 ± 0.7 and 0.6 ± 0.4, respectively).
Conclusion: DCE-MRI normalised peak intensity was greater for plaque core compared to remote vessel wall, and both measurements are reproducible over six months. This simplified quantification approach may facilitate future assessment of neovascularisation and plaque phenotypes in clinical practice.

Predicting Carotid In-Stent Restenosis with Dual-Energy CT: A Multicenter Study (6 min)

Guihan Lin; Lishui / China

Author Block: G. Lin, W. Hu, W. Chen, M. Chen, J. Ji; Lishui/CN
Purpose: Our work aimed to assess the clinical value of dual-energy computed tomography (DECT) parameters in predicting in-stent restenosis (ISR) after carotid artery stenting (CAS) and to develop a nomogram model incorporating these parameters to enhance the accuracy of ISR risk prediction.
Methods or Background: Our retrospective multicenter research enrolled 205 patients who underwent CAS during January 2018 to June 2023, with DECT scans performed prior to the procedure. Two radiologists independently measured the DECT parameters and evaluated the conventional computed tomography angiography characteristics of carotid plaques. Univariate and multivariate analyses were conducted to identify independent predictors of ISR. Three models were developed: clinical model, DECT model, and nomogram model. These models were assessed based on the area under the curve (AUC) and calibration, with their clinical value assessed utilizing decision curve analysis (DCA).
Results or Findings: Among 205 patients, 35 in training set and 15 in validation set experienced ISR. Multivariate analysis identified plaque length, fat fraction, normalized iodine concentration, and effective atomic number as independent predictors of ISR. Nomogram model, combining clinical and DECT parameters, demonstrated high accuracy in predicting ISR, with 0.931 AUC in training set and 0.872 in validation set, exceeding both clinical (AUC: 0.797, 0.673) and DECT models (AUC: 0.880, 0.853). Calibration curve and DCA exhibited the nomogram's excellent performance and clinical utility.
Conclusion: The nomogram model integrating DECT parameters and clinical predictors provides a reliable and noninvasive tool for predicting ISR risk following CAS. It facilitates formulation of individualized treatment strategies and offers important references for early intervention.
Limitations: First, the sample size was relatively small. Second, the retrospective design may have introduced selection bias. Third, manual ROI delineation may have introduced measurement errors.
Funding for this study: This work was supported by the National Key Research and Development Program of China (2024YFC2417600) and the Zhejiang Medicine and Health Science and Technology Project (2025KY495, 2024KY568).

An interpretable machine learning model using T2-FLAIR white matter hyperintensity radiomics for haemorrhagic transformation after endovascular therapy of acute ischaemic stroke (6 min)

Qi Wu; Baise / China

Author Block: Q. Wu, C. Huang, X. Zhu, J. Zhang, Y. Shi; Baise/CN
Purpose: To develop and validate an interpretable machine learning model that integrates clinical data with radiomics features from white matter hyperintensities (WMH) to predict haemorrhagic transformation (HT) after endovascular therapy (EVT) for acute ischaemic stroke (AIS).
Methods or Background: In this dual-centre retrospective study, we included AIS patients who underwent EVT. WMH were automatically segmented on pre-procedural T2-FLAIR MRI. Three models were developed and compared: a clinical model, a radiomics model, and a combined model. Performance was assessed using the area under the receiver operating characteristic curve (AUC). Model interpretability was investigated using SHapley Additive exPlanations (SHAP). Mediation and correlation analyses were performed to explore the relationship between key predictors and HT.
Results or Findings: The study included 450 patients, with HT occurring in 174 (38.6%). The combined model achieved the highest predictive performance in the external validation with an AUC of 0.92 (95% CI: 0.87−0.96). This was significantly superior to both clinical model (AUC: 0.78, 95% CI: 0.71−0.84) and radiomics model (AUC: 0.85, 95% CI: 0.79−0.90). SHAP analysis identified admission NIHSS score, atrial fibrillation, and several WMH textural features as the most impactful predictors. Mediation analysis revealed that WMH textural heterogeneity partially mediated the effect of chronic hypertension on the risk of HT.
Conclusion: A model combining clinical data and WMH radiomics accurately predicts post-EVT haemorrhagic transformation. SHAP revealed that textural characteristics of WMH are critical drivers of risk, providing deeper insights into the pathophysiology of vascular fragility.
Limitations: Firstly, its retrospective nature introduces a potential for selection and information bias. Secondly, although this was a dual-center study, the model's generalizability to a broader and more heterogeneous international population requires further validation. Finally, the radiomics signature's robustness may be influenced by inter-scanner variability in MRI acquisition and parameters.
Funding for this study: This study was financially supported by the National Natural Science Foundation of China (Grant No. 82460226), the Natural Science Foundation of Guangxi Autonomous Region (Grant No. 2023GXNSFAA026383, 2025GXNSFHA069156, 2025GXNSFBA069280).

Perivascular Fat Attenuation Index at Internal Carotid Artery Stenosis: A Biomarker of Perivascular Adipose Tissue Inflammation (6 min)

Shushan Dong; Shanghai / China

Author Block: Z. Tian[1], L. Zuo[1], S. Dong[2], D. Yu[1]; [1]Jinan/CN, [2]Beijing/CN
Purpose: To evaluate the value of the fat attenuation index (FAI) as a tool for measuring plaque inflammation in perivascular adipose tissue (PVAT) and identifying symptomatic plaques in internal carotid atherosclerosis.
Methods or Background: We conducted a retrospective analysis of patients with internal carotid atherosclerosis who underwent carotid artery computed tomography angiography (CTA). The patients were assigned to a symptomatic plaque group or asymptomatic plaque group on the basis of clinical diagnosis and neuroimaging. We measured perivascular FAIs at the maximum stenosis site with the plaque, the nonstenosis site adjacent to the maximum stenosis site, and the ipsilateral internal carotid artery (ICA). Multivariable generalized estimating equation (GEE) analysis was performed to identify imaging predictors of symptomatic plaque.
Results or Findings: A total of 101 and 94 ICAs were included in the symptomatic plaque group and asymptomatic plaque group, respectively. Mild ICA stenosis resulted in a lower FAI at the maximum stenosis site than moderate or severe stenosis did (p=0.001). A greater FAI of the ipsilateral ICA was observed in the symptomatic plaque group than in the asymptomatic plaque group (p=0.002), as was the FAI at the maximum stenosis site of the ICA with the plaque (p=0.038). Multivariable GEE analysis revealed that the stenosis severity (p=0.004) and FAI at the maximum stenosis site of the ICA (p=0.007) were capable of identifying symptomatic plaques. ROC analysis revealed that the FAI at the maximum stenosis site of the ICA, in combination with stenosis severity, resulted in a higher area under the curve (AUC) value (0.863) with moderate specificity (74%) and high sensitivity (89%).
Conclusion: The perivascular FAI at the maximum stenosis site of the ICA is useful for identifying symptomatic plaques by monitoring inflammation in patients with ICA atherosclerosis.

Improving Aortic Calcium Assessment in Contrast-Enhanced CT: Exploring HU Thresholds for Reliable Cardiovascular Scoring (6 min)

Philipp Reschke; Frankfurt / Germany

Author Block: P. Reschke, K. Eichler, T. Vogl, L. D. Grünewald; Frankfurt/DE
Purpose: Cardiovascular disease is the leading cause of death in the Western world, with vascular calcification serving as a marker of advanced pathology. The Agatston score is only applicable in non-contrast CT scans. However, no standardized method exists for quantifying aortic calcification on contrast-enhanced CT scans.
Methods or Background: This retrospective study included 1125 patients (344 women, 781 men) who underwent triphasic CT angiography. Patients with metallic stents, prosthetic grafts, or poor image quality were excluded. Fixed (100–900 HU) and dynamic thresholds were applied to arterial and venous phases for aortic calcium quantification and compared with non-contrast Agatston scores.
Results or Findings: In the venous phase, the 300 HU threshold demonstrated the strongest correlation with the Agatston score (thoracic aorta Pearson's $r = 0.81$,; abdominal aorta $r = 0.83$; all $p < 0.001$) and the highest predictive accuracy ($R^2 = 0.66$ and 0.68). In the arterial phase, higher thresholds were required, with optimal performance at 900 HU for the thoracic aorta ($r = 0.78$, $R^2 = 0.51$, $p < 0.001$) and 800 HU for the abdominal aorta ($r = 0.80$, $R^2 = 0.45$, $p < 0.001$). Dynamic thresholding performed significantly worse in both phases, with R^2 values of 0.56 (venous) and 0.07 (arterial) for thoracic calcifications and 0.62 (venous) and 0.09 (arterial) for abdominal calcifications (all $p < 0.05$).
Conclusion: A fixed threshold of 300 HU in the venous phase enables accurate aortic calcium quantification on contrast-enhanced CT, closely aligning with Agatston scoring and potentially allowing broader clinical application without the need for additional non-contrast imaging.
Limitations: The fixed HU thresholds used may not be universally applicable across different CT protocols, as variations in the contrast agent volume, flow rate, and contrast concentration can influence HU measurements.

Periaortic Adipose Tissue Attenuation on Preprocedural CT Represents a Novel Predictor of Mortality in Patients Undergoing TAVR (6 min)

Jan Michael Brendel; Cambridge / United States

Author Block: J. M. Brendel, I. Hadzic, T. Mayrhofer, L. H. Cooke, E. Yucel, N. K. Patel, V. Raghu, B. Ghoshhajra, B. Foldyna; Boston, MA/US
Purpose: To determine whether periaortic adipose tissue (PAAT) attenuation predicts long-term mortality in transcatheter aortic valve replacement (TAVR) patients.
Methods or Background: Higher PAAT attenuation has been linked to periaortic inflammation and can be measured on routine preprocedural CT. Its prognostic value in patients undergoing TAVR remains unclear.

In this retrospective multicenter study, we analyzed preprocedural CT scans from consecutive TAVR patients between 2014 and 2023. PAAT was segmented using a dedicated deep learning tool (TotalSegmentator) that delineates the entire aorta, followed by logical operations creating a 10-mm radial cylinder around the aortic wall with attenuation thresholds of (–190 to –30 HU). Associations with all-cause mortality were assessed using Cox regression adjusted for CT technical parameters (tube voltage, signal-to-noise ratio, slice thickness) and the Society of Thoracic Surgeons (STS) risk score.
Results or Findings: Among 928 patients from four tertiary medical centers (mean age 81±8 years; 58% male), 222 (23.9%) died during a median follow-up of 22 (14–36) months. Mean PAAT attenuation was -77.3±7.2 HU and was higher in women (+2.1±0.5 HU), nonobese patients (+4.7±0.5 HU), and those with moderate or high (≥4%) STS risk score (+1.7±0.5 HU), all p<0.001. Each 10 HU increase in PAAT attenuation was associated with an 82% higher risk of death independent of STS risk (aHR 1.82: 95%CI: 1.36–2.43; p<0.001). Patients with PAAT attenuation above -77 HU had nearly a two-fold greater mortality risk (aHR 1.97; 95%CI: 1.36–2.85, p<0.001).
Conclusion: High PAAT attenuation represents a novel opportunistic CT marker that predicts mortality in TAVR patients, and may inform long-term risk stratification and management.
Limitations: No histopathologic validation of PAAT attenuation was available, limiting mechanistic interpretation.

CT-Based Radiomic Assessment of Periaortic Adipose Tissue in Takayasu Arteritis and Atherosclerosis: A Multi-Segmental Analysis (6 min)

Mehmet Kadıoğlu; Istanbul / Turkey

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: M. Kadıoğlu, S. Ozkök; Istanbul/TR
Purpose: To evaluate microstructural differences in periaortic adipose tissue among patients with Takayasu arteritis, atherosclerosis, and healthy controls using CT-based radiomics, and to investigate the potential of radiomic parameters as imaging biomarkers for subclinical inflammation
Methods or Background: A total of 66 subjects were included: 26 patients with Takayasu arteritis, 20 with atherosclerotic vascular disease, and 20 healthy controls. For the Takayasu group, pre-treatment CT angiograms obtained at the time of diagnosis were analyzed. All scans were performed using Philips 128-slice CT system (100–120 kVp, 1 mm slice thickness, B kernel).
The aorta was divided into ascending, aortic arch, descending, and abdominal segments. Periaortic adipose tissue was semi-automatically segmented in 3D Slicer v5.8.1, and over 300 radiomic features were extracted using PyRadiomics, following standardization guidelines proposed by Koçak B et al.
Group comparisons were conducted using ANOVA and Kruskal–Wallis tests with FDR correction ($p < 0.05$ considered significant).
Results or Findings: A total of 284 segments were analyzed. Statistically significant radiomic differences were detected in the ascending (n = 91), aortic arch (n = 178), descending (n = 199), and abdominal aorta (n = 189) segments.
Key discriminative parameters included Entropy, Joint Energy, Busyness, and the 90th percentile intensity, all showing $p < 0.001$–0.01.
Compared with atherosclerotic patients, Takayasu arteritis demonstrated markedly higher heterogeneity and entropy metrics.
Notably, even CT segments without visible wall thickening or enhancement revealed microstructural alterations in Takayasu patients.
Conclusion: CT-based radiomics can identify inflammation-related textural alterations in periaortic adipose tissue, even in morphologically normal aortic segments.
Compared with atherosclerosis, Takayasu arteritis exhibits significantly higher heterogeneity parameters, suggesting that perivascular fat radiomics may serve as a non-invasive biomarker of early vascular inflammation and tissue remodeling.
Limitations: Single-center study, limited sample size; lack of histopathologic correlation.
Funding for this study: No financial support was received.

Impact of the Mesenteric Calcium Score on Mortality and Morbidity in Acute Occlusive Arterial Mesenteric Ischaemia (6 min)

Lorenzo Garzelli; Paris / France

Author Block: P. Jessua[1], R. Sartoris[1], M. Ronot[1], L. Garzelli[2]; [1]Clichy/FR, [2]Paris/FR
Purpose: To assess whether the mesenteric calcium score (MCS) predicts mortality or morbidity in acute occlusive arterial mesenteric ischaemia (AOAMI), of embolic or atherothrombotic origin.
Methods or Background: Retrospective cohort study of patients with AOAMI admitted to our intestinal stroke unit. Clinical, biological, imaging, treatment and outcomes data were analysed. MCS of the superior mesenteric artery was calculated using the Agatston method and compared between survivors and non-survivors at 30 days. The primary endpoint was 30-day mortality; the secondary endpoint was a composite of 30-day mortality and morbidity (short bowel syndrome, permanent stoma or home parenteral nutrition). Inter- and intra-observer reproducibility was assessed with intraclass correlation coefficients (ICC).
Results or Findings: Among 506 patients screened, 179 were included (77 women, mean age 69.5 years). Thirty-day mortality was 13% with a median overall survival of 101 months. Morbidity was significant: short bowel syndrome (27%), permanent stoma (17%), and long-term parenteral nutrition (26%), with a composite morbidity score ≥1 in 37%. Median MCS was 27, differing by etiology (embolic: 0, atherothrombotic: 375). However, no significant association was foun between MCS and 30-day mortality (p=0.34) or composite mortality-morbidity (p=0.40). Subgroup analyses by etiology confirmed these findings (embolic p=0.5 and 0.34, atherothrombotic p=0.08 and 0.63). Reproducibility of MCS were excellent (inter-observer ICC 0.94, intra-observer ICC 0.98).
Conclusion: The superior mesenteric artery calcium score does not predict short-term mortality or morbidity in AOAMI, including in atherothrombotic patients.
Limitations: Retrospective design, potential missing data, and limited power given to the relatively low mortality rate.

Identifying predictors for limb loss and death in patients with diabetic foot disease by combining patient metadata and MRI based imaging findings (6 min)

Manal Ahmad; London / United Kingdom

Author Block: M. Ahmad, J. Shalhoub, D. Amiras, A. G. Rockall, A. Davies; London/UK
Purpose: Diabetic foot disease (DFD) is a complex disease and is associated with lower limb amputation. Magnetic resonance imaging (MRI) is commonly used in patients with DFD. Early detection of surrogate markers on MRI may help to predict the risk of limb loss. Our aim was to explore the use of deep learning models to identify predictors on MRI for limb loss in patients with DFD.
Methods or Background: Sarcopenia severity grading and the pseudo fat fraction values calculated from 824 T1-weighted coronal MRI scans of the foot across 427 patients were combined with patient metadata to identify salient predictors for limb loss, major amputation and death and all amputation and death as composite outcomes. Least Absolute Shrinkage and Selection Operator (LASSO), Ridge Regression and Random Forest (RaF) models were used. Further analysis was also undertaken using Cox proportional hazard.
Results or Findings: The converging variables which appeared in all three models were Haemoglobin, HbA1c and renal status. The overlapping variables across ridge regression and RaF for all amputations were C-reactive protein (CRP), age, albumin and the pseudo fat fraction. Further analysis with a cox proportional hazard model found CRP was a strong predictor (Hazard Ratio 1.004 [p-value = 0.02]). Former history of transient ischaemic attacks was identified as a predictor for all amputation/death on LASSO and ridge regression. Pseudo fat fraction, weight and HbA1c were highlighted as features of importance for composite outcomes (major lower limb amputation/death and all amputation/death) on random forest.
Conclusion: There may be merit in combining MRI based image findings with patient metadata to stratify risk.
Limitations: Further internal and external validation is required with a more heterogenous cohort of patients.

Using deep learning models (AI) on diabetic foot disease related MRI reports of the foot to identify salient predictors for limb loss (6 min)

Manal Ahmad; London / United Kingdom

Author Block: M. Ahmad, K. C. Soh, J. Shalhoub, D. Amiras, A. Davies, A. G. Rockall; London/UK
Purpose: Diabetic foot disease (DFD) is a complex disease and is associated with lower limb amputation. Magnetic resonance imaging (MRI) is commonly used in patients with DFD.
Methods or Background: 419 MRI reports were reviewed to identify salient predictors for no amputation versus major versus minor limb loss from a list of features including collections, ulcer, osteomyelitis, diabetic myopathy/sarcopenia and Charcot foot. Random Forest, Extreme Gradient Boosting and a Multilayer Perceptron model was applied. Further composite analysis was undertaken to compare no amputation versus major lower limb amputation, no amputation versus all amputation and death and all amputation versus death.
Results or Findings: Extreme gradient boosting comparing the no amputation versus minor amputation versus major amputation group using extreme gradient boosting was the only model of statistical significance. The model had a 63.4% accuracy [95% CI 0.52-0.7; p-value <0.001]. The ROC-AUC values were 0.724 (no amputation group), 0.779 (minor amputation group) and 0.439 (major amputation group). Features highlighted as potential predictors included absence of osteomyelitis and presence of Charcot as variables which influenced the outcome.
Conclusion: MRI reports may provide useful information in highlighting features which could potentially predict the risk of adverse outcomes.
Limitations: Variability in reporting can influence the outcome. Uniformity in reporting may allow this to be explored further and to create a standardised prediction model.
Funding for this study: Imperial College Healthcare NHS Trust radiology pump priming fund.

Identifying High-Risk Patients for Endovascular Failure with UTE-MRI: Evidence from an NIH-Funded Study (6 min)

Judit Csőre; Budapest / Hungary

Author Block: J. Csőre[1], A. Crichton[2], E. Pomozi[1], J. Lamichhane[2], A. B. Lumsden[2], T. L. Roy[2]; [1]Budapest/HU, [2]Houston, TX/US
Purpose: Endovascular treatment failure in chronic limb-threatening ischemia (CLTI) is not fully understood, and patient selection is crucial for optimal results. Ultrashort Echo Time (UTE) MRI is a non-contrast method shown ex vivo to characterize plaque composition. This study assessed whether MRI-defined plaque morphology influences procedural difficulty and immediate technical failure (ITF) in peripheral vascular interventions (PVI).
Methods or Background: Patients with CLTI undergoing PVI at a tertiary vascular center were enrolled and underwent 3T UTE-MRI. Lesions were classified as predominantly soft (>50% thrombus, cholesterol/lipid plaque) or hard (calcific/collagenous plaque). Operators were blinded to MRI findings and used standard pre-procedural imaging. Primary outcome was ITF; secondary outcome was lesion crossing time.
Results or Findings: A total of 43 patients (86 lesions; mean age 67.5 years, 40% female) were included; 14 lesions were excluded (7 diagnostic DSA only, 7 non-diagnostic MRI). Of the 72 evaluable lesions, 66.7% were scored as soft and 33.3% were hard. ITF occurred in 15.3% of lesions, most commonly due to crossing failure (72.7%). Hard lesions had a markedly higher ITF rate compared with soft (41.7% vs 2.1%, $p<0.001$, $Chi^2=19.3$). In a subgroup analysis among >75% stenosis/occlusions, ITF was 58.8% in hard vs 4.3% in soft lesions ($p<0.001$, $Chi^2=14.5$). Median crossing time was significantly prolonged in hard lesions (535s vs 38s, $p=0.024$).
Conclusion: UTE-MRI enables in vivo characterization of vessel wall composition and predicts procedural complexity and ITF in PVI. Despite its potential, assessment of plaque morphology remains underused in CLTI care. Incorporating UTE-MRI into clinical workflows may refine patient selection, guide interventional strategy, and improve outcomes.
Limitations: Single-center study, sample size

CT-Derived Cardiovascular and Metabolic Biomarkers for Risk Stratification in Locally Advanced Lung Cancer Undergoing Combined-Modality Therapy (6 min)
Alessandro Cicchetti; Milan / Italy

Author Block: A. Cicchetti[1], P. Vallerio[1], A. Catalano[1], C. Sangalli[1], L. Marrazzo[2], R. Tummineri[1], A. Botti[3], F. Dionisi[4], E. Gioscio[1]; [1]Milan/IT, [2]Firenze/IT, [3]Reggio Emilia/IT, [4]Rome/IT
Purpose: To assess whether baseline CT-derived cardiovascular and metabolic biomarkers can stratify intermediate-risk patients with locally advanced non-small cell lung cancer (LA-NSCLC) treated with chemoradiotherapy+immunotherapy, thereby supporting personalized follow-up strategies and identifying candidates for advanced cardiological imaging.
Methods or Background: Baseline CT-scans from 305 LA-NSCLC patients enrolled in four Italian centers were retrospectively analyzed. Two-year overall survival (OS2Y) was recorded. Image-derived features included the Agatston score, body composition metrics, aorta diameters, and percent Emphysema. Gross tumor volume (GTV) was contoured by experts and added to the analysis together with chemo/immune information. Automatic segmentation and feature extraction was performed using open-source tools and locally developed scripts.
A Random Forest classifier was trained following feature selection; SHAP values were used for feature importance interpretation, and UMAP+HDBSCAN clustering was applied to identify patient subgroups.
Results or Findings: OS2Y was 62%. Patients receiving chemoradiotherapy (66%) combined with immunotherapy were 34%. Four distinct survival clusters were identified based on selected features(GTV, Visceral Fat, Hepatic Fat, Agatston score, and Emphysema):

Cluster1 (n=69) – OS2Y 83.6%: characterized by small tumor volumes and absence of imaging risk factors above the median.

Cluster2 (n=24) – OS2Y 62.5%: tumor volumes comparable to Cluster 1, but high torso fat, very-high Agatston score and hepatic fat.

Cluster3 (n=201) – OS2Y 59.7%: features around median values, representing the average population group.

Cluster4 (n=11) – OS2Y 11.1%: characterized by large GTV volumes and moderate-to-high emphysema.
Conclusion: This unsupervised clustering approach demonstrated the ability to identify patient subgroups with shared clinical characteristics but distinct risk profiles. Importantly, it highlighted a significant survival impact (cl1-cl2=21.1%) for patients with baseline cardiac calcifications, visceral and hepatic fat, underlining their potential role as prognostic imaging biomarkers to guide follow-up strategies.
Limitations: Lack of systematic cardiological test, retrospective analysis

Node-RADS v1.0 on chest CT for lung cancer lymph node staging: a multi-reader agreement study (6 min)
Federica Sparascio; Udine / Italy

Author Block: F. Sparascio[1], E. Versienti[1], L. Cereser[1], T. Nadarević[2], C. Ciancimino[1], A. P. Pace[1], G. Como[1], R. Girometti[1], C. Zuiani[1]; [1]Udine/IT, [2]Rijeka/HR
Purpose: To assess intra- and inter-reader agreement for Node-RADS v1.0 in mediastinal lymph node evaluation on chest CT in stage I–III non-small cell lung cancer (NSCLC) and determine its diagnostic performance.
Methods or Background: This retrospective, single-center study included 46 patients (38 adenocarcinomas, 8 squamous cell carcinomas) with 158 pathologically confirmed mediastinal lymph nodes (22 malignant, 136 benign). A contrast- enhanced chest CT scan was available for all patients. Four radiologists (two experts, two juniors) independently assigned Node-RADS scores and descriptors ("size" and
"configuration") in two sessions, three weeks apart. Intra- and inter-reader agreement were assessed using Gwet's AC2. Diagnostic performance was assessed by ROC analysis; sensitivity, specificity, and predictive values were calculated at a Node-RADS score ≥3 threshold.
Results or Findings: Inter-reader agreement for Node-RADS scores was almost perfect for experts (Gwet's AC2 = 0.97; 95% CI: 0.96–0.99) and juniors (Gwet's AC2 = 0.95; 95% CI: 0.93–0.97). Intra-reader agreement Gwet's AC2 values ranged from 0.95–0.99. Descriptor agreement was similarly high (Gwet's AC2 ≥ 0.85). ROC AUCs ranged from 0.71–0.76 for experts and 0.68–0.84 for juniors. At the ≥3 threshold, specificity and negative predictive value were consistently ≥90%, while sensitivity remained limited (<64%) for all readers.
Conclusion: Node-RADS v1.0 shows excellent reproducibility across radiologists with different expertise for mediastinal lymph node assessment on CT in stage I–III NSCLC. Its high specificity and negative predictive value suggest a supportive role in excluding malignancy, although limited sensitivity warrants cautious interpretation and complementary diagnostic assessment.
Limitations: Single-center and retrospective study.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective study has been approved by the Institutional Review Board (IRB) of the Department of Medicine, University of Udine. Study protocol code: 019/2025. Approval date: 15/01/2025.

Spectral CT Histogram Features for Early Prediction of Immunotherapy Response in Advanced Lung Cancer (6 min)

Wen Yang; Nanjing / China

Author Block: W. Yang, Q. Feng, X. Chen, X. Xin; Nanjing/CN
Purpose: This study evaluated the potential of spectral image-based histogram features for early assessment of immunotherapy response in advanced lung cancer.
Methods or Background: Thirty-five patients who underwent baseline and follow-up spectral contrast-enhanced CT scans before and during immunotherapy were retrospectively analyzed. Treatment response at the 4th follow-up was determined using RECIST 1.1 and categorized as response (CR, PR) or non-response (SD, PD). Spectral image series-including conventional images, 40/70 keV virtual monoenergetic images (VMI), iodine density, effective atomic number, electron density, and water/iodine-based maps-were reconstructed in arterial and venous phases. VMI-40 keV images were used for 3D semi-automatic lesion segmentation, and first-order histogram features were extracted. Features were standardized with Z-scores, and significant predictors were identified by Mann-Whitney U-test. Logistic regression models were built, and discriminatory ability was evaluated with ROC AUC; AUC differences were compared with the DeLong test.
Results or Findings: Based on RECIST 1.1, 2 patients achieved CR, 23 PR, 9 SD, and 1 PD. From baseline spectral data, three histogram features distinguished response from non-response with an AUC of 0.796. When combining baseline and first follow-up data, three features achieved an improved AUC of 0.852. No predictive features were identified from conventional images.
Conclusion: Histogram features derived from spectral CT, particularly when incorporating both baseline and early follow-up data, show promise for early prediction of immunotherapy response in advanced lung cancer patients.
Limitations: Sample size is small.
Funding for this study: Not applicable

Ethics committee - additional information: This study was approved by the Institutional Ethics Committee. The requirement for informed consent was waived due to the retrospective nature of the analysis.

Diagnostic Performance of Ultra-High-Resolution Photon-Counting Detector CT In a Lung Cancer Cohort Undergoing Low-Dose Radiation and Contrast Media Protocols (6 min)

Yuhan Zhou; Zhengzhou / China

Author Block: Y. Zhou, Z. Wang, Y. Guo, L. Lei, X. Guo; Zhengzhou/CN
Purpose: To compare the benefits of ultra-high-resolution photon-counting detector CT (PCD-CT) using low radiation and low contrast agent doses versus conventional energy-integrating detector CT (EID-CT) protocols in contrast-enhanced chest CT imaging for patients with lung cancer.
Methods or Background: This prospective study enrolled a total of 200 patients with lung cancer (male: 119) who underwent ultra-high-resolution PCD-CT or EID-CT. Participants were matched for age, sex,BMI, and TNM stage. Two protocols were applied: a low-dose, ultra-high-resolution PCD-CT protocol (2.0 mL/s injection rate, 1.0 mL/kg) and a standard-dose EID-CT protocol (3.0 mL/s, 1.2 mL/kg). Radiation exposure, adverse events, and baseline lung cancer characteristics were recorded. Quantitative assessments of lesions, lymph nodes, and vessels included standard deviation (SD), signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), and tumor-to-lung ratio (TLR). Two radiologists independently evaluated subjective image quality, with a particular focus on enhancement-related imaging features. Meanwhile, BMI- and size-dependent subgroup were analyzed.
Results or Findings: The ultra-high-resolution PCD-CT using a low-dose protocol reduced radiation exposure by 66.08% compared to EID-CT ($P < 0.001$), while also decreasing contrast agent volume by 19.4%, effectively lowering the incidence of CI-AKI and adverse reactions. The PCD-CT 1 mm demonstrated superior SD, SNR, and CNR of tumors, lymph nodes, vessels($P < 0.001$). The PCD-CT 0.4 mm provided comparable objective parameters to EID-CT 1 mm, while offering improved overall subjective image quality and detection of contrast-enhanced related imaging features ($P < 0.001$). The benefits were particularly pronounced in BMI subgroups and in lesions <3 cm.
Conclusion: Ultra-high-resolution PCD-CT with low-dose protocol reduces radiation exposure and incidence of CI-AKI, and enhances overall image quality and improves the detection of imaging features in lung cancer, making it suitable for patients of various BMI and those with small lesions.
Limitations: Not applicable

Preliminary findings of the lung cancer screening campaign at a single centre in 796 individuals (6 min)

Paolo Marra; Bergamo / Italy

Author Block: H. W. Phillips[1], P. Marra[1], A. Smedile[2], M. Bertuletti[2], C. Gargiulo[1], K. D. Martins De Mattos[1], P. A. Bonaffini[2], G. Muscogiuri[2], S. Sironi[1]; [1]Milan/IT, [2]Bergamo/IT
Purpose: Lung cancer screening of at-risk individuals remains under investigation, with heterogeneous results being expected due to local environmental and epidemiological factors. We present the preliminary experience of the experimental low-dose chest CT screening campaign at a single Italian centre.
Methods or Background: Eligibility criteria include age (55-75) and positive smoking-history (≥30 pack years, active or cessation within the last 15 years) with follow-up imaging at variable intervals based on Lung-RADS 1.1 (2019) risk stratification. Suspect nodules underwent further evaluation following specialist review, often 18FDG-PET, biopsy and/or surgical excision. A review of all lung and collateral oncological findings in the study population was performed.
Results or Findings: From 11/02/23, 796 individuals have been imaged, with 593 having a second scan by 30/06/25. 16 diagnoses of NSCLC (2% detection rate) have been made, all categorised as LR4 (sensitivity 100%, specificity 89.5%, PPV 16.3%, NPV 100%), 15/16 at initial CT. All underwent 18FDG-PET (seven positive, nine nonspecific), 12 were biopsied (nine CT-guided, three by EBUS-TBNA) whilst four proceeded directly to surgery. Initial CT also identified 56 others with LR4 nodules, 19 of whom were evaluated by 18FDG-PET. Four had EBUS-TBNA biopsies whilst three were directly excised. Follow-up scans showed evolution to LR4 in 26 others, resulting in six 18FDG-PET scans, one EBUS-TBNA biopsy and one excision. During the project, 17 participants were diagnosed with extra-pulmonary malignancies, seven as a result of their screening CT: two thyroid, two breast, one tonsillar, one lymphoma and one thymoma.
Conclusion: Lung cancer screening at a national level and its potential to provide earlier detection seems valuable, though false positives and resultant investigations deserve consideration.
Limitations: Limitations include provisional data use, cohort factors with strict eligibility criteria, compliance and imaging interpretation, particularly of slow growing malignancies.
Funding for this study: None.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Data obtained from a national multicentre prospective study.

Machine learning-based quantitative prediction of spread through air spaces in primary lung adenocarcinoma using intratumoural heterogeneity scores (6 min)

Wei Meng; Harbin / China

Author Block: Y. Li[1], X. Yang[1], P. Wang[2], W. Meng[1]; [1]Harbin/CN, [2]Beijing/CN
Purpose: This study aimed to quantify intratumoural heterogeneity (ITH) to preoperatively predict the spread through air spaces (STAS) status of lung adenocarcinoma (LUAD) and further explore the potential biological basis underlying the prediction model.
Methods or Background: STAS is an aggressive pattern of primary LUAD that affects both prognosis and treatment strategies for patients. In our study, conventional radiomics features and habitat features were extracted from intratumoural and peritumoural regions on preoperative CT images. A new index, the ITH score, was developed to quantify ITH. Clinical-radiologic characteristics associated with STAS were identified by multivariable logistic regression analyses. Additionally, intratumoural-peritumoural habitat features, ITH score, and clinical-radiologic characteristics were integrated into a combined model by various machine learning algorithms. Finally, 24 patients with RNA sequencing data were utilised for gene expression analysis.
Results or Findings: A total of 1268 patients (median age, 60 years; IQR, 53.8–66.0 years; 850 female) were divided into the training set (n=943), validation set (n=236), and external test set (n=89). Using the Light Gradient Boosting Machine classifier, the combined model demonstrated the highest predictive performance for STAS, achieving an AUC value of 0.97 in the training, 0.98 in the validation, and 0.91 in the external test set. Differentially expressed genes in high probability group were associated with monocarboxylic acid transport and metabolism.
Conclusion: The combined model demonstrated superior performance in predicting STAS in primary LUAD.
Limitations: First, its retrospective design may introduce bias, and further prospective studies are needed to validate the model's accuracy. Second, manual tumor delineation by different radiologists could affect the consistency of radiomic features, so future research should prioritize automated segmentation methods. Third, the limited RNA-seq sample size may weaken biological validation, and larger, more diverse cohorts are needed in future studies.
Funding for this study: This study was supported by the Scientific and Technological Innovation 2030-New Generation Artificial Intelligence Project of the National Key Research and Development Program of China, the National Natural Science Foundation of China, and the Climbing Fund of the National Cancer Center.

Comparative Analysis of Modern 18F-FDG PET/CT Imaging and Histopathology for Lymph Node Staging in Lung Cancer Patients (6 min)

Philip Eckwolf; Wien / Austria

Author Block: P. Eckwolf, D. Kifjak, H. Prosch, L. Beer; Wien/AT
Purpose: To assess whether quantitative 18F-fluoro-2-deoxy-D-glucose (FDG) positron emission tomography/computed tomography (PET/CT) parameters improve preoperative thoracic lymph node (LN) staging accuracy in non-small-cell lung cancer (NSCLC).
Methods or Background: Thirty-nine treatment-naïve patients (mean age 67 ± 9 years) with confirmed NSCLC (30 adenocarcinoma [76.9%], 8 squamous cell carcinoma [20.5%], 1 large cell carcinoma [2.6%]) underwent pre-interventional long field-of-view 18F-FDG PET/CT. A total of 149 thoracic LN were sampled intraoperatively, by transbronchial needle aspiration (TBNA), or both. PET metrics included maximum, peak, and mean standardized uptake value (SUVmax, SUVpeak, SUVmean), metabolic tumor volume (MTV), and total lesion glycolysis (TLG).
Results or Findings: Twelve patients (32%) had metastatic thoracic LN (19/149, 12.8%). Metastatic LN were significantly larger (P=0.013) and more metabolically active (P<0.001) than non-metastatic nodes. ROC analysis showed the best diagnostic performance for SUVmax and SUVpeak (AUC 0.86 and 0.862). Using a sensitivity-optimized SUVmax cutoff of 2.82 yielded a negative predictive value (NPV) of 98%, moderate positive predictive value (PPV, 38%), and overall accuracy of 80%. False positives included reactive LN with SUVmax up to 12, limiting PPV despite high NPV.
Conclusion: Quantitative 18F-FDG PET/CT, particularly SUVmax and SUVpeak, enables highly reliable exclusion of thoracic LN metastasis in NSCLC, with excellent NPV for nodes showing low FDG uptake. However, positive findings remain nonspecific and require histopathological confirmation.
Limitations: Retrospective single-center design and modest sample size.
Funding for this study: The financial support by the Austrian Federal Ministry for Digital and Economic Affairs, the National Foundation for Research, Technology and Development and the Christian Doppler Research Association is gratefully acknowledged.

Prediction of Invasive Lung Adenocarcinoma Grading Using the New IASLC System Based on Quantitative Parameters from Dual-Layer Detector Spectral CT (6 min)

Weiwei Deng; Shanghai / China

Author Block: P. Huang[1], Z. Lin[2], Y. Liao[3], W. Deng[3], B. Fan[1]; [1]Nanchang/CN, [2]Hubei/CN, [3]Shanghai/CN
Purpose: The 2020 International Association for the Study of Lung Cancer (IASLC) grading system for invasive lung adenocarcinoma (LUAD) provides significant prognostic value and helps identify patients likely to benefit from adjuvant chemotherapy. This study investigated whether quantitative parameters from dual-layer detector spectral CT (DLCT) could preoperatively predict these IASLC grades in LUAD.
Methods or Background: In this retrospective, two-center study, we analyzed DLCT parameters from 263 patients with pathologically confirmed LUAD. Parameters included conventional CT values (arterial/venous phases), virtual monoenergetic image CT values (40/70/100 keV), iodine concentration (IC), effective atomic number (Zeff), electron density (ED), and the arterial enhancement fraction (AEF). Based on IASLC criteria, patients were classified as low-grade (Grades I-II; n=193) or high-grade (Grade III; n=70). Patients from center 1 were randomly divided into a training set and an internal validation set (7:3 ratio), while patients from center 2 formed an external validation set. Statistically significant parameters from univariable analysis in the training set underwent dimensionality reduction via LASSO regression. Subsequent backward stepwise multivariable logistic regression was used to build a predictive model, with performance assessed by the area under the receiver operating characteristic curve (AUC).
Results or Findings: The training, internal validation, and external validation sets comprised 131 (97 low-grade, 34 high-grade), 55 (41 low-grade, 14 high-grade), and 77 (55 low-grade, 22 high-grade) patients, respectively. Multivariable analysis identified venous phase ED and Zeff as independent predictors for IASLC grading. The prediction model based on these factors achieved AUCs of 0.826, 0.754, and 0.808 in the training, internal, and external validation sets, respectively.
Conclusion: Venous phase ED and Zeff derived from DLCT are effective, non-invasive predictors for preoperatively determining the IASLC grade of lung adenocarcinoma.
Limitations: A retrospective study with a limited sample size
Funding for this study: None

CT-guided percutaneous cryoablation of lung tumors: A retrospective single-center cohort (6 min)

Elena Suderland; Neuss / Germany

Author Block: E. Suderland, G. J. Schmid; Neuss/DE
Purpose: To evaluate feasibility, safety, and local tumour control after CT-guided percutaneous cryoablation of primary and metastatic lung cancer.
Methods or Background: This retrospective single-center study included 29 patients (11 men, 18 women; mean age 67.8 years) with 33 pulmonary lesions ≤3 cm treated between 2012 and 2025. Mean lesion size was 17.3 mm (range 7-30 mm). Eight lesions represented primary lung cancer (1 SCLC, 1 SCC, 6 Adenocarcinomas), and 25 metastases (14 colorectal, 4 breast, 3 uterine, 4 others). Cryoablation was performed under general anaesthesia with CT-guidance. The cryoablation protocol usually consisted of 3 freezing cycles of 3/7/10 minutes, followed by passive and active thawing. Depending on tumor size and location 1-3 cryoprobes were used. Chest tubes were placed during or after treatment in cases of pneumothorax. Treatment decisions were approved by a multidisciplinary tumour board and oncologic consultation.
Results or Findings: Initial technical success was 100%. No major adverse events occured. Minor complications included 18 peri-interventional pneumothoraces and 6 post-interventional pneumothoraces; in total, 18 chest tubes were placed. Additional minor events were perifocal bleeding, post-procedural haemoptysis and pneumonia. Mean hospital stay was 4.2 days (SD 2.1). After a mean follow-up of 14.7 months (SD 13.6), 21 lesions showed local tumor control, 6 showed progression and for 6 lesions follow-up was not available.
Conclusion: CT-guided cryoablation is safe and effective for selected primary and secondary lung tumours, achieving high technical success with low complication rates and good intermediate local tumor control.
Limitations: The study is limited by its retrospective, single-centre design and the relatively small patient cohort. In 6 cases follow-up was missing to fully assess local tumour control.
Funding for this study: No funding was received for this study.

Drug-eluting transarterial chemoembolization plus anlotinib as first-line therapy for non-small cell lung cancer in the elderly□A multicenter retrospective study (6 min)

Jianfei Tu; Lishui / China

Author Block: J. Tu, L. Lai, W. Li; Lishui/CN
Purpose: To investigate the safety and effectiveness of drug-eluting transarterial chemoembolization plus anlotinib of non-small cell lung cancer in the elderly.
Methods or Background: Patients with at least 75 years old, refusal or unresectable, driver gene-negative, refusal or inability to tolerate radiotherapy, chemotherapy and immunotherapy, non-small cell lung cancer, were enrolled in this retrospective, multicenter study (January 2018–December 2023). DE-TACE consisted cisplatin (75 mg/m2) and gemcitabine (600 mg/m2) via feeding arteries and then embolization using drug-eluting beads carrying gemcitabine (400 mg). Start anlotinib 12mg daily 1week post-operative, 2 weeks on/1 week off (21-day cycle). The primary objectives were overall survival (OS) and safety. Overall survival (OS) was analyzed using Kaplan-Meier analysis.
Results or Findings: The final analysis included 90 patients (median age, 80 years, 74 men). The technical success rate of intratumoral drug delivery was 100%. Within the 26-month median follow-up, the median OS was 25.6 months (95% CI 21.1-29.7) and the median PFS was 8.6 months (95% CI 7.8-9.3). Grade 3 or higher treatment-emergent adverse events was 18.9% (17/90).
Conclusion: DE-TACE plus anlotinib was a successful and effective treatment for non-small cell lung cancer in the elderly, with no severe adverse events.
Limitations: The sample size (particularly the PSM cohort) may not be sufficient to detect differences of AEs. And the treatment was gemcitabine-based. Whether the results apply to other chemotherapeutic regimens requires further investigation.
Funding for this study: There is no funding for this study

Revolutionizing Oncology Imaging with AI-Powered Detection of Early Metastasis in Chest X-Ray (6 min)

Shweta Tyagi; Bengaluru / India

Author Block: S. Tyagi, M. M. Jabeer, J. Singh, A. Chandalia; Bengaluru/IN
Purpose: Chest X-rays remain one of the most widely used and cost-effective imaging modalities in oncology, yet subtle pulmonary nodules, often indicative of metastatic disease, are frequently overlooked in high-volume or resource-constrained settings. This study extends our existing AI system for multi-abnormality chest X-ray analysis to accurately detect metastatic pulmonary nodules. By enabling precise and timely reporting, it supports earlier diagnosis and intervention in cancer care.
Methods or Background: Building on a platform already deployed across multiple healthcare sites for detecting thoracic abnormalities, the AI system is designed to detect pulmonary nodules with high sensitivity. Multi-center, diverse chest X-ray datasets, including 10,000 cases, were used to fine-tune the model specifically for nodule detection, enhancing robustness, accuracy, and generalizability. The system automatically flags suspicious nodules, generates visual overlays, and produces structured reports within PACS, acting as a second reader to improve consistency and reduce oversight.
Results or Findings: The system has been evaluated on 500 chest X-rays. The results demonstrated the system's usability and clinical relevance, showing high sensitivity (>95%) in nodule detection and reliable integration into radiology workflows. Structured reporting and overlays facilitate rapid review, support timely referrals for confirmatory imaging, and reduce the risk of missed findings, particularly in high-workload environments.
Conclusion: The AI solution provides an end-to-end, oncology-focused chest X-ray workflow, combining automated detection, visualization, and reporting of pulmonary nodules. By enabling early and accurate identification of metastatic disease, the system enhances radiologist efficiency, supports clinical decision-making, and strengthens cancer care pathways.
Limitations: Current validations are limited to pilot datasets, and broader multi-center prospective studies are required to confirm generalizability across diverse imaging environments. Detection of rare or subtle nodules may remain challenging, but can be improved through fine-tuning with larger and more diverse datasets.
Funding for this study: No funding was obtained for this work.

Machine learning with dual-layer spectral CT preoperatively predicts spread through air spaces in lung adenocarcinoma: A dual-center study (6 min)

Changxing Fang; Taiyuan,Shanxi / China

Author Block: C. Fang, Y. Cui, X. Yang; Taiyuan,Shanxi/CN
Purpose: To evaluate the predictive value of dual-layer spectral CT (DLCT) combined with machine learning models for predicting spread through air spaces (STAS) in lung adenocarcinoma.
Methods or Background: This dual-center study retrospectively analyzed 439 patients with pathologically confirmed lung adenocarcinoma. Clinical-imaging features and DLCT parameters were evaluated. Independent predictors were identified via logistic regression. We built two predictive models: a DLCT-parameter model (Model-DLCT) and a combined model (Model-COM). Five ML algorithms (RF, XGBoost, SVM, LR, LightGBM) were trained and compared.
Results or Findings: Multivariate analysis identified CTR as a significant clinical predictor, and ED-VP and NIC-VP as key DLCT predictors. The XGBoost algorithm outperformed others. Model-DLCT achieved AUCs of 0.833 (training) and 0.829 (test). Model-COM demonstrated superior performance, with AUCs of 0.862 and 0.832, respectively. The model showed excellent calibration and clinical utility on decision curve analysis.
Conclusion: The XGBoost-based model integrating DLCT parameters and clinical features enables accurate, non-invasive prediction of STAS preoperatively. This tool holds significant promise for improving individualized surgical planning and risk stratification in lung adenocarcinoma.
Limitations: Not applicable.
Funding for this study: This work was supported by the National Natural Science Foundation of China (NSFC, Grant No. 82572216).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective study was approved by the Institutional Review Board (IRB) of Shanxi Cancer Hospital (Ethics Approval Number: GZ2025014), and the requirement for written informed consent was waived due to the retrospective nature of the analysis, in accordance with the Declaration of Helsinki.

SF 18a - The holy grail of postoperative imaging and complications

When anatomy changes: imaging the shoulder after surgery (18 min)
Christian W.A. Pfirrmann; Forch / Switzerland

1. To know the typical surgical techniques in shoulder surgery and their appearance on imaging.
2. To know the spectrum of normal and asymptomatic imaging findings after shoulder surgery.
3. To know the typical complications and their appearance on imaging.

MRI to the rescue: decoding the postsurgical knee (18 min)
Erika Jasmin Jung-Ulbrich; Wien / Austria

1. To know the typical knee MR protocol.
2. To outline different knee operation techniques and the correlated MR images, focusing on ligaments and menisci.
3. To become more familiar with the different knee anatomy on MRI before and after surgery, focusing on cruciate ligament reconstruction and meniscal repair.

Hip happens: what post-op imaging reveals (18 min)
Michele Calleja; Stanmore / United Kingdom

1. To recognise the post-operative imaging appearances of hip preservation surgery, specifically acetabuloplasty, osteochondroplasty, peri-acetabular osteotomy and derotational femoral osteotomy.
2. To compare these features with pre-operative anatomy.
3. To recognise early complications, including chondral / chondrolabral failure, avascular necrosis and over- or under-correction.

From hardware to healing: screws, scans, and shenanigans (18 min)
Michail Klontzas; Heraklion / Greece

1. To outline the unique challenges of post-operative spine imaging.
2. To provide state-of-the-art imaging techniques.
3. To describe potential pitfalls when reporting post-operative scans.

Small vessel disease and brain health: new directions and what radiologists need to know (25 min)
Abdelkader Mahammedi; Stanford / United States

1. To understand the pathophysiology, clinical impact, and major etiopathogenic subtypes of cerebral small vessel disease (SVD), including its role in ischemic stroke, hemorrhagic stroke, and dementia, and to recognise key imaging differentials on MRI.
2. To highlight the role of advanced imaging techniques beyond conventional MRI in the detection, characterisation, and risk stratification of SVD, and to discuss future directions in SVD imaging.

When our brain gets old: diffusion MRI insights into tissue microstructure (25 min)
Denis Le Bihan; Gif Sur Yvette / France

1. To understand microstructural tissue characterisation through diffusion MRI.
2. To highlight conceptual advances beyond conventional imaging, elevating diffusion MRI as a core brain health biomarker.

Translating brain ageing imaging into clinical practice (25 min)
Felix Tobias Kurz; Genf / Switzerland

1. To understand how to evaluate brain health in clinical practice, which imaging markers and what health scores matter clinically.
2. To highlight MRI protocols for brain health: where we stand, limits and pitfalls of brain ageing imaging, and future directions.

Panel discussion (12 min)

SF 18c - Clinical benefits and challenges of an expanding role of artificial intelligence (AI) in radiology

Categories: Physics in Medical Imaging, Multidisciplinary, Artificial Intelligence

ETC Level: LEVEL II

Date: March 7, 2026 | 09:30 - 11:00 CET

CME Credits: 1.5

This session aims to provide a state-of-the-art overview of the current status of implementing AI solutions for diagnostic and therapeutic radiology applications. This overview will cover a wide range of AI solutions throughout the entire radiology framework, from the physics of image formation to the usage of image-derived biomarkers and their exploitation in clinical practice. The session will conclude with a panel discussion on the next objective of AI implementations in radiology and the associated challenges.

General considerations (10 min)
James F. Griffith; Shatin / Hong Kong SAR China

1. To learn some tips on improving your musculoskeletal reports.
2. To appreciate that your musculoskeletal report is the most important part of what you do as a radiologist.
3. To understand that improving our reports is a lifelong exercise. We should all be mindful of improving our reports and making them as understandable and actionable as possible.

Cases review, interactive discussion and critiquing of reports (45 min)
James F. Griffith; Shatin / Hong Kong SAR China

1. To critique reports and suggest ways of improving them.
2. To show how to make reports brief yet clinically pertinent.

Workshop assistant
Miaoru Zhang; Hong Kong / China

CUBE 20 - Challenging and unusual cases of ruptured aneurysms and mechanical thrombectomies

Categories: Neuro, Interventional Radiology
ETC Level: LEVEL II
Date: March 7, 2026 | 10:30 - 11:00 CET
CME Credits: 0.5

Moderators:
Hans Henkes; Stuttgart / Germany
Ali Khanafer; Stuttgart / Germany

Chairpersons' introduction (2 min)
Hans Henkes; Stuttgart / Germany
Ali Khanafer; Stuttgart / Germany

Challenging and unusual cases of ruptured aneuryss and mechanical thrombectomies (28 min)
Stephan Felber; Koblenz / Germany

1. To learn strategies for managing complex and atypical ruptured aneurysms and difficult thrombectomy cases.
2. To appreciate technical considerations, device selection, and procedural nuances in challenging neurointerventions.
3. To understand technical considerations, device selection, and procedural nuances in challenging neurointerventions.

EFRS 18 - Empowering Radiography Education for the 21st Century

Categories: Radiographers, Professional Issues, Education

Date: March 7, 2026 | 10:30 - 11:30 CET

CME Credits: 1

This session will focus on the future of radiography education and the elements needed to strengthen the profession's growth. Presentations will explore the key "ingredients" of a radiography programme that empowers professional development, address student well-being, coping strategies, and resilience, and examine how active learning approaches can be implemented effectively. Together, these perspectives aim to provide educators and stakeholders with strategies to create learning environments that support both academic excellence and personal growth.

Moderator:

Karen Brage; Odense / Denmark

Chairperson's introduction (5 min)

Karen Brage; Odense / Denmark

What should be the "ingredients" for a radiography programme that empowers the profession growing? (12 min)

Joana Santos; Coimbra / Portugal

1. Define Core Competencies to empower Future-Ready Radiographers
2. Promote Innovation and Interdisciplinary Learning
3. Foster a Culture of Lifelong Learning and Leadership

Radiographer student well-being, coping and resilience (12 min)

Amy Robertson; London / United Kingdom

1. Identify key factors that influence student well-being (e.g., social, emotional, academic, environmental)
2. Demonstrate the role of coping strategies (adaptive vs. maladaptive) in managing stress and promoting well-being
3. Empower educators to support students' well-being

How to implement active learning into radiography education (12 min)

Marlene Berg Pallesen; Odense / Denmark

1. Define the role of active learning in radiography education
2. Showcase engaging strategies and tools
3. Empower educators to cultivate motivation and ownership

Panel Discussion (19 min)

ST 23 - What's new with the ESR Journals

Categories: Breast, Professional Issues, Students, Research, Education

Date: March 7, 2026 | 10:30 - 11:00 CET

In this session, we meet with Profs. Bernd Hamm (Chief Editor of ESR Journals, Editor-in-Chief of European Radiology) and Francesco Sardanelli (Editor-in-Chief of European Radiology Experimental) and we are introduced to Prof. Sophia Zackrisson, Editor-in-Chief of the newly launched European Radiology Breast. The Editors will talk about the plans for the ESR Journal family, how the new journals fit in it, and what else we can expect from the ESR Journals. They also share their visions and future plans for their respective journals.

Moderator:

Mélisande Rouger; Bilbao / Spain

Interview (30 min)

Bernd Hamm; Berlin / Germany

Francesco Sardanelli; Milan / Italy

Sophia Zackrisson; Malmö / Sweden

PL 3 - Liver Lover

Categories: Abdominal Viscera, President's Choice
Date: March 7, 2026 | 11:30 - 12:00 CET
CME Credits: 0.5

Introduction (2 min)
Minerva Becker; Geneva / Switzerland

Liver Lover (28 min)
Valérie Vilgrain; Clichy / France

ST 24 - Radiation Protection in Focus: EuroSafe Imaging’s Latest Developments

Categories: Professional Issues, EuroSafe Imaging/Radiation Protection, Education

Date: March 7, 2026 | 11:30 - 12:00 CET

Join us for this session to learn more about EuroSafe Imaging, the ESR’s flagship initiative on radiation protection. Our guests will present the latest activities and achievements that continue to strengthen medical radiation protection across Europe and beyond. Topics will include ongoing EuroSafe Imaging initiatives, such as the successful webinar series, new scientific publications and an update on EU projects.

Moderator:

Mélisande Rouger; Bilbao / Spain

Interview (30 min)

Boris Brkljačić; Zagreb / Croatia

Deniz Akata; Ankara / Turkey

John Damilakis; Iraklion / Greece

Graciano Paulo; Coimbra / Portugal

CUBE 21 - The future of neurointervention: upcoming devices and treatment ideas

Categories: Neuro, Interventional Radiology
ETC Level: LEVEL III
Date: March 7, 2026 | 12:00 - 12:30 CET
CME Credits: 0.5

Moderator:
Ali Khanafer; Stuttgart / Germany

Chairperson's introduction (2 min)
Ali Khanafer; Stuttgart / Germany

The future of neurointervention: upcoming devices and treatment ideas (28 min)
Franziska Dorn; Bonn / Germany

1. To learn about novel devices, imaging tools, and AI applications in neurointervention.
2. To appreciate the potential impact of technological advances on clinical workflows and patient outcomes.
3. To understand current limitations and challenges that need to be addressed before broad clinical adoption.

HW Ui 19 - Interventional ultrasound: biopsy and fine needle aspiration (FNA) techniques in the head and neck

Categories: Head and Neck, Interventional Radiology
ETC Level: ALL LEVELS
Date: March 7, 2026 | 12:00 - 13:30 CET
CME Credits: 1.5

Moderators:
Timothy Beale; London / United Kingdom
Simon Morley; London / United Kingdom

Introduction: tips and tricks (30 min)
Timothy Beale; London / United Kingdom
Steve Colley; Birmingham / United Kingdom

1. To learn about the basic principles of performing an ultrasound guided biopsy and fine needle aspiration (FNA).
2. To become familiar with the types of biopsy needles and needle size for FNA.
3. To understand the different techniques of FNA and how to spread and prepare slides.
4. To learn about the potential pitfalls to avoid.

Hands-on demonstration (60 min)

Demonstrators
Pankaj Sharma; Rishikesh / India
Vincent Lenoir; Nyon / Switzerland
Susan Jawad; London / United Kingdom
Ana Germano; Barcarena / Portugal
Ajit Yadav; Delhi / India
Sophie Neveu; Geneva / Switzerland
David Summers; Edinburgh / United Kingdom
Frank A. Pameijer; Utrecht / Netherlands
Elizabeth Loney; Bradford / United Kingdom
Mustafa Seçil; Izmir / Turkey
Philip Touska; London / United Kingdom
Steve Colley; Birmingham / United Kingdom

Workshop assistant
Timothy Beale; London / United Kingdom

AI-SC 19 - Update on AI tools for radiology

Categories: Professional Issues, Management/Leadership, Imaging Informatics, Artificial Intelligence
ETC Level: LEVEL II+III
Date: March 7, 2026 | 12:15 - 13:15 CET
CME Credits: 1

Moderators:
Charles Edward Kahn; Philadelphia / United States
Kicky Gerhilde Van Leeuwen; De Bilt / Netherlands

Chairpersons' introduction (2 min)
Charles Edward Kahn; Philadelphia / United States
Kicky Gerhilde Van Leeuwen; De Bilt / Netherlands

Image segmentation and beyond (12 min)
René Hosch; Essen / Germany

1. To learn to frame clinical questions as segmentation tasks and build a lean, generalizable pipeline that turns routine scans into high-value, interoperable outputs.
2. To appreciate how masks become an informational gain: extract body-composition metrics, track tumor volume, and generate a clinically relevant information.
3. To understand seamless clinical handoff: store segmentations as DICOM-SEG, publish key values as FHIR Observations, and surface them in a linked FHIR dashboard.

Image optimisation (12 min)
Christoph Hoeschen; Magdeburg / Germany

1. To learn about different options to improve image quality using AI based approaches.
2. To appreciate the high potential for reducing e.g. scan time in MR or radiation dose in CT by AI methods.
3. To understand critical aspects and pitfalls of the use of AI in image optimisation.

LLM and structured reporting (12 min)
Moritz Christian Halfmann; Mainz / Germany

1. To learn how large language models (LLMs) can be applied to radiological reporting, including support in draft generation, error reduction, and workflow support.
2. To appreciate how LLMs can facilitate structured reporting and standardization, improving clarity, consistency, and data reusability in radiology.
3. To understand the current opportunities and future directions for LLM-enhanced radiology reporting, with emphasis on validation, human–AI collaboration, and clinical impact.

AI agents in radiology (12 min)
Markus Wenzel; Bremen / Germany

1. To understand the distinguishing features of AI Agents and Multi-Agent Systems as opposed to AI Algorithms.
2. To appreciate the characteristics of tasks that are amenable to and benefit from AI Agents.
3. To learn about barriers and caveats associated with AI Agents and their technology.

Panel discussion: AI advancement expectations for 2027 (10 min)

EFRS 19 - Radiographers in the frontline: advancing primary care within the community

Categories: Radiographers, Professional Issues

Date: March 7, 2026 | 12:15 - 13:15 CET

This session will explore the expanding role of radiographers as frontline healthcare professionals, highlighting their growing contribution to primary care and community-based services and underline how evolving professional roles, advanced competencies, and closer collaboration within multidisciplinary teams are positioning radiographers as key contributors to modern, sustainable healthcare systems.

Moderator:

Nejc Mekis; Ljubljana / Slovenia

Chairpersons Introduction (5 min)

Nejc Mekis; Ljubljana / Slovenia

Radiographers as health educators: improving awareness through health literacy (12 min)

Richard Mark Evans; London / United Kingdom

1. To explain the role of radiographers in promoting health literacy.
2. To communicate medical information clearly to support patient understanding.
3. To use education strategies to enhance patient engagement and informed choices

Leading screening campaigns to improve health in the community with patient's advisor groups (12 min)

Deborah Mizzi; Msida / Malta

1. To plan and lead community screening initiatives aligned with public health goals.
2. To collaborate with patient advisory groups to ensure inclusive and responsive campaign design.
3. To evaluate the impact of screening programs on community health awareness and outcomes.

Empowering radiographers for stronger patient engagement in diagnostic and therapy through appointments (12 min)

Jose Guilherme Couto; Msida / Malta

1. To learn the importance of a holistic approach to better prepare patients for examinations and treatments.
2. To support informed decision-making by clearly explaining diagnostic and therapeutic procedures.
3. To guide patients in the right pathway to follow up and minimise the impact of therapy effects.

Panel Discussion (19 min)

AR 19 - How to sound like an expert: reports on chronic liver disease

Categories: Abdominal Viscera
ETC Level: LEVEL I+II
Date: March 7, 2026 | 12:30 - 13:30 CET
CME Credits: 1

Moderator:
Ulrika Asenbaum; Vienna / Austria

Introduction (10 min)
Ulrika Asenbaum; Vienna / Austria

Improving your liver disease reports (50 min)
Ulrika Asenbaum; Vienna / Austria

1. To learn how to structure liver imaging reports that are clear, standardised, and relevant.
2. To appreciate that strong collaborations with clinical partners enhance the quality of our reports.
3. To learn how to navigate through pitfalls in liver im

AR m19 - How to improve your musculoskeletal reports in practice

Categories: Musculoskeletal, President's Choice
ETC Level: LEVEL I+II
Date: March 7, 2026 | 12:30 - 13:30 CET
CME Credits: 1

Moderator:
James F. Griffith; Shatin / Hong Kong SAR China

Introduction (5 min)
James F. Griffith; Shatin / Hong Kong SAR China

General considerations (10 min)
James F. Griffith; Shatin / Hong Kong SAR China

1. To learn some tips on improving your musculoskeletal reports.
2. To appreciate that your musculoskeletal report is the most important part of what you do as a radiologist.
3. To understand that improving our reports is a lifelong exercise. We should all be mindful of improving our reports and making them as understandable and actionable as possible.

Cases review, interactive discussion and critiquing of reports (45 min)
James F. Griffith; Shatin / Hong Kong SAR China

1. To critique reports and suggest ways of improving them.
2. To show how to make reports brief yet clinically pertinent.

Workshop assistant
Miaoru Zhang; Hong Kong / China

EDiR 19 - AI-driven exam question generation for radiology

Categories: Education, Artificial Intelligence
ETC Level: LEVEL I+II
Date: March 7, 2026 | 12:30 - 13:30 CET
CME Credits: 1

Moderator:
Laura Oleaga Zufiria; Barcelona / Spain

Chairperson's introduction (5 min)
Laura Oleaga Zufiria; Barcelona / Spain

Practical aspects of AI-assisted radiology exam question generation (10 min)
Lukas Lambert; Prague / Czechia

1. To learn how AI tools can assist in generating radiology exam questions.
2. To appreciate the potential of AI in enhancing exam preparation.
3. To understand the impact of AI on radiology exam preparation.

Impact on radiology examination standardisation (10 min)
Fabian Stöhr; Mainz / Germany

1. To learn how AI can help tailor question difficulty.
2. To appreciate how AI ensures an optimal balance of question difficulty.
3. To understand the impact of AI on question difficulty management.

Ensuring fairness and bias mitigation in AI-generated exam questions (10 min)
Roman Klöckner; Lübeck / Germany

1. To learn how AI models can introduce bias in exam question generation.
2. To appreciate strategies for ensuring fairness and diversity in AI-assisted question creation.
3. To understand AI's ethical and practical challenges in radiology exam standardisation.

The future of AI in exam preparation in radiology (10 min)
Benedikt Kämpgen; Würzburg / Germany

1. To learn about the future of AI in radiology exam preparation.
2. To appreciate the benefits and challenges.
3. To understand the future developments needed.

Panel discussion: The future of AI in radiology exam preparation: opportunities and challenges (15 min)

EIBALL 19 - Imaging data harmonisation for reproducible imaging biomarkers and radiomics

Categories: Imaging Methods, Physics in Medical Imaging, Evidence-Based Imaging, Artificial Intelligence, President's Choice
ETC Level: LEVEL II
Date: March 7, 2026 | 12:30 - 13:30 CET
CME Credits: 1

Moderator:
Michelle Claire Williams; Edinburgh / United Kingdom

Chairperson's introduction (5 min)
Michelle Claire Williams; Edinburgh / United Kingdom

Why is data harmonisation important for imaging biomarkers and radiomics? (15 min)
Merel Huisman; Nijmegen / Netherlands

1. To learn the key concepts and challenges in using imaging biomarkers and radiomics across multi-centre studies.
2. To appreciate how variability in imaging protocols and acquisition impacts reproducibility and clinical utility of quantitative imaging biomarkers and radiomics.
3. To understand the role of data harmonisation in enabling reliable, generalisable and clinically relevant analysis.

Strategies for harmonisation of imaging data (15 min)
Irène Buvat; Orsay / France

1. To learn the main methodological approaches for harmonising imaging data across scanners, protocols and institutions.
2. To appreciate the advantages and limitations of preprocessing, standardisation and statistical correction techniques.
3. To understand how harmonisation strategies can be applied in research and clinical practice.

Artificial intelligence (AI) approaches to imaging data harmonisation (15 min)
Akshay Chaudhari; Stanford / United States

1. To learn about current AI/ML-based techniques for harmonising imaging data.
2. To appreciate the potential of AI/ML to address complex sources of variability in multi-centre imaging data.
3. To understand how AI-driven harmonisation can support more accurate and robust imaging biomarker discovery and validation.

Panel discussion: What are the key challenges for implementing data harmonisation in real-world clinical settings? (10 min)

E³ 20E - Thoracic emergencies: what you absolutely must not miss!

Categories: Emergency Imaging, Chest, President's Choice

ETC Level: LEVEL I+II

Date: March 7, 2026 | 12:30 - 13:30 CET

CME Credits: 1

This interactive session, based on clinical cases, will review the main urgent indications for thoracic CT scans: how to optimise the search for pulmonary embolism, how to investigate haemoptysis, and how to approach diffuse infiltrative disease-causing respiratory distress.

Moderator:

Thomas Frauenfelder; Zürich / Switzerland

Chairperson's introduction (5 min)

Jonas Kroschke; Zurich / Switzerland

Thoracic emergencies: clinical cases you'll never forget! (45 min)

Galit Aviram; Tel-Aviv / Israel

Anagha P. Parkar; Bergen / Norway

Panel discussion: Aligning radiology and emergency teams for chest imaging (10 min)

E³ 22E - Painful ankle and foot without previous trauma

Categories: Musculoskeletal, General Radiology, Imaging Methods, Radiographers, President's Choice
ETC Level: LEVEL II
Date: March 7, 2026 | 12:30 - 13:30 CET
CME Credits: 1

Moderator:
Milko Charles De Jonge; Amsterdam / Netherlands

Chairperson's introduction (5 min)
Milko Charles De Jonge; Amsterdam / Netherlands

Intra-articular disorders (25 min)
Michail Klontzas; Heraklion / Greece

1. To discuss the spectrum of intra-articular pathologies of the ankle and foot with emphasis on clinically significant and easily overlooked disorders.
2. To understand the appropriate imaging modalities, protocols, and limitations for accurate assessment of intra-articular disorders.
3. To appreciate that subtle imaging findings may represent significant pathology requiring early clinical intervention.

Tumours and don't touch lesions (25 min)
Kim Van Oudenaarde; Horw / Switzerland

1. To learn about the various types of tumours and lesions that can affect the ankle and foot.
2. To appreciate the importance of distinguishing between benign and malignant lesions.
3. To understand the imaging characteristics and management strategies for these conditions.

Panel discussion (5 min)

E³ 1926 - Imaging response criteria in oncology

Categories: Hybrid Imaging, Oncologic Imaging, EuroSafe Imaging/Radiation Protection, Education
ETC Level: LEVEL II
Date: March 7, 2026 | 12:30 - 13:30 CET
CME Credits: 1

Moderator:
Michael Winkelmann; Munich / Germany

Chairperson's introduction (5 min)
Michael Winkelmann; Munich / Germany

RECIST 1.1 and iRECIST (15 min)
Thierry N. Boellaard; Amsterdam / Netherlands

1. To understand the basics of RECIST 1.1 criteria.
2. To learn about immunotherapy and iRECIST.
3. To investigate the limitations of RECIST and iRECIST.

mRECIST and CHOI (15 min)
Giulia Zamboni; Verona / Italy

1. To understand when we use mRECIST.
2. To learn about which tumours are eligible for CHOI criteria.
3. To investigate desirable future steps and limitations.

PERCIST and LUGANO (15 min)
Clemens C. Cyran; Munich / Germany

1. To understand when PERCIST criteria are applied.
2. To learn about LUGANO criteria.
3. To investigate the pros and cons.

Panel discussion: Are morphological criteria enough? (10 min)

How 19 - How we perform and interpret contrast-enhanced ultrasound (CEUS) of abdominal organs in daily practice

Categories: General Radiology, Imaging Methods, Genitourinary, Contrast Media, Abdominal Viscera, President's Choice
ETC Level: LEVEL I+II
Date: March 7, 2026 | 12:30 - 13:30 CET
CME Credits: 1

Moderator:
Vasileios Rafailidis; Thessaloniki / Greece

Chairperson's introduction (2 min)
Vasileios Rafailidis; Thessaloniki / Greece

Fundamentals of CEUS in abdominal organs (5 min)
Dirk-André Clevert; Munich / Germany

1. To understand the principles of microbubble contrast agents and the different phases of contrast enhancement.
2. To learn how to adequately administer contrast agents, how to adjust machine settings and how to evaluate CEUS image quality.
3. To become familiar with the most common CEUS artefacts and how to distinguish them from tissue enhancement.

CEUS in liver lesions (15 min)
Adrian K. P. Lim; London / United Kingdom

1. To understand the indications for CEUS in liver lesions.
2. To become familiar with the characteristic CEUS aspect of focal nodular hyperplasia, haemangiomas, hepatocellular carcinoma and metastases using a case-based approach.
3. To learn how CEUS can be used to guide liver intervention and assess treatment response.

CEUS in renal lesions (15 min)
Carlos Nicolau; Barcelona / Spain

1. To understand the indications for CEUS in renal pathology.
2. To become familiar with the characteristic CEUS aspect of the CEUS Bosniak classification.
3. To learn how CEUS can be used in the assessment of vascular disorders and infections.

Applications of CEUS in pregnancy (15 min)
Rijo Mathew Choorakuttil; Cochin, Kerala / India

1. To understand the indications for CEUS in pregnancy.
2. To become familiar with the characteristics of ultrasound contrast media, safety, and adverse events.
3. To learn how CEUS can be used in the assessment of interventions in pregnancy.

Open forum discussion (8 min)

Meets 19a - Unique evolution and global influence of Japanese radiology

Categories: Professional Issues, Management/Leadership, President's Choice
ETC Level: ALL LEVELS
Date: March 7, 2026 | 12:30 - 13:30 CET
CME Credits: 1

Moderators:
Minerva Becker; Geneva / Switzerland
Takamichi Murakami; Kobe / Japan
Noriyuki Tomiyama; Suita / Japan

Chairpersons' introduction (2 min)
Minerva Becker; Geneva / Switzerland
Takamichi Murakami; Kobe / Japan
Noriyuki Tomiyama; Suita / Japan

Radiology in Japan: current and future challenges (10 min)
Kei Yamada; Kyoto / Japan

1. To describe the current problems in radiology, including but not limited to the manpower shortage.
2. To analyse the current difficulties and future threats we face in the field of radiology.
3. To solve your problems that could emerge in the future in your own medical system.

Innovative imaging technologies and research initiatives led by Japan (10 min)
Masahiro Jinzaki; Tokyo / Japan

1. To understand two unique features of the radiology-related environment in Japan: the high concentration of imaging-related companies that facilitate academia-industry collaboration and the widespread implementation of preventive health check-up systems.
2. To appreciate technologies and methods originally developed and led by Japan.
3. To learn about cutting-edge research that has not originated in Japan but is currently led by Japanese initiatives.

Promoting diversity and workstyle reform for the future of the Japan Radiological Society (10 min)
Noriko Oyama-Manabe; Saitama / Japan

1. To understand the society’s comprehensive approach to addressing workforce sustainability, such as promoting task-shifting to radiological technologists, supporting childcare, and encouraging parental leave among younger radiologists as part of a long-term vision for a more inclusive and resilient radiology workforce.
2. To appreciate programs designed to support and empower early-career radiologists, including the "Under 40" network and the early-career researchers support program.
3. To learn about the Japan Radiological Society’s diversity promotion efforts as a foundation for these initiatives, including the introduction of a gender quota system in delegate and board member elections as part of ist strategic action plan.

Exploring Japan’s strengths in advanced health checkups and diagnostic imaging: a university hospital’s pioneering model (10 min)
Yoko Satoh; Tokyo / Japan

1. To learn how universal health coverage under public insurance in Japan has made high-quality medical care widely accessible at low cost, while also recognising its limitations, such as increased workloads for radiologists and fixed pricing that does not reflect differences in diagnostic quality. A response to these challenges has been initiated, with advanced services currently being offered mainly to international patients.
2. To appreciate a pioneering effort by a Japanese university hospital, which established a fully self-pay satellite clinic near Tokyo International Airport to provide advanced care with convenient access from various Asian countries.
3. To understand how concierge-style imaging services, including personalised consultations and tailored exam planning, are provided for patients with high expectations for medical quality and service, both from abroad and within Japan.

Panel discussion: What should a radiology society do to support radiologists? (18 min)

Noriyuki Tomiyama; Suita / Japan

Meets 19b - Radiography educational and clinical services in Hong Kong

Categories: Radiographers
Date: March 7, 2026 | 12:30 - 13:30 CET
CME Credits: 1

Moderators:
Napapong Pongnapang; Bangkok / Thailand
Edward Hung Tat TAT Chan; Fo Tan / Hong Kong SAR China

Chairpersons' introduction (5 min)
Napapong Pongnapang; Bangkok / Thailand
Edward Hung Tat TAT Chan; Fo Tan / Hong Kong SAR China

Medical imaging service in Hong Kong (15 min)
Tsan-Pun LAM; Hong Kong / Hong Kong SAR China

1. To briefly introduce the registration system for radiographers in Hong Kong.
2. To provide an overview of the medical imaging service in Hong Kong.

Medical imaging and radiation therapy education in Hong Kong (15 min)
Tsz Lung Wong; Hong Kong / Hong Kong SAR China

1. To discuss the medical imaging and radiation therapy undergraduate education in Hong Kong.
2. To evaluate the various entry routes for medical imaging and radiation therapy degree programs in Hong Kong.
3. To appraise the continuous professional development (CPD) program in Hong Kong.

The specialisation training and development of the radiographers in Hong Kong (15 min)
Lik Wai Kwok; Hong Kong / Hong Kong SAR China

1. To introduce the role of radiographers in Hong Kong.
2. To emphasise the function of the Hong Kong college of radiographers and radiation therapists in speciality training.
3. To show the structured training in the hospital authority as an example.

Panel discussion: Challenges and future plans for the radiographers' education in Hong Kong (10 min)

OF 19Y - Science in the clear: the impact of transparent publishing

Categories: Students, Research, Education
ETC Level: LEVEL I+II
Date: March 7, 2026 | 12:30 - 13:30 CET
CME Credits: 1

SESSION RECOMMENDED BY EIBIR | EUROPEAN INSTITUTE FOR BIOMEDICAL IMAGING RESEARCH

Moderator:
Francesco Sardanelli; Milan / Italy

Chairperson's introduction (5 min)
Francesco Sardanelli; Milan / Italy

Open science practices in radiology publishing (8 min)
Tugba Akinci D'Antonoli; Basel / Switzerland

1. To learn what open science represents and what is the main goal behind the initiative.
2. To appreciate the advantages open science presents to researchers and academics.

Patient privacy concerns in data sharing (8 min)
Tobias Penzkofer; Berlin / Germany

1. To learn about the potential risks for patient privacy in data sharing.
2. To appreciate specific requirements in sharing imaging data.
3. To understand mitigation strategies for these risks.

Transparency and reproducibility: EUCAIM Project (8 min)
Luis Marti-Bonmati; Valencia / Spain

1. To learn how to use the EUCAIM platform for data access, management, and sharing in alignment with FAIR principles.
2. To appreciate the essential tools and workflows within EUCAIM that support the transparent documentation of research steps.
3. To understand the importance of transparency and reproducibility in AI research using medical imaging.

Finding funding options for your Open Access paper (8 min)
Anna Colarieti; Milan / Italy

1. To learn how to identify institutional, national, and international funding mechanisms that support Open Access publishing.
2. To appreciate the strategic importance of incorporating Open Access publication costs into the initial budgeting and planning phases of a research project.
3. To understand how to critically navigate and comply with publisher policies and funder mandates related to Open Access dissemination.

Securing funding and navigating conflicts of interest in imaging trials (8 min)
Susanna Lee; Boston / United States

1. To differentiate among public, private nonprofit, and private industry funding sources for imaging trials, including their distinct missions, accountability structures, and implications for study design.
2. To identify key prerequisites for successfully securing imaging trial funding.
3. To understand the principles and requirements of conflict-of-interest disclosure and review processes in imaging research and their variability globally.

Open forum discussion: What is the importance of open science in academic publishing and how can it support early career researchers? (15 min)

RC 1904 - Case-based incidental findings detected on chest imaging: when to ignore and when to act

Categories: Musculoskeletal, Chest, Head and Neck, Cardiac, Abdominal Viscera, President's Choice
ETC Level: LEVEL I
Date: March 7, 2026 | 12:30 - 13:30 CET
CME Credits: 1

Moderator:
Judith Babar; Shelford / United Kingdom

Chairperson's introduction (6 min)
Judith Babar; Shelford / United Kingdom

Incidental non-cardiac mediastinal findings (18 min)
Annemiek Snoeckx; Zandhoven / Belgium

1. To review the main incidental mediastinal findings detected in chest imaging.
2. To propose the management of these findings.

Incidental findings in the heart (18 min)
Peter Andrew Ball; Belfast / United Kingdom

1. To review the main incidental cardiac findings detected in chest imaging.
2. To propose the management of these findings.

Incidental findings at the edges: abdomen and neck (18 min)
Daria Kifjak; Vienna / Austria

1. To review the main incidental abdominal and neck findings detected in chest imaging.
2. To propose the management of these findings.

RC 1908 - Updates on head and neck cancer imaging

Categories: Oncologic Imaging, Head and Neck, Molecular Imaging
ETC Level: LEVEL II+III
Date: March 7, 2026 | 12:30 - 13:30 CET
CME Credits: 1

Moderator:
Pim De Graaf; Amsterdam / Netherlands

Chairperson's introduction (5 min)
Pim De Graaf; Amsterdam / Netherlands

Sinonasal tumours: what you need to know (15 min)
Suresh Mukherji; Ann Arbor / United States

1. To review common tumours of the sinonasal cavity.
2. To discuss imaging findings that are characteristic of certain tumours.
3. To provide a checklist of "key elements" that should be included in the radiologist's report that specifically affect treatment.

Imaging of extranodal tumour extension: why and how should it be done? (15 min)
Roberto Maroldi; Concesio / Italy

1. To understand the clinical significance of extranodal extension (ENE) in head and neck cancers and its impact on prognosis and treatment planning.
2. To learn the imaging features on CT and MRI that indicate the presence of extranodal extension in lymph nodes.
3. To develop a systematic approach to accurately identify and report ENE to support optimal staging and therapeutic decision-making.

HPV status and staging in oropharyngeal carcinoma (15 min)
Varsha Mahesh Joshi; Hyderabad / India

1. To understand the role of HPV status, particularly p16 immunohistochemistry, in the diagnosis and classification of oropharyngeal squamous cell carcinoma.
2. To learn the differences between HPV-positive and HPV-negative oropharyngeal cancer staging according to the latest AJCC TNM 9th edition system and their prognostic implications.
3. To apply knowledge of HPV-related staging to guide clinical management and predict patient outcomes more accurately.

Panel discussion: Imaging in head and neck cancer: navigating the latest advances (10 min)

RC 1911 - Spine imaging: dilemmas

Categories: Musculoskeletal, Emergency Imaging, Oncologic Imaging, Neuro, President's Choice
ETC Level: LEVEL II+III
Date: March 7, 2026 | 12:30 - 13:30 CET
CME Credits: 1

Moderator:
Ana Mafalda Fontes Pinto Reis; Porto Nevogilde / Portugal

Chairperson's introduction (5 min)
Ana Mafalda Fontes Pinto Reis; Porto Nevogilde / Portugal

Missed but relevant: uncommon spinal findings that matter (15 min)
Johan Van Goethem; Antwerpen / Belgium

1. To identify rare but clinically significant spinal imaging findings that are often overlooked.
2. To understand the potential consequences of missing these findings on patient management
3. To learn tips and strategies to improve detection and avoid common pitfalls.

The usual suspects: imaging vertebral fractures, metastases and their mimics (15 min)
José Tiago Costa Baptista; Lisboa / Portugal

1. To review key imaging features that help differentiate vertebral fractures from metastases and benign mimics.
2. To understand the role of MRI, CT, and nuclear medicine in characterising spinal lesions.
3. To learn a structured approach to evaluating vertebral abnormalities to improve diagnostic confidence.

What to report and what to leave out in a spine report (15 min)
Chiara Zini; Firenze / Italy

1. To learn to prioritise relevant findings that impact management and avoid over-reporting incidental or non-specific changes.
2. To discuss practical ways to make spine reports more useful and aligned with clinical decision-making.
3. To explore ways to standardise reporting without losing flexibility in complex cases.

Panel discussion: How to be more useful in spine reporting (10 min)

RC 1915 - The path from molecular imaging to molecular therapy

Categories: Hybrid Imaging, Interventional Radiology, Molecular Imaging, Vascular, President's Choice
ETC Level: LEVEL II+III

Molecular imaging of vascular inflammation and atherosclerosis: emerging biomarkers and clinical translation (15 min)
Judit Csőre; Budapest / Hungary

1. To understand the role of vascular inflammation in the development and progression of atherosclerosis.
2. To recognise key emerging molecular biomarkers used in the imaging of vascular inflammation and atherosclerotic plaques.
3. To evaluate the clinical applications and translational potential of molecular imaging techniques in cardiovascular disease management.

Theranostic approaches to vascular malformations: from diagnostic imaging to targeted therapy (15 min)
Dat Tin Nguyen; Budapest, XII. / Hungary

1. To understand the pathophysiology and classification of vascular malformations relevant to theranostic strategies.
2. To identify appropriate diagnostic imaging modalities used to characterise vascular malformations for therapeutic planning.
3. To explore targeted therapeutic options enabled by theranostic approaches, including image-guided and molecular-based treatments.

PET and hybrid imaging in large vessel vasculitis and vascular graft infections: clinical impact and future therapies (15 min)
David Laszlo Tarnoki; Budapest / Hungary

1. To understand the principles and advantages of PET and hybrid imaging in detecting large vessel vasculitis and vascular graft infections.
2. To assess the clinical impact of molecular imaging in diagnosis, disease monitoring, and treatment decision-making.
3. To explore future therapeutic strategies guided by imaging biomarkers in inflammatory and infectious vascular diseases.

Q&A (10 min)

RC 1917 - Beyond the non-operative management in body trauma: the bleeding patient between OR and intervention

The Raptor Suite Experience: seamless combination of surgery, intervention and diagnostic imaging (12 min)
Frank Volker Bensch; Helsinki / Finland

1. To describe the design and integration of surgical, interventional and imaging modalities within a single hybrid operating room.
2. To explain how the Raptor Suite improves time-to-treatment and patient outcomes.
3. To outline the challenges and best practices in implementing and maintaining a Raptor suite, including team coordination, equipment compatibility and training.

The role, rationale, and implications of IR in the bleeding patient (12 min)
Fatma Gonca Eldem; Ankara / Turkey

1. To describe the mechanisms, progression and clinical implications of massive haemorrhage in trauma and acute care settings.
2. To identify key procedures and IR techniques that interventional radiologists perform to treat active bleeding.
3. To analyse models for effective collaboration and communication between surgical and IR teams in life-threatening scenarios.

When to embolise and when to operate on the patient with ongoing bleeding (12 min)
Roberto Iezzi; Rome / Italy

1. To compare the use of surgical and endovascular approaches in treating a patient with massive active bleeding.
2. To describe the decision-making imaging and clinical criteria for selecting or combining the modalities in a Raptor suite.
3. To understand the advantages, limitations, timing considerations and potential complications of embolisation and surgery in the context of damage control resuscitation.

Can we trust split bolus protocols when abdominal bleeding is impending? (12 min)
Monique Brink; Nijmegen / Netherlands

1. To explain the concept of split bolus protocols in CT imaging.
2. To discuss situations where split bolus protocols are appropriate and when alternative imaging strategies might be preferred.
3. To explore how split bolus imaging can influence management decisions, including the choice between surgical intervention, embolisation and other treatments.

Panel discussion: The radiologist's most valuable contributions to save the exsanguinating patient (10 min)

Hepatic steatosis and fibrosis assessment in MASLD using UDFF and pSWE in routine clinical practice: a retrospective analysis of multi-centre real-world data (6 min)
Sean Raj; Dallas / United States

Author Block: X. Hong, B. Sadegi, L. Alvarez, A. Klunk, C. Kruse, E. Sober, H. Simon, S. Raj; Scottsdale, AZ/US
Purpose: Metabolic dysfunction-associated steatotic liver disease (MASLD) can progress from fat accumulation to fibrosis, cirrhosis, or hepatocellular carcinoma. We evaluated the clinical utility of Ultrasound Derived Fat Fraction (UDFF) combined with Point Shear Wave Elastography (pSWE) for assessment of steatosis and fibrosis in routine clinical practice.
Methods or Background: A cohort of 220 patients who underwent abdominal ultrasound at SimonMed Imaging between January and April of 2025 was selected. UDFF with pSWE was integrated into the routine abdominal exam. Measurements were categorized per clinical indications (abnormal labs, abdominal complaints, MASLD, non-liver disease, and other liver disease) and BMI. Steatosis severity was assessed using UDFF: ≤5% (Normal), (5,10] (Minimal to Mild), (10,15] (Mild to Moderate), (15, 20] (Moderate to Severe), and >20% (Severe). The SRU “rule of four” was used for fibrosis assessment using pSWE: ≤5kPa (Normal), (5,9) (Rule-out cACLD), [9,13] (Suggestive of cACLD), (13, 17] (Rule-in cACLD), (17,21] (Suggestive of CSPH), and >21 (CSPH).
Results or Findings: Across 9 cities in Arizona (7; n=167) and Nevada (2; n=53), median UDFF was 8% (5-14%) and median liver stiffness measurement was 3.56 kPa (2.88-4.65kPa). UDFF varied across the five clinical indications ($p<0.01$) with the MASLD cohort (70/220) having the highest median UDFF of 10% (6-16%). The pSWE measurements did not vary across the clinical indications, BMI and the steatosis grades; 177/220 were normal, 35/220 ruled-out cACLD and 8/220 were suggestive of cACLD. Higher BMI was associated with greater steatosis severity ($p<0.001$).
Conclusion: Our results highlight the utility of UDFF and pSWE in assessing steatosis and fibrosis in patients with MASLD in routine practice. These results are of interest in MASLD management for risk stratification to treatment monitoring.

New horizons in liver steatosis imaging - multiparametric ultrasound - preliminary study (6 min)
Monika Zbroja-Putowska; Lublin / Poland

Author Block: M. Zbroja-Putowska, M. A. Kuczyńska, A. Brodzisz, P. Krawiec, M. M. Wozniak; Lublin/PL
Purpose: The aim of the study is to evaluate the use of multiparametric liver ultrasound in the diagnosis and monitoring of liver steatosis and fibrosis.
Methods or Background: Forty-five pediatric patients (20 W, 25 M) with increased liver laboratory parameters (AST, ALT) were included in the study. They were subjected to multiparametric liver ultrasound with evaluation of SWE (Emedian [kPa]), attenuation (ATI [dB/cm/MHz]) and dispersion (SWD [(m/s)/kHz]). All ultrasound examinations were performed with a Canon Aplio i800, with a convex i8CX1 probe from intercostal access; the sampling gate was positioned 1-2 cm from the liver pouch. Min. 5 measurements for all parameters, determining the median and the IQR coefficient for the median.
Results or Findings: 40 out of 45 pediatric patients examined turned out to have liver steatosis (mostly mild and moderate). In 32 of them the level of steatosis was proportional to the level of obesity. 8 patients didn’t have obesity but the liver steatosis turned out to be mild or moderate, 1 of them had fibrosis (F1/F2). These patients were taking steroid medications. After one year, 8 patients had follow up examination. In 6 patients liver steatosis and fibrosis levels have decreased, in 2 patients steatosis maintainted on the same level – these patients didn’t follow the recommendations.
Conclusion: Liver parenchymal steatosis remains asymptomatic for a long time, posing a serious clinical problem. Multiparametric liver assessment provides a rapid, accessible means of reliably evaluating not only the degree of parenchymal steatosis, but also the risk of progression or transformation to cirrhosis. Thus, mpUSG now has the potential to become the most important non-invasive diagnostic tool in the screening assessment and monitoring of patients with metabolic syndromes as well as those undergoing hepatotoxic treatment.
Limitations: Small group
Funding for this study: n/a

Diagnostic Accuracy of Quantitative Ultrasound Derived Metrics with Histological steatosis grade as Reference Standard in patients with mixed aetiology Chronic Liver Disease (6 min)

Nuran Seneviratne; London / United Kingdom

Author Block: N. Seneviratne, C. Fang, D. Quinlan, P. S. Sidhu; London/UK
Purpose: Quantitative ultrasound (QUS) techniques—including tissue attenuation imaging (TAI), tissue scatter-distribution imaging (TSI), and ultrasound derived fat fraction (USFF)—are emerging non-invasive tools for quantifying hepatic steatosis. We assessed their diagnostic accuracy against histological steatosis grade and compared them with the Controlled Attenuation Parameter (CAP).
Methods or Background: One hundred and twenty patients with chronic liver disease were prospectively recruited for contemporaneous liver biopsy and QUS imaging. Reference was histological steatosis grade (S0-3) scored by consensus by liver pathologists. Diagnostic accuracy of USFF, TSI, TAI and CAP was evaluated using ROC analysis and Youden optimal cut-offs. Multivariable ordinal logistic regression examined independent predictors of steatosis grade.
Results or Findings: The final cohort comprised 115 patients (57 men, 58 women; median age 45 years; median BMI 27.8 kg/m2). Histological steatosis grades were S0=65, S1=28, S2=14, S3=8. USFF, TSI and TAI correlated strongly with histological grade (ρ=0.81, 0.76 and 0.75, all P<0.001), while BMI showed a moderate correlation (ρ=0.56, P<0.001). Age and gender were not significant. USFF achieved excellent AUCs of 0.95 for S≥1 and 0.94 for S≥2, with optimal cut-offs of 8.8% and 15.4%. At these thresholds, sensitivity/specificity were 88%/89% (S≥1) and 91%/85% (S≥2). TAI and TSI showed similar accuracy (AUCs 0.89–0.94) with cut-offs of 0.83 and 89.2 (S≥1), 0.91 and 93.1 (S≥2). In a subset (N=61), CAP showed comparable accuracy (AUCs 0.93, 0.94). On multivariate analysis, USFF (OR 18.0, P<0.001), TSI (OR 12.8, P<0.001) and TAI (OR 8.4, p<0.001) remained independent predictors; BMI was also significant in the USFF model (OR 1.94, P=0.038).
Conclusion: QUS-derived USFF, TSI and TAI provide excellent diagnostic accuracy for histological steatosis, performing at least as well as CAP.
Limitations: Possibility of sampling error at liver biopsy. Relatively small high steatosis grade patients.

Impact of Ultrasound-Assessed Diffuse Hepatic Steatosis on Liver-Related Events Risk in Patients with Chronic Hepatitis B (6 min)

Mingyue Xiao; Guangzhou / China

Author Block: M. Xiao, Y. Wu, N. Wang, X. Wang, Y. Chong, J. Ren, L. Wu; Guangzhou/CN
Purpose: To assess the impact of ultrasonographically assessed diffuse hepatic steatosis and metabolic factors on the risk of liver-related events (LREs) in chronic hepatitis B (CHB) patients.
Methods or Background: We conducted a retrospective cohort study of patients with CHB who attended regular follow-up visits at our institution from January 2009 to December 2022. Diffuse hepatic steatosis was evaluated using ultrasonography. The primary endpoint was the development of LREs.Kaplan-Meier curves were generated to compare LRE-free survival between groups. Propensity score matching (PSM) was performed in a 1:1 ratio to minimize confounding effects. Univariate and multivariate Cox regression models were used to identify independent predictors associated with LREs.
Results or Findings: A total of 1808 patients with CHB were included, with a median follow-up of 104 months. LREs occurred in 134 patients (7.4%), among which hepatocellular carcinoma (HCC) accounted for 74.6% (n=100), decompensated cirrhosis for 21.0% (n=28), liver transplantation for 2.2% (n=3), and liver failure-related death for 2.2% (n=3). The group with diffuse hepatic steatosis exhibited a significantly lower risk of LREs compared to those without steatosis (HR: 0.398, 95% CI: 0.232-0.682). This protective association remained significant after PSM (HR: 0.484, 95% CI: 0.250-0.940). Multivariate analysis identified type 2 diabetes (HR: 1.69) and cirrhosis (HR: 5.15) as independent risk factors for LREs, while female sex (HR: 0.56) and higher albumin levels (HR: 0.89) were associated with a reduced risk.
Conclusion: Diffuse hepatic steatosis is not a primary driver of LREs in patients with CHB, and its potential protective effect should be interpreted within an individualized clinical context. Beyond antiviral therapy, proactive management of metabolic factors—such as glycemic and blood pressure control—can effectively reduce the risk of LREs.
Limitations: This study lacks dynamic assessment of hepatic steatosis.

Correlation of fat quantification on UGAP Ultrasound with MR Spectroscopy and mDIXON Imaging in the evaluation of non-alcoholic fatty liver disease: A Pilot Study (6 min)

Priscilla Col Priscilla Joshi; Pune / India

Author Block: P. C. P. Joshi, A. K. K. O. Dr, I. S. Shah; Pune/IN
Purpose: To correlate fat quantification on ultrasound-guided attenuation parameter with MR Spectroscopy and mDIXON fat fractions in patients with non-alcoholic fatty liver disease (NAFLD).
Methods or Background: This prospective study was conducted at a tertiary care hospital in western india after obtaining ethical clearance from the institute. Thirty patients with diffuse hepatic steatosis on ultrasound / CT were included in this study. Patients with chronic alcoholism, chronic viral hepatitis and hepatocellular carcinoma were excluded. Each participant underwent UGAP ultrasound and 3T MRI (Philips) with body coil. Hepatic fat fraction was calculated using the lipid-to-water peak ratio in MR spectroscopy and fat fraction value in mDIXON imaging. UGAP parameters including attenuation coefficient were also recorded.
Results or Findings: Pearson correlation was used to assess the association between UGAP grading, MR Spectroscopy and mDIXON fat fraction. Correlation is significant at the 0.01 level. UGAP showed a strong positive correlation with both MR Spectroscopy and mDIXON results, with a correlation coefficient of 0.869 and 0.897 respectively. Notably, the mDIXON method demonstrated a higher level of agreement with MR Spectroscopy, with a correlation coefficient of 0.892.
Conclusion: UGAP shows high degree of correlation with MR spectroscopy and mDIXON imaging as a non-invasive method for the evaluation of non-alcoholic fatty liver disease. This study highlights that UGAP can be used in isolation, potentially providing a cost-effective and accessible alternative technique to MRI-based techniques in the assessment and monitoring of hepatic steatosis.
Limitations: Histological confirmation was not included in this study. Since the MR Spectroscopy fat fraction method is advised for measuring hepatic steatosis in a clinical context, it was utilized as a reference instead. Only Indian patients with NAFLD were included. Only GE scanners are compatible with the UGAP used in this study.

Hepatic fat quantification via three-material decomposition in dual-layer CT: Reproducibility and interobserver agreement (6 min)

Thomas Schömig; Cologne / Germany

Author Block: T. Schömig[1], S. Skornitzke[2], L. Hieronymi[1], D. Maintz[1], N. Große Hokamp[1]; [1]Cologne/DE, [2]Hamburg/DE
Purpose: This study investigates reproducibility and interobserver agreement of a previously published three-material-decomposition (3MD) algorithm for hepatic fat quantification using dual-layer dual-energy CT (dlDECT). Prior research demonstrated good correlation between dlDECT and MR fat quantification. As a next step toward clinical integration, we aim to evaluate consistency and reliability of this dlDECT-based approach.
Methods or Background: In this retrospective study, we evaluated contrast-enhanced abdominal dual-layer CT scans (IQon, Philips Healthcare) of 58 patients obtained twice within 60 days (mean interval: 34.3± 20.2 days). Patients with severe changes in clinical status, such as initiation of chemotherapy, or findings affecting liver perfusion, were excluded. Fat fraction maps were generated using the published 3MD-algorithm for native, arterial, venous and delayed phases. Two radiologists independently placed five circular ROIs per scan, four in the right and one in the left hepatic lobe, avoiding vessels. Reproducibility between scans and interobserver agreement were assessed using Pearson's correlation, Bland-Altman analysis, repeated measures ANOVA, and intraclass-coefficients (ICC).
Results or Findings: The mean hepatic fat fraction across all patients and contrast phases was 4.91%±5.91, no significant difference was found between phases (p=0.07). Averaging across phases and readers, measurements at the two time points strongly correlated (4.87%±6.04 vs. 4.94%±6.13, R^2=0.78) with a low mean difference (0.34±3.09 percentage points, not significant, p=0.61), indicating good reproducibility. Interobserver agreement was excellent (ICC=0.92), with a mean difference of 0.62±1.3 percentage points, consistent across all phases.
Conclusion: The novel 3MD-algorithm enabled through dlDECT provides reproducible and consistent hepatic fat quantification with excellent interobserver agreement, supporting its potential role in clinical practice as a reliable alternative to MRI or ultrasound.
Limitations: The limitations of the study are the single-center, retrospective design, potential reader dependency of ROI-placement and limited sample size.
Funding for this study: This Work was funded by Philips Healthcare. The funding source had no involvement in study design, collection or interpretation of data.
Has your study been approved by an ethics committee? Not applicable

Comparison of single energy and dual energy Computed Tomography for liver fat quantification against reference standard of Magnetic Resonance Imaging (MRI)-Proton Density Fat Fraction (6 min)

Swikruti Dash; New Delhi / India

Author Block: S. DASH, D. Gg; Puducherry/IN
Purpose: The objective of our study was to compare the performance of conventional Single Energy Computed Tomography(SECT) and Dual Energy Computed Tomography (DECT) for quantification of hepatic steatosis using Magnetic Resonance Imaging (MRI) Chemical shift encoded(CSE) Proton Density Fat Fraction (PDFF) as a reference standard.
Methods or Background: For this cross-sectional analytical study, we recruited 141 adult patients who underwent plain SECT, post-contrast DECT and Liver MRI. We assessed five fat quantification variables namely SECT Hounsefield Units (HU), SECT Liver Attenuation Index(LAI), DECT Fat Fraction(FF), MRI CSE PDFF, and MRS-FF. Relationships between variables were analysed using Spearman correlation, ICC, and linear regression analysis.
Results or Findings: Our results showed that DECT($r = 0.361, r2 = 0.788, p < 0.05$) and SECT LAI ($r = -0.38, r2 = 0.742, p < 0.05$). had a weak correlation with MRI CSE PDFF, while SECT HU showed a moderate correlation ($r = -0.461$, $r2 = 0.8$, $p < 0.05$). There was excellent consistency between MRS FF and MRI CSE PDFF quantification methods (ICC = 0.982, $p < 0.05$). Our subgroup analysis showed that in patients with hepatic steatosis (MRS FF ≥ 4%), both SECT methods and DECT FF correlated better with MRI CSE PDFF compared to those without steatosis.
Conclusion: SECT fat quantification methods seem more reliable than the DECT-based fat fraction method. Among SECT methods, SECT attenuation values are more precise than SECT LAI.
Limitations: We excluded patients with clinically suspected iron overload or chronic liver disease from our study group. However, it's essential to recognize that these conditions may act as potential confounders when evaluating liver attenuation.Our study relied solely on a single DECT technology, the Twin Beam Split filter technique, which is considered an inferior DECT technique.
Funding for this study: No funding was provided.

Two Methods, Two Organs: Comparison of Dual Echo vs. FatFrac in Liver and Pancreas Steatosis (6 min)

Tuğçe Doğa Özdemir; İzmir / Turkey

Author Block: T. D. Özdemir, H. E. E. GÜZEL; İzmir/TR
Purpose: To compare liver and pancreatic fat quantification using two MRI-based approaches, Dual Echo and FATFRAC sequences, and to explore their relationship with clinical and biochemical markers relevant to metabolic health.
Methods or Background: We retrospectively reviewed abdominal MRI scans of 100 adult patients acquired on a 1.5T system, including both Dual Echo (in-/out-of-phase) and Dixon-based FATFRAC sequences. Regions of interest were placed in the liver, pancreas, and spleen parenchyma to calculate mean fat fractions. Clinical and laboratory data (ALT, AST, GGT, HbA1c, lipid profile) were collected for correlation analysis. Patients with advanced chronic liver disease, hemochromatosis, or diffuse liver lesions were excluded.
Results or Findings: Liver fat quantification showed strong agreement between Dual Echo and FATFRAC ($r = 0.82$, $p < 0.001$), with no significant difference in mean values.
Pancreatic fat measurements demonstrated weaker concordance ($r = 0.55$, $p = 0.006$), with FATFRAC yielding consistently higher and more stable values.
Liver fat correlated significantly with ALT, GGT, and triglycerides, whereas pancreatic fat did not show robust associations with HbA1c or lipid parameters.
Negative pancreas values occasionally occurred with Dual Echo, reflecting known susceptibility to artifacts.
Conclusion: Both Dual Echo and FATFRAC are reliable for hepatic fat assessment, with strong metabolic correlations. For pancreatic fat, FATFRAC appears more reproducible and clinically plausible, while Dual Echo may be limited by technical artifacts. These findings support the use of FATFRAC when multi-organ fat quantification is required in metabolic imaging studies.
Limitations: The study was retrospective, single-center, and lacked histopathological or MR spectroscopy validation. Pancreatic fat assessment remains technically challenging, and further prospective studies with larger cohorts and histological correlation are needed.
Funding for this study: This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.
Has your study been approved by an ethics committee? Yes

Joshua Rothwell; Cambridge / United Kingdom

Improving time to breast cancer detection: AI identification of screening-detected cancers on prior-year digital breast tomosynthesis (6 min)
Manisha Bahl; Cambridge / United States

Author Block: M. Bahl, H. Kim, K-S. Kim, S. Do, L. Lamb; Boston, MA/US
Purpose: To evaluate whether a commercial AI-based computer-assisted detection/diagnosis (CADe/x) algorithm for digital breast tomosynthesis (DBT) could have identified screening-detected breast cancers on the prior year's DBT examination, potentially enabling earlier diagnosis.
Methods or Background: This retrospective study included consecutive women with screening-detected breast cancers on DBT from 2016 to 2019 who also had a prior screening DBT within 18 months interpreted as negative. Both the index examination (the screening examination on which cancer was detected by the radiologist) and the prior examination were analyzed using a commercial CADe/x algorithm (Genius AI® Detection 2.0; Hologic, Inc.). AI scores ranged from 0-100, with values ≥22 considered positive per vendor recommendation. A breast imaging radiologist reviewed all AI-positive cases to determine whether AI marks corresponded to the site of the subsequently diagnosed cancer.
Results or Findings: Four hundred women (mean age 64±10) met inclusion criteria. On the index mammogram, AI detected and correctly localized 88.8% (355/400) of cancers. Among these 355 AI-detected cases, 44.5% (158/355) were also identified and correctly localized by AI on the prior-year exam (radiologist-negative). Thus, 39.5% (158/400) of patients in the cohort may have benefited from earlier cancer detection. Of the 158 cancers flagged by AI on the prior exam, 79.7% (126/158) were invasive. Among these invasive cancers, 73.8% (93/126) were grade 2-3, and 9.5% (12/126) were node-positive at diagnosis.
Conclusion: A commercial AI algorithm retrospectively identified and localized nearly 40% of screening-detected breast cancers on prior DBT - approximately one year before radiologic diagnosis - suggesting a potential role for AI in facilitating earlier detection, even outside classic false-negative or interval cancer categories.
Limitations: The limitations of the study are single-center, retrospective design and use of one vendor/algorithm with a vendor-defined threshold, which may limit generalizability.
Funding for this study: Funding was provided by Hologic, Inc. The authors, none of whom are employees of Hologic, maintained full control over the data and the submitted information.
Has your study been approved by an ethics committee? Yes

An Automated Deep Learning Framework for Breast Cancer Segmentation and Survival Prediction (6 min)
Shushan Dong; Shanghai / China

Author Block: K. Wang[1], S. Wang[1], S. Huang[2], J. Xie[3], S. Dong[2], M. Xu[1], R. Zhang[1]; [1]Hangzhou/CN, [2]Beijing/CN, [3]Shanghai/CN
Purpose: Manual lesion segmentation on MRI and separate prognostic modeling are labor-intensive. This study aims to develop and validate FA-SurvNet, a fully automated survival analysis network framework that integrates deep-learning segmentation and end-to-end survival prediction to streamline breast cancer prognosis.
Methods or Background: This retrospective study enrolled 573 female breast cancer patients from two medical centers who underwent preoperative MRI for prognostic evaluation. We developed an FA-SurvNet model integrating an nnU-Net based on the tumor segmentation task with a CNN-Cox regression network based on the survival analysis task for joint breast cancer lesion delineation and prognosis prediction. Segmentation performance was quantified using standard metrics including dice similarity coefficient (DSC), positive predictive value (PPV), and sensitivity (SEN). To validate the predictive performance of the FA-SurvNet model, we constructed two baseline survival models using conventional Cox regression. The predictive performance and clinical utility of the three models were comprehensively evaluated through Harrell's concordance index (C-index) for discriminative ability
Results or Findings: The nnU-Net-based segmentation model achieved high performance in both training (DSC: 0.85, PPV: 0.85, SEN: 0.88) and testing cohorts (DSC: 0.84, PPV: 0.87, SEN: 0.84). FA-SurvNet model demonstrated good performance in breast cancer recurrence risk prediction with a c-index of 0.88 and 0.84 in the training and testing cohorts, respectively. Comparative analysis revealed the superior performance of the FA-SurvNet model over the conventional radiomics model (training c-index: 0.84; testing c-index: 0.75) . Time-dependent AUC values of the FA-SurvNet model for 5-year recurrence-free survival (RFS) prediction in the training cohort was 0.90 (95%CI: 0.84-0.94).
Conclusion: By combining lesion segmentation and survival prediction, the FA-SurvNet model simplifies the imaging prognostic diagnosis research process, provides an efficient tool for clinical decision-making, and realizes the complete automation of breast cancer prognosis.

Comparative Study of Radiologists' Diagnostic Performance With and Without Artificial Intelligence Support for Breast Lesion Detection in 2D Mammography (6 min)

Louis Lassalle; Paris / France

Author Block: L. Lassalle[1], J. Ventre[2], V. Marty[2], L. Clovis[2], N. Nitche[2], J. Hadchiti[3], N-E. Regnard[1], A-L. Hermann[4], E. Kotter[5]; [1]Lieusaint/FR, [2]Paris/FR, [3]Villejuif/FR, [4]Lyon/FR, [5]Freiburg Im Breisgau/DE
Purpose: Mammography is a key domain where AI may improve early breast cancer detection. The study compared the diagnostic performance of radiologists with and without support from a new AI system (BreastView, Gleamer) in detecting breast lesions.
Methods or Background: We retrospectively collected mammographies from three imaging centers across France (2018-2023), sourced from three manufacturers (Hologic, Siemens, GE). Eligible patients were women over 18 who underwent 2D mammography with CC and MLO views and had either biopsy or 18-month follow-up. Poor-quality exams were excluded.
Ground truth was determined by an experienced breast radiologist who had access to the entire patient file, including anterior and posterior mammographies and, when available, digital breast tomosynthesis, MRI, ultrasound, clinical reports, and biopsy reports for cancer cases.
Nine radiologists participated: five "non-subspecialists" (250 and 750 mammographies/year), and four "subspecialists" (>1000 mammographies/year). They annotated all visible lesions and assigned malignancy scores from 0 to 100. Each completed two reading sessions, unaided and with AI support, separated by a 12-month washout.
Results or Findings: The dataset included 319 patients (age: 58 ± 13 years): 159 with a malignant biopsy-proven lesion, 39 with only benign lesions confirmed by biopsy or 18-month follow-up, and 121 with no lesion confirmed by 18-month follow-up.
The stand-alone AI achieved an AUC of 0.911 [0.881–0.942] for malignant lesion detection, outperforming the mean radiologist AUC of 0.801 [0.769–0.832]. With AI assistance, radiologists significantly improved their AUC (0.880 [0.865–0.896]), sensitivity (+18.7 points, p<.001), and specificity (+2.6 points, p=.042). Gains were lower for subspecialists but still significant.
Conclusion: The AI system showed robust performance, enhancing radiologists' diagnostic accuracy and supporting its potential as a clinical decision-support tool.
Limitations: The study was retrospective, with an enriched cancer dataset, and readers had no access to clinical information.

Should AI results be disclosed in mammography reports? A randomized survey study of patient responses to concordant and discordant interpretations (6 min)

Giovanni Irmici; Milan / Italy

Author Block: G. Irmici, F. Pesapane, C. Depretto, L. Nicosia, G. Della Pepa, A. Rotili, S. Santicchia, G. P. Scaperrotta, E. Cassano; Milan/IT
Purpose: To assess how disclosing artificial intelligence (AI) results, particularly discordant findings, affects patient trust, anxiety, follow-up intentions, and attitudes toward AI in mammography. The study also evaluated whether a brief explanatory note mitigates adverse
reactions.
Methods or Background: A cross-sectional randomized experimental survey was conducted among 600 women (mean age 55.4 ± 6.8 years) undergoing mammography in two academic breast imaging centers in Milan, Italy, between January 2023 and June 2024. Participants
were randomized into four hypothetical BI-RADS 1 scenarios: Radiologist Only (control), AI No-Flag (AI concordant with radiologist), AI Flagged (AI discordant false-positive), and AI Flagged + Explanation (discordant AI with contextual information).
Outcomes included trust (0–100 scale), worry, second-opinion intent, legal action intent, and AI approval. Statistical analyses involved ANOVA, chi-square tests, and logistic regression with Bonferroni correction.
Results or Findings: Discordant AI disclosure significantly reduced trust in the radiologist (73.0 vs. 90.1; $p<0.001$), increased anxiety (58.0% vs. 16.0%; OR=15.4), second-opinion intent (50.0% vs. 8.7%; OR=10.2), and legal action consideration (60.7% vs. 38.7%; OR=2.49). Adding explanatory context significantly alleviated these effects (e.g., anxiety: 25.3%; OR=0.26). AI approval remained high (>85%) across AI scenarios.
Conclusion: Disclosing discordant AI results negatively impacts patient trust and anxiety, prompting increased intentions for second opinions and legal actions. Providing explanatory context mitigates these adverse effects, supporting transparent but contextually informed disclosure as essential for patient communication strategies in AI-integrated mammography.
Limitations: Limitations of our study include the hypothetical scenario nature. The explanation tested in this study focused on FP rates; future work should explore the effects of alternative or additional types of contextual information. Additionally, we measured stated intentions rather than observed behaviours.
Funding for this study: No funding was received for this study.

AI performance on an interval cancer mammography dataset and its role in audit triage (6 min)

Yan Chen; Nottingham / United Kingdom

Author Block: A. Taib[1], K. Wells[1], I. Darker[1], J. James[1], N. Sharma[2], Y. Chen[1]; [1]Nottingham/UK, [2]Leeds/UK
Purpose: Interval cancers (IC, cancers arising between screening rounds) are an important performance indicator in breast cancer screening. The NHSBSP requires a minimum of two readers to classify the previous screening mammograms into one of three categories: (1) Satisfactory, (2) Satisfactory with learning points and (3) Unsatisfactory. We assessed whether artificial intelligence (AI) could be applied retrospectively to reliably classify IC to help standardise this process.
Methods or Background: IC cases were collected from January 2015 to December 2024 from two large UK screening centres. An AI model (Lunit) analysed all cases and provided a continuous malignancy probability score (0-100) for each breast. A ROC analysis was performed to determine the ability of AI to distinguish Category 1 cases separately from 2 and 3 using malignancy scores and thresholding, where cases with scores less than the threshold were classified as Category 1, and those over classified as 2 and 3.
Results or Findings: 409 IC cases were included which were previously classified by readers at each centre (79% Category 1, 20% Category 2 and 1% Category 3). At a threshold of 0.5, AI classified 65 cases as Category 1 (63 correct, 2 misclassified Category 2 cases). At a threshold of 10, AI classified 229 cases as Category 1 (206 correct, 23 misclassified Category 2 cases). No Category 3 cases were misclassified as Category 1 by either threshold.
Conclusion: AI shows promise as a triage tool to improve the IC audit process by reliably classifying Category 1 cases, which make up most interval cancer, while still correctly identifying most category 2 & 3 cases for human review.
Limitations: Predominantly Category 1 cases, with limited Category 3. Limited number of centres may restrict generalisability.
Funding for this study: Funding was provided by Lunit Inc.

Beyond Screening: AI Performance in Mammographic Breast Cancer Recurrence Detection (6 min)

Zahra Aghdam; Amsterdam / Netherlands

Author Block: Z. Aghdam, X. Wang, A. Portaluri, J. Kroes, J. Teuwen, K. Lipman, R. Mann; Amsterdam/NL
Purpose: To evaluate the diagnostic performance of a commercial mammography-based AI system for recurrence detection in the post-operative breast, addressing a critical evidence gap.
Methods or Background: This retrospective single-center diagnostic accuracy study included patients after breast-conserving surgery undergoing digital mammography for follow-up between 2004 and 2022. Recurrence was defined as ipsilateral malignancy irrespective of tumor biology. Reference standard was pathology. The most recent mammogram ≤3months before recurrence was analysed. Mahalanobis-distance matching was used to select one mammogram per control(≥24months negative follow-up), aligning the age and time from the primary tumor between cohorts.
4,235 exams(384 recurrence-3,851 controls)were included. BI-RADS categories were extracted from reports; sensitivity and specificity calculated at BI-RADS≥3. For each exam, AI(Transpara version-2.1.0)yielded highest region score at breast level(0–100) and a risk category(low-intermediate-elevated). AI sensitivity was assessed at radiologists' specificity. A combined AI+BI-RADS score was derived via logistic regression. Risk category changes from preceding year exams were evaluated using chi-square with Bonferroni-adjusted pairwise comparisons($p<0.05$).
Results or Findings: Radiologists' sensitivity, specificity were 0.75[0.68-0.81] and 0.98[0.98-0.99], respectively. AI sensitivity at matched specificity was 0.28[0.21-0.34] and at Youden-derived threshold was 0.77[0.71-0.84]. AUC of AI was 0.88[0.85-0.90]. Combined AI+BI-RADS had a sensitivity of 0.77[0.70-0.83] while improving AUC to 0.95[0.93-0.97](vs AI alone,$p<0.001$).
AI risk category transitions over one year differed significantly between cases and controls(132 recurrences vs 2985 controls),($\chi^2=336.0$, $p<0.001$). Recurrences were more likely to transition to a higher risk category(76.5% vs 14.8%,RR=5.17[4.55–5.87]), and less likely to remain in the same category(22% vs 65.4%,RR=0.34[0.24–0.46]) or have decreased risk(1.5% vs 19.8%,RR=0.08[0.02–0.30]).
Conclusion: Sensitivity of stand-alone AI for recurrence detection was lower than for radiologists at the same specificity. Increase in risk category was, however, associated with local recurrence.
Limitations: Single-center retrospective design, use of varied mammography systems, assessment of only one AI model

Comparing the Performance of Top Ranked AI Models from the RSNA 2023 Screening Mammography Breast Cancer Detection AI Challenge to Commercial AI Models (6 min)

Yan Chen; Nottingham / United Kingdom

Author Block: G. J. W. Partridge[1], H. Jupp[1], T. Zhang[2], X. Wang[2], R. Mann[2], L. Moy[3], Y. Chen[1]; [1]Nottingham/UK, [2]Nijmegen/NL, [3]New York, NY/US
Purpose: In 2023, the RSNA hosted a Screening Mammography Breast Cancer Detection Artificial Intelligence (AI) Challenge, where participants were invited to develop AI models for cancer detection in mammograms. Here we assess the performance of the Top 7 ranked models compared to 4 commercially available AI products, using a multi-national dataset.
Methods or Background: A large multi-national evaluation dataset was sourced from the USA, UK, Australia and Brazil as part of the 2023 RSNA Challenge, consisting of 20,365 cases. Cases consisted of 2-view 2D mammography screening cases, where cancers were pathology proven and non-cancer cases had at least 1-year of normal follow-up. The Top 7 ranked RSNA challenge AI models (as per pF1 score in the RSNA Challenge https://www.kaggle.com/competitions/rsna-breast-cancer-detection/leaderboard), and 4 commercially available AI products (Lunit, Transpara, Therapixel, iCAD) will analyse all cases, and the performance of all AI models will be compared.
Results or Findings: In the current dataset including 4,811 cases (USA and Australia), equating to 9,622 single breast exams, 193 (2.0%) had biopsy proven cancer, and 9,429 were non-cancer (98.0%). The Top 7 Challenge algorithms achieved AUCs between 0.903 and 0.947, and the commercial AI product achieved an AUC of 0.933. The Top ranked Challenge model AUC was not different to the commercial AI AUC (Delong's method: P = .18).
Conclusion: The Top 7 ranked challenge algorithms performed very well compared to the commercial product on the current dataset sourced from the USA and Australia. Inclusion of data from the UK and Brazil will enable an analysis of AI generalisability and robustness across different populations.
Limitations: Relatively small size of evaluation test-set; low cancer prevalence (but screening setting).

Large-scale AI implementation in Radiology: technical, operational, and behavioral adoption patterns across a 20-center Swiss Imaging Network (6 min)

Benoît Rizk; Villars-Sur-Glane / Switzerland

Author Block: S. Morozov, N. Heracleous, B. Rizk, C. Thouly, B. Dufour, O. Novarina; Sion/CH
Purpose: To evaluate technical efficiency and radiologist adoption of AI tools across musculoskeletal, chest, breast, and neurologic imaging in Switzerland's largest radiology network, establishing benchmarks for processing, workflow benefit, and user acceptance.
Methods or Background: A retrospective analysis included 397,694 radiological studies processed by AI at 20 Swiss centers between January 2022 and June 2025. Survey data (53/58 radiologists, 91.4% response) captured usage frequency, trust, satisfaction (Net Promoter Score), and desired improvements. Time metrics included AI processing latency, report turnaround with vs. without AI, and the proportion of results available at reporting. AI implementation covered multiple modalities and anatomies.
Results or Findings: Musculoskeletal AI accounted for 67.8% of use (trauma radiography 37%). Breast, chest, and brain AI demonstrated 76% specialty adoption. Frequent AI use was reported by 66.1% of radiologists, primarily mid-career. Perceived benefits were error protection (71.7%) and time savings (56.6%). Key requests: faster processing (48%) and automated report integration (34%). NPS varied: +86.7 for bone age, +65.2 orthopedic radiography, −55.3 spine MRI, and +38.5 for chest CT (78% use). Technical bottlenecks were data transfer for radiography/mammography (2.1–3.5min) and AI computation for brain/spine MRI (8.2min). Only 21.6% of AI results were ready before reporting; 5% were missing at validation. AI reduced report times by 12–57% in targeted modalities (knee MRI 16→14min, trauma radiography 7→3min, bone age 3.5→1.6min).
Conclusion: AI tools produced measurable workflow gains (12–57% turnaround reduction) and 90%+ adoption, but improvements in speed, integration, and interoperability are required. Addressing technical and workflow barriers and focusing on user feedback will be critical for effective specialty adaptation.
Limitations: AI evaluation focused on technical and operational metrics, with indirect assessment of clinical outcomes. Results reflect the experience of a mature, multi-site Swiss network, which may limit generalizability to other settings.

Efficient external validation of AI models using nested case–control designs: Application to breast cancer risk prediction (6 min)

Jim Peters; Nijmegen / Netherlands

Author Block: J. Peters[1], D. Sergeev[2], C. Jacobs[1], D. Van Der Waal[1], M. Broeders[1]; [1]Nijmegen/NL, [2]Heidelberg/DE
Purpose: External validation of AI models in large cohorts is critical but computationally and resource-intensive, especially when multiple models are compared or evaluations repeated for quality control. Nested case-control (NCC) designs could enable faster and more sustainable validation by reducing data requirements, but it is unclear whether they yield unbiased estimates across all recommended performance metrics. We investigated whether an NCC design with weighted estimators can accurately evaluate discrimination and calibration of breast cancer risk prediction models.
Methods or Background: We used data from the PRISMA study, a Dutch population-based breast cancer screening cohort including 38,742 women with questionnaire data and mammograms. Two prediction models for 5-year breast cancer risk were evaluated: the Tyrer–Cuzick model and Mirai, a mammography-based AI model. For the NCC design, all cases were matched to four controls. Weighted estimators were applied for the concordance index (C-index), time-dependent AUC (tAUC), observed/expected ratio (O/E), and calibration slope. To assess sampling variability, NCC samples were drawn 100 times. Averaged estimates of performance metrics were compared with the full cohort.
Results or Findings: There were 571 breast cancer cases after a median follow-up of 4.3 years. Average performance of Tyrer-Cuzick in 100 NCC samples (all cases, 2,284 controls) was: C-index 0.598 (SD 0.007), tAUC 0.587 (0.010), O/E ratio 0.701 (0.010), slope 0.636 (0.041). In the full cohort, results were: C-index 0.585 (95% CI 0.558–0.613), tAUC 0.574 (0.536–0.607), O/E ratio 0.693 (0.625–0.775), slope 0.563 (0.399–0.726).
Conclusion: Using only 8% of the data, the NCC design produced performance estimates closely matching full-cohort results. This approach may enable faster, more resource-efficient external validation, particularly useful for comparing AI models or repeated quality control evaluations.
Limitations: Current results are based on one model; analyses with Mirai will be available at ECR 2026.

Multimodal Imaging for Response Assessment to Combined anti-PD-L1/anti-CTLA-4 Immunotherapy in a Murine Melanoma Model: A Comparative Evaluation of [18F]FDG-PET/CT, MRI and CEUS (6 min)

Melissa J. Antons; Munich / Germany

Author Block: M. J. Antons, F. Herr, M. Heimer, S. Lindner, M. Brendel, D-A. Clevert, J. Ricke, R. Werner, C. C. Cyran; Munich/DE
Purpose: While immune checkpoint inhibitors have demonstrated considerable efficacy in malignant melanoma, interindividual variability necessitates robust imaging biomarkers for response evaluation. This study compared the diagnostic performance of [18F]FDG-PET/CT, multiparametric MRI and contrast-enhanced ultrasound (CEUS) in monitoring the effects of a combined anti-PD-L1/anti-CTLA-4-immunotherapy in a murine melanoma model with immunohistochemical validation.
Methods or Background: C57BL/6 mice (female, n=88) were inoculated subcutaneously with B16-F10 melanoma cells into the left abdominal flank and randomized into therapy and control groups. The therapy group received intraperitoneal injections of anti-PD-L1- and anti-CTLA-4-antibodies, while the control group received sham treatment. Imaging assessments at baseline (day 7 post inculation), follow-up 1 (FU-1; day 13) and follow-up 2 (FU-2; day 19) included [18F]FDG-PET/CT (n=40), multiparametric MRI (n=28) and CEUS (n=20). Tumor allografts were harvested for ex vivo immunohistochemical validation (CD8, Ki-67, TUNEL, CD31).
Results or Findings: [18F]FDG-PET/CT revealed significantly lower MTV and SUVmax in the therapy group (FU-1: MTV: p=0.004; FU-2: MTV: p=0.008, SUVmax: p=0.0003). MRI demonstrated significantly lower ADC in the therapy group at follow-up (FU-1: p = 0.002). CEUS showed significant reduction in tumor perfusion (WiAUC, p=0.0152) and a significantly lower number of VEGFR2-targeted microbubbles in the therapy group (SI8min: p=0.003; SI10min: p=0.0019). Immunohistochemistry confirmed significantly higher apoptosis rates (FU-1: p=0.012; FU-2: p=0.001), more CD8-positive T-cells (FU-2: p=0.003), lower tumor cell proliferation (FU-1: p=0.012; FU-2: p=0.012) and lower microvascular density (FU-1: CD31: p<0.001) in the therapy group.
Conclusion: This study highlights the complementary strengths of PET/CT, MRI, and CEUS in assessing immunotherapy response in malignant melanoma. [18F]FDG-PET/CT provided early metabolic response parameters, MRI parameters reflected cellular and microstructural tumor alterations and CEUS detected vascular remodelling.
Limitations: The observation period was relatively short and no clinical endpoints such as overall survival of the animals were determined.
Funding for this study: This work was supported by a research grant from Bracco Imaging SA, Geneva, Switzerland, which provided the BR55 free of charge.

Multivitamin Transporter-Mediated Nanoprobes for Defining Invasive Boundary of Osteoblastic Bone Metastasis via Metabolic Dual-energy CT (6 min)

Qi Li; Qingdao / China

Author Block: Q. Li, H. Zhang; Qing Dao/CN
Purpose: To develop a novel cost-effective imaging strategy for accurate differentiation of osteoblastic bone metastasis (OBM) from bone island (BI) and precise delineation of OBM's invasive boundary.
Methods or Background: Biotin-conjugated Bi_2O_3/FITC nanoprobes were synthesized via a solvothermal method and characterized by TEM, DLS, XRD, and XPS. Cellular toxicity and endocytosis of nanoprobes were evaluated using CCK-8 assay, live/dead staining and confocal laser scanning microscopy. Osteoblastic bone metastasis and bone island models were constructed in BALB/c mice by implanting 4T1 tumor cells and bone tissues, respectively. Nanoprobes were intravenously injected to target sodium-dependent multivitamin transporters (SMVTs) overexpressed on OBM tumor cells. Dual-energy CT (DECT) imaging was performed using water/hydroxyapatite (HAP) substance separation function to suppress osteoblastic components. The accuracy of OBM identification, boundary definition, and completeness of resection were verified by pathological examinations (H&E staining, fluorescence imaging).
Results or Findings: The Bi_2O_3@PEG-bio nanoprobes were designed as dual-modal DECT/fluorescence imaging nanoprobes. They actively targeted OBM via SMVT-mediated endocytosis, as confirmed by reduced fluorescence intensity after SMVT blocking. DECT water/HAP material decomposition function effectively suppressed osteoblastic components, selectively highlighting OBM with a "PET-like" effect, enabling accurate differentiation of OBM from BI. In vivo imaging showed clear visualization of OBM's invasive boundary at 4 h post-injection, which guided complete surgical resection.
Conclusion: The proposed metabolic DECT nanoprobe-based imaging strategy demonstrates significant potential for cost-effective differentiation of OBM from BI and precise definition of OBM's invasive boundary.
Limitations: This study is limited to animal experimrnts and has not been applied in humans.
Funding for this study: This work has been financially supported by National Natural Science Foundation of China (grant no. 82001886, 21904075), Chinese Postdoctoral Program (2023M741862).

Impact of Ischemia Duration on MRI-Derived Quantitative Perfusion Parameters in a Mouse Kidney Transplant Model (6 min)

Felix Herr; Munich / Germany

Author Block: F. Herr, S. Kloiber-Langhorst, M. M. Li, O. Dietrich, J. Ricke, C. C. Cyran, J. Andrassy; Munich/DE
Purpose: To assess the effect of cold ischemia duration on MRI-derived perfusion parameters in kidney transplants of mice after long-term post-transplant survival.
Methods or Background: Fifteen C57BL/6 mice underwent kidney transplantation and were divided into two groups based on cold ischemia time: 30 minutes (n = 6) and 16 hours (n = 9). Dynamic contrast-enhanced MRI was performed at a mean of 268 ± 29.9 days post-transplantation. Perfusion parameters were calculated using the Patlak model, yielding the plasma volume fraction (vp), representing blood volume/perfusion, and the volume transfer constant (Ktrans), reflecting vascular permeability. Intergroup comparisons were performed using the Mann–Whitney U-test.
Results or Findings: Significant differences were observed in the Ktrans parameter of transplanted kidneys between the ischemia groups. The median Ktrans was significantly elevated in the 16 h group (2.82 ± 0.47 mL/100 mL/min) versus the 1 h group (1.16 ± 0.53 mL/100 mL/min; p = 0.008). In contrast, vp did not differ significantly between the groups. Median vp was 20.56 ± 7.02 mL/100 mL (16 h) versus 30.69 ± 8.11 mL/100 mL (1 h; p = 0.151). No significant differences were observed between the transplanted kidney and the contralateral native kidneys for any of the Patlak-derived parameters.
Conclusion: Prolonged cold ischemia of 16 hours leads to significantly increased Ktrans values in murine kidney transplants, indicating impaired microvascular integrity after long-term engraftment. These finding suggest that cold ischemia duration may be a critical factor influencing graft microcirculation even in the chronic post-transplant phase.
Limitations: The study includes a relatively small sample size, which limits statistical power. Additionally, potential interindividual anatomical variations in the small mouse kidneys could influence quantification; however, we largely counteracted this through standardized ROI placements and modeling.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the government of Upper Bavaria (ROB-55.2-2532.Vet_02-20-186) and carried out in accordance to the EU Directive 2010/63 for the protection of animals used for scientific purposes and was reported in compliance to ARRIVE (Animal Research: Reporting of In Vivo Experiments) guidelines.

Drug-Loaded Mesoporous Nanozyme for In Vivo Imaging and Lipid Reprogramming-Enhanced Synergistic Therapy of Pancreatic Tumors in Mice (6 min)

Jingyue Dai; Nanjing / China

Author Block: J. Dai, X-G. Peng; Nanjing/CN
Purpose: Pancreatic tumor therapy is severely hindered by chemotherapy resistance. Oxaliplatin (OXA) efficacy is limited by dual resistance mechanisms: glutathione (GSH)-mediated detoxification and lipid metabolic reprogramming. Although the metabolic hormone Irisin represents a potential strategy to modulate lipid metabolism, its systemic delivery raises concerns about potentially exacerbating cancer-associated cachexia. Furthermore, non-invasive methods to dynamically monitor metabolic changes and treatment response are critically needed.
Methods or Background: The platinum-palladium-rhodium-iron quaternary mesoporous nanozyme co-loaded with OXA and Irisin (PtPdRhFe@OXA/Irisin) was developed for the targeted co-delivery to pancreatic tumors in mice. This theranostic platform was assessed via a multi-modal imaging strategy: 1) Near-infrared fluorescence (NIRF) imaging for real-time tracking of tumor accumulation; 2) Serial MRI at weekly intervals to quantitatively monitor tumor volume changes and assess lipid content, providing a non-invasive measure of metabolic response.
Results or Findings: The nanosystem demonstrated effective CD44-targeted delivery to tumors, as confirmed by NIRF signals exclusively at the tumor site. Weekly MRI scans revealed that mice treated with PtPdRhFe@OXA/Irisin exhibited a significant suppression in tumor growth compared to control groups. MRI-based assessment indicated a notable decrease in intratumoral lipid content, suggesting Irisin affects pancreatic tumor lipid metabolic reprogramming in mice. This metabolic shift sensitized tumors to OXA, whose effect was further enhanced by the nanozyme's dual enzyme-mimetic activities, scavenging GSH and elevating ROS.
Conclusion: The multifunctional nanosystem PtPdRhFe@OXA/Irisin exerts potent anti-pancreatic tumor effects by targeting lipid metabolic reprogramming in synergy with GSH depletion and oxidative stress induction, while enabling non-invasive monitoring via multi-modal imaging.
Limitations: The precise molecular pathways by which Irisin reprograms lipid metabolism require further elucidation.

PET-MRI Radiogenomics in Alzheimer's: Predicting Tau Pathology Using MRI Features (6 min)

Aditya Chauhan; Bangalore / India

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: A. Chauhan; Bangalore/IN
Purpose: To investigate whether MRI-derived structural and connectivity features can predict tau deposition patterns on PET in patients with early Alzheimer's disease (AD).
Methods or Background: Sixty participants (30 early AD, 30 age-matched controls) underwent T1-weighted MRI, diffusion MRI, resting-state fMRI, and tau PET (Flortaucipir). Cortical thickness, white-matter integrity (FA, MD), and network efficiency were computed. A random-forest model was trained to predict regional tau-PET SUVR values using MRI features alone. Gene expression data from the Allen Human Brain Atlas were used to correlate imaging findings with transcriptional profiles of tau-related genes (MAPT, APOE).
Results or Findings: MRI features alone predicted regional tau accumulation with $r = 0.78$ ($p < 0.001$). Feature importance highlighted precuneus thickness and hippocampal connectivity as key predictors. Gene-imaging correlation revealed strong co-expression between regions with predicted tau and MAPT expression ($p < 0.01$).
Conclusion: MRI-based radiogenomic modeling enables non-PET prediction of tau pathology, offering a cost-effective, radiation-free biomarker for early Alzheimer's diagnosis and progression monitoring.
Limitations: Requires larger datasets and external validation before clinical translation.

Multimodal stroke imaging: the complementary role of 18F-FDG PET/CT in subacute and chronic stages (6 min)

Ricardo Ruano Pérez; Salamanca / Spain

Author Block: B. Pérez López, M. A. Sanchez Ronco, S. Osorio Aria, A. I. Calleja Sanz, E. Cortijo García, F. Sebastian Palacid, R. Ruano Pérez; Valladolid/ES
Purpose: To evaluate the role of brain 18F-FDG PET/CT in the assessment of subacute and chronic stroke and its concordance with CT, MRI, and CT angiography of the supra-aortic trunks (CTA)
Methods or Background: This retrospective study included 24 patients with confirmed subacute/chronic stroke. All underwent brain 18F-FDG PET/CT, with results compared to structural neuroimaging (CT, perfusion MRI, CTA). Clinical and demographic data, including cardiovascular risk factors, neurological focality, and time from diagnosis to PET/CT, were collected. Concordance was analyzed using correlation coefficients
Results or Findings: We included 14 men (58.3%) and 10 women (41.7%), with a mean age of 64.9±14.7 years. Cardiovascular risk factors were present in 70.8% of patients, and 83.3% had neurological focality. Brain PET/CT was positive in 83.3% of cases, showing hypometabolism most frequently in right cortical regions. Concordance between PET/CT and other imaging was moderate (PET/CT–MRI: r=0.53, PET/CT–CT: r=0.25, PET/CT–CTA: r=0.25). The mean interval from stroke onset to PET/CT was 228.5 days, with distribution as follows: <30 days in 70.8%, 30–180 days in 12.5%, and >180 days in 16.7%. In 37.5% of cases, PET/CT demonstrated more extensive metabolic abnormalities than CT or MRI. The right middle cerebral artery was the most frequent culprit vessel (33.3%), followed by the right internal carotid artery (25%). Among patients examined >180 days after stroke, 75% showed discordant findings compared with clinical-radiological correlation. Significant carotid stenosis was detected in 45.8% of cases, more often in patients with cardiovascular risk factors.
Conclusion: Brain 18F-FDG PET/CT is a valuable complementary tool in the evaluation of subacute and chronic stroke. Its ability to reveal functional changes not visible on structural imaging highlights the importance of multidisciplinary collaboration between radiology, nuclear medicine, and neurology, ensuring comprehensive and patient-centered stroke care
Limitations: Preliminar data

Role of PET-CT in Evaluation of Fever of Unknown Origin (FUO) (6 min)

Rathinamoorthy Praveenkumar; Chengalpattu / India

Author Block: F. Abubacker Sulaiman, R. Praveenkumar; Chennai/IN
Purpose: To evaluate the diagnostic role of ^18F-FDG PET/CT in identifying the underlying cause of fever of unknown origin (FUO) and to analyze its clinical impact.
Methods or Background: A prospective observational study was conducted on 15 consecutive patients meeting FUO criteria (temperature >38.3°C for >3 weeks, undiagnosed after standard investigations). All patients underwent whole-body ^18F-FDG PET/CT after inconclusive hematologic, biochemical, and radiologic tests. PET/CT findings were classified as infectious, inflammatory, neoplastic, or non-specific. Final diagnoses were confirmed through biopsy, culture, or follow-up at three months. Diagnostic yield and impact on clinical management were assessed.
Results or Findings: PET/CT identified the probable cause of fever in 12 of 15 patients (80%). The etiologies included infectious (n=6; 40%), malignant (n=4; 27%), and non-infectious inflammatory (n=2; 13%) causes, while 3 cases (20%) remained inconclusive. Common PET/CT findings included focal lymph node, hepatic, and skeletal uptake. Among the infection group, PET/CT localized sites of tuberculosis and abscesses. In malignancy, lymphoma was the predominant diagnosis. PET/CT influenced clinical management in 9 patients (60%) by guiding site-specific biopsy or initiating targeted therapy. The calculated sensitivity and specificity were 92% and 80%, respectively.
Conclusion: 18F-FDG PET/CT provides high diagnostic yield and valuable functional-anatomic correlation in FUO, enabling rapid etiologic localization and improved patient management, even in limited case settings.
Limitations: Small sample size, single-center design, and lack of pediatric cases limit generalizability. Larger multicentric validation is recommended.
Funding for this study: No external funding was received for this study.

Whole-Body 18F-FDG Parametric PET/CT in people with Long COVID: The ERASE trial protocol (6 min)

Karen Knapp; Newton Abbot / United Kingdom

Author Block: H. Abdul Razak[1], w. d. Strain[1], P. Rogers[1], M. Faghy[2], S. Kranen[1], K. Mokbel[1], M. Scott-Cleasby[1], J. Hoare[1], K. Knapp[1]; [1]Exeter/UK, [2]Derby/UK

Purpose: Long-COVID is a long-term sequela arising from an acute infection with SARS-CoV-2. To date there is no known cure. The ERASE feasibility trial will evaluate the efficacy of Remdesivir for the treatment of Long COVID with a wide range of outcome measures. This abstract outlines the nested parametric PET/CT study and the novel protocol utilised.

Methods or Background: Whole body (WB) 18F-FDG PET/CT scans were performed in 20 participants at one centre on day 11 for the baseline scan and day 55 for the follow-up scan with a maximum dose constraint of 31.2mSv for both scans, but a typical dose of 22mSv. Dynamic scans were acquired using the Siemens Motionflow acquisition on a Siemens Biograph Vision 600 scanner (Siemens, Germany) with an acquisition time of 75 to 90 minutes depending on the height of the participant. Patient public involvement and engagement was undertaken throughout the study design.

Results or Findings: The long scan duration was generally well tolerated by the participants. The image quality was diagnostic and both SUV and Ki were calculated for major organs and bone marrow, the latter using the automated Patlak algorithm in Siemens Syngo Via software (Siemens Healthineers, Germany).

Conclusion: In conclusion, this protocol demonstrates a novel use of parametric PET/CT 18F-FDG WB scans for the assessment of Long COVID and response to Remdesivir. The opportunity to quantify metabolic changes in a disease which has a range of presentations provides the potential to identify drug efficacy in different organs, which could provide useful insights for the future in both diagnosing and treating this disease.

Limitations: This study was performed at a single centre on a single scanner and further quantitative analysis of image quality and baseline to follow-up changes is required.

Funding for this study: This study was funded by Gilead Sciences

Binit Sureka; Jodhpur / India

Improving biopsy decision-making in prostate cancer using AI-assisted biparametric MRI (6 min)
Silvia Bottazzi; Rome / Italy

Author Block: S. Bottazzi, A. Iacono, I. Isufi, L. D'Erme, S. Persiani, G. Avesani, L. Russo, E. Sala, B. Gui; Rome/IT
Purpose: To evaluate the biopsy benefit-to-harm ratio of biparametric MRI (bpMRI) alone versus AI-assisted bpMRI in a decision-support setting.
Methods or Background: This retrospective study included patients undergoing pre-biopsy MRI between 2021 and 2024. The MRIs were analysed in two sequential phases with a 45-day washout period. Initially, five readers (2 experts and 3 basics according to ESUR-ESUI) independently assigned PI-RADS on bpMRI. After, AI-generated reports were available, and readers reassessed bpMRI with AI decision support. Benefit-to-harm metrics were biopsy selectivity (GG≥2/GG1) and biopsy efficiency (GG≥2/[GG1+benign]). They were calculated across two different biopsy thresholds: PI-RADS ≥3 and a combined threshold of PI-RADS ≥4 or PI-RADS 3 with PSA density (PSAd) ≥0.15 ng/ml². Metrics were computed per reader and summarised as overall and subgroups (experts and basics readers) means (±SD).
Results or Findings: AI assistance improved benefit-to-harm metrics overall. At PI-RADS ≥3, biopsy selectivity increased from 3.889±0.884 to 5.078±1.602 and efficiency from 1.688±0.404 to 1.992±0.053. At the composite threshold (PI-RADS ≥4 or PI-RADS 3 with PSAd ≥0.15 ng/ml²), selectivity increased from 4.317±0.735 to 5.400±1.188 and efficiency from 2.166±0.699 to 2.363±0.250. Basic readers showed the greatest benefit: at PI-RADS ≥3, efficiency reached 2.000 and NNB 0.50; at the composite threshold, efficiency reached 2.260, with higher selectivity at both thresholds. Among experts, selectivity improved at PI-RADS ≥3 (from 4.688 to 5.378) and at the composite threshold (from 4.989 to 5.833), while efficiency remained stable.
Conclusion: Across the evaluated thresholds, the composite criterion—combining PI-RADS with PSAd—provided the highest biopsy selectivity and efficiency. With AI decision support, basic readers achieved performance comparable to experts, while expert metrics remained stable (efficiency) or slightly improved (selectivity). These findings support AI-assisted bpMRI interpretation to improve biopsy decision-making.
Limitations: Retrospective study with limited number of readers

Artificial intelligence or radiologist interpretation for prostate cancer diagnosis (6 min)
Alexander Ng; London / United Kingdom

Author Block: A. Ng, A. Asif, A. Shah, A. Dudko, R. Kumar, P. Rajwa, F. Giganti, D. Pendse, V. Kasivisvanathan; London/UK
Purpose: With the global incidence of prostate cancer predicted to double in the next 20 years, alongside the potential adoption of biparametric MRI and national MRI screening programmes, demand for prostate MRI is set to rise substantially. Interpretation, however, has a steep learning curve, with optimal performance achieved by expert genitourinary radiologists. With a rising demand for medical imaging and a projected 40% radiologist shortfall by 2027, a prompt international solution is warranted. PARADIGM aims to evaluate whether artificial intelligence (AI) is non-inferior to radiologists in detecting clinically significant prostate cancer (Gleason grade group ≥ 2).
Methods or Background: PARADIGM is an international, prospective, multicentre, non-inferiority, within-patient, level-1 evidence diagnostic study. 500 men will be recruited over 18 months. Men will undergo standard of care MRI with either 1.5 or 3.0 T with at least a pelvic phased array coil. The radiologist and a primary AI algorithm will report the MRI blinded to each other. The radiologist will then be unblinded and produce a merged report, with the ability to overrule AI findings for safety. Suspicious lesions identified by either AI or radiologist will undergo targeted biopsies, with optional perilesional and/or systematic biopsies. The primary outcome is the proportion of men with clinically significant cancer. Planned secondary outcomes include the proportion of men with clinically insignificant cancer (Gleason grade group 1), and test performance characteristics of AI and radiologists.
Results or Findings: 45 centres across 14 countries expressing interest are undergoing pre-trial MRI quality control. PARADIGM will open to recruitment in Q1 2026.
Conclusion: PARADIGM will provide the first prospective, level-1 evidence on the diagnostic performance of AI in the detection of clinically significant prostate cancer on MRI.
Limitations: PARADIGM will not investigate workload reductions. Approvals are in progress.
Funding for this study: The PARADIGM trial is supported by The John Black Charitable Foundation and the European Association of Urology Research Foundation.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The PARADIGM trial has not yet been approved by an ethics committee. Regulatory approvals are currently underway and results of ethics committee approvals will be shown during the presentation if received by date of presentation.

AI-accelerated versus conventional diffusion-weighted imaging for prostate MRI: A head-to-head comparison of quality and quantitative metrics (6 min)

Vlad Sacalean; Freiburg Im Breisgau / Germany

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: V. Sacalean[1], O. Gebler[1], W. Liu[2], R. Strecker[2], E. Weiland[2], F. Bamberg[1], J. Weiß[1], M. Russe[1], H. Engel[1]; [1]Freiburg Im Breisgau/DE, [2]Erlangen/DE
Purpose: Diffusion-weighted-imaging (DWI) is central to prostate MRI but prolongs examinations. We compared an AI-accelerated reduced-field-of-view readout-segmented EPI diffusion sequence (AI-DWI) with a conventional full-field readout-segmented sequence (c-DWI), hypothesising shorter acquisition with non-inferior perceived diagnostic quality and characterising effects on diffusion metrics.
Methods or Background: This prospective, single-center study of diagnostic accuracy enrolled 62 consecutive men with elevated PSA-levels between March and May 2025. The AI-DWI sequence was compared against the standard c-DWI sequence for each patient. Three radiologists independently scored overall image quality, anatomic differentiability, lesion conspicuity and artefacts on five-point Likert scales. Quantitative analysis involved comparing mean Apparent Diffusion Coefficient (ADC) and seven additional texture features (maximum, minimum, standard-deviation, coefficient of variation, entropy, skewness and kurtosis) using a five-millimetre region of interest in each index lesion. Wilcoxon-signed-rank tests assessed ordinal scores, and paired t-tests were used for quantitative metrics.
Results or Findings: The AI-DWI sequence demonstrated a significantly shorter acquisition time compared to c-DWI (3 min 59 s vs. 4 min 21 s; $p < 0.01$). There was no significant difference in subjective scores for overall image quality, lesion conspicuity, artefacts, or anatomic differentiability ($p > 0.05$ for all). AI-DWI yielded significantly lower mean ADC values (975.92 ± 174.57 vs. 1013.21 ± 189.34; adj. $p < 0.01$) and maximum ADC values (adj. $p < 0.01$). No significant differences were found for standard deviation, coefficient of variation, entropy, kurtosis, minimum, or skewness (adj. $p > 0.05$).
Conclusion: The AI-DWI sequence allows for a meaningful reduction of acquisition time while preserving excellent subjective image quality compared to the c-DWI. Quantitatively, it yields lower mean and maximum ADC values, while showing no significant differences in the rest of the quantiative metrics.
Limitations: Single-centre design.
Lack of histopathological correlation.
Funding for this study: The research MRI sequence was provided under an unrestricted collaboration agreement between Siemens Healthineers and the Department of Diagnostic and Interventional Radiology, Medical Center – University of Freiburg. Siemens Healthineers AG provided technical support; study conception and design, as well as data analysis and interpretation, were conducted independently.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study protocol was approved by the Ethics Committee of the Albert-Ludwigs-Universität Freiburg (Approval #22-1185). All participants provided written informed consent prior to inclusion. This prospective study consecutively enrolled 64 men referred for multiparametric prostate MRI between March and May 2025; two were excluded due to incomplete or severely degraded studies, yielding a final cohort of 62 participants.

In Prostate Cancer Diagnosis, Deep Learning Model's Performance Declines as MRI Quality Reduces, while Radiologists' Performance Remains the Same (6 min)

Eduardo H. P. Pooch; Amsterdam / Netherlands

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: E. H. P. Pooch, G. Agrotis, S. Ursprung, A. Dehghanpour, R. Beets-Tan, T. Janssen, I. G. Schoots; Amsterdam/NL
Purpose: To assess the impact of biparametric MRI (bpMRI) scan quality, as determined by PI-QUAL scores, on the diagnostic performance of a deep learning (DL) model and radiologists in correctly detecting Grade Group (GG) ≥2 prostate cancer in prostate cancer suspected men.
Methods or Background: A nnU-Net GG≧2 cancer segmentation model used 1500 bpMRI scans for training, 1000 for testing (PI-CAI cohort), and 573 scans for external validation (PROMIS cohort). The external cohort analysis included MRI assessment by a radiologist (R1) using PI-RADS v2.1 and the original PROMIS study Likert scores as the second assessment (R2). Two readers (QR1, QR2) assessed the image quality of the PROMIS MRI scans and determined a consensus Prostate Imaging Quality (PI-QUAL) v2 score. The reference standard was GG≧2 cancer, confirmed by transperineal saturation biopsy. The model's and radiologists' diagnostic performance (AUCs) were compared. Bootstrap testing (1000 iterations) was used to calculate 95% Confidence Intervals (CI) and determine the statistical significance of the performance differences between quality subgroups.
Results or Findings: On the external dataset, readers' performance achieved AUC[R1] 0.85 [0.82-0.88] and AUC[R2] 0.76 [0.73-0.79], respectively. The DL model's performance on reduced-quality scans (n=141) declined (AUC[DL-PIQUAL1] 0.63 (0.53-0.71), whereas on high-quality scans (n=432), performance increased (AUC[DL-PIQUAL2-3] 0.71 [0.66-0.75] ($p<0.05$)). In contrast, the readers' performance remained consistent across scan quality (AUC[R1-PIQUAL1] 0.88 [0.82-0.93] and AUC[R1-PIQUAL2-3] 0.91 [0.88-0.93] ($p=0.35$); AUC[R2-PIQUAL1] 0.79 [0.71-0.86] and AUC[R2-PIQUAL2-3] 0.80 [0.76-0.84] ($p=0.49$).
Conclusion: The diagnostic performance of the AI model declined significantly on reduced-quality MRI scans as determined by PI-QUAL v2 scoring, whereas radiologists maintained consistent performance regardless of scan quality.
Limitations: Single external cohort, single AI model, subjective quality evaluation
Funding for this study: No

AI in the Hot Seat: Can a Commercial AI tool Triage Prostate MR using a dedicated 3-point scale? (6 min)

Francesco Giganti; London / United Kingdom

Author Block: F. Giganti; London/UK
Purpose: To evaluate a commercial AI algorithm's ability to triage prostate MRI into actionable risk categories for clinically significant prostate cancer (csPCa), benchmarked against radiologist-assigned PI-RADS scores.
Methods or Background: Pathology reports from targeted biopsies of 39 consecutive biopsy-naive men with MRI studies at Rolling Oaks Radiology (CA, USA) were used as ground truth. Radiologists assigned PI-RADS scores in their original reports.

Imaging was analysed by the DeepHealth algorithm, which automatically segmented the prostate and lesions using a 3-point scale: Low (unlikely csPCa, avoid biopsy); Medium (likely csPCa, consider biopsy); High (likely csPCa, biopsy recommended).

CsPCa was defined as grade group ≥2. AI predictions were dichotomised using High alone or High+Medium as positive. PI-RADS thresholds of ≥3, ≥4, and 5 were compared. Patient-level analysis used the highest scoring lesion.
Results or Findings: Twenty patients (51%) had csPCa. Studies included four scanner manufacturers (GE, Siemens, Philips, Hitachi) with 3T, open, and hybrid PET/MR systems.

For ≥Medium risk, the AI sensitivity was 89% (69–97%) and specificity was 45% (26–66%). PI-RADS ≥3 and ≥4 yielded 100% (83–100%) and 95% (75–99%) sensitivity, with specificities of 25% (11–47%) and 50% (30–70%). The PPV for ≥Medium risk was 61% (42–76%), comparable to that of PI-RADS ≥3 (56%, 39–71%) and ≥4 (64%, 46–79%).

High risk achieved 47% (27–68%) sensitivity and 100% (84–100%) specificity, versus PI-RADS 5 with 42% (23-64%) sensitivity and 95% (76-99%) specificity. AI's High risk had 100% PPV (70–100%) with 67% NPV (49–81%).
Conclusion: This pilot study demonstrates the feasibility of AI-based prostate MRI stratification using a 3-point scale, with classifications aligned with expert PI-RADS scores. Further validation is ongoing.
Limitations: Small sample size and a case-level analysis only.
Funding for this study: None

Artificial intelligence-assisted reading of non-contrast prostate MRI: Application and concordance with expert interpretation in a screening population within the PROSA Trial (6 min)

Emanuele Messina; Rome / Italy

Author Block: E. Messina, A. Borrelli, L. Laschena, A. Dehghanpour, M. Pecoraro, V. Panebianco; Rome/IT
Purpose: Bi-parametric MRI (bpMRI), a non-contrast imaging approach, has been explored as potential method for screening clinically significant prostate cancer (csPCa). At the same time, artificial intelligence (AI) is increasingly recognized as potential supportive tool. This study aimed to assess the performance of an AI-based software for csPCa screening with bpMRI, focusing on its value in assisting less-experienced readers.
Methods or Background: Retrospective analysis of the PROSA trial, a prospective, randomized, single-center study that enrolled 759 men eligible for csPCa screening. BpMRI scans were obtained following PI-RADS v2.1 guidelines and independently reviewed by an expert radiologist, a less-experienced reader, AI-software, and the less-experienced reader assisted by AI. Diagnostic accuracy was evaluated through ROC curve analysis and inter-reader agreement (Cohen's kappa), with the expert's assessment serving as reference standard.
Results or Findings: Out of 499 bpMRI scans, the less-experienced reader supported by AI achieved the best diagnostic performance (sensitivity 76.5%, specificity 97.2%, accuracy 95.8%, AUC 0.868), outperforming both AI-alone (sensitivity 58.8%, specificity 96.6%, accuracy 94.0%, AUC 0.777) and the unaided less-experienced reader (sensitivity 67.6%, specificity 95.1%, accuracy 93.2%, AUC 0.814). AI support also enhanced inter-reader agreement (κ=0.84), reducing the number of PI-RADS 3 cases (77→53), and increased exact concordance with the expert from 32.5% to 54.5%, while lowering diagnostic discordance.
Conclusion: AI has the potential to assist less-experienced radiologists and improve the consistency of bpMRI readings, especially considering equivocal cases. In addition, its integration into radiology workflows may reduce reporting workload and facilitate prioritization of suspicious findings, providing important benefits in large-scale screening programs.
Limitations: Reference standard: expert reader's assessment (not histopathology), since only MRI-positive cases undergo biopsy; histology for all would be unfeasible in screening.
AI-software trained mostly on older, clinically suspected patients, not younger screening population.
Funding for this study: No
Has your study been approved by an ethics committee? Yes

AI-supported prostate MRI lesion classification: impact at different reader experience levels (6 min)

Hüdanur Bayraktaroglu; Munich / Germany

Author Block: H. Bayraktaroglu, M. Heimer, P. Lohse, J. F. Kuhnle, R. Lorbeer, C. Stief, J. Ricke, C. C. Cyran, P. M. Kazmierczak; Munich/DE
Purpose: To investigate the impact of a commercially available AI tool for prostate lesion classification according to PI-RADS v2.1 on the diagnostic accuracy of radiologists at different experience levels.
Methods or Background: In this IRB-approved retrospective single-center study, prostate MRI datasets of 477 patients (470 mpMRI, 7 bpMRI; median age 68 years) acquired at 3 Tesla between 09/22 and 11/24 were analysed. Three blinded radiologists with different experience levels (low, intermediate, high) independently assessed the datasets in a two-step approach: first without AI support, then after reviewing AI results with the option to change the initial PI-RADS score. Scoring differences were tested using the McNemar-Bowker test and agreement with the reference standard (board-certified radiologist, >12 years of experience in abdominal imaging) was quantified by weighted Cohen's k.
Results or Findings: Across all readers, AI support led to redistribution of PI-RADS scores, most pronounced in the least experienced reader (p=0.002), including upscoring of PI-RADS 2 lesions: ten to PI-RADS 3, five to PI-RADS 4, six to PI-RADS 5 [21/194, 10.8%]. In 7/11 of the upscored cases, TRUS-guided transperineal fusion biopsy confirmed csPCa (ISUP ≥2). AI improved agreement with the reference standard in all readers, reaching statistical significance in the low experience reader (Cohen's k from 0.54 [0.46-0.61] to 0.59 [0.52-0.66], p=0.009), whereas changes for the other readers did not prove statistically significant (p=0.143 and p=0.731). Overall, agreement of the AI results with the reference standard remained moderate (k=0.59 [0.52-0.66], p<0.001).
Conclusion: AI support significantly improved diagnostic accuracy of low, but not of intermediately or highly experienced readers. However, in view of the moderate agreement of the AI results with the reference standard, supervision by an experienced uroradiologist remains mandatory.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study.

Evaluation of an AI algorithm's performance in MRI follow-up of patients undergoing active surveillance for prostate cancer (6 min)

Gaspard D'Assignies; Nantes / France

Author Block: J. Spilleboudt[1], C. Ruppli[2], G. Herpe[3], D. Bouda[4], G. D'Assignies[2], L. Beuzit[1]; [1]Rennes/FR, [2]Paris/FR, [3]Poitiers/FR, [4]Nantes/FR
Purpose: The PRECISE scoring system is a recently developed tool designed to standardize MRI follow-up in patients undergoing active surveillance (AS) for prostate cancer. This study aimed to evaluate the performance of a deep-learning–based artificial intelligence (AI) software prototype in assessing the likelihood of radiological tumor progression on serial MRI scans using the PRECISE criteria. The performances of the AI prototype and a junior radiologist were compared to those of an expert radiologist, who served as the ground truth.
Methods or Background: A total of 96 patients undergoing active surveillance were included, each with two available MRI scans. For each patient, prostate lesions were detected, measured and classified according to the Pi-RADS 2.1 guidelines by a junior radiologist, an expert radiologist, and the AI algorithm. The PRECISE score was independently assessed by each radiologist, while the AI algorithm inferred the score based on predefined calculation rules. Balanced accuracy was calculated using a threshold of PRECISE score 3 (i.e., scores ≤3 vs >3), comparing the predictions of the junior radiologist and the AI software to those of the expert radiologist.
Results or Findings: The difference between AI protype and junior radiologist PRECISE scores inferences was not statistically significant. AI prototype inferred PRECISE scores with non significant lower accuracy than the junior radiologist. Using a threshold at PRECISE 3, the balanced accuracy was 0.67 for the junior reader and 0.62 for the AI (p-value 0.44).
Conclusion: The AI prototype inferred PRECISE scores with lower accuracy than a junior radiologist, though the difference was not statistically significant. However, AI prototype demonstrated superior performance in lesion detection and segmentation.
Limitations: The ground truth is assessed by a single expert radiologist. Our study is also limited by its retrospective design and single-center setting.
Funding for this study: No funding

Portal hemodynamic response to tips assessed by 4D flow MRI: Association with procedural strategies and prediction of postoperative outcomes in a prospective cohort study (6 min)
Shang Wan; Chengdu / China

Author Block: S. Wan, J. He, X. Luo, B. Song; Chengdu/CN
Purpose: Transjugular intrahepatic portosystemic shunt (TIPS) is an essential intervention for portal hypertension but significantly risks postoperative complications such as hepatic encephalopathy (HE). This study aimed to investigate the prognostic value of portal hemodynamics assessed by four-dimensional (4D) flow MRI in predicting post-TIPS outcomes and to identify associations with procedural strategies
Methods or Background: This prospective single-center study included 20 patients who underwent TIPS between September 2023 and November 2024 and completed both pre- and post-procedural 4D flow MRI for quantitative hemodynamic assessment. Parameters measured included forward volume(FV), total volume(TV), maximum flow(MF), backward volume(BV), peak velocity(PV), pressure difference(PD), wall shear stress(WSS), and regurgitation fraction(RF) across the portal venous system and TIPS-stent. Differences by procedural strategies were evaluated, and correlations with portal pressure gradient(PPG) were analyzed. Cox regression assessed associations with postoperative outcomes.
Results or Findings: Overall, FV, TV, MF, PV, WSS, and PD increased significantly across the portal venous system after TIPS (all P<.001). Patients developing HE (n=4) showed greater FV (P=.02) and MF (P=.007) changes at the proximal main portal vein. VIATORR Controlled Expansion stents had significantly higher mid-stent PD than conventional stents(P<.05). Mid-stent BV correlated positively with post-TIPS PPG (r=0.498, P=.04), whereas higher distal-stent BV was associated with reduced risk of HE or variceal rebleeding(HR=0.48; 95% CI, 0.26-0.90; P=.02).
Conclusion: TIPS significantly improved portal hemodynamics as measured by 4D flow MRI. Backward flow volume emerged as a potential predictor of adverse outcomes, and distinct procedural strategies were associated with specific flow patterns, offering insights for surgical planning and risk stratification.
Limitations: The sample size for this exploratory study was relatively small

Increasing experience with portal vein recanalization in pediatric patients with non-cirrhotic extrahepatic portal vein obstruction: technique and outcomes (6 min)
Paolo Marra; Bergamo / Italy

Author Block: P. Marra, K. D. Martins De Mattos, R. Muglia, F. S. Carbone, L. Dulcetta, M. Bertuletti, M. Cheli, L. D'Antiga, S. Sironi; Bergamo/IT
Purpose: Portal vein recanalization (PVR) without TIPS is being investigated to treat non-cirrhotic portal hypertension resulting from extrahepatic portal vein obstruction (EHPVO). We describe advanced techniques and outcomes of PVR attempted in a cohort of pediatric patients and young adults.
Methods or Background: Consecutive patients suffering from non-cirrhotic portal hypertension due to perinatally-acquired EHPVO were prospectively enrolled since 2021. Wedge hepatic venography and percutaneous portal access (transhepatic and/or transplenic), were performed upon multidisciplinary discussion to attempt PVR. Clinical and procedural data, technical and clinical success, complications and follow-up data were recorded. Technical success was considered at least the partial revascularization of the native portal system.
Results or Findings: Twenty-three patients (16 males; median age 10 years) with severe portal hypertension due to EHPVO underwent 33 percutaneous transhepatic (n=2), transplenic (n=24) or simultaneous transhepatic/transplenic (n=7) for PVR. All but two were judged not eligible for Meso-Rex bypass while it failed 2 patients. Technically successful recanalization was achieved in 18/23 patients (78%), by means of advanced techniques in 4 cases, respectively 2 gun-sight sharp recanalization and 2 collateral vessel angioplasty/stenting. Severe arterial bleeding complications occurred in 2 patients, managed by transarterial embolization. After successful angioplasty, 17/18 patients required primary or secondary stenting to obtain sustained patency. Revisions due to thrombosis/stenosis were necessary in 8/18 patients. After a median follow-up of 12 months, portal vein patency was demonstrated in all but one patients who achieved successful PVR, with clinical and laboratory improvement of portal hypertension.
Conclusion: With increasing experience, more than 70% of patients with non-cirrhotic portal hypertension due to EHPVO can restore the portal flow by endovascular treatment, even when Meso-Rex is unfeasible. Technical challenges still remain but clinical outcomes seem promising.
Limitations: Retrospective cohort. Limited reproducibility due to technical challenges.

Impact of Right Hepatic Artery Caliber on Future Liver Remnant Hypertrophy After Liver Venous Deprivation (6 min)

Domenico Santangelo; Milan / Italy

Author Block: D. Santangelo, R. Vitali, A. Campisi, F. Cipriani, D. Palumbo, C. Canevari, F. Ratti, A. Chiti, F. De Cobelli; Milan/IT
Purpose: To evaluate the influence of right hepatic artery (RHA) caliber on liver regeneration in patients with primary or secondary liver malignancies undergoing liver venous deprivation (LVD), and to assess the impact of the hepatic arterial buffer response (HABR) on post-LVD regeneration.
Methods or Background: Fifty-nine patients (June 2019–September 2024) who underwent LVD were retrospectively analyzed. Right hepatic artery (RHA) caliber was measured on CT scans obtained both before LVD and within 30 days after the procedure. All patients underwent FLR volumetry on CT at three timepoints; pre-LVD (baseline), 5–15 days post-LVD (timepoint 1), and 15–30 days post-LVD (timepoint 2). FLR function was assessed with 99mTc-mebrofenin hepatobiliary scintigraphy pre-LVD and within 30 days post-LVD. Correlation analyses and linear regression were performed.
Results or Findings: A significant correlation between total liver volume and right hepatic artery caliber at baseline was found; therefore, all measured RHA caliber were standardized to the total liver volume, obtaining the new variable “s-caliber”. At baseline, RHA s-caliber showed an inverse correlation with post-procedural volumetric FLR volume ($p<0.001$), degree of hypertrophy ($p=0.008$), and kinetic growth rate ($p=0.014$). No significant associations were observed between s-caliber and functional hypertrophy metrics. The RHA caliber change after LVD didn’t correlate with any volumetric/functional hypertrophy parameters.
Conclusion: This is the first report demonstrating the potential impact of the RHA on volumetric FLR hypertrophy after LVD. Larger arterial calibers may attenuate hypertrophy, likely by sustaining arterial inflow to embolized segments.
Limitations: Retrospective. Small sample size.

Retrograde transvenous obliteration (RTO) versus endoscopic ultrasound (EUS)-guided therapies in fundal varices- A comparative analysis (6 min)

Ranjan Kumar Patel; Bhubaneswar / India

Author Block: R. K. Patel, T. P. Tripathy, M. Panigrahi, H. Nayak; Bhubaneswar/IN
Purpose: To compare the outcome of RTO and EUS-guided therapies in the management of fundal varices.
Methods or Background: We retrospectively analyzed the data of patients with fundal varices undergoing EUS-guided intervention or RTO, and both groups were compared after propensity matching. The study's primary outcome was the incidence of variceal bleeding within 1 year. The secondary outcomes included procedure-related adverse events (AEs), variceal obliteration, reintervention, and mortality within 1 year.
Results or Findings: 167 patients (EUS-guided intervention: 108, RTO: 59) were included in the analysis, of which 59 patients were included in each group after propensity matching. The incidence of variceal obliteration at 4 weeks was comparable between groups (83.1% vs. 91.5%, p = 0.167). The incidence of variceal bleeding (15.3% vs. 13.6%, p = 0.793) within 1 year was also comparable between the EUS and RTO groups. Nevertheless, the need for reintervention for GVs was higher in the EUS group (28.8% vs. 5.1%, p = 0.001), and the need for reintervention for esophageal varices (EVs) was higher in the RTO group (16.9% vs. 1.7%, p = 0.008). Procedure-related adverse events (AEs), primarily new onset or worsening of ascites, were higher in the RTO group. None of the AEs were life-threatening.
Conclusion: RTO provides more complete fundal variceal obliteration, requiring a significantly lower number of reintervention than EUS-guided therapies. Thus, RTO may be considered as a more definite therapy for fundal variceal obliteration
Limitations: Retropsective analaysis
Operator bias

From surgical to endovascular approach in the management of pediatric congenital portosystemic shunts (6 min)

Paolo Marra; Bergamo / Italy

Author Block: P. Marra, K. D. Martins De Mattos, G. De Petri, V. Casotti, R. Muglia, F. S. Carbone, M. Bertuletti, L. Dulcetta, S. Sironi; Bergamo/IT
Purpose: Congenital portosystemic shunts (CPSS) are rare vascular malformations potentially leading to liver transplantation if untreated. We evaluated whether timely, multidisciplinary use of interventional radiology (IR) for diagnostic and therapeutic management reduces complications and the need for liver transplantation in a retrospective cohort.
Methods or Background: In this single-center cohort of pediatric CPSS, all patients underwent multidisciplinary workup. Due to substantial improvement in the management protocol over time, patients were divided into two groups according to treatment period: Early (treatment before 2019) and Late (treatment in 2019 or later). In the Late cohort IR procedures included diagnostic retrograde portal venography with balloon occlusion test and endovascular shunt closure, when technically feasible; alternatively, surgical shunt closure was performed. In the Early cohort, endovascular and surgical closure were not routinely performed. We compared time from diagnosis to treatment, frequency of liver transplantation, and the number of CPSS-related complications between groups.
Results or Findings: Twenty-four patients (male n = 9) were analyzed, 11 in the Early group and 13 in the Late group. IR procedures were undertaken in 4/11 (36%) Early versus 8/13 (62%) Late patients. Liver transplantation was performed in 9/11 (82%) Early patients and in 1/13 (8%) Late patients. Surgical shunt ligation was performed in 3/24 (13%) overall. Mean age at diagnosis was similar between cohorts (~5 years). Median time from diagnosis to treatment decreased from 4 years in the Early cohort to 1 year in the Late cohort. Patients who underwent IR management had fewer documented CPSS-related complications.
Conclusion: Incorporation of IR into a multidisciplinary care pathway was associated with shorter diagnostic-to-treatment intervals, increased utilization of minimally invasive management, and a substantially lower transplant rate in children with CPSS.
Limitations: Retrospective cohort with management shift over a long time.

Percutaneous recanalization of chronic total occlusion of the portal vein: technical aspects and outcomes (6 min)

Ludovico Dulcetta; Bergamo / Italy

Author Block: L. Dulcetta, P. Marra, R. Muglia, F. S. Carbone, M. Bertuletti, S. Sironi; Bergamo/IT
Purpose: Chronic total occlusion (CTO) of the portal vein is a major cause of portal hypertension, which may lead to life-threatening complications often managed by interventional radiology (IR). The aim of this study was to evaluate the feasibility, safety and clinical outcomes of percutaneous revascularization therapy for CTO of the portal vein in pediatric and adult patients.
Methods or Background: From January 2020 to June 2025, consecutive patients with severe portal hypertension due to portal vein CTO undergoing percutaneous recanalization were retrospectively reviewed. Technical success was defined as restoration of portal vein patency at angiography; clinical success was defined as improvement of clinical and laboratory signs of portal hypertension and control of variceal bleeding.
Results or Findings: Twenty-two patients (median age 27 years; range 6–60; 14 males; 5 children) underwent 32 procedures. Eleven (50%) were liver transplant recipients. Cavernous transformation was present in 21/22, with splenomesenteric confluence involvement in 10 patients. Technical success was achieved in 18/22 patients (82%), 11 of whom underwent portal revascularization through extrahepatic stent placement; in 6 cases, a TIPS was performed to achieve sustained portal vein patency. Embolization of varices and/or cavernoma was performed in 17 patients. Three complications (two splenic artery perforation, one hemoperitoneum) were managed conservatively. Clinical success was achieved in all 18 technically successful cases, with a median follow-up of 32 months (IQR 3–41).
Conclusion: Percutaneous revascularization is feasible and effective in managing portal vein CTO, with no significant technical contraindications to attempting the procedure. Restored portal flow physiology alone is possible in most patients; TIPS is not essential to achieve portal vein patency, but it may be useful in a few selected cases to maintain long-term patency and control portal hypertension.
Limitations: Retrospective nature and the small sample size.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The Ethical Committee of Bergamo authorized this retrospective study (Portal01; N.92/21) that was conducted in respect of the ethical standards laid down in the 1964 Declaration of Helsinki.

Antegrade Transvenous Obliteration for Refractory Esophageal Variceal Hemorrhage in Patients Unsuitable for TIPS: A Multicenter Retrospective Study (6 min)

Jimin Yoo; Incheon / Korea, Republic of

Author Block: S. H. Lee, D. Shim, S. Baek, D. Kim, J. Yoo; Incheon/KR
Purpose: Esophageal variceal bleeding (EVB) refractory to endoscopic treatment in some patients with advanced cirrhosis, leaving few options other than transjugular intrahepatic portosystemic shunt (TIPS). However, patients with encephalopathy or heart failure are often ineligible for TIPS, alternatively opt for antegrade transvenous obliteration (ATO). This study aimed to assess the safety and efficacy of ATO compared to TIPS for refractory EVB.
Methods or Background: This study retrospectively reviewed medical records from clinical data warehouse the Catholic University of Korea which encompass eight tertiary hospitals between 2012 and 2024. Although TIPS was initially considered, ATO was indicated for patients who were ineligible for TIPS. ATO were implemented in 20 patients (age=62±10.2 years, men=13), while TIPS were created in 35 patients (age=58±12.6 years, men=26) for refractory EVB. The primary outcome was the difference in the 30-month overall survival (OS) rate between two groups, a noninferiority comparison to exclude a difference of >30 percentage point. The secondary outcomes were comparison of postprocedural adverse events and bleeding-free survival (BFS) between the ATO and TIPS groups.
Results or Findings: At a median 31-month follow-up, 30-month BFS and OS for ATO were 23.2% (95% CI, 7.8–69.7%) and 50.9% (95% CI, 32.0–81.0%); for TIPS, 63.8% (95% CI, 45.4–89.7%) and 52.2% (95% CI, 34.1–79.8%). The absolute OS difference was 1.3% (95% CI, –31.1–33.7%). One-week mortality or liver transplant occurred in 5 TIPS patients (14.3%) but none with ATO. Kaplan-Meier/log-rank analysis showed no significant differences in BFS (p=0.07) or OS (p=0.41).
Conclusion: Although the outcomes fall short for the specified noninferiority, the ATO might be an alternative for those who are ineligible for TIPS in treatment of refractory EVB.
Limitations: This study is limited by its retrospective design and sample size.
Funding for this study: No funding was received for this study.

Non-invasive estimation of hepatic venous pressure gradient in patients undergoing TIPS: A predictive approach (6 min)

Felix Schön; Dresden / Germany

Author Block: F. Schön, P. Hahlbohm, T. Helmberger, S. F. U. Blum, M. Berning, S. Löck, R-T. Hoffmann, J-P. Kühn; Dresden/DE
Purpose: To develop non-invasive models for estimating the hepatic venous pressure gradient (HVPG) using computed tomography (CT) in patients receiving transjugular intrahepatic portosystemic shunt (TIPS).
Methods or Background: Patients with therapy-refractory ascites who underwent TIPS between 2017 and 2024 were retrospectively enrolled. Baseline characteristics were collected, and pre-interventional CT scans were analyzed to extract quantitative parameters (e.g., hepatic vessel diameters, sarcopenia scores). The HVPG was measured during the TIPS procedure prior to shunt placement. Univariate and multivariate linear and logistic regression analyses using backward elimination were performed to (1) predict absolute HVPG values, and (2) distinguish between patients with HVPG ≤20 mmHg and those with HVPG >20 mmHg. Model performances were assessed by area under the receiver operating characteristic curve (AUC), R^2, and mean absolute error (MAE).
Results or Findings: A total of 129 patients (87 men; 61.0+/-10.1 years) were enrolled with an intra-procedural HVPG value prior to shunt placement of 20.21+/-3.61 mmHg. In multivariate linear regression, the superior mesenteric vein diameter (ß = 0.431; p = 0.012) and MELD-Na Score (ß = 0.152; p = 0.031) performed best to estimate the absolute HVPG (R^2 = 0.134; MAE = 2.53+/-2.10 mmHg). Multivariate logistic regression identified the superior mesenteric vein diameter (OR = 1.186; 95%-CI: 1.002-1.405; p = 0.048) and ALAT (OR = 24.218; 95%-CI: 2.395-244.913; p = 0.007) as independent predictors for HVPG ≤ 20 vs. >20 mmHg (AUC = 0.729; 95%-CI: 0.638-0.820). Sarcopenia scores only revealed significant predictive value in univariate analysis.
Conclusion: Non-invasive prediction models may estimate the HVPG in patients undergoing TIPS for therapy-refractory ascites. These models could help identify patients at earlier disease stages with less severe portal hypertension, who might benefit from TIPS placement.
Limitations: Retrospective study in a single-center setting. Small sample size.
Funding for this study: None.

Andrea Vanzulli; Tradate / Italy

AI-Enhanced Placental Radiomics on Diffusion and T2 MRI for Early Prediction of Preeclampsia and Fetal Growth Restriction (6 min)
K Saravanan; Chennai / India

Author Block: K. Saravanan[1], F. Abubacker Sulaiman[2], R. Praveenkumar[2], J. Lydia[2], D. Velan[2]; [1]Melmaruvathur/IN, [2]Chennai/IN
Purpose: To develop and validate an artificial intelligence (AI)–based radiomics model integrating diffusion-weighted imaging (DWI) and T2-weighted MRI features of the placenta for early prediction of preeclampsia (PE) and fetal growth restriction (FGR). The objective is to identify microstructural and textural biomarkers preceding clinical manifestation, enabling proactive obstetric management and improved perinatal outcomes.
Methods or Background: This prospective study included 80 pregnant women (20–32 weeks gestation) who underwent placental MRI on a 3-Tesla scanner. DWI (b-values 0, 800 s/mm²) and high-resolution T2 sequences were analyzed. Placental volumes were segmented semi-automatically, and radiomic features (first-order, texture, and shape) were extracted. Machine learning models—including Random Forest and Gradient Boosting—were trained to classify risk for PE/FGR, with cross-validation and feature selection via LASSO regression.

Clinical parameters (blood pressure, uterine artery Doppler indices) were integrated into a multimodal model for comparison.
Results or Findings: The AI-radiomics model demonstrated an AUC of 0.93 for predicting PE and 0.91 for FGR, outperforming conventional Doppler parameters (AUC 0.76). Key discriminative features included gray-level co-occurrence entropy and ADC histogram kurtosis, reflecting placental microstructural heterogeneity. Combined clinical-radiomics integration improved specificity and early detection (mean 5 weeks before clinical onset).
Conclusion: AI-enhanced placental radiomics from DWI and T2 MRI enables noninvasive early prediction of preeclampsia and FGR with high accuracy. This approach holds promise for precision obstetric imaging, facilitating timely intervention and reducing perinatal morbidity.
Limitations: Single-center design, limited sample size, and variability in placental segmentation may restrict generalizability. Lack of histopathological correlation and absence of external validation cohorts warrant further multicentric studies for clinical translation.

Deep learning-accelerated whole-body MRI for treatment monitoring in pediatric lymphoma: comparison with pet/CT (6 min)
Zheng Bingjie; Zhengzhou / China

Author Block: Z. Bingjie, Y. X. Li, J. Qu, C. Xu, X. Chen, Y. Wu; Zheng Zhou/CN
Purpose: To evaluate the diagnostic performance of deep learning-accelerated whole-body MRI without contrast for treatment monitoring in pediatric lymphoma patients compared with 18F-FDG PET/CT.
Methods or Background: In this multicenter prospective study conducted across five institutions, 176 children (aged 0-14 years; 60% male) with histopathologically confirmed Hodgkin lymphoma (HL, 65%) or non-Hodgkin lymphoma (NHL, 35%) underwent deep learning-accelerated whole-body MRI without contrast and 18F-FDG PET/CT at baseline, after induction chemotherapy, and at end of therapy. MRI scans, performed on 3T scanners, utilized a proprietary deep learning reconstruction algorithm, with its performance evaluated for image quality and scan time reduction compared to standard MRI protocols. Apparent diffusion coefficient (ADC) from MRI was correlated with PET/CT standardized uptake value (SUV). Statistical analysis included Gwet's AC for agreement and Pearson's correlation for quantitative metrics.
Results or Findings: Deep learning-accelerated MRI without contrast achieved 95% sensitivity and 92% specificity for lesion detection compared to PET/CT (Gwet's AC = 0.94 [0.89, 0.97]). Therapy response assessment showed 94% concordance (Gwet's AC = 0.94). The deep learning algorithm reduced scan time by 80% without compromising image quality (signal-to-noise ratio equivalent to standard MRI). ADC values strongly correlated with SUV (r^2 = 0.94) for treatment response. Subgroup analysis showed excellent agreement at end of therapy (Gwet's AC = 0.97), with higher concordance for HL (Gwet's AC = 0.94) than NHL (Gwet's AC = 0.66) after induction chemotherapy.
Conclusion: Deep learning-accelerated whole-body MRI without contrast offers a fast, radiation-free, contrast-free alternative to PET/CT for pediatric lymphoma treatment monitoring, with comparable diagnostic accuracy and significantly reduced scan times.
Limitations: The lower concordance in therapy response assessment for non-Hodgkin lymphoma compared to Hodgkin lymphoma after induction chemotherapy, potentially affecting diagnostic reliability in certain subtypes.
Funding for this study: This study was funded by the Henan Province Medical Science and Technology Research Program (Grand No.20233526)

Addressing data scarcity in paediatric head and neck CT: Cross-age training enables reliable automated lymph node segmentation (6 min)

Andreas Michael Bucher; Frankfurt / Germany

Author Block: B. Wichtlhuber[1], E. Frodl[1], M. Sayed[1], T. Persigehl[2], M. Neitzel[1], J. Dietz[1], M. Eicke[3], D. M. Renz[3], A. M. Bucher[1]; [1]Frankfurt/DE, [2]Koeln/DE, [3]Hannover/DE
Purpose: Paediatric lymph node segmentation faces critical data scarcity challenges. We hypothesised that incorporating adult CT data into deep learning training would overcome this limitation while maintaining clinical relevance for paediatric oncology applications, particularly for detecting pathologically enlarged nodes requiring follow-up.
Methods or Background: We analysed 418 head/neck CTs from University Hospital Frankfurt: 146 paediatric (<18 years) and 272 adult cases. A 3D full-resolution nnU-Net underwent five-fold cross-validation training (250 epochs) using three strategies: paediatric-only, adult-only, and combined training. Approximately 20% of cases were reserved for independent testing. Evaluation metrics included the Dice coefficient, Intersection over Union (IoU). Clinical relevance was assessed through volumetric coverage analysis, with particular focus on nodes >10mm short-axis diameter—the threshold for pathological enlargement requiring clinical action. Values are presented as median and standard deviation.
Results or Findings: Cross-age training outperformed paediatric-only approaches. The combined model achieved Dice=0.714 ±0.151 and IoU=0.575 ±0.176 on paediatric test data versus Dice=0.695 ±0.155 and IoU=0.553 ±0.179 for paediatric-only training, showing clear improvement. Interestingly, this benefit was unidirectional—paediatric patients gained from mixed training, whereas adult test performance remained unchanged (combined model Dice=0.643 ±0.125 vs. adult-only Dice=0.647 ±0.113). Clinical utility analysis showed strong performance: 88.97% of enlarged nodes (>10mm) achieved ≥10% volumetric coverage, ensuring reliable oncological detection. Moreover, 69.08% of all lymph nodes reached ≥50% coverage, supporting accurate volumetric measurements. These metrics translate into improved workflow efficiency, reducing missed findings while preserving precision for follow-up.
Conclusion: Cross-age training addresses the key challenge of paediatric data scarcity in medical imaging AI, improving technical metrics and enabling clinically meaningful detection of pathological lymphadenopathy. This approach supports robust AI use in paediatric radiology with limited annotated data, potentially accelerating adoption in oncology workflows.
Limitations: A limitation of the study is its single-center validation.
Funding for this study: Funding was provided by the German Federal Ministry of Education and Research through the RACOON project (reference number 01KX2021).

Ethics committee - additional information: Ethics approval was obtained by University Medicine Frankfurt (Reference 2023-1459)

Changes in Superb Microvascular Imaging (SMI) Following Antibiotic Therapy in Children with Acute Lymphadenitis (6 min)

Ahmet Faruk Ibil; İzmir / Turkey

Author Block: A. F. Ibil, M. Faraşat, M. Özkol; Izmir/TR
Purpose: Superb Microvascular Imaging(SMI) is an advanced Doppler technique that allows detailed visualization of small, slow-flow vessels without contrast agents. This study aimed to assess the impact of antibiotic therapy on lymph node morphology and hemodynamics in lymphadenitis using SMI.
Methods or Background: Patients admitted to our hospital's pediatric clinic were evaluated. SMI, Advanced Dynamic Flow(ADF) and Power Doppler(PD) US were applied to measure the Vascular Index(VI) within defined regions of interest(ROI) for comparison and diagnostic enhancement, both before and after antibiotics in lymphadenitis. For comparisons of quantitative variables that did not show normal distribution between two groups, the Wilcoxon test was used. The McNemar test and Pearson's chi-square test were applied for the comparison of qualitative data. Statistical analyses were performed using SPSS Software version26.0.
Results or Findings: A total of 17 patients and 65 lymph nodes were evaluated in the study population. Wilcoxon analysis showed significant post-antibiotic vascular index reductions in PD cSMI, and mSMI, while ADF demonstrated a significant increase(all $p<0.05$). Wilcoxon analysis showed significantly reduced post-antibiotic vascular scores in SMI and PD($p<0.05$), while ADF changes were not statistically significant ($p>0.05$), despite negative Z-scores indicating lower post-treatment values.
Conclusion: Our study demonstrated that combining PD, SMI, ADF, and gray-scale US findings may be diagnostically valuable for assessing the efficacy of antibiotic therapy and evaluating lymphadenitis. Recognizing typical features of lymphadenitis may also aid in early differentiation from malignancy and reduce the need for histopathology. As studies investigating ultrasound changes in pediatric lymphadenitis following antibiotic treatment are scarce, our work may serve as a reference.
Limitations: Limitations included patient compliance in young children, exclusion of irregular antibiotic use or follow-up, observer dependency in qualitative assessments, and the small number of pediatric patients receiving planned antibiotic therapy.
Funding for this study: This study received no financial support.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Ethical approval was obtained from the Clinical Research Ethics Committee of Manisa Celal Bayar University (decision no: 20.478.486/2322).

The Anatomical Advantage: CT Radiomics Outperform PET Radiomics and Clinical–PET Models in Pediatric High-Risk Hodgkin Lymphoma (6 min)

Lama Ibrahim; Haifa / Israel

Author Block: L. Ibrahim, A. Ilivitzki, M. Freiman; Haifa/IL
Purpose: To investigate whether radiomic features from post–first-cycle PET and CT scans, alone or combined with clinical variables, improve the prediction of event-free survival (EFS) in pediatric high-risk Hodgkin lymphoma (HL, stage IIIB/IVB), compared with a baseline model incorporating clinical variables and radiological PET assessment.
Methods or Background: Outcome prediction in pediatric HL traditionally relies on risk-adapted protocols combining clinical factors with interim FDG PET/CT, mainly focused on the isotopic PET component. Prior evidence suggests that CT provides additional prognostic information, underscoring the importance of anatomical features.
In this study, post–first-cycle PET/CT scans from 137 patients enrolled in the Children's Oncology Group AHOD0831 trial (NCT01026220) were analyzed. Up to five lesions per patient were segmented; PET images were SUV-standardized, and radiomic features from PET and CT were extracted and averaged using tumor volume weighting. Clinical variables included demographics, histology, stage, bulky disease, and radiological PET response. Machine learning models were trained with stratified 5-fold cross-validation, and performance metrics were averaged across folds
Results or Findings: EFS events occurred in 27 patients (19.7%). CT radiomics outperformed the baseline clinical + PET model (accuracy: 0.78 ± 0.10; balanced accuracy: 0.71 ± 0.09 vs. 0.70 ± 0.11; 0.66 ± 0.04) and exceeded PET radiomics (accuracy: 0.77 ± 0.07; balanced accuracy: 0.66 ± 0.07). The strongest predictive performance was achieved when CT radiomics were combined with clinical variables.
Conclusion: Radiomics from CT improved prognostic prediction beyond the standard clinical + PET model and outperformed PET radiomics, reinforcing the anatomical contribution to risk stratification. CT radiomics represent a promising complementary tool for early prognostic assessment in pediatric high-risk HL.
Limitations: This study was based on internal cross-validation within a single trial cohort (AHOD0831), without external or temporal validation, which may limit generalizability.
Funding for this study: None

Deep learning algorithms for identifying developmental dysplasia of the hip based on sonographic images: a retrospective, prospective, multicenter study in China (6 min)

Na Xu; Shenzhen / China

Author Block: N. XU; Shenzhen/CN
Purpose: This study aims to develop and validate a deep convolutional neural network algorithm, named HipSonoNeuNet model (HSNN), using multicenter hip ultrasound data.
Methods or Background: This multicenter cross-sectional study combined data from 22 Chinese hospitals, enrolling 3082 participants. A total of 7286 hip ultrasound images (1429 dynamic, 5857 static) were collected and were divided into three datasets. The study was conducted in three phases. Phase I trained the models using 2431 participants. Phase II compared diagnostic performance between radiologists of varied experience and the model across 500 participants. Phase III prospectively validated the model's generalizability with 151 participants .
Results or Findings: In Phase I, the HSNN yielded AUC of 0.99 (95%CI: 0.99-1.00), sensitivity of 1.00 (95% CI: 0.99-1.00), specificity of 0.91 (95% CI: 0.88-1.00), F1 score of 0.90 (95% CI: 0.87-1.00) on internal test dataset. In Phase II, the HSNN achieved an accuracy of 0.94 (95% CI: 0.88-1.00), AUC of 0.99 (95%CI: 0.99-1.00), sensitivity of 1.00 (95% CI: 0.99-1.00), specificity of 0.94 (95% CI: 0.87-1.00), F1 score of 0.58 (95% CI: 0.50-0.66), and strong agreement with expert (κ = 0.77). AI assistance improved all 7 junior radiologists' diagnostic performance (accuracy from 0.90 to 0.93, AUC from 0.80 to 0.95, sensitivity from 0.69 to 0.97) and reduced examination time with enhanced interobserver agreement. In Phase III, the model maintained robust performance (accuracy = 0.92, AUC = 0.99, sensitivity = 1.00, κ with experts = 0.76).
Conclusion: The HSNN demonstrates accurate, robust, and generalizable performance in DDH detection. It might potentially enhance diagnostic capabilities for radiologists, particularly in hospitals with varying levels of expertise.
Limitations: 1.DDH image imbalance may reduce model prediction stability.
2.China-only US images limit model performance across regions/ethnicities, affected by culture, genetics and healthcare resources.

Deep Learning Reconstruction in Pediatric Chest CT: A Radiation-Sparing Technique with Enhanced Image Quality (6 min)

Ilaria Bianco; Milan / Italy

Author Block: I. Bianco, D. Ippolito, C. Maino, C. R. G. L. O. M. Talei Franzesi, P. N. Franco, D. G. Gandola, R. Corso; Monza/IT
Purpose: To compare image quality and radiation dose between deep learning reconstruction (DLR) and hybrid iterative reconstruction (HIR) algorithms in unenhanced chest CT scans of pediatric patients.
Methods or Background: We retrospectively reviewed 142 unenhanced, single-phase chest CT scans performed for routine diagnostic purpose. 71 pediatric patients were examined using a 128-slice MDCT scanner (100kV) with a DLR algorithm (Precise Image), while the control group of 71 patients underwent scanning with a 256-slice MDCT scanner (100kV) using HIR algorithm (iDose4). Subjective image quality was assessed using a 5-point Likert scale, and objective quality was evaluated by measuring Hounsfield Units (HU) and Standard Deviations (SD) in lung parenchyma, tracheal lumen, air, aorta and muscle. Radiation dose metrics (CTDIvol and DLP) were recorded for both groups, and the estimated effective dose (EED) was calculated using age-specific k-factors.
Results or Findings: A total of 142 pediatric patients were included (median age:10 years).Inter-reader agreement for Likert scale image quality assessment was moderate (κ=0.432) with significantly higher subjective image quality scores for DLR group compared to HIR group (p=0.03).Quantitatively, air and muscle HU differed significantly between the two scanners (air, p=0.036; muscle, p<0.001). Image noise, assessed by SD was significantly lower in DLR group across the lung parenchyma (p=0.007), tracheal lumen (p=0.002) and muscle (p<0.001). Radiation dose metrics were significantly reduced in DLR group compared to control group (mean DLP: 49.6 vs 188.9 mGy·cm;CTDIvol: 1.6 vs 5.6 mGy;EED:0.8 vs 3.2 mSv;all p<0.001).Age-based sub-analysis using quartiles (0–5,6–12,>13 years) confirmed a consistent threefold reduction in DLP and CTDIvol, and a fourfold reduction in EED across all age groups (all p<0.001).
Conclusion: DLR in unenhanced chest CT allows significant radiation dose reduction in pediatric population while delivering superior image quality compared to HIR algorithms.

Real-World Impact of AI Chest Radiograph Triage on Lung Cancer Pathways and Outcomes Across a UK NHS Trust (11 min)
Geraldine Dean; London / United Kingdom

Author Block: M. Storey, E. Antrum, J. Packer, P. Zalmay, G. Dean, S. C. Shelmerdine; London/UK
Purpose: To assess the real-world clinical impact and safety of artificial intelligence (AI) chest radiograph (CXR) triage following deployment across a large National Health Service (NHS) trust, addressing uncertainties regarding pathway acceleration and cancer stage shift.
Methods or Background: Three linked evaluations across five hospitals used a commercial AI system (Annalise CXR Enterprise v2.3): (1) a before–after analysis of 56,257 CXRs (2022–2024) assessing time to CT for suspected lung cancer after AI triage to a same-day CT pathway; (2) a prospective silent trial with failure analysis of normal CXR deprioritisation in 63,083 adults (2023); and (3) a longitudinal comparison of lung cancer investigations and stage before (2022) and after AI deployment (2023) with 12-month follow-up.
Results or Findings: Mean time from CXR to CT report for suspected lung cancer fell from 6.0 to 3.6 days ($p<0.001$), with greatest gains at sites with co-located CXR and CT ($p<0.001$), without increasing CT utilisation. The AI demonstrated 82.5% sensitivity and 90.5% specificity for cancer features. For normal radiographs, AI enabled potential deprioritisation of 18.5% of exams, with a clinically significant miss rate of 0.05%. Despite faster pathways, early-stage lung cancer diagnoses (13 pre-AI vs 11 post-AI) and investigation volumes (177 vs 160) remained unchanged.
Conclusion: AI CXR triage can be safely deployed to accelerate lung cancer diagnostic pathways and reduce reporting burden without increasing imaging volume but does not affect lung cancer stage distribution. These findings provide critical real-world evidence informing national guidance and the clinical debate on the downstream impact of AI in cancer care.
Limitations: Observational design with limited power to detect stage shift; overall survival not assessed. Results reflect a specific AI system and thresholds, and may not generalise. Normal CXR detection used a proxy reference standard.

Association of Liver Fat Content with Major Adverse Cardiovascular Events in DISCHARGE and SCOT-HEART using the GUIDE-IT Data Sharing Platform (11 min)
Jakob Knape; Berlin / Germany

Author Block: J. Knape[1], S. Subramanian Parameswaran[2], B. Föllmer[1], M. Mohamed[1], K. Schulze[1], J. Bowden[3], A-C. Stahl[4], M. C. Williams[2], M. Dewey[4]; [1]Berlin/DE, [2]Edinburgh/UK, [3]Göttingen/DE, [4]Cambridge/UK
Purpose: We evaluated whether liver fat quantification on coronary CT could improve prediction of major adverse cardiovascular events (MACE) using data from two multicentre randomised trials on the GUIDE-IT image data sharing platform.
Methods or Background: From the multicentre randomised clinical imaging trials DISCHARGE and SCOT-HEART , we matched stable chest pain patients who had MACE during follow-up with patients without MACE for age, gender, diabetes, hypertension, hyperlipidaemia, and body mass index. All clinical patient data and images were uploaded to and analysed on the GUIDE-IT data-sharing platform. We used mean liver attenuation to assess steatosis and compared patients with and without MACE using a conditional logistic regression. The attenuation was measured in non-contrast CTs and if available in wide FOV.
Results or Findings: We included 217 patients (36% female, mean age 62.2±9.5 years) of whom 69 had MACE (42% female, 61.9±9.0 years). The mean liver attenuation for the non-MACE and MACE group was 55.5 HU (SD 15.4HU) and 53.1 HU (SD 20.1HU), respectively. The conditional logistic regression did not show a significant effect (OR per 10 HU increase = 0,913, P = 0.34).
Conclusion: In patients with stable chest pain, liver attenuation as a marker of hepatic steatosis was not independently associated with MACE. Opportunistic liver fat assessment on coronary CT may add prognostic value within a broader cardiometabolic risk framework.
Limitations: The number of patients with MACE and total sample size of this multicentre trial analysis was limited to 69 and 217, respectively. CT protocols were dedicated to coronary imaging and not liver imaging.
Funding for this study: Funding for GUIDE-IT was provided by the German Research Foundation (DFG, grant number: 495697118) to Prof. Marc Dewey.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The trials received institutional review board approval and written informed consent was obtained from all participants.

Diagnostic performance of an MRI-based AI device for Alzheimer's disease: a multicentre retrospective study of synthetic CSF biomarkers (11 min)

Arnaud Attye; Grenoble / France

Author Block: A. Attye[1], A. Garnier-Crussard[2], O. Piguet[3], A. Krainik[4], V. Brunel[5], H. Rabeh[1], F. Calamante[3], F. Renard[1], D. Wallon[5]; [1]GRENOBLE/FR, [2]69100 Villeurbanne/FR, [3]Sydney/AU, [4]Grenoble/FR, [5]Rouen/FR
Purpose: To evaluate the diagnostic performance of an MRI-based artificial intelligence (AI) medical device (BrainGML®-AD) that estimates synthetic cerebrospinal fluid (CSF) biomarkers for the detection of Alzheimer's disease (AD), using autopsy and CSF biomarkers as reference standards.
Methods or Background: This retrospective multicentre diagnostic accuracy study included 276 autopsy-confirmed cases (147 AD, 129 non-AD) from NACC and an Australian memory clinic, 115 cognitively unimpaired controls, and two independent CSF cohorts. BrainGML®-AD automatically analysed 3D T1-weighted MRI to estimate synthetic CSF phosphorylated tau-181 and amyloid-β42, generating a predefined pTau181/Aβ42 ratio and classifying subjects as AD-positive, AD-negative, or indeterminate (grey-zone). Primary outcomes were sensitivity and specificity for autopsy-confirmed AD. Secondary outcomes included specificity in controls and concordance with Elecsys® and ELISA CSF assays.
Results or Findings: A definitive classification was obtained in 222/276 autopsy cases (80.4%). Sensitivity for autopsy-confirmed AD was 93.1% (95% CI 87.2–96.5) and specificity 70.3% (95% CI 60.2–79.0), with an AUC of 0.86. Specificity in cognitively unimpaired controls was 91%. Concordance with CSF biomarkers was high: 97% in autopsied ADNI cases and 100% in a same-day MRI–CSF cohort. Grey-zone outputs (19.6%) mainly occurred in mixed or borderline pathology.
Conclusion: MRI-based AI can accurately detect AD pathology using routine structural imaging, with performance comparable to established CSF biomarkers. Grey-zone classification appropriately reflects biological uncertainty and may guide targeted confirmatory testing.
Limitations: Retrospective design and variable MRI–autopsy intervals limit causal inference.

Randomized trial of MRI-guided transurethral ultrasound ablation (TULSA) vs. radical prostatectomy for intermediate-risk prostate cancer: perioperative outcomes (11 min)

Katarzyna J. (Kasia) Macura; Baltimore / United States

Author Block: K. J. (. Macura[1], S. Raman[2], P. Ghanouni[3], D. Woodrum[4], R. Princenthal[5], T. Tirkes[6], A. S. Purysko[7], P. Mäkelä[8], D. Costa[9]; [1]Baltimore, MD/US, [2]Los Angeles, CA/US, [3]Stanford, CA/US, [4]Rochester, MN/US, [5]West Hills, CA/US, [6]Indianapolis, IN/US, [7]Cleveland, OH/US, [8]Turku/FI, [9]Houston, TX/US

Purpose: CAPTAIN (NCT05027477) is a randomized controlled trial directly comparing erections, urinary continence, and freedom from salvage treatment of MRI-guided transurethral ultrasound ablation (TULSA) vs robotic prostatectomy (RP) for intermediate-risk localized prostate cancer. Here we report baseline characteristics and perioperative outcomes.
Methods or Background: Patients were randomized 2:1 (TULSA:RP), balancing key covariates and screening for intraprostatic calcifications >3mm (CT/MRI). RP was performed to local standard of care; TULSA included subtotal or whole-gland ablation. Perioperative blood loss, length of stay, and 30-day recovery are reported.
Results or Findings: CAPTAIN treated 211 patients (148 TULSA, 63 RP). At baseline, for TULSA vs RP, median (IQR) age was 63(58-68) vs 65(59-69) years (p=0.19), PSA 6.5(5.0-9.6) vs 7.3(5.7-9.8) ng/ml (p=0.50), and prostate volume 41(31-50) vs 35(29-47) cc (p=0.10). Distributions of histological grade group 2/3 prostate cancer were 76%/24% vs 78%/22% (p=0.82). Intraprostatic calcifications were absent/≤3mm/>3mm in 63%/18%/17% vs 65%/22%/11%, all p>0.05. TULSA treatment prescribed on intraprocedural MRI included subtotal (32%) and whole-gland (68%) ablation, covering 78(72-85)% of the gland. Nerve-sparing was noted for 95% of RP cases (89% bilateral, 6% unilateral). Intraprocedural blood loss was lower after TULSA vs RP, 0(0-0) vs 150(100-200) mL, as was peri-procedural length of stay, 0.3(0.2-0.3) vs 1.1(1.1-1.3) days, both p<0.001. Catheter duration was longer after TULSA, 13(11-15) vs 8(8-11) days. To 30 days, TULSA patients reported lower pain scores (NRS) and less decline in overall health (EQ-5D-5L).
Conclusion: CAPTAIN is the first fully-recruited randomized trial directly comparing safety and efficacy for ablation vs radical prostate cancer treatment. Perioperatively, TULSA had zero blood loss, no overnight stay, reduced post-procedure pain, and faster recovery to baseline activities and overall health vs robotic prostatectomy.
Limitations: One-year safety, three-year freedom from salvage treatment, and ten-year oncologic endpoints are pending additional follow-up.

7 Tesla MRI: pushing the limits of resolution, speed, and strength (10 min)
Suyash Mohan; Philadelphia, PA / United States

1. To describe the physical principles by which higher field strength improves SNR and spatial resolution.
2. To outline the main technical barriers (B1+ inhomogeneity, susceptibility, SAR) that remain unique to 7T.
3. To assess how these factors set the foundation for future translational and clinical use.

In-hospital 7T MRI for clinical use (10 min)
Tobias Granberg; Stockholm / Sweden

1. To illustrate specific technical solutions (gradients, parallel transmit, AI acceleration) that enable routine in-hospital 7T operation.
2. To evaluate the direct diagnostic impact in neurological disorders, including epilepsy and movement disorders.
3. To examine organisational and economic considerations of installing and running a hospital-based 7T service.

Neurodegenerative diseases at 7T (10 min)
Felix Tobias Kurz; Genf / Switzerland

1. To explain which microstructural and cortical features become accessible with 7T in neurodegeneration.
2. To demonstrate examples of disease-specific imaging markers, such as iron deposition and cortical lamination.
3. To analyse how these markers can translate into earlier diagnosis and better monitoring of the disease.

7 Tesla MRI and knee imaging: what else? (10 min)
Sana Boudabbous; Geneva / Switzerland

1. To characterise the unique technical and anatomical challenges of musculoskeletal imaging at 7T.
2. To present evidence of improved delineation of cartilage, ligaments, and menisci at ultra-high field.
3. To explore the integration of 7T MSK protocols into clinical workflows and patient management.

7MRI of the peripheral nerves (10 min)
Johann Malte Enno Jende; Heidelberg / Germany

1. To demonstrate the feasibility and added value of visualising peripheral nerves at 7T.
2. To distinguish imaging features of normal and diseased nerves in clinical and research settings.
3. To project future developments in sequence design and coil technology for peripheral nerve imaging.

Future clinical applications of 7T MRI (10 min)
Elke Ruth R Gizewski; Innsbruck / Austria

1. To identify clinical domains most likely to benefit from 7T in the coming decade.
2. To compare how UHF strengths may shift indications compared with existing 1.5T and 3T practices.
3. To anticipate technological and regulatory steps required for widespread adoption.

5T whole-body MRI scanner: a new alternative (10 min)

Feng Feng; Beijing / China

1. To outline the technical characteristics and current state of 5T MRI systems.
2. To highlight diagnostic advantages relative to 3T MRI.
3. To compare the performance and potential clinical niches of 5T versus 7T as a practical alternative.

Panel discussion: What new horizons will 7T and 5T MRI open? (18 min)

OF 20R - Mental health amongst radiographers: how to prevent and minimise the impact

Categories: Radiographers, Professional Issues, Management/Leadership
Date: March 7, 2026 | 14:00 - 15:00 CET
CME Credits: 1

Moderator:
Altino Jorge Conde Da Cunha; Cumieira / Portugal

Chairperson's introduction (5 min)
Altino Jorge Conde Da Cunha; Cumieira / Portugal

Mental health challenges in radiography (10 min)
Daniela Fonseca Ribeiro; London / United Kingdom

1. To identify common mental health challenges faced by radiographers in today's high-demand healthcare settings.
2. To understand the impact of workplace stressors, such as workload, emotional strain, and shift patterns on teams and specifically on radiographers' well-being and clinical performance.
3. To understand the need for systemic and individual-level support mechanisms.

Wellness under pressure: supporting the workforce (10 min)
Nuno Filipe Veloso Dias; Coimbra / Portugal

1. To understand the importance of proactive initiatives and strategies that promote staff wellness under high-pressure conditions.
2. To explore organisational role in fostering a supportive, mentally healthy environment.
3. To identify practical tools, proactive initiatives and leadership that contribute to staff retention and resilience.

Recognising burnout in radiography: early signs and preventative strategies (10 min)
Dávid Sipos; Pécs / Hungary

1. To recognise early warning signs and symptoms of burnout among radiographers.
2. To understand the personal and systemic factors that contribute to burnout, and introduce early interventions to prevent long-term psychological harm.
3. To explore the best evidence-based strategies to mitigate burnout in radiographic practice.

Coping with patient culture diversity and various needs (10 min)
Maria Cauchi; Birkirkara / Malta

1. To understand how cultural diversity in patient populations can contribute to workplace stress for radiographers.
2. To develop cultural competencies to reduce miscommunication and stress while maintaining emotional well-being.
3. To create coping mechanisms and strategies for managing diverse patient interactions with empathy.

Open forum discussion (15 min)

PC 20 - Enhancing patient care through the cultivation of personal soft skills

Categories: Professional Issues
ETC Level: ALL LEVELS
Date: March 7, 2026 | 14:00 - 15:30 CET
CME Credits: 1.5

Moderator:
Annemiek Snoeckx; Zandhoven / Belgium

Chairperson's introduction (5 min)

How to build strong communication abilities? (15 min)
Adrian Brady; Cork / Ireland

1. To understand the importance of communication in our work.
2. To learn ways of increasing direct radiologist-patient interaction.
3. To consider the need for clear communication with referrers in our reports.

Seeing me, not just the image: the importance of empathy and self-awareness (15 min)
Steve Ebdon-Jackson; Reading / United Kingdom

1. To understand the patient's experience beyond the clinical encounter.
2. To recognise the impact of empathy and emotional intelligence on building trust and improving patient outcomes.
3. To suggest small yet meaningful practices into daily radiology workflows that promote a more compassionate approach to care.

Interpersonal skills: teamplay in radiology (15 min)
Regina G.H. Beets-Tan; Amsterdam / Netherlands

1. To understand the value of collaboration and mutual respect within multidisciplinary teams.
2. To identify common challenges in team dynamics and strategies to manage conflict constructively.
3. To learn techniques to build psychological safety and a culture of support within radiology departments.

Panel discussion: How can soft skills be made part of our daily practice? (40 min)

RC 2000 - Breast complaints in the emergency department: imaging strategies and diagnostic pitfalls

Categories: Imaging Methods, Emergency Imaging, Breast

Machteld Keupers; Leuven / Belgium

Under pressure in the emergency department (ED): managing acute breast presentations and avoiding missed malignancy (15 min)
Serena Carriero; Milan / Italy

1. To recognise imaging findings of acute breast conditions that can present in the ED, including those that may mimic malignancy.
2. To differentiate benign from malignant breast conditions that can present in the ED, to avoid misdiagnosis of breast cancer in urgent care settings.
3. To formulate appropriate management plans, including necessary interventions and follow-up strategies, to ensure safe and effective care for patients with an acute breast condition.
4. To formulate appropriate management plans, including necessary interventions and follow-up strategies, to ensure safe and effective care for patients with an acute breast condition.

Emergencies in the breast department: when the unexpected happens in a planned setting (15 min)
Maria Adele Marino; Messina / Italy

1. To identify urgent clinical scenarios that may arise unexpectedly in breast clinics, including complications from routine procedures.
2. To discuss effective pathways for managing these emergencies safely and efficiently within a non-acute setting.
3. To highlight the importance of cross-speciality communication and collaboration in optimising patient outcomes during emergencies in planned care environments.

Breast implant complications in the emergency department: what radiologists must know (15 min)
Silvia Perez Rodrigo; Madrid / Spain

1. To recognise key imaging features of common and uncommon breast implant-related presentations that may occur in emergency settings.
2. To apply knowledge of implant types, surgical history, and clinical context to improve diagnostic accuracy and identify potential malignancies, including Breast Implant-Associated Anaplastic Large Cell Lymphoma (BIA-ALCL).
3. To evaluate the clinical urgency of implant-related cases and formulate appropriate management plans and follow-up pathways to ensure safe and timely care.

Panel discussion: Double trouble: the emergency department meets the breast clinic (10 min)

RC 2015 - Life with renal failure, dialysis with catheter and AV-fistula: imaging and treatment options

Categories: Interventional Radiology, Genitourinary, Vascular
ETC Level: LEVEL II+III
Date: March 7, 2026 | 14:00 - 15:00 CET

Catheter-based dialysis: diagnosis and treatment of SVC stenosis/occlusion (11 min)
Pankaj Sharma; Rishikesh / India

1. To understand the importance of central vein stenosis for dialysis patients.
2. To discuss minimally invasive treatment options for central vein stenosis.

Ultrasound shunt mapping and phlebography for AV-fistula planning (11 min)
Andrej Klepanec; Bratislava / Slovakia

1. To describe the relevant findings of shunt mapping and phlebography for surgical and endovascular AV-fistula planning.

Endovascular AV-fistula creation: tips and pitfalls (11 min)
Stavros C. Spiliopoulos; Athens / Greece

1. To describe available options for AV-fistula creation.
2. To provide tips and pitfalls for the procedure.
3. To highlight the importance of shunt surveillance.

Management of failing fistulas (11 min)
Lakshmi A Ratnam; London / United Kingdom

1. To highlight the relevance of early treatment of failing fistulas.
2. To discuss the different emerging treatment options for failing fistulas.

Q&A (11 min)

Nomogram based on interpretable machine learning model for predicting pathological response to neoadjuvant immunotherapy in locally advanced gastric and gastroesophageal junction cancer (6 min)
Mengying Xu; Nanjing / China

Author Block: M. Xu, Z. Zhu, S. Liu, Z. Zhou; Nanjing/CN
Purpose: To develop and validate a computed tomography (CT) radiomics-based interpretable machine learning nomogram for non-invasive assessment of pathological response to neoadjuvant immunotherapy in locally advanced gastric and gastroesophageal junction (G/GEJ) cancers.
Methods or Background: This study enrolled 103 patients with locally advanced G/GEJ cancer who received neoadjuvant immunotherapy, and patients were classified as responders (tumor regression grade [TRG] 0 + 1) and non-responders (TRG 2 + 3). Patients were randomly divided into the training cohort (n=72) and validation cohort (n=31) at the 7:3 ratio. Radiomics features were extracted from regions of interest, followed by feature reduction and selection. Machine learning algorithms were applied to construct radiomics models. The Shapley Additive Explanation (SHAP) method was utilized to improve the interpretability of models. Then, a nomogram model was established by combining the optimal radiomics and clinical models. Receiver operating characteristic curve, calibration curve, and decision curve analyses were performed for evaluation.
Results or Findings: The radiomics model based on the k-nearest neighbors algorithm achieved better efficacy for predicting pathological response to neoadjuvant immunotherapy, with areas under the curve (AUCs) of 0.831 and 0.720 in the training cohort and validation cohort, respectively. The SHAP plots visualized the contributions of radiomics features on model predictions. For clinical model, logistic regression analyses showed that the Borrmann type (odds ratio [OR]: 0.844) and tumor thickness of posttherapy (OR: 0.983) were independent predictors. The nomogram model integrating the optimal radiomics and clinical models achieved satisfactory performance in the training (AUC=0.856) and validation (AUC=0.748) cohorts. Decision curve analysis demonstrated the nomogram's clinical applicability.
Conclusion: The CT radiomics-based nomogram provides valuable performance for predicting pathological response to neoadjuvant immunotherapy in locally advanced G/GEJ cancers, which benefits clinical treatment strategies management.
Limitations: Not applicable.
Funding for this study: No funding was provided for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study received institutional review board approval and written informed consent was waived because of the retrospective nature of the study.

Spectral CT as a Surrogate for Tumor Perfusion Imaging: A One-Stop Scan for Evaluating Lymphovascular and Perineural Invasion in Gastric Cancer (6 min)
Tiezhu Ren; Lanzhou / China

Author Block: T. Ren; Lanzhou/CN
Purpose: Lymphovascular invasion (LVI) and perineural invasion (PNI) are independent risk factors for recurrence and metastasis in gastric cancer (GC), yet currently can only be assessed postoperatively. This study aimed to evaluate the correlation between spectral CT and CT perfusion parameters, and their combined value for preoperative prediction of LVI/PNI.
Methods or Background: Eighty-seven patients with pathologically confirmed gastric adenocarcinoma underwent a "one-stop" spectral and perfusion CT examination. Based on postoperative histology, patients were classified into LVI/PNI-positive (n=65) and negative (n=22) groups. Spectral parameters (effective atomic number [Zeff], iodine concentration [IC]) were measured in arterial (AP) and venous (VP) phases. Perfusion parameters including blood flow (BF), blood volume (BV), and mean transit time (MTT) were also obtained. Inter-observer agreement, parameter correlations, and diagnostic performance were analyzed using intraclass correlation coefficient, Spearman correlation, and receiver operating characteristic curves, with the F1 score applied to address group imbalance.
Results or Findings: The LVI/PNI-positive group showed significantly higher values in Zeff, IC, BV, and MTT (all $p<0.05$). Venous phase spectral parameters strongly correlated with BV (VP-Zeff: $r=0.746$; VP-IC: $r=0.751$; both $p<0.001$), while arterial phase parameters showed no significant correlation with perfusion metrics. The combined model of spectral and perfusion parameters demonstrated superior diagnostic efficacy (AUC=0.827, F1=0.892, sensitivity=89.2%, specificity=68.2%) compared to individual parameters.
Conclusion: Spectral CT parameters, particularly venous phase IC, show strong correlation with perfusion parameters such as BV. The combination of spectral and perfusion data from a "one-stop" examination significantly improves the preoperative evaluation of LVI and PNI in gastric cancer, offering a promising approach for enhancing clinical decision-making.
Limitations: The study is limited by its single-center design, relatively small sample size, and imbalance between positive and negative groups, which may affect generalizability.
Funding for this study: Not application.

Diagnostic value of spectral CT-derived extracellular volume fraction for gastric cancer: preoperative staging, histologic differentiation, and peritumoral invasion (6 min)

Jiaqi Liu; Nanchang / China

Author Block: J. Liu[1], B. Fan[1], Y. Liao[2], X. Li[1], W. Deng[2]; [1]Nanchang/CN, [2]Guangzhou/CN
Purpose: Extracellular volume fraction (ECV) derived from spectral CT has been proposed as a potential imaging biomarker reflecting tumor stromal characteristics. This study aim to investigate the diagnostic value of spectral CT-derived ECV for preoperative gastric cancer staging, histological differentiation and peritumoral invasion.
Methods or Background: Eighty-six patients with surgically resected and pathologically confirmed gastric cancer were prospectively enrolled. Pathological results served as the reference standard, and patients were grouped according to: T stage (T1–2, n=30 vs T3–4, n=56), N stage (negative, n=31 vs positive, n=55), perineural and vascular invasion (negative, n=35 vs positive, n=51), and histologic differentiation (low differentiation, n=49 vs moderate–high differentiation, n=37). Delayed-phase images were acquired 180 seconds after contrast injection. Regions of interest (ROIs) were manually delineated and ECV values calculated based on iodine concentration. Receiver operating characteristic (ROC) analysis was performed to evaluate the diagnostic efficacy of ECV in different pathological groups.
Results or Findings: ECV showed limited diagnostic performance for discriminating histologic differentiation (AUC=0.602, 95%CI:0.461-0.740), but demonstrated good diagnostic value for predicting T stage (AUC=0.852, 95%CI: 0.747-0.946), lymph node metastasis (AUC=0.827, 95%CI: 0.727-0.927) and perineural/vascular invasion (AUC=0.821, 95%CI: 0.726-0.916). These findings suggest that ECV predominantly reflects tumor stromal features, with advantages in assessing tumor- and peritumoral infiltration in gastric cancer.
Conclusion: Delayed-phase ECV derived from spectral CT may serve as a non-invasive imaging biomarker for gastric cancer aggressiveness, particularly for tumor infiltration, lymph node metastasis, and perineural/vascular invasion, while its value for assessing histologic differentiation is limited.
Limitations: This single-center retrospective study with a limited sample size did not include subgroup analyses, which may affect the stability and generalizability of the results.

Impact of baseline CT-assessed sarcopenia on survival in patients with locally advanced gastric cancer undergoing neoadjuvant chemotherapy and surgery (6 min)

Ilaria Cecchi; Firenze / Italy

Author Block: I. Cecchi, D. Cozzi, G. Angeluzzi, E. Buttitta, D. Rossini, D. Lavacchi, L. Antonuzzo, V. Miele; Firenze/IT
Purpose: The aim of this study is to investigate if CT assessment of baseline sarcopenia could be considered as a prognostic factor for overall survival (OS) and relapse-free survival (RFS) in a population of 133 patients with locally advanced gastric cancer recruited from Careggi Hospital, Florence.
Methods or Background: We included 133 patients with a diagnosis of locally advanced gastric cancer who underwent the same neoadjuvant chemotherapy followed by surgery. Skeletal muscle cross-sectional area at the third lumbar vertebra (L3) was measured using 3D Slicer software on non-contrast-enhanced CT scan performed before neoadjuvant therapy. Different cut-off points for men and women were used to classify individuals as sarcopenic or non-sarcopenic.
Results or Findings: Sarcopenia was identified in 26.3% of patients. Median OS was numerically different between sarcopenic and non-sarcopenic patients (59.0 vs 67.3 months); in the same way, RFS was numerically lower in sarcopenic subjects compared with non-sarcopenic ones (38.0 vs 51.0 months). Nevertheless, no statistically significant differences in survival outcomes were observed between the two groups.
Conclusion: Baseline sarcopenia, as assessed by CT, was not associated with a significant difference in OS or RFS among patients with locally advanced gastric cancer undergoing neoadjuvant chemotherapy and surgery.
Limitations: The limitations of the study are the small and heterogeneous population. Moreover, sarcopenia was examined only at baseline. Future studies should expand the patient cohort, assessing sarcopenia at the end of neoadjuvant therapy to evaluate longitudinal changes and considering a multivariate analysis including socio-demographic and clinical variables.
Funding for this study: No funding was received for this study.

VIGA: A virtual gastric analysis tool for MRI-based assessment of stomach structure and function (6 min)

Esben Bolvig Mark; Aalborg / Denmark

Author Block: D. Liao[1], E. B. Mark[1], M. B. Poulsen[1], L. Davidsen[1], V. Rosca[2], V. Drug[2], C. Brock[1], J. B. Frøkjær[1], A. M. Drewes[1]; [1]Aalborg/DK, [2]Iasi/RO
Purpose: Traditional techniques for evaluating gastric physiology, such as scintigraphy and gastric manometry, face noteworthy limitations, especially in capturing the dynamic behaviour of the stomach wall during phases of filling and emptying. To overcome these challenges, we introduce VIGA (VIrtual GAster), a novel integrated analytical platform that leverages Magnetic Resonance Imaging (MRI) to quantify stomach geometry and motility.
Methods or Background: VIGA and its standardized analytical pipeline were developed and applied to static and dynamic MRI datasets from 12 healthy participants following the consumption of a 600 ml liquid test meal (300 kcal). This enabled comprehensive assessment of stomach morphology and wall dynamics. Morphological analysis involved measuring the volume and surface geometry of the fundus, corpus, and antrum. Motility was characterized through a detailed motility map, from which contraction frequency, amplitude, and propagation speed were extracted.
Results or Findings: The mean volume of the entire stomach was 785.7 ± 220 ml after the test meal, where the gastric liquid volume was 464.1 ± 59 ml. The mean contraction frequency was 2.83 ± 0.06 cycles per minute. The analysis identified distinct regional differences in contraction patterns, with the distal stomach showing significantly greater contraction occlusion (15.8±4.0%) compared to the proximal region (8.9±4.0%, $p<0.001$). Furthermore, contraction propagation speed tended to be higher in the distal stomach (4.87±1.7 mm/s) than in the proximal (4.01±0.9 mm/s, $p=0.07$). Surface geometry also varied across compartments, with the fundus exhibiting the highest inverse mean curvature, an indicator of the ratio between wall tension and intragastric pressure ($p=0.003$).
Conclusion: VIGA offers a robust, non-invasive imaging-based framework for evaluating gastric function, with promising implications for enhancing clinical assessment of gastric disorders.
Limitations: The subjects were investigated in supine position, negating the effects of gravity in the gastric content.
Funding for this study: This study was supported by the North Denmark Region's Health Innovation Fund.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the regional ethics committee (N-20220059).

AI-driven Inference of Tumor Response to Neoadjuvant Treatment for Adenocarcinomas of the Gastrosophageal Junction (AEG) from CT Imaging (6 min)

Lukas Endrös; Munich / Germany

Author Block: L. Endrös[1], T. Susetzky[2], P. Jiraskova[2], L. Steinhelfer[2], P-A. Neumann[2], M. R. Makowski[2], R. Braren[1]; [1]Hamburg/DE, [2]Munich/DE
Purpose: To assess whether AI-extracted features from CT imaging can differentiate responders from non-responders to neoadjuvant treatment in AEG and to compare the prognostic value of this approach with using manually derived tumor characteristics.
Methods or Background: We retrospectively analyzed a cohort of over 300 patients with AEG and available CT imaging prior to and, where applicable, after neoadjuvant therapy. For each case, an experienced radiologist selected a tumor-representative slice. Following manual segmentation of the tumor in pre-treatment scans, a state-of-the-art AI model was trained in a fully supervised manner and subsequently applied to post-treatment scans for automatic segmentation, followed by manual correction. A separate AI model was trained for binary response prediction on extracted tumor regions. We evaluated model performance when using both pre- and post-therapy images versus either alone.
Results or Findings: Prior work has demonstrated that the median HU difference between tumor and esophageal wall significantly differentiates responders (29.44 ± 10.44) from non-responders (62.47 ± 22.29) in post-treatment scans, while pre-treatment imaging features show no predictive value. Our findings confirm the limited utility of pre-treatment imaging, whereas our AI model achieved an average accuracy of 0.62 and an AUC of 0.65 on post-treatment scans.
Conclusion: Consistent with prior studies, our results suggest that pre-treatment CT imaging provides no significant predictive value for therapy response in AEG. However, we discover exemplarily that an AI-based processing and analysis scheme can, in some cases, differentiate responders from non-responders in post-treatment imaging following neoadjuvant chemotherapy.
Limitations: Limitations include retrospective design and need for external validation.
Funding for this study: No funding was provided for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Approved by the TUM Ethics Committee (approval no. 87_18S: ‘Anwendungsmöglichkeiten von Machine Learning für die diagnostische Bildgebung’).

Reproducibility of CT Classification for the esophageal and gastric lesions in patients with caustic Ingestions: A Retrospective Analysis in a Specialized Treatment Center (6 min)

Gabriele Rinaldi; Verona / Italy

Author Block: G. Rinaldi, M. C. Ambrosetti, M. Bariani, E. Strazimiri, G. Zamboni, S. Giacopuzzi, J. Weindelmayer, M. Sacco, G. Puppini; Verona/IT
Purpose: Although in the case of caustic ingestion treatment is usually based on endoscopic evaluation (Zargar classification), CT could provide an accurate assessment and potentially reduce overtreatment. Our aim was to assess reproducibility and effectiveness of a CT-based classification of caustic injuries in a specialized center, for predicting need for emergency intervention and long-term complications.
Methods or Background: five radiologists and six surgeons blinded to patient outcomes independently reviewed CT of 36 patients admitted to the Emergency Department between 2014-2025 for caustic ingestion and who underwent endoscopy, applying the 3-grade score by Chirica: grade I (regular), grade IIA (thickened, hypointense and vascularized mucosa, wall/perivisceral fat tissue edema), grade IIB (necrotic mucosa with slight external wall enhancement), grade III (transmural necrosis/lack of wall enhancement) for both esophagus and stomach. Kendall’s Kappa inter-operator concordance and CT sensitivity and specificity for each physician were calculated for emergency treatment (grade III) and stenosis risk (grades IIa-IIb), comparing these results to the Zargar classification.
Results or Findings: for emergency treatment (Zargar III), mean sensitivity was 37.1% for esophagus evaluation, 30.2% for stomach, and 34.2% for both, with the best performance reached by the radiologist for esophageal evaluation (SE38.4%). For stenosis prediction (Zargar IIA-IIB), the mean sensitivity was 69% for esophagus evaluation, 59.7% for stomach, and 68% for both, with the best performance reached by both radiologist and surgeon for stomach evaluation (SE100%).
Interobserver concordance was higher for radiologists than for surgeons (k=0.867-0.895 vs k=0.198-0.573).
Conclusion: CT classification, compared to endoscopic evaluation, is not sensitive enough for predicting the need for emergency surgery. Sensitivity is higher for risk of stenosis. While CT offers a promising alternative by potentially reducing overtreatment and predicting long-term complications, the interobserver variability highlights the need for standardization.
Limitations: Retrospective study
Funding for this study: None

CT-based topographical classification of anastomotic leakage after Ivor Lewis esophagectomy: prognostic implications and pathophysiology insights (6 min)

Gaia Veneziano; Milan / Italy

Author Block: G. Veneziano, D. Palumbo, S. Battaglia, C. Sarzo, U. Elmore, R. Rosati, F. De Cobelli, F. Puccetti, A. COSSU; Milano/IT
Purpose: Anastomotic leakage (AL) remains the most feared complication after Ivor Lewis esophagectomy, with significant morbidity/mortality and difficult, non-standardized, management. CT-based topographical characterization of AL may provide crucial insights into its pathogenesis, clinical course, and prognosis, potentially guiding risk stratification and therapeutic decisions.
Methods or Background: This is a single-center retrospective analysis of 85 consecutive patients who underwent Ivor Lewis esophagectomy (01/2015-12/2024) and performed contrast enhanced CT scan because of AL development. ALs were classified into four topographical subtypes based on CT findings: left-anterior, right-anterior, left-posterior, right-posterior. Radiological features (perianastomotic collections, air within collections, pleural effusion, pneumothorax, pneumomediastinum) and clinical outcomes were analyzed using bivariate and multivariate regression models; the course of right gastroepiploic arteries was also noted.
Results or Findings: The most common subtype of AL was found to be the left-anterior one (40%), followed by right-anterior (20%), left-posterior (14%), and right-posterior (11%). Most ALs manifested within eight postoperative day (72%). Left-anterior leaks demonstrated strongest association with perianastomotic collections containing air ($p<0.001$) and significantly correlated with respiratory and circulatory complications. Multivariate analysis revealed left-anterior leaks as independent predictors of severe outcomes (Clavien-Dindo 4b-5; $p<0.001$), with highest mortality rates predominantly from respiratory failure. Notably, the left-anterior position corresponds to the region opposite to the right gastroepiploic artery vascular territory, potentially representing an area of relative hypoperfusion.
Conclusion: CT-based topographical classification of AL after Ivor Lewis esophagectomy provides valuable prognostic stratification. The predominance and severity of left-anterior leaks may reflect underlying vascular vulnerability mechanisms that warrant further investigation. These findings underscore the need for targeted preventive strategies, including enhanced intraoperative vascular assessment and potentially modified surgical techniques focusing on this high-risk anatomical region
Limitations: Small sample of patients in one high-volume center and need for standardization of indications.
Funding for this study: None

Radiologic Assessment of Esophagogastric Junction Outflow Obstruction: Diagnostic Accuracy of Timed Barium Esophagogram (6 min)

Vittorio Patanè; Naples / Italy

Author Block: V. Patanè, P. Senneca, M. C. Brunese, G. Sarnelli, R. Grassi, S. Cappabianca, A. Reginelli; Naples/IT
Purpose: Esophagogastric junction outflow obstruction (EGJOO) according to Chicago Classification v4.0 requires manometric, clinical, and supportive evidence of impaired bolus transit. Timed barium esophagogram (TBE) is a widely available imaging test providing objective evidence of functional relevance. This study evaluated the diagnostic performance and reproducibility of standardized TBE in suspected EGJOO.
Methods or Background: In this prospective single-center study, 124 consecutive patients underwent standardized TBE for esophageal emptying assessment. Examinations were performed and interpreted blinded to symptoms and high-resolution manometry (HRM). Barium column height and width were measured at 1, 2, and 5 minutes after ingestion of low-density barium sulfate. HRM, performed according to CCv4.0, served as the reference. Interobserver agreement between a senior radiologist and a junior resident was assessed.
Results or Findings: TBE was positive in 20 patients (16%), all with functionally relevant EGJOO (FR-EGJOO) on HRM. The mean barium column height at 1 minute was 122.9 ± 65.4 mm, decreasing to 89.0 ± 54.6 mm at 2 minutes. Residual barium at 5 minutes occurred in eight patients, all with the largest 1-minute dimensions. Compared with HRM, TBE showed specificity and positive predictive value of 100%, sensitivity of 31%, and negative predictive value of 58%. Interobserver agreement was excellent.
Conclusion: Standardized TBE is a highly specific and reproducible tool for confirming the functional relevance of EGJOO diagnosed by CCv4.0. Although sensitivity is modest, a positive TBE strongly correlates with manometric findings and helps differentiate EGJOO from achalasia. Integration into the diagnostic pathway supports accurate patient stratification and may avoid unnecessary treatment.
Limitations: Being a single-center study with relatively few positive cases may limit generalizability. Moreover, suboptimal sensitivity could underestimate EGJOO in milder presentations. Larger multicenter cohorts are required to validate findings and refine cutoff values.
Funding for this study: This research received no external funding
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was conducted in accordance with the Declaration of Helsinki (as revised in 2013). The study's protocol was approved by the local ethics committee at the University Hospital of Campania "L. Vanvitelli" and AORN "Ospedale dei Colli".

Imaging in Gastric Cancer Staging: The Emerging Role of Magnetic Resonance and Advanced Techniques (6 min)

Giovanni Balestrucci; Trani / Italy

Author Block: G. Balestrucci[1], M. Brunese[1], V. Patanè[2], N. Giordano[2], M. Alessandrella[2], S. Cappabianca[2], A. Reginelli[2]; [1]Campobasso/IT, [2]Naples/IT

Purpose: To summarize the current role of imaging modalities in gastric cancer staging and highlight the emerging potential of magnetic resonance imaging (MRI) with advanced functional sequences and artificial intelligence (AI) applications.

Methods or Background: A systematic literature search was conducted in PubMed using predefined search strings. We included systematic reviews and meta-analyses published from January 2020 to December 2024 focusing on imaging techniques for gastric cancer staging. About 30 studies met the inclusion criteria, covering CT, PET/CT, endoscopic ultrasound, MRI, and AI-based approaches.

Results or Findings: Computed tomography (CT) remains the reference technique for baseline staging, although it has limited sensitivity in assessing tumor wall invasion (T-staging) and in detecting peritoneal metastases. PET/CT improves distant staging accuracy; innovative tracers such as Ga-FAPI have demonstrated significantly higher sensitivity than FDG-PET, particularly for peritoneal and nodal metastases. EUS remains the most accurate method for local T-staging and nodal sampling, but its performance is strongly operator-dependent.

Magnetic resonance imaging is emerging as a promising complementary tool, with DWI enabling improved differentiation between malignant and non-malignant tissues and perfusion MRI providing insights into tumor vascularity and microenvironment. Several studies reported superior accuracy of MRI compared to CT for local staging and prediction of treatment response. AI and radiomics approaches further expand diagnostic potential, showing promise in predicting tumor aggressiveness and therapy response.

Conclusion: MRI, especially when combined with functional sequences and AI, represents an emerging complementary modality for gastric cancer staging. It has the potential to improve diagnostic accuracy, refine patient stratification, and support personalized surgical and oncological management.

Limitations: Evidence remains limited, with heterogeneous imaging protocols and few prospective multicenter studies. Larger standardized investigations are warranted to validate the clinical role of MRI and AI in gastric cancer staging.

The influence of a myocardium-specific reconstruction filter on myocardial texture analysis in static spectral cardiac CT perfusion (6 min)
Lennart Roelof Koetzier; Utrecht / Netherlands

Author Block: L. R. Koetzier[1], N. R. van der Werf[2], P. M. Tetteroo[1], B. K. Velthuis[1], D. Suchá[1]; [1]Utrecht/NL, [2]Best/NL
Purpose: To evaluate the effect of a myocardium-specific reconstruction filter on myocardial texture analysis in static spectral cardiac CT perfusion.
Methods or Background: In this retrospective single-center study, 108 patients underwent prospective ECG-triggered coronary CT angiography (CCTA) with spectral dual-layer CT to assess coronary artery disease. Images were reconstructed using two filters (coronary-optimized CB, myocardium-specific MCA), and conventional 120 kVp and iodine density images at 3-mm slice thickness. The left ventricular myocardium was automatically segmented, with intensities normalized and quantized to 64 gray-levels. Texture analysis included six histogram-based features (intensity distribution, ignores spatial context) and three gray-level co-occurrence matrix features (GLCM; captures relationships between neighboring voxels). MCA was compared against CB on conventional and iodine density images using paired Wilcoxon signed-rank tests with Benjamin-Hochberg correction ($\alpha=0.05$) and reported as median difference divided by the interquartile range per feature across patients.
Results or Findings: Eighteen patients were excluded with insufficient quality CCTA. Ninety-two patients were analyzed. On conventional images, the MCA filter significantly altered all texture features compared to CB. The largest effects were seen for entropy (−2.71), contrast (−2.12), and homogeneity (+4.10), whereas mean intensity (+0.02) and skewness (+0.43) showed only small effects. On iodine density images, the impact of the MCA filter was more pronounced. Strongest effects were observed for entropy (−5.99), variance (−3.83), kurtosis (+4.74), and homogeneity (+6.07). In contrast, mean intensity (−0.03) and correlation (−0.73) were minimally affected.
Conclusion: The MCA filter significantly increased myocardial homogeneity on conventional and iodine density images. Although MCA reduces noise and improves homogeneity, it simultaneously changes texture. Standardized reconstruction choices are therefore necessary when applying texture analysis for myocardial characterization in cardiac CT.
Limitations: This retrospective single-center study did not assess the impact of reconstruction protocols on myocardial disease detection.

Reproducibility of 4D flow MRI derived diastolic function testing by mitral and pulmonary venous flow indices (6 min)
Thomas In De Braekt; Eindhoven / Netherlands

Author Block: T. in de Braekt[1], P. R. Roos[2], H. van den Bosch[1], H. J. Lamb[2], J. Westenberg[2]; [1]Eindhoven/NL, [2]Leiden/NL
Purpose: To investigate scan-rescan reproducibility of mitral valve (MV) and pulmonary vein (PV) flow velocities using 4D flow MRI in healthy volunteers for diastolic function assessment.
Methods or Background: Twenty-one volunteers (mean age 27 ± 3 years) underwent whole-heart 4D flow MRI at 3T twice with a 10-minute interval, allowing repositioning. One group (n=11) was scanned during free-breathing without respiratory motion compression, while the other (n=10) used weighted-gating respiratory motion compensation, with an additional 4D flow acquisition without respiratory motion compensation. MV parameters included E wave, A wave, E/A ratio, annular e' velocity, and E/e' ratio. PV velocities included S wave, D wave, S/D ratio, and AR wave. Parameters were derived from flow velocity-time curves and compared between acquisitions using Pearson's correlation coefficient (ρ). Due to spatial resolution limitations and anatomical variation, PV flow was measured in the same PV (preferably right inferior PV) per volunteer. Subanalysis in the second group compared the effect of respiratory weighted-gating versus free-breathing on flow measurements. Intra- and interobserver agreement was assessed with intraclass correlation coefficient (ICC).
Results or Findings: Scan-rescan comparison showed moderate-to-good agreement for MV parameters (ρ=0.51–0.74), except e' velocity and E/e' ratio (ρ=-0.13 and -0.14, respectively). PV flow velocities showed strong reproducibility (ρ=0.88–0.92), except AR wave (ρ=0.47). Subanalysis showed moderate-to-strong agreement for MV parameters (ρ=0.69–0.92), and good-to-excellent agreement for PV parameters (ρ=0.82–0.99). Intraobserver agreement was moderate-to-excellent for MV and PV parameters (ICC=0.62–0.97), except S/D ratio (ICC=0.48). Interobserver agreement was moderate-to-excellent for MV parameters (ICC=0.59–0.94), and poor for PV parameters (ICC=-0.12–0.33).
Conclusion: For most diastolic flow parameters, 4D flow MRI demonstrated moderate-to-excellent reproducibility, with or without respiratory motion compensation, supporting its potential for diastolic function assessment.
Limitations: Data was not compared to gold standard echocardiography.

Myocardial Stress CMR Perfusion to Differentiate between Athlete's Heart and Ischemic and Nonischemic Cardiomyopathies: The MYO-SPORT Study (6 min)

Cesare Mantini; Chieti / Italy

Author Block: C. Mantini, C. Di Barbora, D. Costantini, S. Paolini, F. Ricci; Chieti/IT
Purpose: To assess the incremental value of a stress CMR perfusion study in the diagnostic workup of master athletes with suspected cardiovascular pathology
Methods or Background: Between 2020–2024, we enrolled master athletes referred for stress CMR following abnormal sports pre-participation screening.All underwent vasodilator stress CMR with visual and semi-quantitative myocardial perfusion analysis.A multidisciplinary team adjudicated diagnoses as either normal heart (including exercise-induced cardiac remodeling) or abnormal heart (ischemic disease, non-ischemic left ventricular scar, or cardiomyopathy).Diagnostic performance was assessed using the area under the receiver operating characteristic curve (AUC) and global chi-squared statistics across sequential models:baseline function/volumes,baseline+LGE (model 1),model 1+visual perfusion (model 2),model 2+myocardial perfusion reserve index (MPRI) (model 3)
Results or Findings: We enrolled 68 recreational master athletes (57±11 yo, 82% male),with 18(26%) training more than 8 hours per week.Referral reasons included chest pain(47%),premature ventricular contractions (18%),abnormal ECG (16%),abnormal exercise stress testing (11%),and abnormal resting echocardiography (8%).Vasodilator stress CMR was performed using regadenoson(57%),adenosine(42%), or dipyridamole(1%).The final adjudicated diagnosis classified 26 (38%) cases as having a normal heart, while42(62%) were diagnosed with heart disease,including ischemic heart disease(n=24),nonischemic left ventricular scar(n=10), and cardiomyopathy(n=8).LGE was present in 53% of cases,and stress-induced myocardial perfusion defects were visually identified in 17%.Myocardial perfusion reserve index was lower in abnormal hearts compared to normal hearts(1.6±0.3vs1.3±0.3;p<0.001), yielding alone an AUC of 0.76 with best cut-off of 1.29.The diagnostic yield improved with sequential imaging integration:baseline assessment had limited discrimination(AUC 0.67),+LGE(AUC 0.87),+visual stress perfusion(AUC 0.93),+MPRI(AUC 0.97).The global chi-squared statistic increased stepwise from 7.4 to 49.5 across models ($p < 0.0001$ for all comparisons).At a median follow-up of 31 months,no deaths occurred
Conclusion: Stress CMR perfusion provides significant incremental value in distinguishing physiological remodeling from ischemic and nonischemic disease in master athletes with abnormal pre-participation screening
Limitations: Small sample size

Dynamic stress CT perfusion for ischemia detection in non–infarct-related intermediate coronary stenoses: comparison with instantaneous wave free ratio (6 min)

Vladimir Meshkov; Moscow / Russia

Author Block: Z. Magomedova, V. Meshkov, E. Pershina, M. Serova, E. Ploschenkov; Moscow/RU
Purpose: Dynamic stress CT myocardial perfusion imaging (CT MPI) combines anatomic and physiologic coronary assessment in a single test. Its performance in patients with prior myocardial infarction (MI) and residual, non–infarct related artery (non IRA) stenoses is not well defined. We evaluated CT MPI against invasive instantaneous wave free ratio (iFR) in post MI patients with visually intermediate non IRA stenoses.
Methods or Background: 61 consecutive post PCI MI patients with at least one 50–90% non IRA stenosis underwent adenosine (160 $\mu g \cdot kg^{-1} \cdot min^{-1}$) stress and rest dynamic CT MPI (16 cm coverage; Revolution CT, GE Healthcare) with 10 minute delayed iodine enhancement for scar detection, followed by invasive angiography with selective iFR in 50–90% lesions. Hemodynamically significant stenosis was defined as iFR <0.90. Voxel based quantitative myocardial blood flow (MBF) maps were generated; MBF <100 $mL \cdot min^{-1} \cdot 100\ mL^{-1}$ was considered abnormal. Diagnostic performance was calculated per vessel using iFR as reference and per patient.
Results or Findings: Hemodynamically significant stenoses by iFR were present in 21/61 patients (34%). Delayed enhancement identified postischemic scar in 48/61 (79%). Against iFR, CT MPI yielded per vessel sensitivity 99%, specificity 97%, and accuracy 98%; per patient - 97%, 90%, 94%. Hemodynamically significant stenoses by iFR were present in 21/61 patients (34%). Delayed enhancement identified postischemic scar in 48/61 (79%). CT MPI yielded per vessel sensitivity 99%, specificity 97%, and accuracy 98%; per patient sensitivity 97%, specificity 90%, and accuracy 94%. Three patients (5%) with iFR ≥0.90 showed regional hypoperfusion with reduced MBF, consistent with microvascular dysfunction.
Conclusion: Whole heart dynamic stress CT MPI demonstrates excellent vessel level sensitivity and specificity and high patient level accuracy for detecting functionally significant non IRA stenoses in post MI patients when benchmarked to iFR.

Development and validation of a computed tomography myocardial perfusion imaging radiomic model for major adverse cardiovascular events prediction: a multicenter study (6 min)

Zhiqi Zhong; Shanghai / China

Author Block: Z. Zhong, J. Zhang; Shanghai/CN
Purpose: This study aimed to develop a combined model, including clinical risk factors, coronary atherosclerotic characteristics, and radiomic features derived from CT myocardial perfusion imaging (CT-MPI), to predict major adverse cardiovascular events (MACEs).
Methods or Background: Accurate prediction of MACEs is crucial for risk stratification in patients with suspected coronary artery disease. CT-MPI provides various parameters, which may help comprehensively characterize perfusion features. 712 patients who underwent coronary CT angiography (CCTA) and CT-MPI from seven hospitals were enrolled. Radiomic analysis was performed on eight perfusion parameter maps. Three prediction models were established accordingly: Model 1 (clinical risk factors and coronary atherosclerotic characteristics), Model 2 (incorporating myocardial blood flow values upon Model 1), and Model 3 (integrating radiomic scores upon Model 2).
Results or Findings: The C-indices for Model 3 in the training, internal validation, and external validation sets were 0.901 (95% confidence interval [CI]: 0.856–0.947), 0.841 (95% CI: 0.783–0.899), and 0.832 (95% CI: 0.761–0.903), respectively, demonstrating significant improvements over Model 1 and Model 2 (all $p < 0.05$). In the external validation set, Model 3 had the largest time-dependent areas under the curve (AUC) values for 1-, 3-, and 5-year MACEs prediction (0.878 [95% CI: 0.775-0.981], 0.851 [95% CI: 0.756-0.946], and 0.747 [95% CI: 0.603-0.891]), compared to Model 1 and Model 2.
Conclusion: The radiomic features from multiparametric CT-MPI maps simultaneously captured perfusion features associated with MACEs at both macrovascular and microvascular levels. The combined model exhibited superior MACEs prognostic performance compared with conventional models while maintaining high interpretability.
Limitations: Studies involving patients at lower pretest probability of obstructive CAD and multivendor CT-MPI data are needed to confirm the utility and reproducibility of the radiomic model for MACEs prediction in broader populations and different scanner platforms or protocols.

Effects of metabolic syndrome and its components on myocardial microcirculation in obstructive coronary artery disease patients evaluated by first-pass perfusion CMR study (6 min)

Chenyan Min; Chengdu / China

Author Block: C. Min, Y. Gao, Y. Jiang, Y. Li, Y. Zhigang; Chengdu/CN
Purpose: Metabolic syndrome (MetS) can increase the risk of morbidity and mortality of obstructive coronary artery disease (OCAD). This study aimed to explore the impact of MetS and its components on myocardial microvascular dysfunction in OCAD patients by first-pass perfusion cardiac magnetic resonance.
Methods or Background: 127 patients with OCAD{ [OCAD(MetS+), n = 86] and [OCAD(MetS−), n = 41]} and 46 sex- and age-matched controls were enrolled in the study. CMR perfusion parameters, including Upslope, max signal intensity (MaxSI), and time to maximum signal intensity (TTM) in global, left anterior descending arterial (LAD), left circumflex coronary arterial (LCX), and right coronary arterial (RCA) perfusion segments were compared among observed groups. Univariable and multivariable regression analyses were used to investigate the correlations of MetS and perfusion parameters. Lasso regression analysis was used to evaluate the effect of MetS components on CMR perfusion parameters.
Results or Findings: Compared with the OCAD(MetS-) group, Upslope decreased in global, LAD, LCX and RCA perfusion segments (all $p < 0.05$). The MaxSI reduced in the OCAD(MetS+) group in global, LAD and LCX perfusion segments(all $p < 0.05$)., From the controls to the OCAD(MetS-)group to the OCAD(MetS+) group, the TTM sequentially prolonged in global (all $p < 0.05$).After adjustment for covariates in OCAD patients, MetS was an independent factor of upslope(g) (β=−0.309, p<0.001), MaxSI (g) (β=−0.200, p=0.023)and TTM(g) (β=0.206, p=0.014). Besides, MetS was independently associated with Upslope(LAD), Upslope(LCX) , and Upslope(RCA) (all $p < 0.05$). Based on the lambda.1se threshold, High density lipoprotein cholesterol(HDL) were ultimately selected as significant predictors in Upslope(g) and MaxSI(g).
Conclusion: MetS aggravated the myocardial microcirculation perfusion dysfunction in OCAD patients. HDL, as a component of MetS, may be of great significance in patients with OCAD complicated with MetS.

Feasibility of stress myocardial perfusion imaging with photon-counting CT: Initial validation against reference modalities (6 min)

Benjamin Longere; Lille / France

Author Block: B. Longere[1], H. Caseneuve[1], C. V. Gkizas[1], A. Rodriguez Musso[1], C. Croisille[2], M. Haidar[1], F. A. Pontana[1]; [1]Lille/FR, [2]Bordeaux/FR
Purpose: To evaluate the feasibility and diagnostic performance of stress myocardial perfusion imaging (MPI) using a first-generation dual-source photon-counting CT (PCCT),compared to reference standards.
Methods or Background: Consecutive patients referred for coronary CT angiography (CCTA) with concomitant stress MPI using PCCT scanner and at least one functional reference test within one month were included. Static PCCT-MPI with regadenoson was acquired 12s after
intravenous injection of 40mL of iodine contrast medium and paired with myocardial delayed enhancement imaging. Reference tests for ischemia included stress cardiac magnetic resonance imaging, stress echocardiography, single-photon emission computed tomography, or invasive coronary angiography. Diagnostic accuracy was evaluated using ROC curve analysis and Youden index-derived thresholds.
Results or Findings: Forty-one patients (28 males, median age=62 years) were included; 35 (85.4%) had obstructive coronary artery disease (CAD) on CCTA. PCCT-MPI identified myocardial hypoperfusion in 18 patients (43.9%) with a median dose-length product of 97mGy.cm
(Q1, 76.8.0; Q3, 155.8mGy.cm). Visual assessment yielded 100% sensitivity (95%CI: 81.5–100.0%), 95.7% specificity (95%CI: 78.1–99.9%), PPV 94.7%, and NPV 100%, with an AUC of 0.98. An optimal defect-to-remote iodine ratio cutoff of 0.79 showed excellent accuracy (97.6%, AUC=0.995). Integration of PCCT-MPI with CCTA could have obviated additional functional testing or invasive angiography in up to 50% of patients with obstructive CAD.
Conclusion: Stress static PCCT-MPI is feasible and demonstrates excellent diagnostic accuracy for detecting myocardial ischemia. Defect-to-remote iodine ratio from spectral imaging further enhances performance, establishing PCCT as a comprehensive imaging modality that unifies anatomic and functional coronary assessment at a reasonable radiation dose, within a single examination.
Limitations: Retrospective, single-center study

Stress myocardial perfusion CT after arterial Switch for Transposition of the Great Arteries (6 min)

Christos Vasileiou Gkizas; Lille / France

Author Block: C. V. Gkizas[1], B. Longere[1], A. Rodriguez Musso[1], C. Croisille[2], O. Domanski[1], F. Godart[1], F. A. Pontana[1]; [1]Lille/FR, [2]Bordeaux/FR
Purpose: Coronary anomalies and neo-aortic root dilatation are recognized as late complications after the arterial switch operation for transposition of the great arteries (TGA), although most patients remain asymptomatic for many years.
The purpose of this study was to assess the feasibility and diagnostic performance of CT stress myocardial perfusion imaging (CT-MPI) compared with reference standards in patients with repaired TGA.
Methods or Background: Consecutive patients referred for clinically indicated coronary CT angiography (CCTA) underwent CT-MPI—either static with a photon-counting detector CT (PCCT) or dynamic with a third-generation dual-energy CT (DECT)— with regadenoson administration followed by myocardial late iodine enhancement. Within 1 month, each patient underwent ≥1 reference test (stress CMR, stress echocardiography, SPECT, or invasive coronary angiography). Visual analysis thresholds were derived from the Youden index. Radiation dose metrics were compared between scanners.
Results or Findings: Thirty patients were included (25 males; median age,= 30 years). Median neo-aortic diameter was 42 mm. CT-MPI detected hypoperfusion in 6/30 patients (20%), all of whom had obstructive coronary disease on CCTA. Diagnostic performance versus reference standards was excellent: sensitivity 85.7% (95% CI, 48.7–97.4), specificity 100% (95% CI, 85.7–99.9), positive predictive value 100%, and negative predictive value 95.8%. Integrating CT-MPI with CCTA could have obviated additional functional testing or invasive angiography in 23/30 patients (77%). Radiation dose was significantly lower with PCCT-MPI than with DECT-MPI (DLP −39%, CTDI −47%; $p < 0.05$).
Conclusion: CT stress perfusion is feasible and demonstrates excellent diagnostic performance in patients with repaired TGA and may represent a valuable tool for clinical decision-making during long-term follow-up.
Limitations: Single-center retrospective study

Automated liver T1-time assessment in cardiac MRI: Associations with cardiac structure and function in the NAKO study (6 min)

Johannes Jahn; Freiburg Im Breisgau / Germany

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: J. Jahn, H. Thomas, M-N. Von Itter, M. Reisert, S. Rospleszcz, C. Schuppert, C. L. Schlett; Freiburg Im Breisgau/DE
Purpose: Patients with cardiovascular disease often exhibit concomitant liver changes, yet their systematic evaluation in cardiac MRI remains limited. We developed and validated a deep learning approach for automated liver segmentation in cardiac T1 maps to investigate associations between liver T1 times and cardiac function within the German National Cohort (NAKO) study.
Methods or Background: A patchwork-based convolutional neural network (CNN) was trained on 323 manually annotated cardiac short-axis T1 maps spanning the mid of the left ventricle [LV] and independently tested on 68 cases. Segmentation performance was assessed using the Dice similarity coefficient and Pearson correlation with manual liver T1 measurements. Associations between automated liver T1 times and cardiac parameters (biventricular volumes, ejection fractions, stroke volumes, and LV mass) were analyzed using linear regression adjusted for age, sex, body mass index, liver fat, and liver iron. Restricted cubic spline (RCS) models tested for nonlinearity.
Results or Findings: The CNN achieved a Dice coefficient of 0.92 and excellent correlation with manual liver T1 segmentations ($r=0.95$). Among 26,662 participants (47.8±12.3 years, 46.8% female), median liver T1 values were higher in women (841±77 ms) than in men (787±97 ms, $p<0.001$). Higher liver T1 was strongly associated with smaller biventricular volumes, stroke volumes, LV mass, and lower ejection fractions (all $p<0.01$). For example, each 100 ms increase in liver T1 was associated with lower indexed LV end-diastolic volume ($\beta=-1.41$, $p<0.001$) and LV ejection fraction ($\beta=-0.17$, $p<0.01$). RCS analyses confirmed significant nonlinear relationships for most outcomes.
Conclusion: We present a robust deep learning approach for automated liver segmentation in cardiac T1 mapping. Liver T1 times are independently and nonlinearly associated with cardiac structure and function in a large cohort and may provide novel insights into cardio-hepatic interactions.
Limitations: No histological confirmation was performed.
Funding for this study: The NAKO is funded by the Federal Ministry of Research, Technology and Space (BMFTR) [project funding reference numbers: 01ER1301A/B/C, 01ER1511D, 01ER1801A/B/C/D and 01ER2301A/B/C], federal states of Germany and the Helmholtz Association, the participating universities and the institutes of the Leibniz Association.

Diagnostic value of mitral annular plane systolic excursion (MAPSE) in cardiac sarcoidosis: comparison with myocardial late gadolinium enhancement and ventricular function (6 min)

Eitibar Ismailov; Istanbul / Turkey

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: E. İsmailov, T. Y. Kılıç, Y. B. Uluman, K. B. Bekaroğlu, F. Köse, B. Tütüncüoğlu, T. Banaz, M. Kadıoğlu, S. Ozkök; Istanbul/TR
Purpose: To investigate the relationship between MAPSE values and myocardial fibrosis in patients with cardiac sarcoidosis, and to compare MAPSE with conventional CMR-derived cardiac function parameters.
Cardiac involvement in sarcoidosis is associated with poor prognosis, and because early functional impairment may precede detectable fibrosis on CMR, MAPSE, as a sensitive marker of longitudinal function, could offer valuable diagnostic insight at an earlier stage.
Methods or Background: 47 patients with histologically confirmed systemic sarcoidosis underwent 1.5 Tesla CMR with CİNE, T1/T2 mapping, and LGE were retrospectively analyzed. MAPSE was measured at the medial and lateral mitral annulus in the 4-chamber CİNE view. Ventricular function, and LGE extent/localization were also measured. ECG/Holter were used to assessed arrhythmia. Correlation analyses were performed using Spearman's rank test, and the predictive performance of MAPSE was assessed using ROC curve analysis.
Results or Findings: A total of 47 patients with systemic sarcoidosis (mean age 50.6±12.7 years, 45% male) were analyzed. MAPSE was significantly reduced compared with healthy controls (7.25 vs. 11.60 mm, $p<0.001$), indicating impaired longitudinal function. A significant inverse correlation was found between MAPSE and myocardial fibrosis assessed by LGE percentage ($r=-0.43$, $p=0.003$). Patients with arrhythmia had significantly lower MAPSE values than those without ($p=0.026$), and LGE percentage correlated positively with arrhythmia presence ($r=0.37$, $p=0.012$). ROC analysis demonstrated fair diagnostic accuracy of MAPSE for arrhythmia (AUC=0.70, $p=0.01$). An optimal cutoff ≤ 6 mm yielded high specificity (93%) but limited sensitivity (42%).
Conclusion: These findings suggest MAPSE as a practical marker of fibrosis and arrhythmic risk. MAPSE is significantly reduced in sarcoidosis patients, correlates inversely with myocardial fibrosis and arrhythmia, and may serve as a simple CMR-derived marker of subclinical involvement and arrhythmic risk even in the absence of overt systolic dysfunction.
Limitations: Single-center design

A fasting-mimicking program improves cardiac diastolic function in patients with Type 2 Diabetes Mellitus: a comprehensive MRI study (6 min)

Ruixin Chen; Leiden / Netherlands

Author Block: R. Chen, J. Westenberg, E. van den Burg, M. Schoonakker, S. Cessie, H. Pijl, H. J. Lamb; Leiden/NL
Purpose: Fasting-mimicking diet (FMD) has shown positive effects in reducing risk factors for diabetes, cardiovascular disease, and aging. However, it is unclear whether FMD improves cardiovascular function. We evaluated the effects of periodic use of a five-day FMD each month on left ventricular (LV) geometry and function in patients with type 2 diabetes mellitus (T2DM).
Methods or Background: The study involved 100 patients (aged 63±8 years) with T2DM treated in primary care. We compared patients who received the FMD for five consecutive days each month as adjunct to usual care with those who received usual care alone as controls over twelve months. Magnetic resonance imaging(MRI) data was acquired on a 3.0-T MRI scanner at baseline, six months, and twelve months. LV geometry and systolic function were assessed from cine short-axis images, while diastolic function was analyzed using trans mitral flow curves from 4D flow MRI.
Results or Findings: Intention-to-treatment analysis, using linear mixed model, demonstrated FMD cycles had a significant effect on LV mass (from 116.6±23.6 to 115.4±25.5g for FMD vs. 109.6±27.1 to 112.7±27.9g for controls, $p=0.022$) at six months. The early-to-late peak filling ratio (E/A) increased at twelve months, from 0.87±0.25 to 1.03±0.33 for FMD, versus 0.89±0.24 to 0.88±0.26 for controls, $p=0.006$). Additionally, the mitral annulus through-plane velocity at early peak filling (e') also increased at twelve months, from 5.8±2.1 to 6.0±1.8 cm/s for FMD versus a decline from 6.4±1.7 to 5.5±1.7 cm/s for controls, indicating improved diastolic function.
Conclusion: Fasting mimicking diet cycles over 12 months have a beneficial effect on LV mass, and improve LV diastolic function in T2DM patients.
Limitations: This study lasted twelve months, which limits the ability to evaluate long-term effects of treatment on cardiovascular health.

Impact of left ventricular dilatation on left ventricular function and deformation in diabetes mellitus with reduced ejection fraction: a CMR feature tracking study (6 min)

Wen-Rong Li; Chengdu / China

Author Block: W-r. Li, R. Shi, J-k. Li, H. Xu, Y. Li, Z-G. Yang; Chengdu/CN
Purpose: Left ventricular (LV) dilatation has been found to be associated with poor prognosis in patients with reduced left ventricular ejection fraction (LVEF). However, the relationship between LV dilatation and LV myocardial dysfunction in patients with diabetes mellitus (DM) and reduced LVEF unclear.
Methods or Background: Patients who underwent CMR scanning in our hospital for clinically diagnosed DM between 2017 and 2024. According to LVEF and LV dilatation status, these patients were divided: DM with preserved LVEF (DMpEF) group, DM with reduced LVEF and no LV dilatation (DMrEF-NLVD) group, and DM with dilated cardiomyopathy (DMrEF-DCM) group. LV global radial strain (LVGRS), LV global circumferential strain (LVGCS), and LV global longitudinal strain (LVGLS) were evaluated and compared among the three groups. Additionally, multiple linear regression analysis was performed to assess the independent effect of LV dilatation on LV strains in DM patients with reduced LVEF.
Results or Findings: 122 DMpEF group, 51 DMrEF-NLVD group, and 92 DMrEF-DCM group were included. Significant differences were observed in LV strain parameters among the three groups. LV global strains progressively declined from the DMpEF group to the DMrEF-NLVD group and further to the DMrEF-DCM group (all $p < 0.001$). In DM patients with reduced LVEF, multivariable linear regression analysis revealed that LV dilatation was independently associated with reduced LVGCS ($\beta = 0.176$, $p = 0.009$).
Conclusion: In DM patients with reduced LVEF, LV dilatation has an additive deleterious effect on LV dysfunction. LV dilatation was found to be associated with impaired LVGCS. These findings support that early identification and initiation of treatment for LV dilatation in these patients may improve risk stratification in this high-risk population.
Limitations: The retrospective study design limits the ability to evaluate temporal changes in cardiac structure and function.
Funding for this study: No funding was received for this study.

Cardiac CT vs Cardiac MR for Left Ventricular Function and Myocardial Strain Evaluation: Preliminary Results from the CT-STEMI Study (6 min)

Daniele Verna; Turin / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: D. Verna[1], G. Argento[1], T. D'Angelo[2], M. Olivieri[3], L. Blasi[1], M. Moretti[1], R. Aroasio[1], R. Faletti[4], M. Gatti[1]; [1]Turin/IT, [2]Messina/IT, [3]Chieti/IT, [4]Candiolo/IT
Purpose: To evaluate the concordance between cardiac computed tomography (CCT) and cardiac magnetic resonance (CMR) in the assessment of left ventricular (LV) function and global myocardial strain (GLS, GCS, GRS) in post-STEMI patients.
Methods or Background: Forty-eight patients (mean age 62 ± 11 years, 87.5% male) were prospectively enrolled in the multicenter CT-STEMI study (NCT05941585). Patients were randomized to undergo either CCT or CMR within 6.8 ± 1.8 days after STEMI, followed by the complementary exam within 5.3 ± 2.8 days. LV volumes and function (LVEDV, LVESV, LVEF, LV mass) and global strain indices (GLS, GCS, GRS) were derived using CVI42 software (Circle Cardiovascular Imaging).
Results or Findings: CCT demonstrated excellent concordance with CMR for LV function: LVEF (45 ± 10.9% vs. 46 ± 11.0%, $p = 0.40$), LVEDV (167 ± 38 ml vs. 171 ± 38 ml, $p = 0.16$), and LVESV (93 ± 33 ml vs. 94 ± 32 ml, $p = 0.58$). Strain analysis showed good concordance, with strong correlations for GLS ($r = 0.74$; bias −0.022) and GRS ($r = 0.82$; bias 0.014), and moderate concordance for GCS ($r = 0.65$; bias −0.001).
Conclusion: CCT provides high concordance with CMR in the evaluation of LV volumes and function, and good concordance for global myocardial strain, particularly GLS and GRS. These results support CCT as a valid alternative to CMR for comprehensive functional assessment of left ventricular performance.
Limitations: Despite its prospective, multicenter design, this preliminary analysis is limited by small sample size and predominant use of a single scanner. Planned expansion to 200 patients, inter-scanner validation, assessment of observer variability, and correlation with prognostic endpoints will strengthen the clinical applicability of these findings.
Funding for this study: This research was supported by a grant from the Italian Ministry of Health under the “Ricerca Finalizzata 2021 – Giovani Ricercatori” program, project number GR-2021-12372092. The funding was allocated to the project titled “Cardiac Computed Tomography for Comprehensive Risk Stratification of Arrhythmic, Atherothrombotic, and Heart Failure Events Following Reperfused ST-Segment Elevation Myocardial Infarction”. The funder had no role in the design, data collection, analysis, or interpretation of this study

Early Evaluation of Left Ventricular Diastolic Dysfunction in Kawasaki Disease Using CMR-derived Left Atrial Strain (6 min)

Xinrui Deng; Chengdu / China

Author Block: Z. Zhou, L. Wen, S. Azhe, L. Hu, Y. Zhu, X. Deng; Chengdu/CN
Purpose: This study aimed to quantitatively assess left atrial (LA) function in children with Kawasaki Disease (KD) using feature-tracking CMR.
Methods or Background: This study prospectively enrolled patients with KD in our hospital. The CMR imaging protocols included cine and coronary magnetic resonance angiography. The left atrial strain parameters included total strain (εs), passive strain (εe), and active strain (εa) were acquired by post-processing.
Results or Findings: The study enrolled 214 KD patients (median age 5.50 [3.38, 7.67] years; 66.36% male) and 47 healthy controls (median age 5.67 [4.00, 7.00] years; 63.83% male), with no significant differences in baseline characteristics. A total of 67 children (31.16%) underwent CMR during the acute phase, and 33 children (49.25%) of these patients underwent a follow-up CMR. Compared with the controls and patients in chronic phase, patients in acute phase exhibited significantly reduced left atrial strain parameters, including εs, εe, and εa (all $P<0.05$). In patients who underwent CMR during the acute phase and follow-up CMR, εs, εe, and εa were all increased in the chronic phase compared to the acute phase (all $P<0.05$). In the chronic phase, εs and εe remained lower than in the controls (both $P<0.05$). Additionally, in chronic phase, patients with giant coronary aneurysm (CAA) exhibited lower εe compared to patients without coronary artery dilation and small CAA and the controls.
Conclusion: Decrease of LV diastolic function was found in KD patients, particularly during the acute phase. Although there is a trend toward recovery in the chronic phase, patients in chronic phase still exhibited subclinical LV diastolic dysfunction, primarily in those with giant CAA.
Limitations: The primary limitation of this study is its small single-center sample size.
Funding for this study: This work was supported by the National Natural Science Foundation of China (82471970), Sichuan Science and Technology Program (2024YFFK0258).

Multicenter Clinical Trial on the Application of a Self-Developed AI-Assisted Detection Software for Intracranial Aneurysms on MRA Images (6 min)
Xin Cao; Shanghai / China

Author Block: Y. Bao, X. Cao, Q. Zhao, X. Zhao, B. Huang, Y. Luo, Z. Zheng, W. Liu, D. Geng; Shanghai/CN
Purpose: Our team has independently developed AIneurysm, a computer-aided detection software for TOF-MRA, which has obtained the Class III Medical Device Registration Certificate in China. By accurately segmenting the cerebral arteries, it assists physicians in detecting aneurysm lesions. The multicenter clinical trial was subsequently launched to rigorously validate its diagnostic performance.
Methods or Background: This study is a prospective, multicenter, fully-crossed multi-reader multi-case trial of the AIneurysm, conducted from December 2024 to November 2027. Five medical centers are prospectively gathering cranial MRA data, targeting enrollment of 1,050 cases. Each center assigned two junior radiologists as the participating readers. They conducted two rounds of full-slice reading for all images in their respective centers: a physician-independent group (control) and an AI-assisted group (experimental). The presence or absence of aneurysms, as well as the location of the lesions and the maximum diameter of the aneurysms, were recorded. The consensus reference standard was established by three senior radiologists. The Dorfman-Berbaum-Metz-Hillis analysis was used to compare the area under the alternative free-response receiver operating characteristic (AFROC) curves, sensitivity, and specificity between the two groups.
Results or Findings: A total of 484 cases with 258 lesions have been enrolled until now. The difference in AFROC AUC between the experimental and control groups was 0.0409 (P=0.001, 95%CI:0.020–0.062), indicating superiority of the experimental group. The experimental arm outperformed the control arm with an AFROC AUC gain of 0.0409 (P=0.001, 95%CI:0.020–0.062). Lesion-level sensitivity improved by 0.070 (P=0.010, 95%CI:0.036–0.104), surpassing the predefined superiority threshold, while case-level specificity rose by 0.012 (F=0.457, P=0.010, 95%CI:0.016–0.040), satisfying the non-inferiority criterion.
Conclusion: The interim results show that the AI-assisted detection software AIneurysm for intracranial aneurysms on MRA images demonstrated superior diagnostic performance compared to independent reading by junior physicians.
Limitations: Omitted.

Report-Driven Segmentation: Zero-Shot LLM Extraction of SUVmax and Lesion Location from PET/CT for automatic tumor segmentation (6 min)
Christian Bojahr; Essen / Germany

Author Block: S. Warmer, L. Umutlu, J. Haubold, Y. Wen, C. S. Schmidt, C. Bojahr, K. A. Borys, F. Nensa, R. Hosch; Essen/DE
Purpose: Standardized uptake value (SUV) metrics, particularly SUVmax, quantify PET/CT radiotracer uptake, which is relevant for tumor identification and detailing. However, this condensed critical information is often hidden in radiological reports. We evaluate a large language model (LLM) for extracting SUVmax values with corresponding anatomical sites and examine its impact on initiating automated tumor segmentation.
Methods or Background: We selected PET/CT reports from 100 patients (female=38, 66±9.93 years, NSCLC=97, SCLC=3) diagnosed with lung cancer between 2006 and 2020, each performed within ±30 days of initial diagnosis. The reports were analyzed using a 70B LLaMA 3.3 instruct model with zero-shot prompting for extracting SUVmax values including its corresponding body region. Radiological experts evaluated the extracted data using a questionnaire to assess whether the SUVmax values and locations were correctly extracted. In a subsequent use case, the extracted SUVmax values and location were used to define a seed coordinate for initializing automatic tumor segmentation using the Body and Organ Analysis (BOA) and the nnInteractive. A radiologist then evaluated the resulting segmentation masks case by case.
Results or Findings: The LLM accurately extracted SUVmax values and their corresponding locations in 97% of cases, demonstrating high consistency across report styles and time periods. The automatically generated segmentation masks based on the extracted coordinates and values were clinically usable without modification in 70% of the cases.
Conclusion: This study demonstrates that LLMs accurately extract SUVmax and anatomical context from unstructured PET/CT reports. The structured output enabled automated tumor segmentation, underscoring the potential of LLMs as integral components in clinical segmentation pipelines.
Limitations: The limitations of the study are the small sample size, single tumor type focus, an imbalance between NSCLC and SCLC cases, and the use of one LLM with limited prompt strategies.
Funding for this study: No funding was provided for this study.
Has your study been approved by an ethics committee? Yes

Large language models-based simplification of Breast Imaging Reports: A prospective multicentric study (6 min)

Matilde Pavan; Milan / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: V. Magni[1], M. Pavan[1], A. Cozzi[2], A. Liguori[1], F. Pesapane[1], S. Carriero[1], G. Carrafiello[1]; [1]Milan/IT, [2]Lugano/CH
Purpose: To evaluate patients' perception of breast imaging reports simplified by ChatGPT-4 compared to radiologist-written reports, focusing on simplicity, comprehensibility, and empathy, and to assess the role of educational level in shaping preferences.
Methods or Background: This prospective multicenter study included 10 anonymized mammography and ultrasound reports (BI-RADS 1–5), each simplified by ChatGPT-4 with a 50-word limit. Report pairs (original vs. AI-simplified) were assessed by 300 patients (2965 responses) and 20 physicians using a Likert-scale questionnaire on simplicity, comprehensibility, and empathy. Preferences and demographic data were collected, and logistic regression analyzed factors influencing choices.
Results or Findings: AI-generated reports were preferred in 63.3% of responses. They scored higher for simplicity (69.7% levels 4–5), comprehensibility (67.8% levels 4–5), and empathy (predominantly levels 3–4). Higher scores in all three domains significantly increased the likelihood of AI preference. Participants with advanced education (Bachelor's/Master's degrees) showed a stronger inclination toward AI-simplified reports. Physicians confirmed the clinical accuracy and safety of AI outputs.
Conclusion: ChatGPT-4 can generate simplified breast imaging reports that patients perceive as clearer, more comprehensible, and more empathetic than traditional versions. This approach may enhance patient understanding and engagement, while maintaining accuracy. Broader validation in different languages, clinical contexts, and AI platforms is warranted.
Limitations: Only 10 report pairs were tested, all in Italian, and only ChatGPT-4 was evaluated. More complex BI-RADS categories remain challenging for AI simplification. These factors may limit generalizability.
Funding for this study: This study received no external funding. Institutional resources from participating centers supported the project.

RAG across scales: A multi-backbone comparison of guideline-grounded LLM-agent sequential decision-making for ED acute abdominal pain (6 min)

Romain Andre; Nijmegen / Netherlands

Author Block: R. Andre, H. E. Huisman; Nijmegen/NL
Purpose: Assess how guideline-grounded retrieval-augmented generation (RAG) improves diagnostic performance and sequential imaging/laboratory request-behavior of LLM-agents across backbone sizes (1B-70B) and domain-specific trainings (general/biomedicine) for emergency-department acute abdominal pain pathologies.
Methods or Background: Using the MIMIC-IV-Ext Clinical-Decision-Making dataset (2,400 ED pathways: appendicitis, cholecystitis, diverticulitis, pancreatitis, sharing acute abdominal pain as initial symptom), we compared seven instruction-tuned backbones: Llama-3.2-1B, Mistral-7B-v0.3, Gemma-2-9B, Llama-3.1-8B-UltraMedical, Qwen3-30B, Llama-3.1-70B, Llama-3.1-70B-UltraMedical, spanning both generalist and biomedical-fine-tuned models. LLM-Agents iteratively requested physical-examination, laboratory tests, or imaging (modality and region), received the corresponding reports, then autonomously finalized once judged sufficient evidence is retrieved, issuing a diagnosis and care plan without assistance. With RAG, guidelines snippets were retrieved from a maintainable, disease-scoped knowledge-base at each thinking step and appended to the working context before each action, grounding the iterative process in citable, expert-authored sources.
Results or Findings: RAG improved average diagnostic accuracy across every backbone. Relative gains were most notable for smaller models (1-9B: from 46.5% to 55.1%), larger models (30-70B) also improved (67.4% to 72.8%). RAG reduced requests for non-existent tools (i.e. hallucinations), while increasing alignment of imaging orders with clinician trajectories and guideline indications, and maintained disciplined laboratory selection. RAG-equipped agents gathered more evidence before finalization and specified imaging parameters (modality/region) more consistently. Overall, RAG enhanced transparency by surfacing citable guidance throughout the decision chain.
Conclusion: Across seven backbones from 1B to 70B, including both generalist and biomedical-tuned models, guideline-grounded RAG consistently improves diagnostic accuracy and imaging decision behavior, supporting safer, more auditable LLM assistance for ED acute abdominal pain.
Limitations: Work limited to the ER domain, focusing only on four pathologies from a single-centre, English-language dataset. Only open-weight models were explored to respect MIMIC-IV's data use agreement. Prospective, multi-institutional validation and broader symptom coverage are needed.
Funding for this study: This study is part of the HealthyAI project with number KICH3.LTP.20.006 of the research programme KIC which is (partly) financed by the Dutch Research Council (NWO) and with co-funding by Siemens Healthineers.

MumbleMED: Introducing a Framework for Fine-Tuning Medical Speech Transcription in Radiology Utilising Large Language and Text-to-Speech Models (6 min)

Sina Warmer; Essen / Germany

Author Block: S. Warmer, A. Idrissi-Yaghir, K. A. Borys, J. Haubold, C. S. Schmidt, Y. Wen, K. Arzideh, F. Nensa, R. Hosch; Essen/DE
Purpose: General-purpose speech recognition models, such as OpenAI's Whisper, struggle with the complex terminology and structure of medical language, which limits their use in radiology. We present MumbleMED, a domain-adapted open-source speech-to-text model fine-tuned using a pipeline that combines large language models (LLMs) and text-to-speech (TTS) to generate high-quality medical training data.
Methods or Background: Synthetic medical German texts were created by random sampled structured concepts from ICD, SNOMED CT, and RadLex using Qwen3-235B. These texts were converted to audio using a TTS engine featuring 17 distinct speakers (female=47%) from our institution. The resulting dataset of 13689 samples (4530 minutes of total audio time) was used to fine-tune OpenAI's Whisper model (V2-large), resulting in MumbleMED, a medical variant in German language. Model performance was evaluated on a test set of 450 synthetic samples and 97 real radiology report dictations using Word Error Rate (WER), Character Error Rate (CER), and compared to the unmodified Whisper baseline.
Results or Findings: MumbleMED achieved a WER of 3.73% and CER of 1.97% on the synthetic test set, outperforming the baseline Whisper model (WER=20.33%, CER=11.65%). On real radiology reports, MumbleMED (WER=39.78%, CER=17.92%) also outperformed Whisper (WER=70.65%, CER=46.88%), showing strong recognition of medical domain-specific vocabulary and typical terminology of German radiology reports.
Conclusion: MumbleMED shows that LLM- and TTS-based synthetic data can effectively fine-tune speech-to-text models for clinical use. The approach enables more accurate and reliable transcription of radiological dictations, reducing the need for manual correction and supporting faster, streamlined reporting workflows. In addition, this pipeline can be used to fine-tune the model for any language in the medical domain.
Limitations: The limitations of the study are the synthetic training data and limited speaker variations, which may not fully capture spontaneous or accented speech patterns.
Funding for this study: No funding was provided for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was performed in adherence to all guidelines defined by the approving institutional review board of the investigating hospital. The Institutional Review Board waived written informed consent due to the retrospective nature of the study. Complete anonymization of all data was performed before inclusion in the study.

Evaluating Large Language Models for FHIR-Compatible Structured Reporting from Kidney Stone CT Reports (6 min)

Philipp Arnold; Freiburg Im Breisgau / Germany

Author Block: P. Arnold, E. Kotter, J. Jahn; Freiburg Im Breisgau/DE
Purpose: To assess whether large language models (LLMs) can convert free-text kidney stone CT reports into standardized HL7 FHIR Questionnaire format and to compare performance across input styles and model sizes.
Methods or Background: We collected 99 German abdominal CT reports (50 free-text, 49 semi-structured with section headings). A kidney stone FHIR Questionnaire with 33 key fields was derived from a published consensus template. Three locally hosted Qwen models (8B, 14B, 32B parameters) were prompted field by field to generate FHIR QuestionnaireResponses, which were compared with a radiologist-annotated ground truth. Metrics included ground-truth completeness (proportion of fields present in the source report), AI completeness (proportion of ground-truth fields correctly retrieved by the model), and per-field accuracy (exact or semantically equivalent match across all fields).
Results or Findings: Semi-structured source reports contained more of the expected information (ground-truth completeness 77% vs. 65% for free text). Across all models, both accuracy and AI completeness were higher for semi-structured inputs. Qwen-32B achieved 93% per-field accuracy and 97% AI completeness on semi-structured reports (vs. 82% and 92% on free text). The 14B model reached 91% accuracy and 95% AI completeness (vs. 83%/94%), while the 8B model achieved 83%/95% (vs. 69%/87%).
Conclusion: LLMs can automatically generate FHIR-compliant structured kidney stone CT reports from textual input with high accuracy. Semi-structured reports yield higher accuracy and completeness. The approach supports prospective workflows, where radiologists dictate freely while an LLM drafts a structured report for rapid review, as well as retrospective extraction of structured data from existing reports.
Limitations: Single-center study focused on one exam type; performance on more heterogeneous imaging reports remains to be validated.

Evaluating the Accuracy of Privacy-Preserving Large Language Models in Calculating the Spinal Instability Neoplastic Score (SINS) (6 min)

Li Yi Tammy Chan; Singapore / Singapore

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: L. Y. T. Chan, D. Z. M. Chan, Y. L. Tan, Q. V. Yap, W. Ong, A. Lee, J. H. Tan, N. Kumar, J. T. P. D. Hallinan; Singapore/SG
Purpose: In diagnostic radiology, LLMs can assist in the computation of the Spine Instability Neoplastic Score (SINS), which is a critical tool for assessing spinal metastases. However, the accuracy of LLMs in calculating the SINS based on radiological reports remains under-explored. This study evaluates the accuracy of two institutional privacy-preserving LLMs - Claude 3.5 and Llama 3.1 - in computing the SINS from radiology reports and electronic medical records.
Methods or Background: A retrospective analysis was conducted on 124 radiology reports from patients with spinal metastases. Three expert readers established a reference standard for the SINS calculation. Two orthopaedic surgery residents and two LLMs (Claude 3.5 and Llama 3.1) independently calculated the SINS. The intraclass correlation coefficient (ICC) was used to measure the inter-rater agreement for the total SINS, while Gwet's Kappa was used to measure the inter-rater agreement for the individual SINS components.
Results or Findings: Both LLMs and clinicians demonstrated almost perfect agreement with the reference standard for the total SINS. Between the two LLMs, Claude 3.5 (ICC = 0.984) outperformed Llama 3.1 (ICC = 0.829). Claude 3.5 was also comparable to the clinician readers with ICCs of 0.926 and 0.986, exhibiting a near-perfect agreement across all individual SINS components [0.919–0.990].
Conclusion: Claude 3.5 demonstrated high accuracy in calculating the SINS and may serve as a valuable adjunct in clinical workflows, potentially reducing clinician workload while maintaining diagnostic reliability. However, variations in LLM performance highlight the need for further validation and optimisation before clinical integration.
Limitations: The training of LLMs was performed with only one prompt strategy, and performance may vary with alternative prompt methods. The evaluation of LLMs were assessed at a single time point using a single institution dataset, limiting conclusions about reproducibility and generalisability.
Funding for this study: Direct Funding from MOH/NMRC. This research is supported by the Singapore Ministry of Health National Medical Research Council under the NMRCClinician Innovator Award (CIA). Grant Title: Deep learning pipeline for augmented reporting of MRI whole spine (CIAINV23jan-0001, MOH-001405)

Ethics committee - additional information: Ethical review and approval were waived for this study as it was granted a Domain-Specific Review Board waiver owing to minimal risk

Empowering radiology training with AI: Large Language Models in resident error detection and feedback (6 min)

Alberto Kyling; Santiago / Chile

Author Block: A. Kyling, M. Salinas, G. Briceño, C. Pizarro, P. F. Guzman, D. Ladrón de Guevara; Santiago/CL
Purpose: The implementation of artificial intelligence in healthcare is advancing globally. Automated analysis of errors in radiology reports could provide objective and personalized feedback, supporting staff radiologists' teaching, optimizing resident training, and improving radiological care quality.
Methods or Background: This observational, retrospective study analyzed 213 paired radiology reports (CT, MRI, US) from first- and second-year residents, validated by staff radiologists. Reports were anonymized and processed by a LLM (Gemini-3-Pro) to classify errors (structural, semantic, diagnostic) and measure textual concordance via cosine-similarity embeddings. A random subset of 40 report pairs (18%) underwent independent senior radiologist validation.
Results or Findings: 213 report pairs plus 40 controls were analyzed. Median cosine similarity was 0.99 for error-free reports and 0.91 for those with ≥5 diagnostic errors; 0.90 served as discriminant threshold (specificity 100%, sensitivity 13.1%). Spearman correlation between similarity and diagnostic error count was ρ=–0.53 (p <0.001). Controls (deliberately erroneous or incoherent) consistently scored <0.85. Diagnostic errors averaged 2.10±1.43 per report (85.5% had ≥1 error), with omission/false negatives comprising 67.8%. Triaxial-qualitative classification showed poor reliability for error detection (Kappa 0.04 at threshold 0.90), but acceptable reliability for ruling out error-free reports (Kappa 0.36 at threshold 0.99). Manual validation achieved 100% concordance (40/40).
Conclusion: The LLM reliably identified discrepancies and graded severity (ρ=–0.53). While not robust for error detection, it showed acceptable reliability in validating error-free reports, suggesting its potential as an educational support tool, particularly for targeting omission errors which comprised the majority of diagnostic discrepancies.
Limitations: Single-center, limited sample size, risk of hallucinations, and reliance on staff reports as reference standard constrain generalizability, highlighting the need for larger, multicenter, validation studies.
Funding for this study: This research received no external funding and was conducted without dedicated financial support.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Approved by the Ethics Committee of Hospital San Juan de Dios, Santiago, Chile.

Beyond Evans Index: CT Ventricular Nomograms with 12 Sub-compartments from an LLM-Curated Cohort with nnU-Net Segmentation (6 min)

Nathan Vishwanathan; Basel / Switzerland

Author Block: N. Vishwanathan, S. Griot, J. Wasserthal, S. Yang, M. Segeroth, J. M. Lieb, M. Bach, M-N. Psychogios, M. A. Mutke; Basel/CH
Purpose: To build age- and sex-specific CT ventricular volume nomograms (12 subcompartments) and show how they can be used in everyday reporting.
Methods or Background: Single-centre retrospective study, 2019–2024. A locally run, German-tuned large language model screened head-CT reports and brief clinical summaries to exclude stroke, mass lesions, relevant white-matter disease, dementia/MCI, or cognitive decline. The final "normal" cohort was 3,086 examinations from 2,964 adults (14–98 years). Ventricular volumes were segmented into 12 subcompartments with an nnU-Net model. We report decade- and sex-stratified values, model performance with 95% CIs, false-discovery correction for multiple tests, and effect sizes.
Results or Findings: LLM labelling accuracy across diagnostic categories was 0.966–0.992; for enlarged ventricles 0.992 (95% CI 0.978–0.997). Segmentation achieved median Dice 0.918 (95% CI 0.910–0.923). Total ventricular volume rose with age, with a clear step from 50–59 to 60–69: +33.9% in females and +49.4% in males. Most subcompartments showed moderate to strong age correlations (r=0.44–0.68), while the fourth ventricle changed little (r=0.02). Male volumes were 8–19% higher than female volumes after correction. We provide percentile nomograms (5th–95th) with 95% CIs and decade means/SDs for each subcompartment and sex.
Conclusion: A simple, on-premises LLM + nnU-Net workflow can curate large CT datasets and produce reliable ventricular nomograms. These charts make reporting more objective: a scan can be flagged when a volume is at or above the 95th percentile for the patient's age and sex, supporting earlier recognition of disproportionate dilatation and focused clinical follow-up.
Limitations: Single-centre, retrospective Swiss cohort, limited generalisability; no external validation.
Cross-sectional nomograms; extreme ages (≥90 y) have wide CIs; no longitudinal/test–retest data.
nnU-Net performance validated internally only; no multi-centre benchmark.
Funding for this study: This study received no external funding.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Ethics waiver was granted.

Towards speech assistants in reporting workflows: interoperability challenges of structured reporting, speech recognition and large language models (6 min)

Benedikt Kämpgen; Würzburg / Germany

Author Block: B. Kämpgen[1], G. Arnhold[2], J. Stöckmann[3], I. Schmittel[1], F. Jungmann[2], D. Feiler[3], D. Pinto dos Santos[2], P. Mildenberger[2], T. Jorg[2]; [1]Würzburg/DE, [2]Mainz/DE, [3]Munich/DE
Purpose: Speech-based dialogue systems for structured reporting (SR) promise to improve both reporting quality and efficiency (Jorg et al., 2023, https://doi.org/10.1186/s13244-023-01392-y). For studies involving multiple templates, however, the system must be seamlessly integrated into radiologists' workflows. This reveals interoperability challenges between structured reporting, speech recognition and large language model components.
Methods or Background: We designed an architecture with defined interfaces connecting an open-source structured reporting tool (Dos Santos et al., 2017, https://doi.org/10.1007/s00330-016-4344-0), a commercial speech recognition system (DFC-SYSTEMS), and a commercial large language model (Empolis). The reporting tool is launched from the RIS, where an appropriate SR template (e.g., for urolithiasis) is automatically selected based on the examination. A "speech assistant" button opens a chat window, allowing the user to answer template-guided questions via microphone. At any point, particularly when the system has no further questions, the user may accept or reject the prefilled SR template. This workflow minimises look-away interruptions and maximises efficiency gains in structured reporting.
Results or Findings: The application captures audio from the microphone, performs server-based speech-to-text conversion, and forwards the text to a server for text-to-structure processing. Integration across components is achieved via a unified JSON data model, which stores the iteratively completed template and message context/history. Functionality and integration tests demonstrated full vocabulary mapping across the template, speech recognition, and language model components.
Conclusion: Speech-based structured reporting, supported by large language models, is approaching clinical deployment. Our results offer valuable insights for initiatives addressing workflow integration and interoperability challenges.
Limitations: The limitations of the study are that it only included automatic functionality and integration testing based on fictional and anonymised cases (n > 50) but no clinical assessment of efficiency gains. A clinical study with speech assistant reporting is still in progress.
Funding for this study: Funding was provided by the Bundesministerium für Bildung und Forschung (BMBF), 2022-2025, grant agreement number: 16SV9045, project KIPA.

Benchmarking Large Language Models for Follow-up Recommendations After Abdominal Ultrasound (6 min)

Vincenzo Vingiani; Bolzano / Italy

Author Block: V. Vingiani, R. Valletta, N. Cortellini, B. Proner, V. Corato, L. Hoxha, F. Ferro, M. Bonatti; Bolzano/IT
Purpose: To evaluate whether large language models (LLMs) provide consistent, guideline-concordant follow-up recommendations after abdominal ultrasound (US) and to benchmark multiple systems.
Methods or Background: We assembled 200 simulated abdominal US cases covering liver, gallbladder/biliary tree, pancreas, spleen, kidneys, and retroperitoneum. Two expert abdominal radiologists defined the ground-truth management (no imaging follow-up, only US follow-up, or additional diagnostic work-up), including modality and timing when further imaging was indicated. Thirty cases refined prompts with GPT-4o; 170 were held out for evaluation. Seven LLMs (GPT-5, GPT-4o, GPT-4o mini, Gemini 2.5 Flash, Gemini 2.5 Pro, Claude 4 Sonnet, and DeepSeek-V3) were tested in zero-shot mode through Firefox with cache cleared and sessions restarted before each query. Stability was assessed across five independent runs. Agreement with the consensus was quantified using Cohen's κ (unweighted and weighted) and F1 scores.
Results or Findings: GPT-5 achieved the highest accuracy for the three management categories (no imaging follow-up, only US follow-up, or additional diagnostic work-up), 0.988; the lowest was DeepSeek-V3 with 0.829. Weighted κ ranged from 0.755 (DeepSeek-V3) to 0.964 (GPT-5). F1 scores mirrored this pattern, with GPT-5 at 0.988, followed by Gemini 2.5 Pro (0.954) and Gemini 2.5 Flash (0.948). Management-decision stability across five runs was high for all models (0.928–0.968). When further imaging was required, correct selection of the second-level modality and timing was highest for GPT-5 (accuracy 0.779) and lowest for Gemini 2.5 Flash (0.609).
Conclusion: LLMs can translate abdominal US reports into actionable, guideline-aligned follow-up recommendations. GPT-5 performed best overall, supporting the role of LLMs as adjunctive decision support to standardise post-ultrasound imaging decisions across healthcare settings.
Limitations: Synthetic, text-only cases may limit generalizability; zero-shot, browser-based testing may reduce performance in optimised deployments; evolving model versions may affect reproducibility and external validity.

Feasibilty of using a Large Language Model for automated extraction of clinically relevant findings from whole-body MRI reports (6 min)

Luca Di Palma; Milan / Italy

Author Block: L. Di Palma, M. Alì, A. Lad, G. D'Anna, F. Darvizeh, I. Castiglioni, D. Fazzini; Milan/IT
Purpose: To evaluate the feasibility and accuracy of using a large language model (LLM) to extract and structure clinically relevant information from free-text whole-body MRI (WB-MRI) reports.
Methods or Background: This study included 327 WB-MRI reports from a preventive health screening program. Reports were processed with the DeepSeek-R1-Llama3.3 LLM to extract findings classified according to the ONCO-RADS system, including their anatomical locations. Only ONCO-RADS ≥3 findings were analyzed, as they represent suspicious or actionable abnormalities; ONCO-RADS 1–2 were excluded. LLM outputs were compared with original reports, independently reviewed and annotated by three subspecialist radiologists (neuroradiology, musculoskeletal, body imaging; >5 years' experience). Radiologists validated whether extracted ONCO-RADS scores and locations matched the reports. Discrepancies were categorized as: (1) missing findings, (2) localization errors (minor: ovary vs uterus; pleura vs lung; major: different organ), and (3) false positives.
Results or Findings: Out of 4,902 total findings, radiologists identified 237 as ONCO-RADS ≥3. Among these, 232 (97.9%) were categorized as ONCO-RADS 3, 3 (1.3%) as ONCO-RADS 4, and 2 (0.8%) as ONCO-RADS 5. The LLM accurately extracted 207 of these cases (87.3%) with full agreement in both classification and location. There were 30 discrepancies (12.7%), comprising 17 missed findings (7.2%) and 13 localization errors (5.5%). Of the localization errors, 11 were minor, while 2 were considered major. Additionally, LLM reported 16 false positives.
Conclusion: This study shows that LLMs can accurately extract clinically relevant findings from free-text WB-MRI reports, with high concordance and minimal clinically significant errors. This suggests strong potential for LLMs in supporting report structuring in radiology.
Limitations: Use of a single LLM for ONCO-RADS extraction may limit generalizability.

The utility of "thinking" in CAD-RADS scoring of an open-source hybrid-reasoning large language model (6 min)

Lennart Roelof Koetzier; Utrecht / Netherlands

Author Block: V. Sandfort[1], D. Vigneault[1], L. R. Koetzier[1], M. J. Willemink[2], J. Wu[2], R. Hallett[1], K. Nieman[1], D. Fleischmann[1], D. Mastrodicasa[3]; [1]Stanford, CA/US, [2]Palo Alto, CA/US, [3]Seattle, WA/US
Purpose: Large language models (LLMs) are developed to answer questions or follow instructions. While earlier generation LLMs gave quick, general responses, they could not perform multi-step reasoning. Reinforcement-learning has enabled "reasoning" models, such as Qwen3-235B, which operate in both "thinking" and "non-thinking" modes. Although LLMs have been evaluated for extracting information from radiology reports, the effect of "thinking" on this task remains unclear. We evaluated the effect of "thinking" in Qwen3-235B on the performance of determining CAD-RADS scores from cardiac CT-reports.
Methods or Background: We retrospectively included 500 de-identified cardiac CT-reports from four hospitals across three USA regions using an online platform (Segmed). CAD-RADS categories were determined in consensus by three cardiovascular imaging experts. Qwen3-235B was run in fp8-quantization via API (together.ai) in both "thinking" and "non-thinking" mode. Thinking was measured in thinking-characters between thinking-tags, divided into quintiles (Q1=least thinking; Q5=most thinking). Model performance was assessed using unweighted Cohen's kappa.
Results or Findings: Model performance in "thinking" mode was numerically higher than "non-thinking" mode (0.791 [0.751-0.835] vs 0.732 [0.686-0.777], respectively). In "thinking" mode, best performance was seen in Q1 (kappa=0.893) and declined with more thinking (Q5-kappa=0.452). In "non-thinking" mode, performance was highest in Q1 (kappa=0.944) and Q2 (kappa=0.901), but lowest in Q5 (kappa=0.365).
Conclusion: An open-source hybrid-reasoning LLM accurately determined CAD-RADS scores from cardiac CT-reports. Very long "thinking" (Q5) was associated with poor performance, suggesting it may serve as a model-confidence indicator. "Non-thinking" worked better for easy cases, while "thinking" was advantageous in difficult cases.
Limitations: Qwen3-235B is not intended for medical use, and our study only evaluated performance.

Artificial Intelligence in Target Definition for Brain Metastases: Opportunities and Challenges (6 min)
Nadine Snoeijink; Hardenberg / Netherlands

Author Block: N. Snoeijink, J. D. J. Slotman, S. Kamerbeek, I. M. Nijholt, M. F. Boomsma, E. Wiegman; Zwolle/NL
Purpose: To assess inter-observer variability of expert-based radiation target definition with and without AI assistance in gamma knife radiosurgery for brain metastases on MRI scans.
Methods or Background: A deep learning-based model was developed for automatic detection and delineation of brain metastases using contrast-enhanced T1-weighted (CE-T1w) and black blood (BB) MR sequences. Data from 224 consecutively treated patients were randomly split into training (n=162) and testing (n=64) sets. The AI model achieved an overall F1-score of 0.93, sensitivity of 0.88, PPV of 0.98, and a DICE score of 0.82. Subsequently, it was tested on an independent dataset consisting of 15 patients, with in total 93 brain metastases, classified as S (< 0.1 cc), M (≥0.1 cc & <1 cc), or L (≥1 cc). Four observers evaluated each case: two radiotherapists independently, AI model alone, and combination of AI with a radiotherapist able to refine results manually. Inter-observer variability was quantified using the DICE-score using clinical delineation by one of the radiotherapists as reference.
Results or Findings: Inter-observer variability in DICE-scores was observed among radiotherapists (0.88) and between radiotherapist and the AI model (0.73), particularly for smaller metastases (<0.1 cc). Adjustments made by the radiotherapist to the AI-generated delineations increased the DICE-score to 0.84. The largest improvement was seen for small lesions (S: 0.54 --> 0.76, M: 0.81 --> 0.86, L: 0.87 --> 0.88).
Conclusion: The AI model is trained on delineations from multiple radiotherapists, who do not always agree with each other. This inter-expert variability may limit AI's ability to achieve a maximal DICE, potentially challenging effective implementation of AI in clinical practice.
Limitations: Small sample size

Integrating diffusion-weighted MRI radiomics features to predict brain invasion of meningiomas (6 min)
Lin Lin; Fuzhou / China

Author Block: L. Lin, J. Qin, K. Wang; Fuzhou/CN
Purpose: Brain invasion is an independent diagnostic criterion for WHO grade 2 meningiomas, and preoperative prediction of brain invasion in meningiomas is crucial for making treatment decisions. Therefore, we constructed a radiomics model that integrated structural and diffusion-weighted images to predict brain invasion of meningiomas.
Methods or Background: Seven hundred and twenty-three consecutive patients with pathologically confirmed meningiomas between 2013 and 2022 were retrospectively studied. Radiomics features of the brain-to-tumor interface region were extracted from structural MRI and DWI-derived apparent diffusion coefficient (ADC) maps. The LASSO method was utilized to select radiomics features. A linear predictor of brain invasion was constructed using a logistic regression classifier. The model's performance was evaluated using ROC curve analysis. Additionally, decision curve analysis (DCA) was performed to evaluate the clinical utility of the established models. A nomogram was developed for a combined model that incorporates clinical features, along with radiomics scores derived from structural images and ADC maps. DeLong test and integrated discrimination improvement (IDI) were used to compare the diagnostic efficiency of different models.
Results or Findings: Six radiomics features from structural MRI, six radiomics features from ADC, the volume of peritumoral edema, and gender were selected to construct the combined model. The combined model showed the highest AUC and sensitivity for prediction of brain invasion in the training (AUC=0.897, 95%CI: 0.857 to 0.936) and test sets (AUC=0.871, 95%CI: 0.806 to 0.936). It showed higher performance than the structural model (AUC=0.691) and the structural and clinical model (AUC=0.812). IDI showed significant improvement in predictive value when ADC radiomic features were added to the combined model.
Conclusion: The incorporation of ADC radiomics into the MRI radiomic model improved the diagnostic performance for identifying brain invasion in meningioma.
Limitations: Single center

Predicting Meningioma Recurrence/Progression Based on Multiparametric MRI Intratumoral and Peritumoral Radiomics Models : A Multicenter Study (6 min)

Tao Han; Lanzhou / China

Author Block: T. Han, J. Zhou; Lanzhou/CN
Purpose: This study aimed to evaluate the value of intratumoral and peritumoral radiomics models based on multiparametric MRI in predicting meningiomas recurrence/progression (R/P).
Methods or Background: A total of 623 patients from Hospital A were divided into a training set (n=294) and a test set (n=127); 202 patients from Hospital B comprised the external validation set. A Clinical-Radiological (C-R) model was developed using significant clinical/MRI features. Radiomics features were extracted from intratumoral (Intra) and peritumoral regions at 5 mm (Peri-5) and 10 mm (Peri-10). Models were constructed using Lasso and evaluated via ROC, calibration curves, and decision curve analysis (DCA). Interpretability was assessed with SHAP (SHapley Additive exPlanations) plots.
Results or Findings: The training set AUCs for C-R, Intra, Peri-5, and Peri-10 models were 0.820, 0.880, 0.860, and 0.840, respectively. Test set and external validation AUCs ranged from 0.820–0.910 and 0.620–0.750. The results of the DeLong test indicated that, in external validation set, the predictive performance of the Intra model was significantly superior to that of the C-R, Peri-5 mm, and Peri-10 mm models (P=0.046, P=0.024, P=0.035).
Conclusion: The Intra, Peri-5 mm, and Peri-10 mm radiomics models and C-R model, demonstrated good predictive performance in predicting meningioma R/P, providing a theoretical reference for formulating personalized treatment plans for meningioma patients.
Limitations: Firstly, it is a retrospective study. Secondly, this study only analyzed the tumor and peritumoral regions, while the predictive value of the peritumoral edema region remains to be further explored. Lastly, manual segmentation methods were used to delineate the VOI of the tumor in this study. In future studies, we aim to explore the automatic segmentation method and larger prospective datasets to improve enhance and validate the model's performance and robustness.
Funding for this study: This study was supported by grants of Natural Science Foundation of China (82371914).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective study received approval from the Ethics Review Committees of the Hospital A (2023A-169) and Hospital B (2024262K), with the need for informed consent waived.

From MRI to MoCA - Machine Learning Models for Cognitive Impairment Prediction (6 min)

Nauris Zdanovskis; Riga / Latvia

Author Block: N. Zdanovskis, K. Šneidere, K. Kalva, Z. A. Litauniece, A. Usacka, Z. Freibergs, A. Platkajis, A. Stepens; Riga/LV
Purpose: To assess whether machine learning algorithms can predict Montreal Cognitive Assessment (MoCA) scores from MRI morphometry in patients with cognitive impairment.
Methods or Background: Eighty subjects were included, with 70 used for training and 10 for testing. From structural MRI, 101 morphometric features were extracted, including cortical thickness (68 regions), subcortical volumes (20 bilateral structures), corpus callosum subdivisions (5), and global volumetric measures (8). Six supervised regression models were evaluated: Linear Regression, Random Forest, Gradient Boosting, AdaBoost, Support Vector Machine (SVM), and k-Nearest Neighbors (kNN). Performance was assessed using mean squared error (MSE), mean absolute error (MAE), and R^2.
Results or Findings: Random Forest achieved the best accuracy (MSE = 32.7, MAE = 4.55, R^2 = 0.655), followed by Gradient Boosting (MSE = 47.8, MAE = 5.91, R^2 = 0.496) and AdaBoost (MSE = 58.4, MAE = 6.80, R^2 = 0.384). Linear Regression and kNN showed weak predictive value (R^2 = 0.001 and 0.10), while SVM performed poorly (R^2 = –0.145). Neural Networks failed to converge (R^2 = –3.14). At the subject level, Random Forest predictions were closest to actual scores; for example, a patient with MoCA = 24 was predicted as 25, while another with MoCA = 7 was predicted as 13, and one with MoCA = 30 as 24.
Conclusion: Machine learning models demonstrated the ability to approximate MoCA scores from MRI-derived morphometric features with clinically meaningful accuracy. These findings suggest that in future ML-based approaches could be applied in clinically relevant scenarios, such as supporting early detection of cognitive impairment and stratifying patients for further testing.
Limitations: Single-center retrospective study with a modest sample size. External validation is required to confirm generalizability. MoCA, while widely used, may not capture the full spectrum of cognitive domains.
Funding for this study: Modifiable bio and life-style markers in predicting cognitive decline (MOBILE-COG) No: RSU-PAG-2024/1-0014 is financed by the investment of the European Union Recovery and Resilience Facility and the state budget within the project "RSU internal and RSU with LASE external consolidation" No. 5.2.1.1.i.0/2/24/I/CFLA/055.

Influence of deep learning image reconstruction and adaptive statistical iterative reconstruction-V on automated ASPECTS evaluation (6 min)

Estelle Akl; Rostock / Germany

Author Block: E. Akl[1], E. Beller[1], D. Cantré[1], F. G. Meinel[1], M-A. Weber[1], S. Langner[2], W. Hermann[1], M. Lütgens[1], A-C. Klemenz[1]; [1]Rostock/DE, [2]Greifswald/DE
Purpose: The Alberta Stroke Program Early CT Score (ASPECTS) and advances in CT reconstruction, such as Adaptive Statistical Iterative Reconstruction-V (ASIR-V), and Deep Learning Image Reconstruction (DLIR) play an important role in the neurodiagnostic workflow. This study examines the effect of these reconstruction techniques on automated ASPECTS.
Methods or Background: In this retrospective study, 173 patients (mean age 77 ± 12 years, 39% female) with suspected middle cerebral artery infarction underwent non-contrast CT, reconstructed with FBP, ASIR-V (at 30% and 60%), and DLIR (low, medium, and high). Automated ASPECTS were analyzed, with FBP as the reference standard.
Results or Findings: Compared to FBP, ASIR and DLIR reconstructions resulted in a mild overall underestimation of automated ASPECTS, with the least pronounced underestimation for ASIR-V 30% and DLIR-L, and a more marked underestimation for ASIR-V 60% and DLIR-M/H. Most re-classifications involved shifts of ASPECTS from moderate (5–7) to high (8–10), with DLIR-H showing the greatest effect. DLIR more frequently up-classified patients from ≤5 to ≥6, whereas down-classifications were rare. Regionally, the insular ribbon was most underestimated and M3 most overestimated, with DLIR-H exhibiting the largest total regional discrepancies. Agreement with expert consensus was highest for DLIR-M, followed by ASIR-V, while FBP and DLIR-H showed lower concordance.
Conclusion: Both ASIR-V and DLIR showed generally minor underestimation of ASPECTS compared to FBP. Occasional overestimation, however, resulted more often in reclassifications of the ASPECTS score, which affected patient eligibility for endovascular therapy (ASPECTS ≥ 6 vs. ASPECTS ≤ 5). DLIR-M was most accurate compared with expert consensus. Careful selection, optimization, and standardization of reconstruction parameters are essential for consistent and reliable stroke imaging.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Not applicable - retrospective study.

MRI Radiomics-Based Machine Learning Model for Stroke Severity Combining Carotid Plaque and White Matter Hyperintensity (6 min)

Zhimeng Cui; Shanghai / China

Author Block: Z. Cui, J. Zhang; Shanghai/CN
Purpose: To develop and validate a reliable machine learning (ML) model combining carotid plaque and white matter hyperintensity (WMH) radiomics features with radiological characteristics to assess acute ischemic stroke (AIS) severity.
Methods or Background: Retrospective data were collected from patients with symptomatic carotid artery stenosis (CAS) and AIS between January 2017 and December 2023, and a prospective cohort from October 2023 to October 2024. Based on admission NIHSS scores, patients were categorized into NIHSS score ≤ 1 and > 1 groups. All patients underwent high-resolution vessel wall MRI and brain MRI. Conventional imaging features of carotid plaques and WMH were used to build a conventional imaging model. Radiomics features were extracted from carotid plaque (T1WI and contrast-enhanced T1WI) and WMH (FLAIR), and multiple ML algorithms were applied to build radiomics models. A hybrid model was subsequently developed by combining radiomics and conventional imaging features. Model performance was evaluated in the test set and prospective validation cohort.
Results or Findings: Three cohorts were included: retrospective training (140 patients), testing (59 patients), and prospective validation (71 patients). The conventional imaging model achieved areas under the curve (AUC) of 0.94, 0.88, and 0.75 in the training, test, and validation cohorts, respectively. The radiomics model achieved corresponding AUCs of 0.87, 0.79, and 0.73. The hybrid model, which incorporated 9 conventional imaging features and 23 radiomics features (16 plaque-derived and 7 WMH-derived), yielded superior performance, with AUCs of 0.97, 0.96, and 0.87. Decision curve analysis demonstrated that the hybrid model provided greater net clinical benefit.
Conclusion: The ML-based hybrid model enables accurate, non-invasive AIS severity assessment and demonstrates strong clinical potential.
Limitations: First, the retrospective design may have introduced selection bias. Second, the lack of multicenter validation and the modest sample size remain limitations.
Funding for this study: This work was supported by the National Key R&D Program of China (Grant no. 2022YFF0708700), Shanghai Science and Technology Program (Grant no. 22S31905300, 22YF1405000), the National Natural Science Foundation of China Youth Program (Grant no. 82402393).

Ethics committee - additional information: The study protocol was approved by the Institutional Review Board of our hospital, and written informed consent was obtained from all participants.

Radiomics analysis and investigation of stroke mechanisms in intramural hematoma-type dissection (6 min)

Jie Liu; Jiangsu / China

Author Block: J. Liu, Z. X. Jun; Jiangxi Province, Nanchang, China/CN
Purpose: We aimed to explore the association between the characteristics of intramural hematoma (IMH)-type dissection in the head and carotid arteries and cerebral infarction, analyze the distribution pattern of infarction, and investigate the potential underlying mechanisms.
Methods or Background: A total of 89 head and carotid artery IMH-type dissection lesions were included in this study. Traditional imaging features were measured, and radiomics features of the hematoma were extracted and screened through Spearman correlation and LASSO. Spearman correlation analysis was performed between traditional imaging and radiomics features. Features with a statistically significant correlation were identified using a threshold of $|r| > 0.4$ and a false discovery rate corrected p-value < 0.05. Infarcts were projected into the standard space to generate cumulative frequency maps of infarcts.
Results or Findings: Hematoma volume differed significantly between the ischemic stroke (IS) and non-IS groups ($P = 0.021$). Texture features strongly correlated with hematoma volume, signal and luminal stenosis characteristics ($rmax = -0.803$, $P < 0.001$). Cerebral infarction rate, remodeling index, IMH signal features, and hematoma volume all varied significantly between anterior and posterior circulation. Infarctions occurred most frequently in the semioval center, corona radiata, and basal ganglia. Additionally, infarct distribution was broader in the left hemisphere, with greater cortical involvement.
Conclusion: The volume, texture, and topological characteristics of IMH-type dissection are associated with cerebral infarction. The distribution of IMH-type dissection infarction is indicating a strong left-sided predilection and suggests that its infarction mechanism may mainly be artery-to-artery embolism and watershed infarction.
Limitations: Small sample size of cases
Funding for this study: This study was supported by the National Natural Science Foundation of China (Grant No. 82360341), the Natural Science Foundation of Jiangxi Province (20242BAB26158), the Clinical Research Center For Medical Imaging In Jiangxi Province(Grant No.20223BCG74001).

Predicting Functional Brain Recovery After Stroke Using Radiomics and Connectomics: A Multimodal Imaging-Based Machine Learning Study (6 min)

Aditya Chauhan; Bangalore / India

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: A. Chauhan; Bangalore/IN
Purpose: Predicting individual recovery trajectories after stroke remains a clinical challenge. Traditional imaging assessments are limited in capturing the complex neural changes that underlie post-stroke recovery. This study integrates radiomics (quantitative imaging features) and connectomics (brain network analysis) to build a predictive model of functional recovery following ischemic stroke.
Methods or Background: I analyzed data from 127 patients in the ATLAS v2.0 Stroke Lesion Segmentation Dataset, who underwent MRI within 7 days of stroke onset. Imaging included T1, FLAIR, DWI, DTI, and resting-state fMRI. Radiomic features were extracted from lesion masks using PyRadiomics, while structural and functional connectomes were derived from DTI and rs-fMRI, respectively. Graph-theoretical metrics (e.g., global efficiency, clustering) were computed. Machine learning models (Random Forest, XGBoost) were trained using combined features to predict outcomes at 3 and 6 months, including Modified Rankin Scale (mRS) and Montreal Cognitive Assessment (MoCA) scores.
Results or Findings: The combined radiomics-connectomics model achieved AUC = 0.91 for predicting motor recovery (mRS ≤2) and AUC = 0.88 for cognitive recovery (MoCA ≥26). Key predictors included lesion texture entropy, surface-to-volume ratio, and reduced global efficiency in ipsilesional networks. The integrated approach outperformed models based on radiomics or connectomics alone.
Conclusion: Multimodal neuroimaging features derived from acute MRI can predict long-term functional outcomes in stroke survivors with high accuracy. This integrative framework may enable personalized rehabilitation planning and improve early prognostication in clinical practice.
Limitations: Simulated outcome data, motion artifacts, and lack of external validation may limit clinical generalizability. Future work will focus on real-world validation and model interpretability.

Multimodal Integration of Radiomics, Clinical, and Immune Features Improves Survival Prediction in Glioblastoma (6 min)

Yingqian Huang; Guangzhou / China

Author Block: Y. Huang[1], J. Chu[1], L. Zhao[2], R. Xu[2], W. Zhou[3], H. Wei[3]; [1]Guangzhou/CN, [2]Beijing/CN, [3]Shanghai/CN
Purpose: Accurate preoperative prognosis remains challenging in glioblastoma (GBM). This study developed a multimodal nomogram integrating radiomic, clinical, and immunological features to predict overall survival (OS).
Methods or Background: We retrospectively analyzed 298 training and 123 validation GBM patients. A total of 6,792 radiomic features were extracted from tumor core and peritumoral edema regions on T1CE, T2WI, and T2-FLAIR MRI. Clinical variables (cortical, ependymal, and contralateral invasion) and immune markers (PD-1, CD68+, CD86+, CD163+, HIF-1α+, etc.) were evaluated. Tumor and peritumoral radiomic scores were constructed via LASSO-Cox regression. A Cox model integrated these scores with clinical and immune scores to predict OS.
Results or Findings: Tumor-core radiomic scores: 2 wavelet-based features were selected via LASSO-Cox regression to construct the tumor core score (HR=3.02, 95%CI 1.38–6.64, p=0.006). Peritumoral radiomic scores: 5 skewness-based features were identified for the peritumoral score (HR=3.18, p=0.049). Clinical score: Multivariate Cox analysis confirmed cortical invasion, ependymal invasion, and contralateral invasion as independent prognostic factors (all p<0.05). The clinical score stratified patients into high- and low-risk groups with distinct survival trajectories (p<0.05). Immune stratification: Based on densities of nine immune markers (PD1+, CD68+, etc.), patients were classified into immune-cold, -intermediate, and -hot subgroups. Survival analysis revealed significant OS differences among subgroups (p<0.05). Multimodal integration: The integrated nomogram combining Tumor-core radiomic scores, peritumoral radiomic scores, clinical scores, and immune scores demonstrated superior predictive accuracy compared to unimodal models.It achieved an AUC of 0.86. High-risk patients had significantly shorter OS (p<0.05).
Conclusion: The nomogram synergizes radiological, pathological, and immunological data to refine GBM prognostication. Peritumoral skewness features and specific invasion patterns signal aggressive biology, while immune-hot phenotypes correlate with poorer outcomes. This framework aids personalized therapy decisions.
Limitations: This study was a single-center design.
Funding for this study: No.

Super-Resolution APTWI Radiomics Enhances IDH-1 Status Prediction in Glioma (6 min)

Yifei Su; Taiyuan / China

Author Block: Y. Su, L. Wang, D. Jia, J. Wang, K. Yang, X. Yang, Y. Meng, C. Wang, H. Ji; Taiyuan/CN
Purpose: To investigate the added value of super-resolution (SR) reconstruction and radiomic modeling in predicting IDH-1 status and Ki-67 level in glioma.
Methods or Background: A total of 76 glioma patients were retrospectively enrolled and randomly assigned to training (n=50) and testing (n=26) cohorts. A total of 833 radiomic features were extracted from both original and reconstructed APTWI images. Features were selected via z-score normalization, Mann–Whitney U test ($p < 0.05$), and Spearman correlation filtering ($p < 0.9$). Least absolute shrinkage and selection operator regression was used to construct radiomics scores. Five machine learning models (LR, SVM, KNN, LightGBM, MLP) were trained to predict IDH-1 status and Ki-67 level, and model performance was evaluated using ROC and decision curve analysis (DCA).
Results or Findings: For IDH-1 prediction using original APTWI, the best AUCs were achieved by SVM (training: 0.893; testing: 0.775) and LR (testing: 0.882). For Ki-67 prediction, MLP performed best (training: 0.906; testing: 0.833). Ki-67 prediction using SR-APTWI was not pursued due to model overfitting. In the training cohort, LightGBM, LR, and MLP improved (AUC from 0.738 to 0.839, 0.760 to 0.818, 0.816 to 0.859, respectively, all $p< 0.05$); in the testing cohort, KNN and LightGBM also showed modest gains.
Conclusion: Radiomic modeling based on super-resolution reconstructed APTWI improves or maintains performance in predicting IDH-1 mutation status and shows potential for enhancing clinical decision-making in glioma management.
Limitations: First, as a retrospective, single-center study with a limited sample size, it is subject to various biases and lacks generalizability. Second, our 2D APTWI protocol captured only the largest tumor slice, with ROI manually delineated—an approach insufficient to reflect the marked intra-tumoral heterogeneity of gliomas. Third, the absence of ground-truth high-resolution images limits the interpretive strength of our results.

Hospital-integrated deep learning system for real-time glioma analysis with advanced diffusion MRI (6 min)

Milan Nemy; Prague / Czechia

Author Block: M. Nemy, E. Stoklasa, D. Bojko, V. Sedlák, A. Kavková, L. Polášková, I. Jacečková, M. Majovsky; Prague/CZ
Purpose: This study presents a hospital-integrated real-time system for multi-shell diffusion MRI (dMRI) analysis in gliomas, including its architecture, secure PACS-connected workflow, and embedded machine-learning models for molecular prediction and automatic segmentation.
Methods or Background: A cohort of 210 patients with histologically confirmed intra-axial gliomas underwent a 3T MRI protocol including high-angular, multi-shell dMRI (134 directions, 7 b-values). Advanced diffusion models (DKI, RSI, VERDICT, NODDI) were derived to characterize microscopic tissue composition. Cellularity maps were used to train classical machine-learning models (XGBoost, random forest) and deep-learning models (CNNs, ResNet50), with data augmentation and transfer learning to address sample size. Automatic tumor and peritumoral segmentation was performed using CNNs and benchmarked against semi-automatic annotations. A secure hospital-integrated pipeline was implemented to enable real-time use: scans are anonymized at acquisition, transferred via encrypted channels to a high-performance cluster, processed under strict time limits, and results returned directly into PACS for radiologist review.
Results or Findings: Advanced dMRI models outperformed conventional ADC in glioma characterization. For IDH mutation prediction, AUC improved from 0.82 (ADC) to 0.91 with advanced models, and for glioma grading from 0.88 to 0.94. Deep-learning achieved the best performance with IDH classification (AUC >0.95, sensitivity >0.93). Automatic segmentation achieved mean Dice coefficients of >0.83 for enhancing tumor and >0.78 for peritumoral zones. The hospital-integrated system processed cases end-to-end robustly within clinically acceptable time limits.
Conclusion: This work demonstrates a clinically viable hospital-integrated system that combines advanced multi-shell dMRI and machine learning for accurate molecular prediction and automatic glioma segmentation. The architecture enables secure, real-time analysis with seamless PACS integration, provides advanced imaging biomarkers directly to radiologists, and may reduce manual workload in routine practice.
Limitations: The limitations of the study are its single-center design and relatively limited sample size.
Funding for this study: Funding was provided by the Ministry of Health of the Czech Republic, grant no. NW25J-08-00023, and by Charles University, project GA UK no. 222623.

OMT and tensor SVD based deep learning model for segmentation and predicting genetic markers of glioma: a multicenter study (6 min)

Zhengyang Zhu; Nanjing / China

Author Block: Z. Zhu[1], H. Yang[1], H. Wang[2], Y. Song[1], M. Xu[1], X. Zhang[1], W-W. Lin[2], T. Li[2], B. Zhang[1]; [1]Nanjing/CN, [2]Shanghai/CN
Purpose: Our study focused on tumor regions segmentation and predicting the World Health Organization (WHO) grade, isocitrate dehydrogenase (IDH) mutation, and 1p/19q codeletion status using deep learning models on preoperative Magnetic Resonance Imaging (MRI).
Methods or Background: Glioma is the most common primary malignant brain tumor and preoperative genetic profiling is essential for management of glioma patients. We developed an optimal mass transport (OMT) approach to transform irregular MRI brain images into tensors. In addition, we proposed an algebraic pre-classification (APC) model utilizing multi-mode OMT tensor singular value decomposition (SVD) to estimate pre-classification probabilities. The fully automated deep learning model named OMT-APC was used for multitask classification. Our study incorporated preoperative brain MRI data from 3,565 glioma patients across 16 datasets spanning Asia, Europe, and America. Among these, 2,551 patients from 5 datasets were used for training and internal validation. In comparison, 1,014 patients from 11 datasets, including 242 patients from The Cancer Genome Atlas (TCGA), were used as independent external test.
Results or Findings: OMT segmentation model achieved mean lesion-wise Dice scores of 0.880. The OMT-APC model was evaluated on the TCGA dataset, achieving accuracies of 0.855, 0.917 and 0.809, with AUC scores of 0.845, 0.908 and 0.769 for WHO grade, IDH mutation, and 1p/19q codeletion, respectively, which outperformed the four radiologists in all tasks.
Conclusion: These results highlighted the effectiveness of our OMT and tensor SVD-based methods in brain tumor genetic profiling, suggesting promising applications for algebraic and geometric methods in medical image analysis.
Limitations: Lacking prospective validation cohort.

Ultra-low iodine PE-CTA across body-weight groups and PSI adjustments: achieving the ≥250 HU target in real-world practice (6 min)

Hortência De Jesus Ferreira; Campinas / Brazil

Author Block: J. T. d. S. d. Castro, H. d. J. Ferreira, D. C. Novais da Silva, D. Yamada, S. San Juan Dertkigil, F. Reis; Campinas/BR
Purpose: Computed tomographic pulmonary angiography (PE-CTA) must achieve ≥250 HU for reliable diagnosis; doing so with ultra-low iodine volumes across different body-weight groups is challenging. The aim is to evaluate the impact of weight-stratified, PSI-adapted PE-CTA protocols on arterial enhancement and iodine load.
Methods or Background: Single-centre retrospective longitudinal analysis within ANGIO-MONITOR. Consecutive PE-CTA exams were split by protocol change (go-live 01-Jun-2025): pre (fixed volumes; N=339) vs post (personalised 30–50 mL by weight with PSI ceilings; N=129). Primary endpoint: arterial attenuation (HU) in the pulmonary trunk. Secondary endpoints: proportion ≥250 HU, contrast volume (mL; mL/kg), peak PSI, and repeat acquisitions. Statistics: Welch's tests for means; χ^2 for proportions; 95% CIs.
Results or Findings: Arterial enhancement increased from 313.5 HU (95% CI 301.3–325.7) to 499.7 HU (95% CI 465.5–533.9); $p=5.38\times10^{-19}$. The proportion ≥250 HU rose from 72.3% (95% CI 67.3–76.8; 245/339) to 95.3% (95% CI 90.2–97.9; 123/129); absolute Δ +23.1 pp, RR 1.32; $p=5.26\times10^{-8}$. Mean contrast volume fell from 60.0 mL (95% CI 58.3–61.8) to 43.8 mL (95% CI 41.5–46.1); −27.0%, $p=1.22\times10^{-24}$. Normalised dose decreased from 0.825 mL/kg (95% CI 0.797–0.853) to 0.577 mL/kg (95% CI 0.547–0.606); −30.1%, $p=2.31\times10^{-28}$. Peak PSI remained within operational safety, with a modest rise (98.9 to 107.8; 95% CIs 95.5–102.3 vs 102.1–113.5; p=0.0089). Repeat-acquisition rates were rare and stable (p=0.45).
Conclusion: Weight-stratified, PSI-adapted ultra-low iodine PE-CTA substantially increased enhancement above the 250 HU threshold while reducing iodine by ~27% (mL) and ~30% (mL/kg), without operational penalty. This supports iodine stewardship and safe high-flow practice in routine care, highlighting technologist-led implementation and hospital–industry synergy.
Limitations: The study is a single-center retrospective analysis, which may limit the generalizability of the findings.

Image Quality Evaluation of Standard Knee versus AI-Enhanced Knee MRI Protocols (6 min)

Lucas Buttex; Lausanne / Switzerland

Author Block: L. Buttex, L. Gallus, Y. Cottier, C. S. D. Reis, S. S. Ghotra; Lausanne/CH
Purpose: To evaluate the application of artificial intelligence(AI) to reconstruct knee MRI imaging compared to standard protocols and identify if there is add-value for clinical practice.
Methods or Background: An exploratory study was conducted to evaluate AI-based image reconstruction methods in MRI compared to the standard(STD) knee MRI protocol. T1 Fast Spin Echo(FSE), PD FSE Fat saturation(FS) and T2 FSE in sagittal view, with PD FSE FS axial, and PD FSE FS coronal views were acquired. Protocols were optimised to enhance image quality(IQ) and reduce acquisition time. The final protocol was applied in 10 healthy volunteers using a 3T MRI to acquire the images. Visual assessment was performed by three MRI-experienced observers using the ViewDEX software. Visual Grading Analysis(VGA), Kappa statistics for inter-observer agreement and Visual Grading Characteristics(VGC) were performed to analyse data.
Results or Findings: Overall, the VGA scores indicate that the values for AI protocol are generally higher or equivalent to those for STD sequences across nearly all criteria of anatomical reproduction and IQ and 36.9% of time reduction was achieved as well 8min22s versus 13min15s. Kappa statistics indicated a medium to good agreement for AI protocol sequences(0.44-0.71) compared to low to good agreement for STD protocol sequences(0.13-0.71). VGC analysis showed that sequences reconstructed with the AI tool performed statistically better than STD sequences at 3T, with AUCVGC of 0.76 to 0.81(95% CI and p-value≤0.05).
Conclusion: This study demonstrates that the use of AI in knee MRI investigations has a tangible impact on the overall IQ, as well as on acquisition time, which was reduced by 36.9%. Further research is required to emphasise the clinical validation of the results with a larger sample size and cases including pathology.
Limitations: Small sample of healthy volunteers

Quantifying the carbon footprint of [^{18}F]FDG PET/CT imaging through Life Cycle Assessment (6 min)

Andrea Roletto; Milan / Italy

Author Block: A. Roletto[1], A. Savio[2], E. Bertagna[2], N. S. Chiodini[1], G. R. Bonfitto[1], A. Chiti[1], S. Zanoni[2]; [1]Milan/IT, [2]Brescia/IT
Purpose: While the environmental impact of diagnostic imaging is increasingly acknowledged, comprehensive analyses of nuclear medicine remain scarce. This study presents a Life Cycle Assessment (LCA) of routine [^{18}F]FDG PET/CT examinations, with the aim of quantifying their Greenhouse Gas (GHG) footprint and identifying opportunities for impact reduction.
Methods or Background: A cradle-to-grave LCA was performed in accordance with ISO 14040 standards within a nuclear medicine department. A standard [^{18}F]FDG PET/CT protocol was evaluated. Direct measurements were used to determine scanner electricity consumption, whereas heating, ventilation, and air conditioning (HVAC) energy demand was estimated for each relevant area based on data from the hospital trigeneration plant. Radiopharmaceutical production and single-use materials were modeled using SimaPro software.
Results or Findings: GHG footprint of a single PET/CT examination was estimated at 7.6 kg CO_2 eq. HVAC systems were the largest contributor (47% of CO_2 eq, 3.6 kg CO_2 eq.), encompassing the scan room, control room, injection room, and cyclotron facility. Radiopharmaceutical production represented 36% of the footprint, while direct scanner electricity accounted for only 5.4%. Single-use disposables were notable contributors to toxicity-related impacts and waste generation (2.1 kg CO_2 eq., 28%). Sensitivity scenarios suggested that ongoing decarbonization of the electricity grid could lower PET/CT-related carbon emission by up to 50%.
Conclusion: The environmental impact of [^{18}F]FDG PET/CT is predominantly driven by HVAC energy demand and radiopharmaceutical production. Mitigation strategies, such as enhancing HVAC efficiency, increasing reliance on renewable energy, and replacing single-use items with reusable or lower-impact alternatives, could substantially reduce the carbon emission of nuclear medicine services.
Limitations: This analysis was conducted in a single-center setting with one representative PET/CT protocol, which may limit generalizability of the results.

Dual-energy CT pulmonary angiography using dual-flow mixture bolus tracking□Potential for contrast medium and radiation exposure reduction (6 min)

Mingjue Jian; Guangzhou / China

Author Block: M. Jian, L. Ding, M. Chen, Y. Wu, Z. Chen, C. Yan; Guangzhou/CN
Purpose: To assess the feasibility and image quality of a bolus tracking protocol with dual-flow mixture for contrast medium and radiation dose reduction in dual-energy CTPA.
Methods or Background: 121 patients with suspected PE were prospectively included and randomly divided into two groups: dual-low dose CTPA group or routine CTPA group on a third-generation DSCT. Virtual monoenergetic imaging (VMI) at 40-keV from the dual-low dose CTPA group were reconstructed from dual-energy CT and compared with 100-kVp polyenergetic CT images from the routine CTPA group. Attenuation, noise, CNR, and figure of merit were measured and calculated in multiple pulmonary arteries. Qualitative image quality and PE detection was independently rated by two radiologists on a 5-point scale.
Results or Findings: The dual-low dose CTPA group showed significantly higher CT attenuation at 40-keV VMIs (1027.0 ± 287.6 HU vs. 391.8 ± 109.0 HU; $p<0.001$), with comparable median CNR (33.6 vs. 41.0; $p=0.115$) and superior FOM (711.4 vs. 461.5; $p=0.001$) in the pulmonary trunk compared to the routine CTPA group. Superior vena cava artifacts were significantly reduced (both $p<0.05$), while visualization of pulmonary branches was preserved ($p=0.660$ and 0.763). Effective radiation dose was markedly lower in the dual-low dose CTPA group (1.61 mSv vs. 3.62 mSv; $p<0.001$), without compromising PE diagnostic accuracy.
Conclusion: Utilizing a dual-flow mixture bolus tracking technique and a low contrast volume, dual-source CTPA allows for substantial radiation dose savings while maintaining sufficient image quality in patients with suspected PE.
Limitations: This single-center study with a relatively small sample size used a dual-source DECT from one vendor, limiting generalizability. Only VMIs at 40–70 keV were assessed, and the manufacturer-recommended Qr36 kernel for dual-energy mode may have increased image noise in the dual-low dose group.
Funding for this study: Funding was provided by the National Natural Science Foundation of China (Grant No.82271987).

Predicting radioiodine-refractory thyroid cancer through the use of nuclear medicine and radiogenomic biomarker analysis: The RADAR study (6 min)

Karen Borg Grima; Naxxar / Malta

Author Block: K. Borg Grima, J. L. Portelli, J. Borg, A. Rasalam Iris; Msida/MT
Purpose: Differentiated thyroid cancer (DTC) is primarily treated with surgery and radioactive iodine (RAI) ablation, achieving excellent outcomes in most patients. However, 5–10% of metastatic cases develop RAI-refractory disease (RAI-R), representing 60–70% of those with progressive disease. RAI-R patients face poor prognoses, with an average survival of 3–5 years. At present, clinicians lack biomarkers to predict RAI refractoriness, delaying the initiation of targeted therapies. The RADAR project aims to integrate the results of nuclear medicine imaging and molecular profiling into a radiogenomic framework of a unique population sample.
Methods or Background: This prospective study involves patients with DTC presenting at the only oncology centre in Malta. Data relating to clinical, biochemical, and histopathological findings, combined with imaging (I-131 SPECT/CT, 18F-FDG PET/CT) and molecular analyses, such as the microRNA profile, are collected longitudinally. Radiogenomic correlations are performed to identify patterns of RAI uptake and FDG avidity, potentially predictive of resistance. Candidate biomarkers will be validated and incorporated into a predictive risk algorithm.
Results or Findings: Previous research has shown that high FDG uptake (specificity 87.5%; sensitivity 83.3%) and certain genetic variants in the symporters are strongly associated with early loss of RAI avidity. By project completion, the study aims to achieve Technology Readiness Level 5 by delivering a validated biomarker panel and predictive model capable of stratifying high- versus low-risk patients for RAI-R progression.
Conclusion: The RADAR study introduces an innovative radiogenomic precision oncology approach, combining data obtained from nuclear medicine, radioiodine therapy and pathology. Early prediction of RAI-R could enable personalised treatment planning, reduce unintended toxicity and improve overall survival of DTC patients.
Limitations: RAI-R cases present a limited number of patients; however, data collection will run for the whole duration of the RADAR project.
Funding for this study: Funding for the RADAR project was obtained from the government agency , Xjenza Malta, responsible for promoting and coordinating scientific research in Malta.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: RADAR project team are currently in the process of obtaining ethical permission from the University of Malta Research Ethics Committee (UREC)

Diagnostic Performance of Photon-Counting Detector CT for Lung Cancer: Utility of Virtual Non-Contrast and Purecalcium Reconstruction (6 min)

Yuhan Zhou; Zhengzhou / China

Author Block: Y. Zhou, Z. Wang, Y. Guo, X. Guo, L. Lei; Zhengzhou/CN
Purpose: To assess the diagnostic value of virtual non-contrast (VNC) and PureCalcium (PC) images on photon-counting detector computed tomography (PCD-CT) in lung cancer detection.
Methods or Background: The study prospectively enrolled 100 patients diagnosed with lung cancer between September and December 2024, all of whom underwent plain and contrast-enhanced chest scans using PCD-CT. The true non-contrast (TNC), VNC, and PC images were reconstructed with slice thicknesses of 5.0 mm, 1.0 mm, and 0.4 mm, respectively, and were labeled as TNC, VNC-AP, VNC-VP, PC-AP, and PC-VP. Objective parameters included CT attenuation, image noise, signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR). Subjective evaluation encompassed image noise, anatomical structure delineation, lesion sharpness, and overall image quality. The maximum diameter (MD) of lesions and lymph nodes was measured, and the absolute error (MDerror) between the VNC, PC, and TNC images was calculated. Radiological features of lung cancer lesionswere assessed on all images.
Results or Findings: There were no significant differences in objective parameters or subjective image quality between the PC-VP and TNC images ($P > 0.05$). In terms of radiological feature detection, VNC and PC images were inferior to TNC images for identifying calcification. The detection rate of radiological features was lowest in 5.0 mm images. Reducing the slice thickness from 5.0 mm to 1.0 mm improved detection rates across all features. Further reduction from 1.0 mm to 0.4 mm resulted in increased detection rates of the bubble sign, calcification, and bronchial stenosis/cutoff sign.
Conclusion: VNC and PC images are reliable for the assessment of lung cancer and PC-VP images provide image quality comparable to that of TNC images. Images with 0.4 mm slice thickness notably enhancing the detection rate of malignancy-related radiological features.
Limitations: Not applicable.

Assessing Image Quality in Adolescent Idiopathic Scoliosis: A Comparative Study of EOS and X-ray Imaging (6 min)

John O'Neill; Cork / Ireland

Author Block: M. F. Mcentee, A. England, C. Rainey, A. O'Donovan, S. Coakley, J. O'Neill; Cork/IE
Purpose: Adolescent Idiopathic Scoliosis (AIS) is a spinal deformity requiring accurate, high-quality imaging for diagnosis and treatment. While Digital Radiography (DR) remains the gold standard, EOS, a low-dose, biplanar imaging system, have emerged as an alternative. This study compares EOS and DR formage quality for whole-spine X-rays.
Methods or Background: A quantitative design assessed whole-spine imaging using anthropomorphic phantoms in two size configurations: Standard and Large. AP and lateral images were acquired with EOS and DR. Subjective image quality was assessed via a Visual Grading Analysis (VGA) questionnaire completed by 39 radiology professionals. Objective image quality was evaluated using Signal-to-Noise Ratio (SNR) and Contrast-to-Noise Ratio (CNR) metrics on ImageJ software, with statistical analysis via SPSSv27.
Results or Findings: Subjectively, DR scored higher in AP projections (standard: 72%vs.68%, p = 0.015; large:64%vs.60%, p=0.0004), while EOS led in lateral views (standard: 73%vs.69%, p=0.0001; large: 66%vs.60%, p<0.0001).EOS received more "Good" and "Moderate" ratings, but DR had more "Perfect" scores. Both DR and EOS had nearly identical numbers of "Inadequate" ratings. Objectively, DR showed higher SNR and CNR values, but significance was only seen for SNR in the large phantom AP view (DR 46.05 vs. EOS 28.00, p=0.004). Both systems showed reduced image quality with increased phantom size.
Conclusion: EOS demonstrated more consistent imaging across sizes and projections. DR showed marginally better SNR/CNR in some conditions. Subjective results favoured DR in AP views, and EOS in the lateral. Both modalities offer comparable image quality. EOS remains a promising option for AIS imaging; however, several key factors must be considered.
Limitations: Future research should involve real patient imaging, ideally in a multicenter, prospective design. Including a diverse sample of AIS patients would allow assessment of diagnostic performance, interobserver agreement, and real-world utility.

From Pixels to Catheters: Correlating CTA with Coronary Angiography (6 min)

Alket Collaku; Tirana / Albania

Author Block: A. Collaku[1], Z. Mulla[1], E. Dybeli[2], F. Goga[1]; [1]Tirana/AL, [2]Elbasan/AL
Purpose: Coronary Computed Tomography Angiography (CTA) has emerged as a powerful non-invasive tool for evaluation of coronary artery disease (CAD). this study aimed to corelate CTA findings with Invasive Coronary Angiography (ICA), consider the gold standard, over a 10 year experience.
Methods or Background: We retrospectively reviewed cases in which patients underwent both CTA and ICA within a comparable clinical timeframe. Degree of stenosis in major coronary arteries was categorized, and CTA results were compared with ICA findings. Diagnostic accuracy, including sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV), was calculated for detection of significant stenosis (≥50%)
Results or Findings: CTA demonstrated high sensitivity and NPV in ruling out significant CAD, showing strong concordance with ICA in the majority of cases. The technique was particularly reliable in single- and double-vessel disease, whereas specificity decreased in the presence of extensive calcification or motion artifacts. Despite these limitations, CTA consistently reduced the need for unnecessary invasive procedures.
Conclusion: CTA correlates strongly with ICA in the detection of significant CAD and can serve as an effective gatekeeper to invasive testing. In routine clinical practice, CTA offers a safe, accurate, and patient-friendly alternative that complements—but does not fully replace—the diagnostic value of ICA.

Performance evaluation of the Hyperscint™ RP-200 scintillation detector for dosimetry in FLASH radiotherapy (6 min)

Sujeeta Recordon; Pully / Switzerland

Author Block: S. Recordon, M. Scheidegger, M. Thiébaud, I. Buchillier-Decka, K. Sprengers, V. Grilj; Lausanne/CH
Purpose: FLASH radiotherapy (FLASH-RT) delivers ultra-high-dose rates (UHDR >40 Gy/s) with the potential to preserve healthy tissue while maintaining tumor reduction efficacy. Accurate dosimetry is essential for clinical implementation. This study evaluates the performance of the Hyperscint™ RP-200 plastic scintillation detector for routine dosimetry in FLASH-RT, in comparison with detectors considered as references.
Methods or Background: The experiments were performed with the Oriatron eRT6 linear accelerator (CHUV, Lausanne) delivering 6 MeV pulsed electron beams in conventional (CONV) and FLASH modes. The RP-200 was tested for linearity, pulse dose response (PDR), repetition rate (PRF), and depth dose profiles (DDP). The measurements were compared with those of a AdvancedMarkus ionisation chamber and Gafchromic™ EBT3 films. The data were normalised by beam monitor and analysed by linear regression and dose ratios.
Results or Findings: The RP-200 demonstrated excellent linearity in CONV mode (R^2=0.9996) with doses consistent with the reference detectors. In FLASH mode, a systematic underestimation occurred with deviations of 9 to 30%, increasing with PRF and DPP. PDD profiles differed from the references, particularly at a source-surface distance of 600 mm. These results confirm the limitations of the RP-200 in UHDR conditions, potentially related to Cherenkov light contamination.
Conclusion: Although reliable in conventional dosimetry, the RP-200 requires correction factors for routine dosimetry in FLASH-RT. Newer models such as the RP-100 may offer better UHDR performance. Further research is needed to optimise scintillator dosimetry in clinical FLASH.
Limitations: The main study limitation is the definition with certainty of the exact causes leading to differences in doses measured by the scintillator compared to the doses indicated by the films.

Orthopedic Metal Artifact Reduction (OMAR) combined with Dual Energy Computed Tomography (DECT) improves diagnostic image value (6 min)

Ian Blom; De Lier / Netherlands

Author Block: I. Blom[1], M. Olsthoorn[2]; [1]De Lier/NL, [2]Rotterdam/NL
Purpose: Computed Tomography (CT) is frequently used in orthopedic imaging to assess implant failure and complications such as periprosthetic fractures. However, the presence of metal implants often leads to metal artifacts (MA), which can significantly impair diagnostic image quality. Due to the wide variety of implant types and materials, the extent of MA varies considerably. As a result, a combination of artifact reduction techniques is often required to optimize visualization of both the implant and surrounding tissues. To evaluate the effectiveness of metal artifact reduction, multiple kiloelectron volt (keV) reconstructions were performed, with and without Orthopedic Metal Artifact Reduction (OMAR).
Methods or Background: Various orthopedic implants (hip, knee, shoulder, and spine) were scanned using a spectral CT scanner (IQon, Philips, The Netherlands) at 140 kV to reduce metal artifacts. Image reconstructions were performed both with and without OMAR, across a range of virtual monochromatic energy levels up to 200 keV. Hounsfield Units (HU) were measured using regions of interest (ROIs), with average (AVG) and standard deviation (SD) values recorded. Two musculoskeletal radiologists independently assessed diagnostic image quality using a 5-point Likert scale.
Results or Findings: Application of OMAR reduced SD in bone by approximately 10 HU, while increasing metal HU by 40. Bone AVG HU decreased by roughly 150 with OMAR across most joint revisions. Combining OMAR with high keV levels resulted in a 200 HU (AVG) increase in metal component.
Conclusion: Images reconstructed at 130–150 keV with OMAR yielded the highest diagnostic quality scores. However, 130 keV images without OMAR provided the most balanced HU values for both bone and metal, suggesting optimal contrast for diagnostic assessment.
Limitations: Case Study

Does Anterior Cruciate Ligament (ACL) tear alter the Lateral collateral ligament (LCL) Bicep femoris (BF) angle and its radiological significance? (6 min)

Arnav Gupta; Birmingham / United Kingdom

Author Block: A. Gupta[1], K. Shirodkar[1], S. Saxena[2], R. Botchu[1]; [1]Birmingham/UK, [2]JODHPUR/IN
Purpose: There are multiple indirect signs for predicting ACL tears on imaging, apart from the direct visualization of the tear.The primary goal of this study was to assess the correlation between the angle of the LCL-Biceps femoris and ACL injury on MRI and to explore its potential as an ancillary indirect radiological sign.
Methods or Background: A retrospective cohort study was conducted on 142 consecutive patients who had been referred for an MRI due to suspected ACL and knee injuries. Among the patients examined, 92 had an intact ACL on MRI, whereas 50 had ACL tears. The angle between the LCL and biceps femoris was measured on the sagittal PDFS (proton density fat-suppressed) sequence. Two readers independently measured the angle, and intra-observer and inter-observer reliability were assessed.
Results or Findings: The mean angle in the intact ACL group was found to be 28.29° (N=92, SD=6.63, SEM=0.69), while the mean angle in the ACL tear group was 20.24° (N=50, SD=7.13, SEM=1.01). The mean difference between the groups was 8.05° (95% CI=5.69°–10.42°), which was statistically significant with a p-value of less than 0.0001. There was good intra- and inter-observer reliability, with a kappa value of 0.8.
Conclusion: Our study demonstrated a statistically significant trend toward a decreased angle between the LCL and biceps femoris secondary to an ACL tear, owing to the posterior translation of the femur in relation to the tibia. This angle can be used to predict the probability of ACL tears.
Limitations: Limitations include the retrospective design, single-centre setting, and relatively small sample size. Variations in MRI positioning and anatomy may affect angle measurements. Further multicentric, prospective studies are needed to validate the LCL-BF angle as a reliable indirect sign.

Optimisation of chest computed tomography dose values considering image quality indicators (6 min)

Joana Santos; Coimbra / Portugal

Author Block: J. Santos, F. Caseiro Alves; Coimbra/PT
Purpose: For lung diseases the literature recommends Computed Tomography (CT) for diagnostic, follow-up, planning and intervention. This study aims to redefine image quality indicators in chest CT, for pulmonary pathology, analysing CT exposure and image quality values.
Methods or Background: Ethical approval was obtained. In phase 1, the most relevant clinical CT indications for pulmonary pathology were identified. Dose values (n=90), described in the CT Dose Index (CTDIvol-mGy) and Dose Length Product (mGy.cm), were analysed. In phase 2, new imaging criteria were defined by 10 radiologists, using Delphi method. Image quality was evaluated objectively [10 Regions of Interest (ROI's)] and subjectively [(2 radiologists - Visual Grading Characteristic (VGC)]. In phase 3, dose values were analysed (n=100). Examinations performed on the same patients were analysed in terms of exposures and image quality.
Results or Findings: Microbacterial pathologies (MB), Lung nodules (NO) and Pulmonary fibrosis (FB) were the defined pathologies. The DLP values on phase 1, were 457mGy.cm for MB, 430mGy.cm for NO and 372mGy.cm for FB, without differences in quality criteria. The exposure values on phase 2, were 305mGy.cm for MB, 300mGy.cm for NO, and 372mGy.cm for FB. Analysis of the dose values of the same patients, revealed a variation from 399 to 324mGy.cm for MB, and from 378 to 324mGy.cm for NO. On phase 3 objective image quality identified lower noise values and higher area under the VGC curve (MB and NO).
Conclusion: The definition of new image quality criteria, with the application of robust statistical methods, allows a detailed analysis per imaging quality criteria. A reduction in DLP of 33% for MB, 30% for NO was obtains with an image quality improvement.
Limitations: The chest pathologies in study are focus on lung parenquima.
Funding for this study: No funding.

Reducing the Need for Sedation in Pediatric CT: Experience with Aquilion ONE 640-Slice (6 min)

Alket Collaku; Tirana / Albania

Author Block: Z. Mulla[1], A. Collaku[1], E. Dybeli[2], F. Goga[1]; [1]Tirana/AL, [2]Elbasan/AL
Purpose: To evaluate the impact of ultra-fast 640-slice CT (Aquilion ONE) on the reduction of sedation requirements in pediatric patients undergoing emergency and routine imaging.
Methods or Background: A retrospective review was performed on pediatric CT examinations (ages 1–12 years) conducted with the Aquilion ONE 640-slice system over a 12-month period. Parameters recorded included scan time, diagnostic image quality, presence of motion artifacts, and the rate of sedation. Protocols were optimized using individualized low-dose settings and iterative reconstruction techniques.
Results or Findings: The mean scan time was below 1 second for most brain, chest, and abdominal studies. Diagnostic quality was preserved in 95% of cases, with minimal need for repeat scanning. Only 7% of patients required sedation, compared with published rates of 30–40% with conventional CT. Motion artifacts were significantly reduced due to volumetric coverage in a single rotation.
Conclusion: The Aquilion ONE 640-slice CT significantly decreases the need for sedation in pediatric imaging by providing ultra-fast acquisitions with high diagnostic quality at optimized radiation doses. This approach improves patient safety, comfort, and clinical workflow, representing an important advancement in pediatric CT practice.

Quantitative Differentiation of Myocardial Tissue Using Photon-Counting CT Cardiac Imaging: A Pilot Study (6 min)

Karima Tissir; Milan / Italy

Author Block: K. Tissir, P. Spagnolo; Milan/IT
Purpose: To quantitatively evaluate Cardiac imaging with Photon-Counting Computed Tomography (PCCT) for differentiating healthy myocardium, scar tissue, and edema using material decomposition maps and objective imaging metrics.
Methods or Background: Anonymised images from twenty-five patients with confirmed myocardial disease (acute or chronic infarction, myocarditis-related edema) undergoing PCCT with ECG-synchronised iodinated contrast were analysed. Reconstructions included conventional images, monoenergetic images (40–70 keV), and material decomposition maps (iodine, calcium, soft tissue). Myocardial regions of interest were segmented using Cardiac Mgnetic Resonance (CMR) imaging as reference. For each tissue type (healthy, scar and edema), mean attenuation associated to HU or iodine concentration, standard deviation, Signal-to-Noise Ratio (SNR), and Contrast-to-noise Ratio (CNR) were calculated. Receiver Operating Characteristic (ROC) analysis assessed discrimination performance between healthy and pathological tissue.
Results or Findings: Mean attenuation or iodine concentration differed significantly among tissues: healthy myocardium 55 ± 5 HU, scar 80 ± 8 HU, edema 65 ± 6 HU. CNR between scar and healthy tissue was 5.8 ± 1.2, SNR of healthy myocardium 32 ± 4. ROC analysis yielded area under the curve (AUC) of 0.87 for scar versus healthy myocardium and 0.81 for edema versus healthy myocardium. Voxel-wise concordance with CMR segmentation was 86%, indicating high agreement.
Conclusion: PCCT enables quantitative differentiation of myocardial tissues through material decomposition maps, providing reproducible SNR and CNR measurements. This pilot study demonstrates the feasibility of using PCCT for objective assessment of scar and edema, potentially complementing CMR in clinical practice.
Limitations: The study is limited by the small sample size and single-center design. Material decomposition maps require further validation against larger cohorts, and current results may not generalize to all PCCT scanners or acquisition protocols.

Spectral CT Imaging Study of Gastric Stromal Tumors and Extra-gastric Stromal Tumors (6 min)
Mengchen Yuan; Zhengzhou / China

Author Block: M. Yuan; Zhengzhou/CN
Purpose: To explore the value of spectral CT in characterizing gastric stromal tumors and extra-gastric stromal tumors by combining clinical and conventional imaging features and spectral CT quantitative parameters.
Methods or Background: The clinical data of 55 patients with gastrointestinal stromal tumor (GIST) scanned by spectral CT from March 2022 to November 2023 were retrospectively collected from the First Affiliated Hospital of Zhengzhou University, which were classified into the gastric stromal tumor (GST) group (n = 42) and the extra-gastric stromal tumor (E-GST) group (n = 13) according to the location of the tumor. The clinical, conventional imaging features and spectral CT quantitative parameters of the two groups were compared and analyzed, and the differences between the two groups were compared by univariate analysis.
Results or Findings: Compared to the E-GST group, only CD34 showed a significant difference in clinicopathological indexes ($P < 0.05$), while no significant differences were found in other demographics and biomarkers. Regarding conventional imaging features, significant differences were observed in lesion diameters, shape, ulceration, enhancement homogeneity, and growth pattern ($P < 0.05$), but not in peritumoral fat, necrosis, calcification, or lymph node status. Among spectral parameters, IC, NIC, CT values at 40–140 keV, λHU, and Zeff in both arterial and venous phases differed significantly ($P < 0.05$), whereas ED values did not.
Conclusion: GST and E-GST have many similarities and differences in pathology and clinical presentation. Spectral CT is of high clinical value for quantitative and qualitative assessment of imaging features of both.
Limitations: this is a small single-center study with limited E-GST cases

Nomogram based on Dual-layer spectral detector CT parameters for Ki67-index stratification in pancreatic neuroendocrine tumors (6 min)
Tiansong Xie; Shanghai / China

Author Block: J. Sun[1], Z. Zhou[2], T. Xie[2], W. Liu[2], Y. Chen[2], Y. Wang[2]; [1]FuZhou/CN, [2]Shanghai/CN
Purpose: To preoperatively predict the Ki-67 index of pancreatic neuroendocrine tumors (pNETs) using quantitative and qualitative variables obtained from dual-layer spectral detector CT (DLCT).
Methods or Background: This retrospective study assessed 196 patients with pathologically confirmed pNETs who underwent DLCT between November 2020 and December 2024. Patients were randomly divided into a training set (n=138) and a testing set (n=58) . Quantitative DLCT parameters included iodine concentration (IC), VMI40keV, VMI70keV, and effective atomic number (Zeff) during arterial phase (AP) and venous phase (VP). Morphological CT features included tumor location, shape, margin, heterogeneity, calcification, necrosis, parenchymal atrophy, and main pancreatic duct dilatation. Patients were stratified into low- and high-proliferation groups using a 5% Ki-67 cutoff. Univariate analysis identified significant predictors, followed by forward stepwise binary logistic regression for further screening and prediction model construction. A multiparametric model was visualized as a nomogram, and its performance was evaluated using ROC analysis.
Results or Findings: A total of 196 patients (124 low- and 72 high-proliferation; median age 54.3 years, IQR 44.2–62.3) were included. Multivariate analysis revealed that heterogeneity (OR = 3.96, 95% CI: 1.77-9.08, p = 0.001) and Zeff_PP (OR = 0.24, 95% CI: 0.12-0.47, p < 0.001) were independent predictors. The nomogram combining Zeff_PP and heterogeneity achieved the highest AUCs of 0.808 (95% CI: 0.731-0.886) and 0.809 (95% CI: 0.686-0.932) for the training and testing sets, significantly exceeding the morphological CT model (p=0.0009 and p=0.0014, respectively).
Conclusion: DLCT-derived parameters, particularly when combined with morphological CT features in a nomogram, provide valuable noninvasive preoperative prediction of Ki-67 stratification in pNETs, which may aid in surgical planning and treatment stratification.
Limitations: Single-center retrospective design and limited sample size

Dual-Layer Spectral CT in Preoperative Prediction of Pancreatic Neuroendocrine Tumor Grade: A Clinical Study (6 min)

Yi Chen; China

Author Block: J. Sun[1], Z-R. Zhou[2], T. Xie[2], W. Liu[2], Y. Chen[2], Y. Wang[2]; [1]FuZhou/CN, [2]Shanghai/CN
Purpose: To predict the histological grade of pancreatic neuroendocrine tumors (pNETs) preoperatively using quantitative and qualitative variables obtained from dual-layer spectral detector CT (DLCT).
Methods or Background: This retrospective study assessed 177 patients with pathologically confirmed pNETs who underwent DLCT between November 2017 and December 2024. For quantitative analysis, both conventional and spectral parameters, such as effective atomic number (Zeff) and iodine concentration (IC), were measured in each phase. The iodine enhancement fraction (IEF_PP/VP) was calculated as the ratio of IC in pancreatic parenchymal phase to venous phase. Normalized IC (nIC) was derived from the lesion-to-aortic IC ratio at the same slice level. Qualitative variables of necrosis and enhancement uniformity were evaluated on virtual mono-energetic images (VMIs) at 40 keV. Univariate analysis identified significant predictors, followed by forward stepwise binary logistic regression for further screening and prediction model construction. A multiparametric logistic regression model integrating spectral parameters was constructed. Diagnostic performance was evaluated using receiver operating characteristic (ROC) analysis.
Results or Findings: Among 177 pNETs, 62 (35%), were grade G1 and 115 (65%) were grade G2 and G3. Independent predictors included necrosis (OR = 3.546, p < 0.001), enhancement uniformity (OR = 0.103, p < 0.001), Zeff_VP (OR = 0.141, p = 0.001), and IEF_PP/VP (OR = 0.208, p < 0.001). IEF_PP/VP (AUC = 0.708, p = 0.016) exhibited better predictive performance than Zeff_VP (AUC = 0.663), enhanced uniformity (AUC = 0.680), and necrosis (AUC = 0.523). The combination model integrating necrosis, enhancement uniformity, Zeff_VP, and IEF_PP/VP achieved superior diagnostic efficacy, with an AUC of 0.822 (p < 0.001), sensitivity of 88.7%, and specificity of 66.1%.
Conclusion: DLCT-derived spectral parameters are valuable for noninvasive preoperative prediction of pNET histological grade.
Limitations: Single-center retrospective design and limited sample size
Funding for this study: This work was supported by the following projects: National Nature Science Foundation of China (82471981); Shanghai Science and Technology Innovation Action Plan and Hongkong, Macao and Taiwan Science and Technology Cooperation Project (22490760800); Artifical Intelligence Medical Hospital Cooperation Project of Shanghai Xuhui District Science and Technology Commission (23XHYD-13); Shanghai Anticancer Association Soar Project (SACA-AX202309); Shanghai Anticancer Association Eyes Project (SACA-CY23B05); Clinical Research Special Project of Shanghai Municipal Health Commission (202340123)

Accurate Noninvasive Differentiation of Intrapancreatic Ectopic Spleen from Pancreatic NET with SPIO-Enhanced MRI (6 min)

Philipp Sorgo; Vienna / Austria

Author Block: P. Summer[1], P. Sorgo[1], P. M. Sbeghen[2], A. Y. Yasin[1], S. Pötter-Lang[1], N. Bastati-Huber[1], A. Ba-Ssalamah[1], U. I. Attenberger[1]; [1]Vienna/AT, [2]Verona/IT
Purpose: Intrapancreatic ectopic spleen (IPES) is a benign entity that often mimics pancreatic neuroendocrine tumors (NETs) on imaging. Conventional CT, ECCM-MRI, Ga-68 DOTA-NOC PET/CT, and Tc-99m HDRBC SPECT have important diagnostic limitations. Superparamagnetic iron oxide (SPIO)–enhanced MRI may allow reliable noninvasive differentiation. We evaluated the diagnostic performance of multimodal imaging with emphasis on SPIO-MRI.
Methods or Background: This retrospective study included 23 patients (10 NET, 13 IPES; mean age 59 ± 14 years) who underwent ECCM-MRI and SPIO-MRI. Subsets also had CECT (n=22), Ga-68 DOTA-NOC PET/CT (n=13), and Tc-99m HDRBC SPECT (n=6). Two blinded abdominal radiologists assessed qualitative and quantitative imaging features and diagnostic confidence. ROC analyses were performed to evaluate modality performance.
Results or Findings: NETs were significantly larger than IPES (1.9 vs. 1.3 cm, $p<0.05$). ECCM-MRI and CECT showed overlapping enhancement patterns with low accuracy (~50%). Ga-68 DOTA-NOC PET/CT demonstrated higher uptake in NETs compared with IPES (SUVmax 82 vs. 36, $p=0.06$), but with poor discriminatory value. Tc-99m HDRBC SPECT was inconclusive due to limited spatial resolution. In contrast, all IPES lesions showed marked T2/T2* signal loss after SPIO administration, whereas NETs remained unchanged. Both readers achieved 100% accuracy, with excellent interobserver agreement ($\kappa=0.95$, ICC=0.91). ROC analysis confirmed SPIO-MRI as the only modality with near-perfect diagnostic performance (AUC 0.79–1.00, $p<0.001$).
Conclusion: SPIO-enhanced MRI enables confident, noninvasive differentiation between IPES and NET, clearly outperforming conventional imaging and nuclear medicine techniques. It should be implemented as the preferred next step in suspected IPES to avoid unnecessary interventions.
Limitations: This retrospective, single-center study included a small cohort with uneven availability of comparator imaging modalities, limiting generalizability. The reported 100% accuracy of SPIO-MRI requires prospective validation in larger, multicenter cohorts.
Funding for this study: No funding.

Whole-body magnetic resonance imaging (WB-MRI) for cancer screening in adult patients with neurofibromatosis type 1 (NF1) (6 min)

Maria Giovanna Di Niso; Pavia / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: L. Carone, M. G. Di Niso, S. Kalantari, M. Zacchino, F. Sirchia, L. Preda; Pavia/IT
Purpose: NF1 is a rare inherited genetic syndrome characterized by wide phenotypic variability and a predisposition to tumor development. In recent years, WB-MRI has emerged as a valuable imaging tool for the comprehensive evaluation of multisystem alterations associated with NF1 and for the early detection of incidental findings of potential clinical relevance. This prospective, monocentric observational study aimed to assess the role of WB-MRI in the characterization of clinically relevant radiological findings (ONCO-RADS) in adult NF1 patients, promoting a tailored approach.
Methods or Background: Since July 2024, 20 adult patients with NF1 (mean age 36 years, range 18–68) referred to the Medical Genetics Unit of Policlinico San Matteo, Pavia, underwent WB-MRI from head to toe. Each case was discussed by a multidisciplinary team to evaluate disease-related alterations and define appropriate management.
Results or Findings: Plexiform neurofibromas (PN), with variable size and location, were identified in 11/20 patients (55%), of which 6 were newly diagnosed.
Other extracranial findings included cutaneous and subcutaneous neurofibromas (100%), skeletal alterations (60%), thyroid nodules (20%), splenomegaly (15%), diffuse neurofibromas (15%), and bullous dystrophy (5%).
In one patient, an early-stage malignant lung tumor was diagnosed, allowing timely treatment. In another patient with a symptomatic inoperable PN, experimental treatment with Selumetinib was proposed.
Conclusion: This case series confirms the established role of WB-MRI as a safe tool for surveillance and multidisciplinary management of NF1-related manifestations, enabling the detection of previously unknown and clinically relevant lesions.
Limitations: Small cohort study; limited observation period; only preliminary restults are avalaible..
Funding for this study: No

The Role of Molecular Imaging in the Diagnostic Process of Unknown Primary Origin and Suspected NETs (6 min)

Pierpaolo Alongi; Palermo / Italy

Author Block: L. Alonzo[1], R. Cannella[1], R. Laudicella[2], V. Benfante[1], P. Purpura[1], G. Micci[1], M. Galia[1], G. Brancatelli[1], P. Alongi[1]; [1]Palermo/IT, [2]Messina/IT
Purpose: The diagnosis of Neuroendocrine Tumors (NETs) can be challenging because of small lesion size, indolent growth, and variable metabolic activity, particularly in cases of unknown primary origin (CUP-NETs). Early and accurate identification of the primary lesion is essential for therapeutic decisions, including surgery, peptide receptor radionuclide therapy (PRRT), or somatostatin analogues.
This systematic review investigated the diagnostic accuracy and clinical impact of molecular imaging, with particular emphasis on PET/CT with radiolabeled somatostatin analogs, in patients with suspected NETs and CUP-NETs.
Methods or Background: A comprehensive search of PubMed and Scopus was performed following PRISMA guidelines. Twenty-one clinical studies published between 2010 and 2024 were included, encompassing 1,857 patients (420 CUP-NETs and 452 suspected NETs). Extracted data included study design, radiotracers, detection rates, and changes in patient management. Methodological quality was assessed using CASP tools.
Results or Findings: PET/CT with [68Ga]Ga-DOTA-peptides consistently outperformed conventional [111In]Pentetreotide SPECT. Reported detection rates for primary tumors in CUP-NETs ranged from 38% to 83% with PET/CT, compared with less than 10% with SPECT. In suspected NETs, PET/CT achieved sensitivity up to 95% and specificity above 85%, leading to therapeutic changes in up to one-third of cases. Additional diagnostic yield was provided by dual-tracer protocols combining [68Ga]Ga-DOTATATE with [18F]FDG and by newer tracers such as [18F]DOPA and [18F]-OC, particularly for aggressive variants and rare subtypes (e.g., paragangliomas, insulinomas). Detection of unknown primaries frequently enabled curative surgery or more tailored systemic treatment.
Conclusion: [68Ga]Ga-DOTA-peptide PET/CT is a key tool in the diagnostic evaluation of suspected and unknown primary NETs. Beyond its superior sensitivity compared with conventional imaging, it significantly influences clinical decision-making and should be integrated into standard diagnostic algorithms.
Limitations: Several retrospective, single-center, and with small sample sizes articles, which may limit generalizability.

Differentiating Endometrial Stromal Sarcoma from Cellular Leiomyoma Based on a Nomogram Integrating Multimodal MRI and Clinical Data (6 min)

He Zhang; Shanghai / China

Author Block: H. Zhang, Y. Zhou; Shanghai/CN
Purpose: To develop and validate a nomogram combining ADC histogram parameters with conventional MR features for preoperative differentiation between endometrial stromal sarcoma (ESS) and cellular leiomyoma (CL).
Methods or Background: This retrospective, dual-center, diagnostic accuracy study received institutional review board approval. The reference standard was postoperative histopathology. A total of 155 women were included (ESS: n=57, CL: n=98), split into a derivation cohort (n=111 from Hospital A) and an external validation cohort (n=44 from Hospital B). All underwent preoperative contrast-enhanced pelvic MRI. A nomogram was built using stepwise logistic regression on MRI features and ADC histogram parameters and was evaluated with receiver-operating characteristic curve analysis.
Results or Findings: A total of 155 women (mean age, 44 years ± 9 [standard deviation]) were analyzed. A nomogram incorporating irregular margin, cystic change, and mean ADC value was developed. The nomogram achieved an area under the curve (AUC) of 0.828 (95% CI: 0.742, 0.911) in the derivation cohort and 0.873 (95% CI: 0.768, 0.977) in the external validation cohort. At an optimal threshold of 0.477, the nomogram showed a sensitivity of 78.5% and a specificity of 87.9% in the derivation set, and 87.5% and 75.0% in the validation set, respectively.
Conclusion: The nomogram integrating ADC histogram parameters and MR features provides an accurate tool for the preoperative differentiation of ESS from CL.
Limitations: It is a retrospective stufy.
Funding for this study: This study has received funding by the Science and Technology Commission of Shanghai Municipality (Project No. 25ZR1401036).

Quantitative magnetic resonance imaging for the differentiation of soft tissue tumors (6 min)

Felix Schön; Dresden / Germany

Author Block: F. Schön, P. Günther, A. Weidlich, J. Kirchberg, M-L. Kromrey, R-T. Hoffmann, H. Fritzsche, J-P. Kühn; Dresden/DE
Purpose: This study investigated the potential of quantitative magnetic resonance imaging (MRI) to differentiate benign from malignant soft tissue tumors.
Methods or Background: Between 10/2022 and 01/2025, patients with soft tissue tumors were prospectively enrolled for quantitative MRI prior to histopathological confirmation. All 3.0T MRI examinations included chemical shift-encoded MRI, T1-/T2-mapping, and diffusion-weighted imaging (intravoxel incoherent motion [IVIM]). All MRI datasets were post-processed to generate R2*-, PDFF- (proton density fat fraction), T1-/T2-maps, and Diffusion (IVIM D), Pseudo-Diffusion (IVIM D*), Perfusion-Fraction (IVIM f). Histopathological diagnosis was defined as standard of reference. Mean values of two readers of each map were compared using Mann-Whitney U tests. A logistic regression model was established to predict malignancy.
Results or Findings: Fifty-nine patients (30 women; mean age 59.1+/-15.5 years) were examined, including 23 with malignant and 36 with benign tumors. Malignant tumors revealed significantly lower values for R2* (13.5+/-25.9 vs. 42.7+/-29.2; p<0.001), PDFF (29.3+/-38.1 vs. 60.2+/-42.4; p=0.003), IVIM D (1221.5+/-716.6 vs. 683.4+/-810.7; p=0.007), and IVIM D* (26.0+/-48.2 vs. 107.0+/-170.6; p=0.004) compared to benign tumors. In contrast, T1 relaxation times were significantly higher (1843.0+/-1065.4 vs. 1113.6+/-948.3; p=0.031). No significant differences were observed for IVIM f and T2 relaxation times (p>0.05). Univariate logistic regression analyses identified R2*, PDFF, IVIM D, and T1 as predictors for malignancy (p<0.05). Following backward elimination, R2* remained as independent variable in the multivariate model (p=0.002; odds ratio=0.96), yielding an AUC of 0.800 with a Youden-Index of 0.539.
Conclusion: By enabling non-invasive differentiation of soft tissue tumors, quantitative MRI - particularly through the independent predictive value of R2* - may serve as a valuable tool to determine lesion dignity in clinical practice.
Limitations: Limited sample size and single-center setting.
Funding for this study: This work was supported by the Clinical Scientist Program MeDDrive of the University Medicine Dresden.

Beyond Nodules: CT Spectrum of Pulmonary Metastases in osteosarcoma (6 min)

Aruba Nawaz Khattak; Peshawar / Pakistan

Author Block: A. K. Nawaz, S. Ahmed, K. Siddique; Lahore/PK
Purpose: - To illustrate diverse diverse CT appearances of pulmonary metastasis in osteosarcoma.
- To correlate imaging appearances with their frequency in clinical cohort.
- To highlight the role of CT in staging, surveillance and treatment response assessment.
Methods or Background: Lungs are the most common site of metastasis in osteosarcoma. While soft tissue and calcified nodules are well known, atypical patterns such as cavitary, pleural or endobronchial disease are often underappreciated. Pulmonary metastasis in osteosarcoma are not just nodules - they represent a spectrum every radiologist must recognize.
For this purpose, we retrospectively reviewed chest CTs of 46 patients with histologically confirmed osteosarcoma and pulmonary metastasis betrween 2023-2025. Imaging appearances were categorized into six groups: soft tissue nodules, calcified nodules, cavitary lesions, pleural involvement, endobronchial disease and mass like lesions.
Results or Findings: Soft tissue nodules were frequent finding, observed in 15 patients (32.6%). Calcified metastases were present in 14 (30.4%), pleural involvement in 11 (23.9%) and mass like lesions or consolidations in 5 (10.8%). Cavitary lesions and endobronchial disease were less common, identified in 2 patients each (4.3%).
Conclusion: Pulmonary metastases in osteosarcoma demonstrate a wide CT spectrum. Beyond the classic nodule, recognizing calcified, cavitary, pleural and airway patterns is essential for accurate staging, guiding treatment decisions and monitoring disease progression.
Limitations: None

Extra skeletal Ewing Sarcoma: Five-Year Review of 12 Rare Presentations (6 min)

Aruba Nawaz Khattak; Peshawar / Pakistan

Author Block: A. K. Nawaz, M. Nawab, A. Usman, K. Siddique; Lahore, Pakistan/PK
Purpose: Ewing sarcoma is typically a bone tumor, but extra skeletal forms, though uncommon, can occur in diverse anatomical sites. Early recognition of these rare presentations is essential for accurate diagnosis and management. The objective of this study was to analyze the anatomical distribution and imaging characteristics of 12 histologically proven extra skeletal Ewing sarcoma cases from 2020–2025.
Methods or Background: In this retrospective study, we analyzed 208 cases of histologically proven cases of Ewing Sarcoma from January 20202 to January 2025. From these 208 cases, 12 extra skeletal cases were identified after excluding lesions in the upper limb, lower limb, mandible, and thorax. Demographic, anatomical, and imaging data were reviewed.
Results or Findings: Extra skeletal disease represented 5.8% of the cohort. Sites included: head & neck (5, 41.7%), pelvis (3, 25%), abdomen/retroperitoneum (2, 16.7%), thyroid (1, 8.3%), and uterus (1, 8.3%). Patients ranged from 14–32 years; male-to-female ratio was 1.3:1. Imaging revealed well-defined soft tissue masses without bone involvement.
Conclusion: Although rare, extra skeletal Ewing sarcoma can involve head & neck, pelvis, abdomen, thyroid, and uterus. Recognizing these histologically proven atypical sites is vital for timely diagnosis and guiding therapy. This five-year review highlights their frequency, distribution, and imaging features, emphasizing the need for awareness among radiologists and oncologists.
Limitations: None
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective anonymized review was conducted in accordance with our institutional IRB guidelines. No additional patient consent was required.

Primary hepatic angiosarcoma: Distinct imaging phenotypes mirroring histopathologic growth patterns (6 min)

Ji Yeong Kim; Daegu / Korea, Republic of

Author Block: B. J. Kim, M. J. Kim, J. Y. Kim; Daegu/KR
Purpose: To date, there are no studies examining radiologic findings based on histologic patterns of primary hepatic angiosarcoma. This study aims to elucidate radiologic findings of primary hepatic angiosarcoma according to distinct histologic patterns.
Methods or Background: From January 2010 to October 2024, a cohort of 17 patients was included in this study. All patients were pathologically diagnosed with primary hepatic angiosarcoma and underwent CT with or without MRI. Histologic patterns were categorized into mass-forming and non-mass forming groups. The mass-forming type was subdivided into vasoformative and non-vasoformative (epithelioid, spindled) patterns, while the non-mass forming type was divided into sinusoidal and peliotic patterns. Two radiologists independently reviewed the CT and MRI images, categorizing the lesions into diffusely infiltrating and mass-forming types. Additionally, the presence of hypervascular portions and targetoid patterns was analyzed. The correlation between histologic patterns and radiologic findings was assessed using Fisher's exact test.
Results or Findings: The mass-forming pattern was observed in 13 patients (76.5%), while the non-mass-forming pattern was identified in 4 patients (23.5%). There was a significant correlation ($P<.05$) between the radiologically classified patterns of diffusely infiltrating and mass-forming lesions and their pathological counterparts. However, the pathological classification of vasoformative and non-vasoformative lesions did not show a significant correlation with the presence of a hypervascular portion on imaging.
Conclusion: The pathological classification of hepatic angiosarcoma into mass-forming and non-mass-forming patterns closely corresponds to the radiological classification of mass-forming and diffusely infiltrating lesions, indicating that pathological findings are well reflected in imaging characteristics.
Limitations: Due to its retrospective design and relatively small number of patients, there may be inherent selection and sampling biases, and in cases with mixed histologic patterns, both histologic classification and radiologic interpretation were based on the predominant component, potentially limiting accuracy.
Funding for this study: The histologic pattern of primary hepatic angiosarcoma may be reflected in imaging as diffusely infiltrating or mass-forming appearances.

Rhabdomyosarcoma Revisited: The Radiologist's Perspective - Good, Bad and Unusual (6 min)

Supriya Kaur; Delhi / India

Author Block: S. Kaur, S. S. Victory, M. S. Swarup, G. Sindhwani, C. Paruthi, R. Kanaujiya, R. G. Ghasi, A. Malik; Delhi/IN
Purpose: To present the clinical spectrum and imaging features of rhabdomyosarcoma in children resulting in early diagnosis and better patient outcome.
Methods or Background: The retrospective analysis was done at a tertiary care institute providing comprehensive radiological services from August 2023 to April 2025. Cases of rhabdomyosarcoma were assessed and findings compiled.
Results or Findings: A wide spectrum of rhabdomyosarcoma presentations was observed across diverse anatomical locations.
• Head and Neck: Orbital lesions presented with rapidly progressive proptosis and soft tissue masses; non-parameningeal sites revealed well-defined masses with local infiltration, whereas parameningeal tumors demonstrated aggressive features with skull base and intracranial extension.
• Genitourinary System: Bladder involvement was identified with intraluminal polypoid masses causing obstructive symptoms. Testicular rhabdomyosarcoma in males presented as painless testicular enlargement, while vaginal involvement in females appeared as polypoid soft tissue masses often misdiagnosed clinically.
• Perianal Region: Rare cases manifested as infiltrative perianal soft tissue masses, mimicking other benign and malignant conditions.
Conclusion: Rhabdomyosarcoma is a biologically diverse pediatric sarcoma with varied anatomical presentations. Cross-sectional imaging remains pivotal in accurate diagnosis, staging, and treatment planning, thereby guiding multidisciplinary management and improving overall outcomes.
Limitations: No limitations were identified for this study.
Funding for this study: No funding was received for this study.

Diagnostic performance of Node-RADS in predicting lymph node metastases in abdominal and pelvic malignancies: a systematic review and meta-analysis (6 min)

Mariem Ben Salah Faria; Fribourg / Switzerland

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: M. Ben salah Faria, G. Raia, F. Peier, L. Widmer, H. Thoeny; Fribourg/CH
Purpose: Our systematic review and meta-analysis aim to evaluate the diagnostic performance of Node Reporting and Data System 1.0 (Node-RADS) for identifying lymph node (LN) metastases, using histopathology as a reference standard, across a range of abdominal and pelvic malignancies.
Methods or Background: This review was conducted according to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. PubMed, ScienceDirect and Cochrane Library databases were systematically searched until August 2025. We included studies analysing patients diagnosed with an abdominal or pelvic malignancy, who underwent contrast-enhanced CT or MRI for loco-regional work-up, with LN assessment by Node-RADS, associated with LN histopathological analysis. Study quality was assessed by modified Quality Assessment of Diagnostic Accuracy Studies (QUADAS-2) tool. Diagnostic performance was estimated by the random-effects model. Forest plots of pooled sensitivity and specificity were generated for two different Node-RADS thresholds.
Results or Findings: Eighteen retrospective studies were included, comprising 10 using CT and 8 using MRI. These studies covered a variety of malignancies: gynecologic (endometrial, ovarian, cervical), urologic (prostate, bladder, renal), and gastrointestinal cancers (colon, rectal, gastric, cholangiocarcinoma, periampullary). When applying a Node-RADS threshold of ≥3 to define malignant LN, the pooled sensitivity and specificity were 0.80 (95%CI, 0.69-0.87) and 0.79 (95%CI, 0.68-0.87), respectively. For a threshold of ≥4, sensitivity decreased to 0.60 (95%CI, 0.50-0.69), while specificity improved to 0.94 (95%CI, 0.90-0.96). The hierarchical summary receiver operating characteristic (HSROC) analysis showed area under the curves (AUCs) of 0.85 (95%CI, 0.79-0.89) and 0.87 (95%CI, 0.80-0.92) for thresholds ≥3 and ≥4, respectively.
Conclusion: Node-RADS score demonstrated reliable diagnostic performance in assessing lymph node malignancy across abdomino-pelvic malignancies, allowing a standardized approach that enhances reproducibility and supports clinical decision-making in oncologic staging.
Limitations: Heterogeneity of the included studies, which are of retrospective design.

Habitat Subregion Radiomics for Predicting Overall Survival in Immunotherapy-Treated Pleural Mesothelioma: A Multicenter Study (6 min)

Wen Zhao; Kunming / China

Author Block: W. Zhao, D. Han, B. He; Kunming/CN
Purpose: Pleural mesothelioma (PM) is a rare malignancy with a poor prognosis. This study aimed to develop and validate a habitat subregion radiomics model for predicting the prognosis and overall survival (OS) of PM under immunotherapy.
Methods or Background: The PM patients with immunotherapy from two medical centers were enrolled as the training cohort (119 cases), while patients from a third medical center served as the external validation cohort (48 cases). Based on unenhanced CT images, tumor clustering was performed to extract highly correlated radiomic features from habitat subregions. A habitat subregion radiomic model was constructed using the Cox proportional hazards model to predict OS at 6, 12, 18, and 24 months, respectively. Furthermore, a clinical-habitat radiomic combined model and nomogram were developed, incorporating both clinical factors and radiomic features. Finally, the clinical-habitat radiomics model was validated using the external validation cohort.
Results or Findings: The clinical-habitat subregion radiomics combined model outperformed both the pure habitat radiomics model and the clinical model in predicting prognostic outcomes. The clinical-habitat subregion radiomics combined model was visualized as a nomogram, with OS at 6, 12, 18 and 24 months yielding AUC values of 0.807, 0.826, 0.846, and 0.839 in the training set, and 0.769, 0.809, 0.769, and 0.874 in the validation set, respectively.
Conclusion: The clinical-habitat radiomics model showed strong potential for predicting OS in patients with PM undergoing immunotherapy and provided insights into imaging and biological markers potentially implicated in immunotherapy-related tumor progression.
Limitations: First, as a retrospective study, it is prone to selection bias. Second, some patients in this study did not undergo enhanced CT imaging, so radiomic features were extracted only from non-enhanced CT images.
Funding for this study: National Natural
Science Foundation of China(82360344).

Radiology Trainees Forum

This year's quiz features seven clinical cases chosen by seven panellists, all rising stars in their respective subspecialties. Professors Francone and Jacquier orchestrate this interactive session to showcase knowledge sharpened by technology, speed, and vision, a true testament to the ECR's theme. Athena, goddess of wisdom, embodies the search for truth and clarity, while her owl symbolises vision in darkness — a perfect metaphor for radiologists unveiling the unseen. In parallel, artificial intelligence (AI) represents modern precision, deepening our ability to see beyond appearances.

SF 20a - Opportunistic screening for cardiovascular disease and clinical implications: looking for cardiac findings on non-cardiac scans

Categories: General Radiology, Chest, Cardiac
ETC Level: LEVEL II+III
Date: March 7, 2026 | 14:00 - 15:30 CET
CME Credits: 1.5

Moderator:
Gregor Petrun; Vuhred / Slovenia

Chairperson's introduction (10 min)
Gregor Petrun; Vuhred / Slovenia

Coronary calcifications (20 min)
Matthias Eberhard; Zurich / Switzerland

1. To learn about the prognostic value of coronary calcifications.
2. To appreciate how to assess coronary calcifications on non-ECG-gated chest CT practically.
3. To understand the potential of combining calcium assessment and lung cancer screening.

Epicardial adipose tissue (20 min)
Michelle Claire Williams; Edinburgh / United Kingdom

1. To learn to identify and quantify epicardial adipose tissue (EAT) on non-cardiac CT.
2. To appreciate the clinical significance of EAT as a marker of cardiovascular risk and its potential role in opportunistic screening.
3. To understand the pathophysiological links between EAT, coronary artery disease and other cardiometabolic conditions.

Cardiac morphomatrix (20 min)
Rodrigo Salgado; Antwerp / Belgium

1. To understand the possibilities and limitations of assessing cardiovascular pathology on non-gated chest CT.
2. To develop a systematic approach to evaluate the heart on routine chest CT examinations.
3. To understand and describe the underlying pathophysiology of common findings using the correct terminology.

Panel discussion: What is a good practice for reporting incidental cardiac findings? (20 min)

SF 20b - Update on Meniere's disease imaging

Categories: Imaging Methods, Head and Neck, Multidisciplinary, President's Choice

Date: March 7, 2026 | 14:00 - 15:30 CET
CME Credits: 1.5

Moderator:
Yeliz Pekçevik; Izmir / Turkey

Chairperson's introduction (5 min)
Yeliz Pekçevik; Izmir / Turkey

How to establish a Meniere's disease imaging service? (18 min)
Anja Bernaerts; Antwerp / Belgium

1. To choose the optimal MR equipment and sequences.
2. To implement the latest hydrops imaging guidelines for radiographers and radiologists.
3. To identify the criteria for patient selection in hydrops imaging.

How I report delayed post-gadolinium MR imaging for hydropic ear disease: tips and pitfalls (18 min)
Jan Casselman; Brugge / Belgium

1. To list the imaging characteristics of primary hydropic ear disease.
2. To define the current grading systems for endolymphatic hydrops, including their clinical correlation and role in treatment follow-up.
3. To identify anatomical pitfalls and other findings typically seen in hydrops imaging.

Secondary endolymphatic hydrops and other non-hydropic imaging diagnoses in Meniere's symptoms (18 min)
Anne Renée Juliette Péporté; Frauenfeld / Switzerland

1. To describe the term hydropic ear disease and explain the differences between primary and secondary hydropic ear disease.
2. To identify the specificities of common aetiologies of secondary hydropic ear disease.
3. To describe and reflect on the common final pathway in the disruption of the endolymphatic fluid balances in primary and secondary hydropic ear disease.

Endolymphatic hydrops: the growing role of the endolymphatic duct and sac (18 min)
Bernhard Schuknecht; Zürich / Switzerland

1. To learn the imaging anatomy and pathology of the endolymphatic duct and sac.
2. To know the non-visualisation of the endolymphatic duct as an imaging marker of Meniere’s disease.
3. To distinguish different phenotypes of Meniere’s disease based on the angular trajectory of the vestibular aqueduct.

Panel discussion: How can we integrate imaging techniques of endolymphatic hydrops easily in clinical practice? (13 min)

SF 20c - Unraveling the brain: can molecular imaging and theranostics transform neuropsychiatric and oncologic care?

Categories: Hybrid Imaging, Imaging Methods, Molecular Imaging, Neuro, Nuclear Medicine, President's Choice

ETC Level: LEVEL II

Date: March 7, 2026 | 14:00 - 15:30 CET

CME Credits: 1.5

This session explores how molecular imaging and theranostic strategies redefine diagnosis and treatment across brain disorders, from neuropsychiatric conditions to oncologic care. Experts will present advances in mapping brain connectivity disruptions, targeted radioligand therapies for brain tumours, and PET-guided disease-modifying therapies in neurodegenerative disorders. Attendees will gain insights into translating these applications into clinical practice to improve patient outcomes.

Moderator:

Valentina Garibotto; Geneva / Switzerland

Chairperson's introduction (5 min)

Molecular imaging of brain disconnectivity (25 min)

Igor Yakushev; Munich / Germany

Towards theranostics in neuro-oncology (25 min)

Nelleke Tolboom; Amsterdam / Netherlands

PET imaging in the era of Alzheimer's disease modifying drugs (25 min)

Valentina Garibotto; Geneva / Switzerland

Panel discussion: How do we translate methodological advances into clinical practice? (10 min)

AR a20 - How to sound like an expert: reports on chronic liver disease in practice

Categories: Abdominal Viscera
ETC Level: LEVEL I+II
Date: March 7, 2026 | 14:30 - 15:30 CET
CME Credits: 1

Moderator:
Ulrika Asenbaum; Vienna / Austria

Introduction (5 min)
Ulrika Asenbaum; Vienna / Austria

General considerations (10 min)
Ulrika Asenbaum; Vienna / Austria

1. To learn how to structure liver imaging reports to highlight the most relevant imaging features of chronic liver disease.
2. To appreciate the importance of using clear, standardised terminology to ensure seamless communication with clinicians.
3. To understand how to develop strategies to address uncertainty while keeping reports precise.

Cases review, interactive discussionand critiquing of reports (45 min)
Ulrika Asenbaum; Vienna / Austria
Florian Lindenlaub; Vienna / Austria

AI-SC 20 - The regulatory landscape: navigating regulatory clearance, reimbursement, and liability

Categories: Professional Issues, Imaging Informatics, Artificial Intelligence
ETC Level: LEVEL II+III
Date: March 7, 2026 | 14:45 - 15:45 CET
CME Credits: 1

Moderator:
Elmar Kotter; Freiburg Im Breisgau / Germany

Chairperson's introduction (5 min)
Elmar Kotter; Freiburg Im Breisgau / Germany

Panel discussion (45 min)
Shahriar Islam; London / United Kingdom
Sergey Morozov; Brussels / Belgium
Catherine Mary Jones; Brisbane / Australia
Luis Marti-Bonmati; Valencia / Spain

1. To clarify current FDA regulatory pathways for AI/ML-based medical devices.
2. To discuss evolving reimbursement models for AI-augmented radiology services.
3. To address medicolegal considerations and liability distribution between radiologists, institutions, and AI vendors.
4. To explore international regulatory harmonization efforts.
5. To examine the role of continuous learning algorithms and post-market surveillance.

Q&A: Untangling regulation, payment and risk in AI radiology (10 min)

CUBE 24 - Percutaneous approaches in neurointervention: indications, techniques and clinical cases

Categories: Neuro, Interventional Radiology
ETC Level: LEVEL II
Date: March 7, 2026 | 15:45 - 16:15 CET
CME Credits: 0.5

Percutaneous approaches in neurointervention: indications, techniques and clinical cases (28 min)
Alexandru Cimpoca; Rosenheim / Germany

1. To become familiar with the spectrum of percutaneous procedures in neuroradiology, including cranial and spinal interventions.
2. To understand the technical aspects and image-guided approaches of these treatments.
3. To recognise appropriate patient selection criteria, complication management, and safety strategies for minimally invasive neurointerventional procedures.

BS 21 - Radiation safety and dose optimisation

Categories: Imaging Methods
ETC Level: LEVEL I+II
Date: March 7, 2026 | 16:00 - 17:00 CET
CME Credits: 1

SESSION RECOMMENDED BY ESR EUROSAFE IMAGING

Moderator:
Boris Brkljačić; Zagreb / Croatia

Chairperson's introduction (4 min)
Boris Brkljačić; Zagreb / Croatia

Fundamentals of radiation protection (14 min)
Timo De Bondt; Sint-Niklaas / Belgium

1. To explain the basic physics of ionising radiation, including x-ray production and interaction with tissue.
2. To present the ALARA (As Low As Reasonably Achievable) principle as a practical implementation.
3. To explain radiation units and dose metrics, such as absorbed dose (Gy), effective dose (mSv), and dose-length product (DLP).
4. To explain the biological effects of radiation: deterministic vs stochastic effects.

Optimising dose in common imaging modalities (14 min)
Mika Kortesniemi; Espoo / Finland

1. To explain computed tomography (CT) optimisation.
2. To present safety for fluoroscopy and interventional radiology (IR).
3. To present the optimised dose for digital radiography and mammography.

Radiation protection in special populations (14 min)
Claudio Granata; Trieste / Italy

1. To present radiation protection for pregnant patients.
2. To present radiation protection in paediatric radiology.
3. To present occupational radiation safety.

AI and technological innovations in dose optimisation (14 min)
John Damilakis; Iraklion / Greece

1. To explain the role of AI in reducing radiation dose.
2. To present future trends in radiation safety.

ESR/EANM - Pushing the boundaries: emerging fields for interdisciplinary collaboration for better patient care

Categories: Hybrid Imaging, Oncologic Imaging, Neuro, Breast, Cardiac, President's Choice

ETC Level: LEVEL II+III

Date: March 7, 2026 | 16:00 - 17:30 CET

CME Credits: 1.5

All speaker duos comprise experts from both disciplines – radiology and nuclear medicine. They will, together, highlight the complementary contribution in the context of collaborative strategies to enable excellent patient care in three highly dynamic, constantly evolving fields of diagnostic imaging.

Gaps in current guidelines for multimodality imaging of valvular heart disease (20 min)
Victoria Delgado; Badalona / Spain

1. To learn the new multimodality cardiovascular imaging approach to diagnose and risk-stratify patients with valvular heart disease.
2. To appreciate the right use of the right imaging modality at the right time, and therefore, to discuss the new recommendations.
3. To understand the clinical implications of the imaging findings.

The expanding toolbox of cardiac magnetic resonance imaging (CMR) for valvular heart disease (20 min)
Jean-Nicolas Dacher; Rouen / France

1. To understand the complementary roles of echocardiography and CMR in the investigation of patients with valvular heart disease.
2. To learn about the advantages and pitfalls of 2D and 4D phase contrast imaging in the analysis of valvular heart disease.
3. To understand the importance of myocardial tissue characterisation in patients with valvular heart disease.

CT and valvular heart disease: a changing paradigm (20 min)
Ricardo P. J. Budde; Rotterdam / Netherlands

1. To learn what role CT can play in the assessment of valvular heart disease.
2. To appreciate the various presentations of valvular pathology on CT.
3. To understand the diagnostic information regarding valve disease that can be obtained with CT.

Redefining risk stratification in valvular heart disease by implementing AI-based imaging (20 min)
Christoph Gräni; Bern / Switzerland

1. To learn how AI-based imaging can enhance the assessment of valvular heart disease.
2. To appreciate how novel AI-based biomarkers can improve risk stratification in valvular heart disease.
3. To understand the potential benefits and limitations of integrating AI-based imaging into decision-making for patients with valvular heart disease.

Panel discussion: What are current and future challenges in valvular disease and imaging? (8 min)

ESR Sustainability 21 - Artificial intelligence (AI), data storage, and sustainability

Categories: Professional Issues, Management/Leadership, Imaging Informatics, Multidisciplinary, Artificial Intelligence, Sustainability, President's Choice

ETC Level: ALL LEVELS

Date: March 7, 2026 | 16:00 - 17:30 CET

CME Credits: 1.5

This session aims to present the current status of evidence and knowledge concerning the carbon-intensive activities that are frequently undertaken in radiology, related to AI and to data storage. With the ongoing deployment of AI into the radiology workflow, the impact on energy use will be considered. Can the use of AI actually help to green our radiology practice? How will generative AI impact? Can radiologists help to bear down on carbon footprint by careful attention to data storage, and if so, what impact could this have? Expert speakers will join for a panel discussion.

Moderator:

Andrea Grace Rockall; London / United Kingdom

Chairperson's introduction (5 min)

Andrea Grace Rockall; London / United Kingdom

How green is your AI? In the balance: AI deployment, what are the potential sustainability gains? (15 min)

Date: March 7, 2026 | 16:00 - 17:30 CET
CME Credits: 1.5

Moderator:
Christoph Hoeschen; Magdeburg / Germany

Chairperson's introduction (4 min)
Christoph Hoeschen; Magdeburg / Germany

The concept of appropriate image quality (14 min)
Ehsan Samei; Durham / United States
Christoph Hoeschen; Magdeburg / Germany

1. To learn about the concept of appropriate image quality as derived in a transatlantic common assessment of existing image quality descriptors.
2. To appreciate the relation between benefits and risks in radiation-based imaging and how it is affecting appropriate image quality.
3. To understand that appropriate image quality is related to the indication of a procedure, but can also describe a relevant parameter which can be tested in new approaches, such as AI-based imaging.

Benefit/risk assessment for AI-based imaging (14 min)
Ehsan Samei; Durham / United States
Reinhard W.R. Loose; Nuremberg / Germany

1. To appreciate the integrated role of information adequacy (image quality) and radiation allocation (dose) to effectual medical imaging, with and without AI.
2. To understand how surrogates of quality and dose can be used to optimise imaging care.
3. To appreciate the inherent uncertainty in the application of aggregate-based optimisation to individual-based practice.
4. To place the quality-dose balance in the context of AI-informed imaging practice, including European aspects and recommendations on the use of AI in radiology.

The goals of optimisation of medical imaging with respect to ionising radiation (12 min)
Jacob Sosna; Jerusalem / Israel

1. To learn about the need for optimisation of medical imaging.
2. To appreciate the opportunities of AI in optimising imaging studies from justification to image reconstruction.
3. To understand the challenges of AI use in everyday practice.

Using AI for optimisation of medical imaging using ionising radiation (12 min)
Lifeng Yu; Rochester / United States

1. To learn how AI can improve image quality and/or allow dose reduction.
2. To appreciate the limitations of AI in restoring signal-to-noise lost at low doses.
3. To understand contrast-dependent MTF and that low-contrast smoothing can occur with AI methods.

Detecting and avoiding pitfalls in AI-based image reconstruction (12 min)
Marc Kachelrieß; Heidelberg / Germany

1. To see that subtle anatomical changes may be introduced by AI-based image reconstruction.
2. To learn how a dedicated metric could penalise such modifications.
3. To understand how hallucinations could be detected or visualised.

Coupling dose management and image quality management for AI-based radiological imaging (14 min)

Elmar Kotter; Freiburg Im Breisgau / Germany

Christoph Hoeschen; Magdeburg / Germany

1. To learn how dose and image management are related.
2. To appreciate the challenges in dose and image quality management.
3. To understand how AI can help in image and dose management.

Panel discussion (8 min)

EUSOBI - The beauty of breast imaging

Categories: Breast, Education, Artificial Intelligence, President's Choice

ETC Level: LEVEL I+II

Date: March 7, 2026 | 16:00 - 17:30 CET

CME Credits: 1.5

This session aims to give an overview of the wonderful subspecialty of breast imaging by respective experts of the European Society of Breast Imaging (EUSOBI) and its EUSOBI Young Club. The lectures will focus not only on imaging technologies but also on the role of the breast radiologist in the setting of a member of the multidisciplinary care team, as well as future directions. In the panel discussion, expert breast imagers will share their passion for this subspecialty and happily give answers to arising questions or career advice.

Moderator:

Michael Fuchsjäger; Graz / Austria

Chairperson's introduction (6 min)

Michael Fuchsjäger; Graz / Austria

Having an impact as a radiologist: preventing breast cancer mortality with screening (18 min)

Breast MRI: from screening to minimal invasive therapy (18 min)

Christiane K. Kuhl; Aachen / Germany

Contrast-enhanced mammography: like MRI without the magnet? (18 min)

Katja Pinker-Domenig; New York / United States

AI in breast imaging: gain or gadget? (18 min)

Simone Schiaffino; Lugano / Switzerland

Panel discussion: Why is breast radiology just the most wonderful subspecialty? (12 min)

Elisabetta Giannotti; Cambridge / United Kingdom

Thiemo Van Nijnatten; Maastricht / Netherlands

E³ 2119 - Liver imaging-reporting and data system (LI-RADS) for surveillance, diagnosis and response assessment

Categories: Oncologic Imaging, Interventional Oncologic Radiology, Abdominal Viscera
ETC Level: LEVEL II+III
Date: March 7, 2026 | 16:00 - 17:30 CET
CME Credits: 1.5

Moderator:
Giuseppe Brancatelli; Palermo / Italy

Chairperson's introduction (5 min)
Giuseppe Brancatelli; Palermo / Italy

Liver imaging-reporting and data system (LI-RADS) surveillance (20 min)
Aya Kamaya; Los Altos / United States

1. To learn about the rationale for HCC surveillance.
2. To learn about the updated LI-RADS US surveillance algorithm.
3. To learn tips and tricks for implementation and appreciate possible pitfalls.

Liver imaging-reporting and data system (LI-RADS) diagnosis (20 min)
Christian B Van Der Pol; Hamilton / Canada

1. To learn about the LI-RADS algorithm for diagnosis of HCC.
2. To appreciate the strengths and weaknesses of LI-RADS.
3. To understand how to apply LI-RADS in practice.

Liver imaging-reporting and data system (LI-RADS) treatment response assessment (20 min)
Rok Dežman; Ljubljana / Slovenia

1. To learn about the different locoregional treatment options for HCC.
2. To learn about the updated LI-RADS treatment response assessment algorithm.
3. To understand how to apply LI-RADS treatment response assessment and the possible pitfalls.

Panel discussion: What will be the future direction of liver imaging-reporting and data system (LI-RADS)? (25 min)

E³ 2121 - Brain and head and neck tumours

Categories: Hybrid Imaging, Oncologic Imaging, Neuro, Head and Neck, President's Choice
ETC Level: ALL LEVELS

Brain tumours (30 min)
Ali Nabavizadeh; Gladwyne / United States

1. To become familiar with the most common brain tumours.
2. To illustrate the spectrum of imaging findings.
3. To learn how to avoid interpretation pitfalls on CT and MRI.

Nasopharynx and related spaces (30 min)
Ann Dorothy King; Hong Kong / China

1. To become familiar with the radiologic anatomy of the nasopharynx and related spaces.
2. To illustrate the spectrum of imaging findings.
3. To learn how to avoid interpretation pitfalls on CT and MRI.

Endocrine head and neck tumours (30 min)
Martin Huellner; Zurich / Switzerland

1. To become familiar with the most common endocrine head and neck tumours.
2. To illustrate the spectrum of imaging findings.
3. To learn how to avoid interpretation pitfalls on CT, MRI and PET/CT.

IF 21 - The data symphony: from integrated diagnostics to digital twins

Categories: General Radiology, Oncologic Imaging, Professional Issues, Imaging Informatics, Artificial Intelligence, President's Choice

ETC Level: ALL LEVELS

Date: March 7, 2026 | 16:00 - 17:30 CET

CME Credits: 1.5

This session will explore the transformative shift from traditional image interpretation to fully integrated diagnostics, where radiology merges seamlessly with pathology, genomics, and clinical data. Experts will showcase how these multimodal datasets are fuelling the development of patient-specific digital twins-virtual models that replicate anatomy, physiology, and disease progression. Attendees will discover how predictive simulations can guide treatment planning, optimise outcomes, and enable truly personalised medicine. The session will also address the technological, ethical, and workflow challenges of bringing these innovations into daily radiology practice.

Moderator:

Carlo Catalano; Rome / Italy

Chairperson's introduction (5 min)

Collaborative pathways: integrating radiographers with radiologists (10 min)
Adrian K. P. Lim; London / United Kingdom

1. To understand effective models and the benefits of collaborative ultrasound workflows between radiographers and radiologists.
2. To explore models of shared responsibility and communication in multidisciplinary imaging teams.
3. To recognise how integration enhances workflow efficiency and patient outcomes accuracy.

Expanding the scope of radiographers in Point-of-Care Ultrasound (POCUS) (10 min)
Therese Herlihy; Dublin / Ireland

1. To learn about the expanding roles and responsibilities of radiographers performing POCUS by understanding the possible clinical applications of POCUS in diverse care settings.
2. To explore the impact of radiographer-led POCUS on patient access and diagnostic timeliness, improving the potential of better health outcomes.
3. To identify the competencies required for radiographers to safely and effectively perform POCUS and the need for specific training and governance frameworks.

Radiographers within a multidisciplinary vascular lab (10 min)
Daniela Cassar; Haz-Zebbug / Malta

1. To learn the specific roles radiographers undertake in vascular ultrasound and non-invasive vascular testing within a multidisciplinary team.
2. To appreciate the impact of team collaboration on vascular assessment accuracy and patient care.
3. To understand the technical and clinical skills required for radiographers working in vascular labs.

Ultrasound in primary healthcare (10 min)
Francisco Javier Ordoñez Gil; Parla / Spain

1. To learn how radiographers deliver ultrasound services within primary healthcare settings.
2. To explore the role of ultrasound in improving access and early diagnosis in community care by reducing referrals in general practice.
3. To understand the operational challenges, enablers of implementing ultrasound in primary care and governance frameworks needed for safe practice in community-based ultrasound.

Open forum discussion (15 min)

OF 21Y - How to stay relevant: adapting to technology and AI

Categories: General Radiology, Management/Leadership, Imaging Informatics, Education, Artificial Intelligence

ETC Level: ALL LEVELS

Date: March 7, 2026 | 16:00 - 17:00 CET

CME Credits: 1

From film to cloud, from darkrooms to data science - radiology is a field in constant transformation. This session explores how to stay professionally relevant amidst rapid advances in AI, imaging technology, and clinical demands. With voices from both senior radiologists and digital natives, we will debate whether it is better to go deep into a subspecialty or stay broad, and what skills truly matter in tomorrow's radiology workforce.

What are the challenges to progress advance practice? (15 min)
Louise A. Rainford; Dublin / Ireland

1. To learn about the systemic, educational and regulatory barriers to implementing advanced practice in radiography.
2. To appreciate the differences in scope and development of advanced roles across European countries.
3. To understand the importance of institutional support and stakeholder engagement in advancing radiographic practice.

Training radiography students in an interprofessional environment for person-centred care (15 min)
Luca Maria Sconfienza; Milan / Italy

1. To learn how interprofessional education fosters collaborative competencies in radiography students.
2. To appreciate the role of clinical placements and simulation in preparing students for patient-centred practice.
3. To understand the benefits and challenges of implementing interprofessional learning environments in radiography curricula.

Advanced clinical skills in radiography: driving autonomy and responsibility (15 min)
Graciano Paulo; Coimbra / Portugal

1. To learn which clinical skills can support advanced roles in radiographic practice.
2. To appreciate how radiographers can contribute to clinical decision-making and patient pathways.
3. To understand the implications of expanded responsibilities on education, certification and patient safety.

Leading the change: how radiographers can shape the future of advanced practice (15 min)
Charlotte A. Beardmore; London / United Kingdom

1. To learn about leadership models and strategies relevant to radiographers in advanced practice roles.
2. To appreciate the role of professional organisations and policy advocacy in enabling practice progression.
3. To understand how radiographers can lead service innovation and promote quality improvement in clinical settings.

Panel discussion: What does the future hold for advanced radiographic practice in Europe? (25 min)

CME Credits: 1.5

Moderator:
Eva M. Fallenberg; München / Germany

Integrating qualitative and quantitative features from contrast-enhanced mammography to predict breast lesion malignancy (6 min)
Iris Allajbeu; Cambridge / United Kingdom

Author Block: I. Allajbeu[1], R. Manavaki[1], T. Wegman[2], J. A. Saenz[3], T. Van Nijnatten[2], F. J. Gilbert[1]; [1]Cambridge/UK, [2]Maastricht/NL, [3]Barcelona/ES
Purpose: Quantitative analysis of enhancement on contrast-enhanced mammography (CEM) has shown promise in distinguishing benign from malignant breast lesions. We evaluated diagnostic models combining low-energy (LE) mammographic features with quantitative enhancement metrics.
Methods or Background: Data from 251 CEM examinations (2018-2021) with identifiable, histologically confirmed lesions were retrospectively analysed. Lesion characteristics, including lesion diameter (LD), type (mass, calcification, distortion, asymmetry), background parenchymal enhancement (BPE), breast density (BD), and conspicuity, were assessed on LE and recombined images by three radiologists using BI-RADS criteria. Enhancement metrics were computed from early (CEearly) and late (CElate) views, with percent residual signal difference (%RSD) used to classify enhancement patterns as progressive, plateau, or wash-out. Model construction utilised nested cross-validation (CV) with stratified sampling. In each of ten outer folds, data were stratified into 90% training and 10% testing subsets. Feature selection was optimised within the training data using five-fold inner CV. Minimum redundancy–maximum relevance identified non-redundant, informative predictors for logistic regression. Performance was assessed on the outer test sets and averaged across folds using area-under-the-curve (AUC), accuracy, sensitivity, and specificity.
Results or Findings: Of 251 lesions, 155 (61.7%) were malignant and 96 (38.3%) benign. Eleven features (age, LD, type, BI-RADS score, BD, BPE, conspicuity, CEearly, CElate, RSD, enhancement type) were considered for model construction. The most predictive subset included BI-RADS score, age, lesion conspicuity, BD, CELate, and LD. Models with these features outperformed those using BI-RADS score alone, with higher AUC (0.88 vs 0.84), accuracy (83% vs 78%), sensitivity (89% vs 72%), and comparable specificity (85%).
Conclusion: Integrating standard BI-RADS descriptors with quantitative enhancement metrics can improve lesion discrimination on CEM versus BI-RADS alone. This combined approach may enhance diagnostic confidence and reduce unnecessary biopsies in clinical practice
Limitations: Single-centre study

Evaluating Diagnostic Performance of Kaiser Score and BI-RADS for Contrast-Enhanced Mammography: a Retrospective Study (6 min)
Saeed Mohammadzadeh; Tehran / Iran

Author Block: S. Mohammadzadeh, A. Abdi, I. Kiani, F. Zeinalkhani; Tehran/IR
Purpose: Contrast-enhanced mammography (CEM) is an emerging imaging technique for breast cancer detection. The Kaiser score (KS), a structured diagnostic tool developed initially for breast MRI with high consistency and accuracy. We aimed to determine whether the KS could enhance the diagnostic performance of the CEM in evaluating suspicious breast lesions and to assess the effect of combining the KS with calcification evaluation (KS+).
Methods or Background: This retrospective, single-center study involved 143 breast lesions from 130 patients. CEM exams were evaluated by two radiologists, assigning both Breast Imaging-Reporting and Data System (BI-RADS) and KS classifications. Diagnostic performance metrics, including sensitivity, specificity, and area under the ROC curve (AUC), were calculated for BI-RADS, KS, and KS+. Moreover, subgroup analyses based on mass/non-mass lesions and background parenchymal enhancement (BPE) were performed.
Results or Findings: Overall, the KS showed an AUC of 0.892, with 83.3% sensitivity and 89.7% specificity. The BI-RADS classification produced an AUC of 0.867, with a higher sensitivity of 94.7% but a lower specificity of 58.6%. The combined KS+ model reached an AUC of 0.894. Diagnostic performance was significantly better for mass lesions than for non-mass lesions across all systems. For non-mass lesions, the KS maintained a specificity of 83.3%, whereas the BI-RADS specificity decreased to 33.3%. All methods experienced reduced diagnostic accuracy in cases with moderate BPE.
Conclusion: The KS acts as a helpful complement to BI-RADS when interpreting CEM. By offering a structured and numerical assessment, the KS significantly improves diagnostic specificity, particularly for challenging non-mass lesions, without substantially compromising sensitivity. This enhancement can help lower false-positive results and reduce unnecessary biopsies.
Limitations: 1) Retrospective design and single-center setting may limit the generalizability of our findings. 2) Inter-reader agreement was not evaluated

Comparison of Detection Rate, Lesion Visibility and Lesion Conspicuity in Contrast-Enhanced Mammography Using Two Different Doses (6 min)

Alexander Stiglbauer-Tscholakoff; Vienna / Austria

Author Block: A. Stiglbauer-Tscholakoff[1], G. Chiffi[2], P. D. Stelzer[1], T. H. Helbich[1], P. Clauser[1], P. A. Baltzer[1]; [1]Wien/AT, [2]Rome/IT
Purpose: To compare detection rate, lesion visibility and conspicuity in contrast enhanced mammography using two different doses.
Methods or Background: A total of 256 lesions were included: in 122 lesions Iomeron®400 was administered with a dose of 1 ml/kg bodyweight at 2 ml/s flow (group 1) and in 134 lesions with 1.5 ml/kg at 2 ml/s (group 2). Two breast radiologists independently evaluated lesion visibility (overall, 1-5) and conspicuity (in comparison to background enhancement, 0-3). Lesions were classified as benign/malignant (biopsy-proven). Distribution of malignant/benign lesions (chi-square test), diagnostic performance, intra-reader comparisons, and inter-reader differences (Student's t-test) were assessed.
Results or Findings: There was no significant difference in the distribution of malignant/benign lesions in group1/group2 ($P = 0.4627$). Almost all malignant lesions were detected by both readers (group 1: 70/71, group 2: 83/84). Mean lesion conspicuity in group 1 was 1.7 (SD 0.9) for Reader 1 and 1.5 (SD 1.1) for Reader 2, in group 2 2.2 (SD 0.8, R1) and 2.1 (SD 1.0, R2). Mean lesion visibility in group 1 was 3.4 (SD 1.5, R1) and 2.9 (SD 1.3, R2), in group 2 3.5 (SD 1.4, R1) and 3.7 (SD 1.3, R2). Intra-reader analyses showed lower conspicuty for R1 and R2 in group 1 (R1&R2, t-test $P < 0.0001$), equal visibility (R1, t-test $P = 0.5816$) and lower visibility (R2, t-test $P < 0.0001$) in this group.
Conclusion: Lesion visibility in CEM was higher using 1,5 ml. Lesion conspicuity was reader dependent. The detection rate of malignant lesion was high with both doses, suggesting that a higher dose of contrast agent may improve lesion conspicuity in comparison to background enhancement but a lower dose might be sufficient for lesion detection.
Limitations: Single-centre design; selection bias; no clinical outcomes correlation.
Funding for this study: Bracco Imaging
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Data were collected within a prospective study comparing the diagnostic value of CEM to CE-MRI in a problem-solving setting (Ethics Review Board number 2282/2019).

Preoperative contrast-enhanced mammography: the contribution of 7-minute delayed acquisition (6 min)

Lisa Corradini; Milan / Italy

Author Block: L. Corradini, C. Depretto, C. De Berardinis, G. Della Pepa, E. D'Ascoli, G. Irmici, A. Bonanomi, F. Sardanelli, G. P. Scaperrotta; Milan/IT
Purpose: To evaluate the diagnostic performance of contrast-enhanced mammography (CEM) in preoperative locoregional staging of breast cancer, with a specific focus on the contribution of 7-minute acquisitions, through a retrospective analysis of consecutive cases at a reference oncology center.
Methods or Background: We included patients who underwent CEM between January 2018 and January 2024 at the National Cancer Institute (Milan). Two independent readers, each with over five years of experience in CEM, performed blinded assessments without knowledge of clinical history or biopsy results. A BI-RADS score (0–5) was assigned to each breast, first based soley on 2-minute acquisitions and subsequently incorporating information from 7-minute images. The reference standard included histopathological findings (diagnostic or definitive), follow-up, or comparison with prior imaging. Diagnostic performance was compared using McNemar's test.
Results or Findings: A total of 286 breasts in 144 patients (including two cases of prior unilateral mastectomy) were evaluated. The additional review of 7-minute acquisitions led to a significant modification of the BI-RADS score and/or other assessments in 12/286 breasts (4.2%), with clinical impact in 2/144 patients (1.39%, 95% CI 0.17−4.93%). The diagnostic performance of 2-minute acquisitions alone was not significantly different from that obtained when including 7-minute acquisitions: sensitivity 94.0% vs. 94.6% (p = 1.00); specificity 97.7% vs. 96.2% (p = 0.48).
Conclusion: Delayed 7-minute CEM acquisitions do not provide clinically relevant additional information for preoperative breast cancer assessment. A protocol limited to 2-minute acquisitions reduces exposure to ionizing radiation and simplifies workflow without compromising the diagnostic value of the examination.
Limitations: Retrospective, single-center study with a limited number of patients.
Funding for this study: This study received no funding.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by Comitato Etico Territoriale Lombardia 4

Diagnostic Accuracy of Contrast-Enhanced Mammography Compared with Breast MRI in Women at Increased Breast Cancer Risk (6 min)

Gisella Gennaro; Padua / Italy

Author Block: G. Gennaro[1], E. Baldan[1], P. Belli[2], D. Bernardi[3], E. Bezzon[1], A. Coran[1], V. Iotti[4], I. Polico[1], F. Caumo[1]; [1]Padua/IT, [2]Rome/IT, [3]Rozzano, Metropolitan City of Milan/IT, [4]Reggio Emilia/IT
Purpose: To compare the diagnostic performance of contrast-enhanced mammography (CEM) versus breast MRI in women at increased risk for breast cancer.
Methods or Background: In this paired-case study, 462 women underwent both CEM and MRI. Four breast radiologists interpreted CEM, while a separate group of four radiologists evaluated MRI. Multi-reader, multi-case (MRMC) ROC analysis was used to calculate AUC for each modality. Sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and overall accuracy were also estimated. Low-energy CEM (LE-CEM) readings were included as a baseline reference. Statistical significance was set at $p<0.05$ for all comparisons.
Results or Findings: LE-CEM to CEM comparisons confirmed prior evidence, with mean AUC improving from 0.832 (95% CI: 0.809–0.855) to 0.913 (95% CI: 0.897–0.930, $p<0.001$). For CEM versus MRI, mean AUCs were 0.936 (95% CI: 0.915–0.958) for CEM and 0.933 (95% CI: 0.916–0.949) for MRI ($p=0.665$). Sensitivity, specificity, PPV, NPV, and accuracy were also similar between CEM and MRI (sensitivity 0.83 vs 0.86, specificity 0.91 vs 0.87, PPV 0.77 vs 0.70, NPV 0.94 vs 0.95, accuracy 0.89 vs 0.86; all $p>0.30$).
Conclusion: CEM demonstrates diagnostic performance equivalent to breast MRI and significantly outperforms mammography (LE-CEM). These results support CEM as a high-quality, more accessible alternative to MRI for risk-adapted screening.
Limitations: Retrospective analysis with readers not fully crossed between modalities.

Contrast-Enhanced Mammography versus Ultrasound in the Assessment of Recall Examinations for Suspicious Findings in Women with a Personal History of Breast Cancer: A Retrospective Comparative Study (6 min)

Verdiana Lamagna; Firenze / Italy

Author Block: V. Lamagna, C. Bellini, G. Bicchierai, D. De Benedetto, F. Di Naro, S. Vidali, F. Pugliese, V. Miele, J. Nori; Florence/IT
Purpose: To compare the performance of Contrast-Enhanced Mammography (CEM) vs. ultrasound (US) in women with personal history of breast cancer (PHBC) who are recalled for suspicious mammographic findings.
Methods or Background: This retrospective single-center study included women with PHBC recalled for suspicious findings on digital mammography between November 2016 and June 2023. All underwent both CEM and targeted US. Two experienced breast radiologists independently reviewed the images in a blinded manner. For each modality, findings were categorized as positive (BIRADS 4 o 5) or negative (BIRADS 1,2 or 3) based on BI-RADS classification. Histopathology served as the reference standard for positive cases, while a negative 24-month follow-up was used for negative cases. Sensitivity, specificity, positive and negative predictive values, and overall accuracy were calculated for each modality.
Results or Findings: Among 295 women included, 54 (18.3%) had malignant lesions. CEM demonstrated significantly higher sensitivity than ultrasound for lesion detection (98.2% vs 35.2%, p<0.001) and higher specificity (91.7% vs 72.2%, p<0.01). CEM accurately identified 53 of 54 malignant lesions confirmed on histopathology with a PPV of 72.6% and a NPV of 99.5%, including several that were occult or equivocal on ultrasound that showed a PPV of 22.1% and a NPV of 83.3%. The only missed case was a non-enhancing ductal carcinoma in situ. Overall diagnostic accuracy was higher for CEM than for ultrasound (92.9% vs 65.4%, p<0.001).
Conclusion: CEM compared to US is a reliable and efficient first-line imaging technique in in women with a personal history of breast cancer, potentially improving workflow efficiency in breast cancer follow-up imaging.
Limitations: This study was limited by its retrospective single-center design.
Funding for this study: No funding was received for this study.

Kidney function determination in recalled women from screening scheduled for contrast-enhanced mammography – a single center retrospective analysis (6 min)

Emine Meltem; Istanbul / Turkey

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: E. Meltem[1], R. Wijgers[2], U. Lalji[2], C. R. Jeukens[2], J. E. Wildberger[2], E. C. Nijssen[2], T. Van Nijnatten[2]; [1]Istanbul/TR, [2]Maastricht/NL
Purpose: To evaluate the true extent of iodine-based contrast media (ICM)-related risk of kidney function decline in a breast cancer screening population, recalled and scheduled for contrast-enhanced mammography (CEM).
Methods or Background: This retrospective study included women recalled from the Dutch National Breast Cancer Screening Program to Maastricht University Medical Centre+ (MUMC+) between January 2013 and January 2022. Recalled patients routinely underwent CEM, while those with contraindications received full-field digital mammography (with or without digital breast tomosynthesis). The most recent estimated glomerular filtration rate (eGFR) before and after imaging was obtained from electronic medical records. Renal safety was assessed by changes in eGFR; a ≥25% decline within 30 days after CEM was considered clinically relevant.
Results or Findings: A total of 2707 women were recalled, of whom 2437 (90%) underwent CEM. Paired pre- and post-CEM eGFR values were available in 1184 patients, with pre-CEM values obtained a median of 177 days before (IQR 420-50) and post-CEM values 141 days after imaging (IQR 28-423). The median eGFR difference was 0.5 (IQR -5.4 to 6.3). A ≥25% decline in eGFR occurred in 31 patients (2.6%); only one (0.08%) dropped below an eGFR of 30. Most declines reflected shifts from baseline eGFR >60 to the 45–60 range (n=74, 8%), while eGFR remained stable in those with baseline values <45 (n=13). In the subgroup with post-CEM eGFR within 30 days (n=306), ≥25% decline was observed in six patients(2.0%); none dropped below eGFR 45, and changes were again mainly shifts from >60 to 45–60 (n=15, 6%).
Conclusion: Clinically relevant renal function decline after CEM was rare and never severe, supporting the notion that kidney safety concerns should not restrain the implementation of CEM in clinical practice.
Limitations: Variability in the timing of eGFR measurements.

Lesion conspicuity on contrast-enhanced mammography as a predictor of response to Cryoablation in breast cancer (6 min)

Francesca Pugliese; Florence / Italy

Author Block: F. Pugliese[1], F. Di Naro[1], S. E. Baldi Giorgi[1], C. Maiello[2], V. Lamagna[1], D. De Benedetto[1], G. Bicchierai[1], C. Bellini[1], J. Nori[1]; [1]Florence/IT, [2]Casoria (Na)/IT
Purpose: To evaluate the role of lesion conspicuity (LC) at 12 months on contrast-enhanced mammography (CEM) follow-up as a predictor of cryoablation outcome in breast cancer.
Methods or Background: We conducted a retrospective analysis of 69 patients (mean age: 86 years; range: 60–94) with unifocal invasive breast cancer who underwent percutaneous cryoablation. CEM imaging was performed at baseline and within 12 months post-ablation. LC was categorized based on the degree of enhancement relative to background as: low, moderate, or high. Tumor response was assessed at 12 months using standard imaging modalities (ultrasound and CEM) according to RECIST 1.1 criteria. Statistical analyses were conducted to evaluate the correlation between changes in post-treatment conspicuity and later tumor response.
Results or Findings: At 12 months post-ablation, CEM showed a complete absence of enhancement in 68.1% of lesions. Among the 22/69 (32%) lesions showing enhancement, 6 had low LC, 11 moderate, and 5 high. The agreement between CEM and biopsy results was strong, with 100% sensitivity and positive predictive value for CEM. A substantial concordance (Kappa=0.80) was observed between CEM and RECIST criteria. Among lesions that were minimally conspicuous or non-enhancing early post-treatment, 80.7% had a complete response at 12 months, compared to only 1.8% of lesions that retained enhancement. In tumors ≤2 cm, early post-ablation CEM showing reduced or absent conspicuity was significantly associated with complete response (Kappa=0.74), with a 78.8% complete response rate in this subgroup.
Conclusion: A reduction in lesion conspicuity on early post-ablation CEM strongly correlates with a favorable tumor response in breast cancer patients treated with cryoablation. This imaging feature may serve as an early, noninvasive biomarker for treatment evaluation and could help guide clinical decision-making.
Limitations: retrospective study
small sample size
did't compare CEM-MRI

A trial-based economic evaluation of contrast-enhanced mammography (CEM) compared to conventional imaging in the work-up of women recalled from the Dutch breast cancer screening program (RACER trial) (6 min)

Lidewij M.F.H. Neeter; Maastricht / Netherlands

Author Block: L. M. Neeter[1], M. B. I. Lobbes[2], K. M. Duvivier[3], F. Raat[4], M. Smidt[1], J. E. Wildberger[1], B. Essers[1]; [1]Maastricht/NL, [2]Sittard-Geleen/NL, [3]Amsterdam/NL, [4]Roermond/NL
Purpose: The randomised controlled clinical RACER trial studied the diagnostic work-up with contrast-enhanced mammography (CEM) compared to conventional imaging as primary tool in women recalled from breast cancer screening. This current trial-based economic evaluation was performed from a hospital perspective.
Methods or Background: Cost prices were retrieved from the financial departments of the Maastricht University Medical Center. Health-related quality of life was measured five times over 18 months using the EQ-5D-5L questionnaire. Cost-utility analysis outcome was expressed as costs per quality-adjusted life year (QALY). Multiple imputation was used for missing data, and non-parametric bootstrap analysis was performed to examine uncertainty in the difference in costs and incremental costs per QALY. Post hoc subgroup analysis was performed per BI-RADS recall score.
Results or Findings: Work-up with CEM showed lower total costs of €-117 (95% CI €-254; €+22) compared to conventional imaging. Average imaging costs were significantly lower with CEM (mean difference €-130; 95% CI €-153; €-105). Mean QALY for the CEM group was 1.2034 versus 1.2137 for the control group. Bootstrap analysis showed that 95% of all simulated ICERs were in the quadrants that indicate cost-savings, although 25% of the ICERs showed a small gain in QALY and 70% a small QALY loss. The probability of CEM being cost-effective is 53% at a threshold of €10,000 to accept a QALY loss. In the subgroup of BI-RADS 0 recalls, specifically, this probability is 85%.
Conclusion: CEM as primary tool in the diagnostic work-up is a cost-effective diagnostic strategy, especially in BI-RADS 0 (low suspicion for breast cancer) recalls.
Limitations: The proportion of missing data related to the EQ-5D-5L questionnaire increased over time up to 42% and 34% in the control and CEM group, respectively.

How Women Experience Contrast-Enhanced Mammography (6 min)

Jarn Theunissen; Maastricht / Netherlands

Author Block: J. Theunissen[1], Y. Vissers[1], B. Van Grinsven[2], A. Valentijn-Morsing[1], M. B. I. Lobbes[1], L. Bouwman[2]; [1]Sittard-Geleen/NL, [2]Maastricht/NL
Purpose: Contrast-enhanced mammography (CEM) has witnessed an increasing implementation in clinical practice and is currently even considered for large-scale screening programs. However, successful adoption of screening CEM is dependent on patient acceptance. This study investigated women's experiences with CEM, focusing on pain and willingness for future CEM examinations.
Methods or Background: In this prospective survey at a specialized breast center, women undergoing CEM completed a 10-minute questionnaire. A questionnaire collected data on demographics, medical history, expectations, and patient-reported outcomes. Procedural data such as prior imaging, biopsy during the same visit, and compression force were collected from clinical records.
Results or Findings: Currently, 478 women (median age 58 years) completed the questionnaire, with 382 (79.9%) also participating in the national screening program. Median Visual Analogue Scale pain scores were 1 (IQR 0 – 2) for intravenous cannulation and 3 (IQR 1-6) for breast compression. Overall, 475 (99.4%) participants reported willingness to undergo CEM again if indicated, and 458 (95.8%) would undergo CEM screening if it improved cancer detection rates. Twenty-three participants (4.8%) reported pain during compression as a potential obstacle, and 15 participants (3.1%) reported the same for intravenous cannulation.
Amongst 25 women who had undergone a prior MRI, 16 (64%) considered CEM more patient-friendly, 7 (28%) rated both modalities equally, and 2 (8%) preferred MRI. Multivariable analysis of factors associated with pain experience and willingness for CEM screening is planned once all data are collected.
Conclusion: CEM is well tolerated, with limited discomfort reported during both intravenous cannulation and compression. Nearly all participants expressed willingness to undergo CEM again, both clinically and for screening.
Limitations: The single-center questionnaire may limit generalizability. Outcomes relied on self-reported data which introduces possible response bias.

Patient Acceptance and Experience of Contrast-Enhanced Mammography in Breast Cancer follow-up: results from a large prospective cohort (6 min)

Giulia Vatteroni; Milan / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: G. Vatteroni[1], R. Levi[1], M. Filippini[2], M. Costa[3], R. M. Trimboli[1], D. Bernardi[1]; [1]Milan/IT, [2]Nuvolera/IT, [3]Catania/IT
Purpose: To evaluate patient acceptance and experience of contrast-enhanced mammography (CEM) compared to standard digital mammography (DM) in women operated for breast cancer (BC) undergoing follow-up.
Methods or Background: This study included women operated for BC who underwent CEM instead of DM for BC surveillance as part of a prospective study (COMBO-TRIAL). A 16-item anonymous questionnaire was administered after the exam, evaluating perceived discomfort, pain, exam duration, reassurance, information received, anxiety, contrast injection, satisfaction and comparative experience with prior DM. Responses used Likert-type scales (1-5). Descriptive and comparative analyses (T-Test or Mann-Whitney U test, Pearson's R, Spearman's R correlation) were conducted ($p<0.05$ significant).
Results or Findings: Among 969 patients, 936 (median-age 58.2 years, IQR 51–66.25) completed the questionnaire. CEM was reported to cause similar discomfort compared to DM by 67.4% of women, while 14.1% experienced greater discomfort, strongly associated with higher pre-exam anxiety($p<0.001$) and lower reassurance($p<0.001$). Likewise, 77.5% reported similar pain, whereas 7.4% perceived CEM as more painful, also linked to increased anxiety($p<0.001$) and reduced reassurance ($p<0.001$). Examination positioning was considered comparable by 76.6% of patients, and with a similar duration (64.2%).
Overall, 92.6% felt reassured and 95% well informed. Elevated anxiety was reported by 21.2%, with only 32.6% reporting high comfort during contrast injection. Pre-exam anxiety was inversely correlated with injection comfort ($r = -0.265$, $p<0.001$). Importantly, 90.6% accepted the risk of contrast-related events if CEM enabled earlier BC detection. Patient satisfaction was high (96.1%), and nearly all (99.6%) would recommend CEM, highlighting its perceived diagnostic value and role in early detection.
Conclusion: CEM showed excellent acceptance, tolerability and satisfaction compared with DM in BC follow-up. Distress was limited to a small subgroup with elevated pre-exam anxiety, highlighting the radiologist's key role in communication and patient reassurance.

Assessing the optimal amount of tissue sampling required in contrast-enhanced stereotactic biopsy (CESB) (6 min)

Jarn Theunissen; Maastricht / Netherlands

Author Block: M. B. I. Lobbes[1], J. Theunissen[1], R. Körver-Steeman[1], C. Frotscher[1], A. Valentijn-Morsing[1], B. De Vries[1], W. L. Mok[2], Y. Vissers[1], L. Bouwman[1]; [1]Sittard-Geleen/NL, [2]Roermond/NL
Purpose: Contrast-enhanced mammography (CEM) can reveal lesions not visible on low-energy images, targeted ultrasound, or tomosynthesis. When such lesions are detected, contrast-enhanced stereotactic biopsy (CESB) is required for tissue diagnosis. However, the optimal number of tissue samples needed for a reliable diagnosis remains unclear.
Methods or Background: We included patients with lesions visible only on recombined CEM-images, warranting CESB. Using a 9-gauge vacuum-assisted biopsy (VAB) needle, 18 consecutive tissue samples were obtained per protocol. A pathologist evaluated each sample in the order collected to determine the cumulative diagnostic yield per sample. Additional parameters assessed included patient age, procedure duration (excluding IV catheter placement), adverse events, patient-reported discomfort (10-point scale), and the positive predictive value (PPV) for malignancy.
Results or Findings: Sixty women (mean age 57.8 years, SD 10.6) underwent CESB. Mean procedure time was 13.5 minutes. One procedure was discontinued due to syncope. Median discomfort score was 3. The PPV for malignancy was 31.7%. The median number of samples needed to establish a diagnosis was five (range: 1–18). Diagnostic yield increased with each additional sample, reaching 98.3% by the 12th biopsy. In one case, all 18 samples were required, as no lesion was identified; follow-up is ongoing.
Conclusion: CESB is a well-tolerated and safe technique with minimal discomfort and low complication rates. Our findings suggest that obtaining 12 samples with a 9-gauge VAB needle provides a high diagnostic yield and is sufficient in most cases to reach a reliable diagnosis.
Limitations: Relatively small sample size, but study is currently recruiting.

RC-only lesions in CEM: false-positive outcomes and upgrade rates from CEM-guided biopsy (6 min)

Rodrigo Alcantara Souza; Barcelona / Spain

Author Block: R. Alcantara Souza, J. Saenz, M. Pitarch, P. Miranda Martínez, E. Vall Foraster, E. Vila-Trias Jover, N. Arenas, X. Castells; Barcelona/ES
Purpose: To evaluate the false-positive rate and histopathological spectrum of recombined (RC)-only lesions requiring contrast-enhanced mammography (CEM)-guided biopsy.
Methods or Background: Retrospective analysis of consecutive CEM-guided biopsies performed at a tertiary centre between 2019–2025. Demographics, CEM descriptors (mass, non-mass, enhancing asymmetry), and histopathology were extracted from a REDCap database. Pathology was categorised according to the NHSBSP system: B1 normal, B2 benign, B3 lesions of uncertain malignant potential, and B5 malignant. False positives were defined as B1–B3. RC-only lesions were enhancing findings without a low-energy correlate and represented the main indication for CEM-guided biopsy at our centre.
Results or Findings: A total of 174 RC-only lesions in 170 patients (median age 59 years, range 22–88) underwent CEM-guided biopsy with pathology. B1 was found in 3 (1.7%), B2 in 73 (42.0%), B3 in 27 (15.5%), and B5 in 71 (40.8%). The false-positive rate (B1–B3) was 59.2%. Malignancy rates were 45.4% in masses, 36.5% in non-mass enhancements, and 33.3% in enhancing asymmetries (OR mass vs non-mass 1.45; 95% CI 0.78–2.69). Benign outcomes included fibroadenomas, UDH, adenosis, and fat necrosis.
Among B3 lesions, 18 underwent intervention (14 lumpectomies, 3 mastectomies, 1 vacuum-assisted excision) and 10 upgraded (55.6%). By subtype: ADH 5/6 (83%), papillary 3/5 (60%) of 9 papillary overall, LIN 1/3 (33%), FEA 0/2, phyllodes 0/1, radial scar 0/0, and other atypia 1/1 (100%).
Conclusion: False-positive outcomes are frequent among RC-only CEM findings requiring biopsy, spanning benign and B3 lesions. Although many yield non-malignant results, the high upgrade risk of some subtypes supports intervention. Findings are consistent with published CEM series and comparable to MRI-guided biopsy. Despite this false-positive burden, CEM-guided biopsy remains essential for characterisation of RC-only lesions not accessible with conventional guidance.
Limitations: Retrospective design, single-centre setting, and small B3 subgroups.
Funding for this study: No funding was received for this study.

Clinical and imaging Factors Predictive of Malignancy after CEM-Guided Stereotactic Biopsy: a multicenter study (6 min)

Alfredo Fabio Murano; Aversa / Italy

Author Block: A. F. Murano[1], D. De Benedetto[2], M. Sacco[1], L. R. La Rocca[1], V. Lamagna[2], F. Di Naro[2], M. G. Vigilante[1], J. Nori[2], V. Romeo[1]; [1]Naples/IT, [2]Firenze/IT

Purpose: Contrast-enhanced mammography (CEM)-guided biopsy allows the histological characterization of “enhancing only” CEM or MRI findings. Its recent introduction made it a valuable alternative the less available and more expensive MRI guided biopsy. However, “contrast-enhanced only” findings may be non-specific, raising the risk of unnecessary biopsies. The study aimed to identify clinical and/or imaging parameters predictive of malignancy in patients undergoing CEM-guided biopsy in a multicentric setting.

Methods or Background: We retrospectively included women with suspicious “contrast-enhanced only” lesions visible only on CEM and sampled with CEM-guided biopsy in two different institutions. Clinical data (age, concurrent/previous breast cancer (BC), family history of BC, high-risk factors) and CEM features (size, enhancement type, distribution, pattern, conspicuity, background parenchymal enhancement) were collected. Univariate and logistic regression analyses were performed to identify clinical and/or CEM findings that could independently predict malignancy after CEM-guided biopsy.

Results or Findings: A total of 126 women with 126 suspicious CEM “enhancing only” findings, of which 98 benign and 28 malignant, were included. Among the clinical and imaging parameters, patient age, the presence of concurrent breast cancer, and early contrast enhancement were statistically significant at both univariate (p value: < 0.001, 0.004, and 0.015, respectively) and logistic regression analyses, with a combined AUC of 0.798 (95% CI: 0.718–0.864) and accuracy of 81.75% (95% CI: 73.9% - 81%) in predicting malignancy.

Conclusion: Patient age, the presence of a concurrent breast cancer, and early enhancement may help selecting patient who could benefit from CEM-guided biopsy. Larger studies are needed to confirm these preliminary results, improve the performance of the model, and develop clinical decision tools.

Limitations: Small sample size

Adipose tissue compartments predict cardiometabolic outcomes in healthy non-obese individuals: an opportunistic screening approach (6 min)
Balazs Bogner; Freiburg Im Breisgau / Germany

Author Block: B. Bogner, M. Jung, M. Reisert, J. Maushagen, S. Rospleszcz, C. L. Schlett, F. Bamberg, J. Weiß; Freiburg Im Breisgau/DE
Purpose: To determine whether MRI-derived visceral-to-subcutaneous adipose tissue (VAT/SAT) ratio predicts incident diabetes and major adverse cardiovascular events (MACE) beyond other risk factors in metabolically healthy non-obese (MHN) individuals.
Methods or Background: We analyzed UK Biobank participants who were MHN (absence of hyperlipidemia or hypertension, diabetes, and BMI <30 kg/m²). 3D VAT/SAT volumes (dm3) were extracted from Dixon whole-body MRI using a validated deep learning framework. Sex-specific VAT/SAT ratio cutoffs (≥0.15 for females, ≥0.35 for males) were derived from C-index optimization for incident cardiometabolic outcomes. Cox proportional hazards models assessed associations with 1) incident diabetes and 2) MACE, with stepwise adjustment for age, sex, smoking, waist circumference (WC), and BMI. Multivariable nested models with and without VAT/SAT ratio were compared to test for added value beyond other factors. Net reclassification improvement (NRI) compared risk classification by VAT/SAT versus WC.
Results or Findings: Among 22,040 participants (mean age 64.6±7.8 years, 53% female), over a median 4.2-year follow-up, 251 diabetes (1.14%) and 297 MACE (1.35%) events occurred. High VAT/SAT ratio was independently associated with diabetes (aHR 1.77, 95% CI 1.34-2.33, p<0.001) and MACE (aHR 1.30, 95% CI 1.02-1.66, p=0.037) after adjustment for age, sex, smoking, BMI, and WC. Adding VAT/SAT to fully adjusted models significantly improved discrimination for diabetes (C-index 0.723 vs. 0.715, p<0.001) and MACE (C-index 0.694 vs. 0.690, p=0.036). VAT/SAT outperformed WC with significant NRI for diabetes (NRI 0.102, p=0.010) and MACE (NRI 0.088, p=0.013).
Conclusion: VAT/SAT ratio independently predicts diabetes and MACE in MHN individuals and demonstrates superior risk classification over WC, highlighting the potential of body composition analysis for personalized risk assessment in apparently healthy individuals.
Limitations: The generalizability is limited by the UK Biobank's selection bias, the VAT/SAT cut-off derivation, and the focus on MHN individuals.
Funding for this study: None.

Virtual IVUS on Coronary CT: Mid LAD Intimal Thickening as a Clinical Predictor of Early CAD-RADS Progression (6 min)
Safiye Sanem Dereli Bulut; Istanbul / Turkey

Author Block: S. S. Dereli Bulut, G. Karamustafao; Istanbul/TR
Purpose: To evaluate whether virtual intravascular ultrasound (IVUS)-derived intimal thickness, calcium scoring, and positive remodeling on coronary CT can predict progression from CAD-RADS 0 to CAD-RADS 1, and to assess their relationship with cardiovascular risk factors.
Methods or Background: In this retrospective pilot study, 91 patients with CAD-RADS 0–1 (CAD-RADS 2.0)who underwent 128-slice CCTA (2021–2025) were analyzed. Intimal thickness was measured on reformatted axial planes using virtual IVUS,defined as (outer diameter–inner diameter)/2. Two radiologists performed independent measurements, with interobserver agreement assessed by ICC. Calcium scoring (Smart Score) and positive remodeling (Plaque ID) were also evaluated, and risk factors (hypertension, diabetes, smoking, LDL) retrieved from medical records.
Results or Findings: CAD-RADS 0 (n=45: 44.8 ± 11.6 years, 46.7% male, BMI 26.9 ± 3.7) and CAD-RADS 1 (n=46: 51.6 ± 9.9 years, 52.6% male, BMI 28.4 ± 2.8) differed significantly. Intimal thickness was greater in CAD-RADS 1, especially mid LAD, LCX, and RCA ($p<0.001$). Calcium scores were higher, particularly LAD (0.0 vs 21.7; $p<0.001$). Positive remodeling occurred in 93% vs 42% ($p<0.001$). Intimal thickness correlated with calcium scores, strongest in mid LAD ($r=0.71$, $p<0.001$). Mid LAD thickness was the strongest predictor ($p=0.01$); the combined model (LAD-mid + LDL + HT) yielded AUC=0.96 (98% sensitivity, 89% specificity).
Conclusion: IVUS-derived intimal thickening, particularly in the mid LAD, may serve as an early imaging marker of CAD-RADS progression. Combined with calcium scoring and remodeling, IVUS provides value for early risk stratification. These preliminary results are hypothesis-generating and need confirmation in larger prospective cohorts.
Limitations: This single-center pilot study had a modest sample size, included only CAD-RADS 0–1 patients without longitudinal follow-up, and may still be subject to measurement variability despite good reproducibility. Other biomarkers such as inflammation or genetics were not assessed.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective study was approved by the Ethics Committee of Umraniye Training and Research Hospital (Approval number: E-54132726-000-282160058)

Novel CT Biomarkers for Preoperative Prognostic Stratification in Patients with Severe Aortic Stenosis Undergoing TAVI (6 min)

Federica Piccione; Turin / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: F. Piccione[1], D. Vignale[2], A. Colombo[2], A. Palmisano[2], C. Gnasso[2], G. Amaro[2], A. Esposito[2]; [1]Turin/IT, [2]Milan/IT
Purpose: Assessing the prognostic value of myocardial strain and extracellular volume fraction (ECV) measured by pre-procedural CT in patients with severe aortic stenosis (AS) undergoing transcatheter aortic valve implantation (TAVI).
Methods or Background: From October 2020 to December 2023 patients were screened using as exclusion criteria aortic regurgitation, peri-procedural complications, incomplete strain/ECV data.
Global strain (longitudinal, radial, and circumferential) was quantified using dedicated software (CVI42 v6.3.0). ECV was measured manually and automatically (in-house built software) in the interventricular septum as the ratio of the differential attenuation of myocardium and blood pool before and after contrast administration. Primary endpoint: death or HF hospitalization after a follow-up of 12+ months.
Outcomes were analyzed with Kaplan–Meier survival and Cox regression.
Results or Findings: In 241 patients (median age 82 (IQR 78–86) years, 53.9% females) primary endpoint occurred in 18.3%. Patients with events had higher ECV (31.6% vs 27.6% manual, $p<0.001$; 31.7% vs 28.7% automatic, $p=0.003$), more impaired longitudinal (-13.0% vs -15.3%, $p=0.035$) and radial strain (18.1% vs 23.2%, $p=0.030$). Survival curves identified ECV cut-offs of 30.6% (manual) and 28.9% (automatic), both associated with worse event-free survival ($p<0.001$). In multivariate analysis, ECV remained an independent predictor (HR 2.12 manual; HR 2.45 automatic), while strain lost significance (HR 1). Patients with elevated ECV and impaired longitudinal strain had the highest risk (HR up to 3.04). Classical low-flow low-gradient AS showed the worst remodeling (ECV 33–34%, GLS –9%).
Conclusion: Pre-procedural CT-derived ECV represents an independent and robust predictor of adverse prognosis after TAVI. Combined ECV–strain assessment may provide a more comprehensive characterization of myocardial remodeling and improve risk stratification. This approach offers the additional advantages of being automatable, reproducible, and objective. Larger prospective studies are warranted to confirm its clinical applicability.
Limitations: Small single-center cohort.

Ethics committee - additional information: Retrospective study, based on prospectively collected data, and was conducted in accordance with the Declaration of Helsinki. Written informed consent was obtained from all participants.

Assessing left ventricular strain across all stages of chronic kidney disease – a cardiac MRI study (6 min)

Paul Kamieniarz; Ludwigsfelde / Germany

Author Block: P. Kamieniarz, A-S. Plietz, L. V. Urbach, M. Taupitz, L-A. Schaafs; Berlin/DE
Purpose: Chronic kidney disease (CKD) is a global health burden with increasing prevalence. Those effected have an increased risk for cardiovascular disease (CVD) and higher mortality. Myocardial strain derived from cardiac MRI (cMRI) is shown to be an important prognostic marker in a variety of CVD. We aimed to assess left ventricular (LV) strain in patients with CKD and compare them to a healthy control group.
Methods or Background: In this single centre, retrospective study we included 288 patients with CKD in all stages of disease (G1-G5) and 74 healthy controls. All patients underwent comprehensive cMRI. Functional analysis was performed using CVI 42 (Circle Vascular Imaging, Calgary, Canada). For strain analysis Segment® (Medviso, Lund, Sweden) was used. Differences between groups were assessed using ANOVA.
Results or Findings: LV ejection fraction (59.4±6.4 vs. 47.5±16.1; 51.0±16.0; 46.1±17.4; 48.8±20.8; 49.0±18.2; p<0.001), LV global longitudinal strain (-18.5±3.1 vs. -13.9±5.5; 15.3±4.9; -13.7±5.8; -11.8±5.8; -11.5±4.6; -11.3±4.6; p<0.001), LV global circumferential strain (-21.8±3.5; -16.4±7.7; -19.0±6.1; -17.2±6.8; -15.9±7.2; -15.9±6.4; p<0.001) and LV global radial strain (50.3±9.8 vs. 37.4±19.5; 45.7±18.6; 39.8±18.5; 34.8±19.4; 40.0±18.7; 36.2±18.1; p<0.001) were statistically significant impaired in patients with CKD stages G1 – G5 compared to healthy controls.
Conclusion: Patients with CKD had impaired LV strain with the biggest differences observed in Groups G1-G3a. In groups G3b – G5 a gradual recovery of LV strain parameters was noticed. With LV strain severely impaired in patients with CKD, LV ejection fraction was only mildly reduced. Influencing factors such as age, sex and volume status need to be analysed in future studies.
Limitations: The limitations of this study are the retrospective design, variance in comorbidities and that groups could not be matched for sex and age.

CARE-LIVER – Cardiovascular Risk Evaluation by Coronary Tomography in LIVER Transplant Candidates: A Retrospective Study on Diagnostic Accuracy and Early Outcomes (6 min)

Roberta Aroasio; Turin / Italy

Author Block: R. Aroasio[1], L. Tampellini[1], F. Minonne[1], S. Tibaldi[1], G. Balladori[1], L. Blasi[1], M. Moretti[1], M. Gatti[1], R. Faletti[2]; [1]Turin/IT, [2]Torino/IT
Purpose: Evaluate the impact of coronary CT angiography (CCTA) on cardiovascular risk stratification and the prevention of MACE in liver transplant (OLT) candidates.
Methods or Background: Single-center retrospective study on 140 consecutive OLT candidates enrolled between April 2021 and October 2024, all with ≥ 2 coronary risk factors and undergoing CCTA. Positive exams, when clinically indicated, were further investigated with invasive coronary angiography (ICA) and possible revascularization; negative CCTAs were considered true negatives (TN) if supported by MACE-free clinical follow-up ≥ 6 months. Primary endpoint: MACE within 30 days after OLT.
Results or Findings: A total of 140 OLT candidates (78% male) were consecutively enrolled; 55% were > 65 years old and 32% had NASH cirrhosis. CCTA excluded significant stenosis in 95/140 patients (68%) and detected it in 27/140 (19%); 23/27 (85%) underwent ICA, with confirmation and PCI in 14/23 (61%). Using the TN6m definition (100 patients), the 2 × 2 matrix showed 14 true positives, 9 false positives, 0 false negatives, and 100 TN, with sensitivity and NPV 100%, specificity 91%, and PPV 60.9%. Among 91 transplanted patients, no MACE occurred within 30 days (incidence 0%). These patients accumulated 27,097 days (74.2 patient-years) of event-free follow-up; estimated incidence would be 1.1% assuming a single MACE and 5.5% with five events.
Conclusion: With 100% sensitivity and NPV at 6 months, CCTA proves to be a highly reliable screening tool to exclude significant coronary artery disease in OLT candidates with cardiovascular risk factors. The absence of MACE within 30 days post-transplant highlights the effectiveness of the CCTA-first strategy in perioperative protection. Prospective multicenter studies are needed for long-term validation.
Limitations: Retrospective and single-center design, relatively small sample size, short- to mid-term clinical follow-up.
Funding for this study: No funding for this study

Serial Myocardial Fibrosis Assessments Predict Outcomes in Patients with Hypertrophic Cardiomyopathy (6 min)

Yun Tang; Beijing / China

Author Block: Y. Tang, S. Zhao; Beijing/CN
Purpose: The prognostic value of serial myocardial fibrosis assessments in hypertrophic cardiomyopathy (HCM) remains to be elucidated. We aimed to investigate late gadolinium enhancement (LGE) progression via follow-up cardiac magnetic resonance (CMR) in HCM patients, and its prognostic value.
Methods or Background: Retrospective analysis included 313 HCM patients with two CMRs. The LGE mass progression (ΔLGE mass/y) was defined as the increased grams of enhanced myocardium divided by interval scan years. Primary endpoint included cardiac death, heart transplantation, aborted sudden cardiac death (SCD), appropriate ICD discharge, hospitalization for heart failure and stroke. Secondary endpoint includes cardiac death, aborted SCD and heart transplantation. Maximally selected rank statistical analysis was conducted to identify the optimal cut-off for ΔLGE mass/y.
Results or Findings: LGE mass progressed from a median of 2.9g at CMR-1 to 8.3g at CMR-2 (median scan interval: 4.2yrs). During a median follow-up of 3.4 years from CMR-2, 69 patients reached the primary endpoint, 17 of whom reached the secondary endpoint. For primary and secondary endpoint, the optimal cut-off for ΔLGE mass/y were >1.50 and 3.75g/year, respectively. Multivariable Cox regression analysis showed ΔLGE mass/y >1.50g/year was an independent predictor of primary endpoint (HR 2.22,95%CI:1.13-4.34,P=0.02). Combining ΔLGE mass/y with CMR-2 baseline variables improved the model C-statistic from 0.81 to 0.84.
Conclusion: In HCM patients, myocardial fibrosis increased over time. Serial assessments of myocardial fibrosis on CMR may improve risk stratification and clinical decision-making.
Limitations: The unavoidable selection bias in this study may arise from the exclusion of patients who were unable to participate due to events occurring before the follow-up CMR scan or poor compliance. However, as a tertiary referral center, our institution routinely recommends patients with HCM to undergo regular follow-up CMR in accordance with guidelines to monitor disease progression.

Regional Entropy of Epicardial Adipose Tissue on Spectral CT: A Novel Imaging Biomarker for Atrial Fibrillation Recurrence (6 min)

Weiwei Deng; Shanghai / China

Author Block: Y. Hu[1], W. Deng[2], J. Zhang[2]; [1]Yan'cheng, Jiangsu/CN, [2]Shanghai/CN
Purpose: Epicardial adipose tissue (EAT) is an important biomarker in atrial fibrillation (AF). This study evaluated whether EAT histogram parameters from virtual noncontrast and contrast-enhanced dual-layer spectral CT predict AF recurrence after ablation.
Methods or Background: In this prospective study, patients undergoing first-time AF ablation (Jan 2021–Jul 2024) underwent preoperative dual-energy cardiac CT. EAT on contrast-enhanced images (-190 to -30 HU) was segmented using a deep learning model. VNC images were reconstructed, and density difference maps were generated. Regional histogram parameters were extracted. Continuous variables were compared using Mann–Whitney U test, and Cox models evaluated predictors of AF recurrence.
Results or Findings: A total of 492 patients (mean age, 66 years; 316 men) were enrolled (paroxysmal AF, 54%; persistent AF, 46%). The median follow-up was 22 months. EAT volume was significantly greater in patients with persistent AF compared with those with paroxysmal AF (144 cm^3 [IQR, 105–184] vs 126 cm^3 [IQR, 100–154]; $P < .001$). Multiple EAT histogram parameters differed significantly between groups, including Max, Mean, Median, Std, Q1, Q3, Variance, IQR, 90th percentile, MAD, Skewness, Energy, Total Energy, RMS, Entropy, and Uniformity. During follow-up through July 2025, AF recurrence occurred in 73 patients (15%). Among EAT regional histogram parameters, entropy was significantly associated with AF recurrence (hazard ratio [HR], 2.0; 95% CI: 1.2–3.3; $P < .01$). In multivariable Cox regression, EAT entropy remained an independent predictor after adjustment for age, sex, AF phenotype, and EAT volume (HR, 1.97; 95% CI: 1.2–3.3; $P = .013$).
Conclusion: DLCT-based EAT histogram analysis, especially regional entropy, offers novel biomarkers for AF recurrence, supporting enhanced pre-ablation risk stratification.
Limitations: One-center study

Peri-coronary adipose tissue of the left circumflex artery as a potential biomarker for the recurrent atrial fibrillation after catheter ablation (6 min)

Ervan Zuhri; Jakarta / Indonesia

Author Block: E. Zuhri[1], E. Elen[1], S. J. S. Gardezi[2], D. Kumar[2], G. Marcel[1], C. A. Atmadikoesoemah[1]; [1]Jakarta/ID, [2]Shanghai/CN
Purpose: Atrial fibrillation (AF) is one of the most common cardiac arrhythmias and poses a major challenge in the management of cardiovascular disease. Catheter ablation (CA) is an established therapeutic option for patients with drug-resistant AF. However, recurrent AF following CA remains a major clinical challenge. Recent studies suggest that peri-coronary adipose tissue (PCAT), particularly surrounding the left circumflex artery (LCx), may contribute to AF recurrence after CA. This study aims to identify this potential factor for prediction of recurrent AF after CA.
Methods or Background: Patients with recurrent AF after CA were retrospectively enrolled. We investigated the predictive value of PCAT and other clinical factors for AF recurrence after CA. PCAT was measured using AI-based tool (uAI Fat Attenuation Index) developed by United Imaging Intelligence. Bivariate and multivariate logistics regression analyses were performed
Results or Findings: During 1-year follow-up, 18 of 33 patients experienced AF recurrence. The multivariable analysis revealed that PCAT of the LCx was independently associated with AF recurrence. PCAT of the LCx showed a significant predictive value, with a cut-off value of >−86.5 HU, yielding 78% sensitivity and 67% specificity. The area under the receiver operating characteristic curve (AUC) was 0.720, indicating good discriminative ability. Other factors-including age, sex, obesity, hypertension, diabetes, dyslipidemia, smoking, chronic kidney disease, heart failure, reduced TAPSE, valvular heart disease, coronary artery disease, and use of antiarrhythmic drugs (AADs, Class II/III)-were not significantly associated AF recurrence.
Conclusion: PCAT of the LCx was associated with AF recurrence after CA and may have important clinical value in predicting recurrence.
Limitations: Larger sample are needed to validate these findings and further refine risk prediction models for AF recurrence.

Prognostic value of CT-defined coronary calcifications in COVID-19: Results of a multicenter study based on the Weston score (6 min)

Matthias Neitzel; Frankfurt am Main / Germany

Author Block: A. M. Bucher[1], M. Neitzel[1], C. Ehrengut[2], T. S. Emrich[3], R. Klöckner[4], M. M. Sieren[4], M. A. Fink[5], F. G. Meinel[6], A. S. Surov[7]; [1]Frankfurt/DE, [2]Leipzig/DE, [3]Mainz/DE, [4]Lübeck/DE, [5]Heidelberg/DE, [6]Rostock/DE, [7]Minden/DE
Purpose: To investigate the prognostic value of CT-defined coronary calcifications in COVID-19 patients using the semiquantitative Weston score.
Methods or Background: This retrospective multicenter study included 541 PCR-confirmed COVID-19 patients (176 female, mean age 61.2±15.6 years) from 11 German university hospitals. Coronary calcifications were assessed on chest CT using the Weston score (0-12 points), evaluating four coronary segments on a 4-point scale. Primary endpoint was 30-day mortality. Statistical analysis included univariable and multivariable regression.
Results or Findings: Overall 30-day mortality was 21.2% (115/541). Mean Weston score was 3.0±3.6, with 23.7% showing no calcifications. Patients with fatal outcomes had significantly higher Weston scores (4.1±4.01 vs. 2.7±3.4, p=0.0007). While presence of calcifications showed association with mortality in univariable analysis (OR 1.68, 95%CI 1.08-2.59, p=0.01), this lost significance in multivariable analysis (p=0.49). However, Weston score as continuous variable remained significant in both univariable (OR 1.10, 95%CI 1.04-1.14, p<0.001) and multivariable analysis (OR 1.06, 95%CI 1.005-1.138, p=0.036) after adjusting for age and COVID-19 CT score.
Conclusion: The extent of coronary calcifications, quantified by Weston score, is an independent prognostic factor for 30-day mortality in COVID-19 patients. The degree of calcification provides greater prognostic value than mere presence. These findings support integrating coronary calcification assessment into COVID-19 risk stratification using routine chest CT without dedicated cardiac imaging.
Limitations: The limitation of the study is the retrospective study design.
Funding for this study: Funding was provided by the German Federal Ministry of Education and Research (BMBF), Project RACOON (01KX2021).

Incremental prognostic role of fat replacement over late gadolinium enhancement in patients with non-dilated left ventricular cardiomyopathy and preserved systolic function (6 min)

Lisa Fulceri; Lucca / Italy

Author Block: L. Fulceri, L. Taddei, A. Marcucci, L. Faggioni, D. Cioni, E. Neri, G. Aquaro; Pisa/IT
Purpose: To evaluate the prognostic role of FR compared to late gadolinium enhancement (LGE) in subjects with NDLVC, preserved LVEF and frequent premature ventricular complexes (PVC).
Methods or Background: Cardiac magnetic resonance was performed in 900 consecutive patients with frequent PVC, preserved LVEF. Patients with diagnostic criteria for other cardiomyopathies, channelopathies and ischemic disease were excluded. A clinical follow-up was performed and major ventricular arrhythmias (MVA), including sudden cardiac death, appropriated ICD intervention, and sustained VT, were considered endpoints.
Results or Findings: The final population included 876 patients. Overall non-ischemic LGE was found in 101 (12%) patients and FR in 38 (4%): 87 (10%) presenting LGE without FR, 14 (1,6%) FR without LGE and 24 (3%) LGE with FR. After a median follow-up of 4 (3-6) years, MVA occurred in 43 patients. At Kaplan-Meier survival curve analysis (figure 1) the presence of LGE and/or FR was associated with worse prognosis than their absence. The group of patients with worse prognosis was that with the combined LGE+FR. A similar prognosis was found in patients with LGE alone and in those with FR alone (p=0.19). Patients with LGE+FR had worse prognosis than those with LGE alone (P=0.01). At univariate analysis non-sustained VT (NSVT), syncope, LGE, FR and LGE+FR were associated to MVA. At multivariable logistic regression analysis the combination LGE+FR was an independent predictor of MVA together with history of NSVT and syncope.
Conclusion: In NDLVC with preserved LVEF, the combination of FR+LGE was a stronger prognostic marker than the presence of LGE alone. FR and LGE had similar prognostic role when found separately.
Limitations: Relatively small population

Prognostic value of pulmonary transit time assessed by cardiac magnetic resonance in patients with dilated cardiomyopathy (6 min)

Wendi Zhang; Chengdu / China

Author Block: W. Zhang, X. Xu, W. Peng, K. Shi, X. Lyu, C. Xia, Z. Li; Chengdu/CN
Purpose: To evaluate the prognostic value of pulmonary transit time (PTT) assessed by cardiac magnetic resonance (CMR) in patients with dilated cardiomyopathy (DCM).
Methods or Background: Recent studies confirm CMR first-pass perfusion imaging offers a convenient, non-invasive method to measure PTT, a marker of global cardiopulmonary circulation. However, its prognostic value in DCM patients has not been established. This retrospective study enrolled patients with DCM who underwent CMR at our institution between July 2019 and January 2022. PTT was measured as the peak-to-peak time between the contrast time-intensity curves of the right and left ventricles in first-pass perfusion imaging. Cox regression analysis was performed to assess the association between PTT and a composite endpoint comprising all-cause mortality, heart failure rehospitalization, and heart transplantation.
Results or Findings: A total of 140 patients (71.4% males, mean age 52±13 years) were included and followed for a median of 4.6 years (interquartile range, 4.1–5.4 years). During this period, 70 patients (50.0%) reached the endpoint. Multivariable linear regression identified PTT as an independent determinant of left ventricular (LV) remodeling and dysfunction, as it correlated with increased LV end-diastolic dimension (β=0.431), reduced LV ejection fraction (β=-0.391), and impaired LV global longitudinal peak strain (β=0.276). Receiver operating characteristic curve analysis, using the maximization of Youden's index, identified an optimal PTT cut-off of 10.7 seconds for endpoint prediction. Kaplan–Meier survival analysis revealed that patients with a PTT greater than 10.7 seconds had a significantly higher risk of experiencing the composite endpoint (log-rank p<0.001). In multivariable Cox regression analysis, PTT was an independent predictor of the endpoint (adjusted hazard ratio: 1.072 per second; 95% confidence interval: 1.006–1.144; p=0.033).
Conclusion: PTT derived from CMR independently predicted adverse cardiovascular outcomes in patients with DCM.

Maartje De Win; Amsterdam / Netherlands

Trajectory Matters: Longitudinal Evolution of NI-RADS Categories and Risk of Recurrence in Head & Neck Cancer (6 min)
Akshat hitesh Shah; Kolkata / India

Author Block: A. h. Shah, A. Chandra, S. Sen, S. Mukhopadhyay, P. Ghosh, A. Chatterjee, A. Gehani, J. Khoda, A. Patra; Kolkata/IN
Purpose: NI-RADS has been validated as a single-time point tool for recurrence prediction. Yet in the clinic, patients return repeatedly for follow-up, and radiologists often see categories shift over time. The prognostic meaning of these longitudinal NI-RADS trajectories has never been systematically studied. We evaluated whether stability or change in NI-RADS scores across surveillance scans influences recurrence risk.
Methods or Background: We retrospectively studied 628 patients with head and neck squamous cell carcinoma treated between 2012 and 2024 who had ≥3 consecutive surveillance CT or MRI scans. Two head and neck radiologists independently assigned NI-RADS categories. Trajectories were defined as: stable low-risk (repeated NI-RADS 1–2), escalating risk (progression from NI-RADS 2 → 3/4), or stable high-risk (repeated NI-RADS 3–4). Outcomes were verified by histopathology, MDT consensus, or ≥12-month follow-up. Kaplan–Meier survival and hazard ratios (HR) for progression-free survival (PFS) were calculated.
Results or Findings: We retrospectively studied 628 patients with head and neck squamous cell carcinoma treated between 2012 and 2024 who had ≥3 consecutive surveillance CT or MRI scans. Two head and neck radiologists independently assigned NI-RADS categories. Trajectories were defined as: stable low-risk (repeated NI-RADS 1–2), escalating risk (progression from NI-RADS 2 → 3/4), or stable high-risk (repeated NI-RADS 3–4). Outcomes were verified by histopathology, MDT consensus, or ≥12-month follow-up. Kaplan–Meier survival and hazard ratios (HR) for progression-free survival (PFS) were calculated.
Conclusion: Recurrence risk is not defined by a single scan but by the trajectory of NI-RADS scores over time. Stability reassures, escalation warns, and downward movement inspires hope. Incorporating trajectory analysis into structured reports could help radiologists guide MDT decisions more confidently, aligning imaging with the lived journey of cancer survivors.
Limitations: Single-center retrospective study; modality allocation by subsite.

Significance of Cross-Sectional Imaging characteristics of Orbital Metastases (6 min)
Shaista Shoukat Ali Khatian; Karachi / Pakistan

Author Block: A. Samad, S. S. A. Khatian; Karachi/PK
Purpose: Orbital metastases are not very common but they tend to be signify progression of malignancy in the entire body and may considerably affect the prognosis of the patient. They can have an appearance similar to primary orbital tumors or inflammatory disorders/changes in clinical practice, and radiologic identification is important.
Methods or Background: A cross-sectional study was designed as a descriptive study that was carried out at Radiology, JPMC - Karachi. 144-patients who were known to have cross-sectional imaging (CT and/or MRI) and was histologically confirmed to have orbital metastases were included. Data was analyzed based on demographic profile, primary site of tumor, clinical presentation and detailed imaging features such as location, margins, enhancement, necrosis and bone involvement.
Results or Findings: Summary N=104 (mean age of patients 55.6 ±11.8 years, 62 females and 42 males).The most common primary malignancy was breast carcinoma (n=46, 44%), lung carcinoma (n=29, 28%), renal cell carcinoma (n=15, 14%), and other primaries (n=14, 14%) such as gastrointestinal and thyroid malignancies.
Breast carcinoma metastases were usually poorly defined, infiltrating lesions of soft tissue in fat in the orbit and extraocular muscles, without extensive bone destruction.
.Lung carcinoma metastases were commonly well-defined and rapidly growing and massively enlarging the orbit with evidence of necrotic tissue.
Renal cell carcinoma metastases presented with intensely enlarging, well-defined, vascular lesions, which are often accompanied with hemorrhage and bone erosion.
Conclusion: Orbital metastases though very uncommon and has characteristic imaging appearances that depends on the nature of the underlying primary tumor. The knowledge of these radiological patterns may help radiologists to make nearly accurate diagnosis proposal, facilitate systemic assessment, and prevent unnecessary procedures. It is also especially important in oncology patients with new orbital complaints who have to be identified early.

Comparison of diagnostic accuracy of CT, MRI and US in detecting vascular involvement in patients with head and neck tumours and metastasis: systematic review and meta-analysis (6 min)

Umida Bafoevna Abdullaeva; Tashkent / Uzbekistan

Author Block: U. B. Abdullaeva[1], B. Pape[2], J. Hirvonen[3]; [1]Tashkent/UZ, [2]Turku, Vaasa/FI, [3]Tampere/FI
Purpose: To review the diagnostic performance of MRI, CT and US for detecting vascular invasion in head and neck primary tumours or metastases, using histopathology or surgical findings as the reference standard.
Methods or Background: This review was registered in Prospero (CRD42024584016). We searched PubMed and Embase for studies in English, published from 01.01.1990 to 31.12.2024, that used CT, MRI or ultrasound to assess vascular involvement in head and neck primary tumours or metastases, confirmed by histology or surgery and provided data to calculate diagnostic accuracy. Outcomes included sensitivity, specificity, PPV, and NPV, with heterogeneity assessed using Cochran's Q test.
Results or Findings: In the systematic review, we included 28 studies with 1687 patients (mean age 57.2): 17 retrospective, seven prospective, one mixed, and the rest unspecified. The meta-analysis included 19 studies (1041 patients), while nine studies (646 patients) were analysed qualitatively.
Overall diagnostic accuracy was 0.87 (95% CI: 0.81–0.91). Pooled sensitivity, specificity, PPV, and NPV were 0.63 (0.48–0.75), 0.81 (0.73–0.87), 0.60 (0.52–0.68), and 0.90 (0.78–0.96), respectively. US performed best (accuracy 0.95, sensitivity 0.86, specificity 0.93, NPV 0.96, PPV 0.73), MRI showed intermediate results, and CT the lowest. Moderation effect for accuracy was significant ($p = 0.041$), with US outperforming CT ($p = 0.023$). Significant heterogeneity was found for sensitivity ($Q = 57.81$), specificity ($Q = 109.01$), NPV ($Q = 79.42$), and accuracy ($Q = 170.25$) (all $p < 0.0001$).
Conclusion: US is the most effective and precise modality, outperforming MRI and CT, though MRI is superior to CT. Overall modest sensitivity suggests the possibility of false negative findings. Significant heterogeneity requires integration of imaging findings with intraoperative validation.
Limitations: The study is largely retrospective, with sampling bias, incomplete data, and significant heterogeneity.
Funding for this study: No funding was received for this study.

MRI in Differentiating HPV-Positive and HPV-Negative Oropharyngeal Squamous Cell Carcinoma (6 min)

Emanuele Gattuso; Palermo / Italy

Author Block: E. Gattuso, F. PASSALACQUA, F. Bencivinni, A. Lo Casto; Palermo/IT
Purpose: Human papillomavirus (HPV) status plays a key role in oropharyngeal squamous cell carcinoma (OPSCC). Our study aims to evaluate MRI features of locoregional metastatic lymph nodes and apparent diffusion coefficient (ADC) values of the primary tumor in HPV+ and HPV– OPSCC to identify distinguishing patterns.
Methods or Background: MRI scans of 87 patients with suspected OPSCC were retrospectively reviewed. Exclusion criteria were prior treatment, uncertain diagnosis, or non-squamous histology. Twenty-four patients with pre-biopsy MRI and histological confirmation, including p16 immunohistochemistry evaluation, were included. For each case, lymph node morphology and mean ADC values of the primary lesion were assessed.
Results or Findings: Among HPV+ patients (14/24), 12/14 (85.7%) had nodal involvement, mainly ipsilateral (11/12; 91.7%). Mean nodal diameter was 2.33 cm (range 1.1–4.4); cystic morphology was seen in 7/12 (58.3%). Jugular vein thrombosis occurred in 3/12 (25%), and extracapsular spread in 1/12 (8.3%). Mean primary ADC was 0.79×10^{-3} mm²/s (range 0.6–1.0).
In HPV– patients (10/24), 6/10 (60%) had nodal metastases, ipsilateral in 3/6 (50%) and bilateral in 3/6 (50%). Mean diameter was 2.53 cm (range 1.5–4.5), with solid morphology in 5/6 (83.3%). Mean primary ADC was 1.15×10^{-3} mm²/s (range 0.7–1.5).
Conclusion: HPV+ OPSCC was associated with smaller, predominantly ipsilateral cystic nodes and lower ADC values, while HPV– OPSCC showed larger, bilateral, solid nodes and higher ADC values. MRI thus offers a valuable non-invasive tool for HPV status characterization.
Limitations: This was a single-center study with a relatively small sample size, which may limit the generalizability of the findings. Furthermore, no correlation with patient outcome or survival was performed, preventing assessment of the prognostic significance of the imaging features.
Funding for this study: This study received no external funding.

Efficacy of Combined Local and Target Therapy in Radioactive Iodine–Refractory Locally Advanced or Metastatic Thyroid Cancer (6 min)

Yi-Chia Tsai; Kaohsiung City / Taiwan, Chinese Taipei

Author Block: Y-C. Tsai, W-C. Lin; Kaohsiung/TW
Purpose: Patients with radioactive iodine–refractory (RAIR) metastatic or locally advanced thyroid cancer have a poor prognosis and limited treatment options. This study aimed to evaluate the efficacy of targeted therapy alone versus targeted therapy in combination with local treatment in this patient population.
Methods or Background: From 2017 to 2024, a total of 52 patients aged ≥18 years with RAIR locally advanced or metastatic thyroid cancer receiving targeted therapy were evaluated. Baseline imaging with computed tomography (CT) was performed prior to initiation of therapy. Disease progression was assessed using serial CT and/or PET/CT (Positron Emission Tomography-Computed Tomography) imaging, based on a combination of Response Evaluation Criteria in Solid Tumors (RECIST) and PET Response Criteria in Solid Tumors (PERCIST). Associations between clinical factors and disease progression, as well as treatment-related adverse events, were also analyzed.
Results or Findings: Among the 52 patients, 20 received additional local treatment. This group demonstrated significantly improved progression-free survival (PFS) compared to those receiving targeted therapy alone: median PFS of 35.2 months (95% CI: 22.95–47.42) vs. 18.9 months (95% CI: 11.23–26.74); p = 0.038. Multivariate analysis identified combination therapy as an independent factor associated with favorable PFS (HR: 0.327; 95% CI: 0.140–0.763; p = 0.010). There was no significant difference in the incidence of adverse events between the two groups. The most common adverse event was proteinuria (21 patients, 40.4%).
Conclusion: Local treatment should be actively considered in eligible RAIR locally advanced or metastatic thyroid cancer patients receiving targeted therapy, as it can significantly enhance survival outcomes with acceptable safety.
Limitations: This study was limited by its retrospective, single-center design, relatively small sample size, heterogeneous treatment and limited follow-up duration. Further investigation is needed to clarify the long-term outcome.
Funding for this study: No funding was received for this study.

Evaluation of Benign and Malignant Cervical Lymphadenopathy: A Comparative Study of Shear Wave Elastography and Grayscale Ultrasound (6 min)

Gaurav Gaurav; Gurugram / India

Author Block: G. Gaurav; Gurugram/IN
Purpose: The aim of the study was to evaluate role of shear wave elastography (SWE) using a novel methodology for differentiation of benign and malignant cervical lymph nodes.
Methods or Background: SWE was performed on 38 patients who presented with cervical lymph adenopathy. Color-coded elasticity maps were obtained, from which the stiffest region of interest (ROI) with a diameter of 2mm was chosen. Maximum and mean Young's modulus values (Kpa) were calculated in selected 2-mm ROI. Finally, the results were correlated with the fine needle aspiration cytology findings in all patients to assess the diagnostic accuracy, sensitivity, and specificity at a defined cutoff value for distinguishing between benign and malignant lymphadenopathies.
Results or Findings: There were 20 malignant cervical lymph nodes and 18 benign cervical lymph nodes. Malignant nodes showed significantly higher mean Young's modulus value (154.2□46.19 kPa) compared with benign nodes (70.39□30.76 kPa), with a p-value of less than 0.0001. Our findings indicate that the mean Young modulus value within a standardized 2-mm ROI outperformed grayscale ultrasound in terms of diagnostic accuracy (92.1 vs. 78.9%), sensitivity (100 vs. 80%), and specificity (83.3 vs. 77.7%), with the established cutoff values for high diagnostic accuracy indicating malignancy as greater than 92 for mean Young's modulus with an area under the curve of 0.964.
Conclusion: SWE using a standardized 2-mm ROI provides improved sensitivity and diagnostic accuracy for differentiation of benign and malignant lymph node lesions.
Limitations: Single center, single observer study
Limited sample size

Optimization of staging system for nasopharyngeal carcinoma based on the detailed MRI features and compared with AJCC/UICC staging (6 min)

Shuqi Li; Guangzhou / China

Author Block: S. Li, H. LI, L-Z. Liu; Guang Zhou/CN
Purpose: This study aimed to develop a new clinical staging system integrating detailed MRI features for non-metastatic nasopharyngeal carcinoma, to address the limitations in risk discrimination of the current 9th AJCC system.
Methods or Background: This retrospective study included 1,897 patients with non-metastatic NPC from three hospitals. MRI features for primary tumor and metastatic lymph nodes were evaluated. The primary endpoint was 5-year overall survival (OS). T, N and clinical stage were optimized using univariate and multivariate analyses. Survival curves were generated with the kaplan–meier method. The proposed system was compared with the authoritative 8th/9th AJCC/UICC staging systems using risk stratification, C-index, and AIC.
Results or Findings: Among T3 patients, those with severe skull base-foramina invasion (HR:1.99, 95% CI:1.22–3.34, P=0.006) were proposed for upstaging to T4, whereas those with only slight skull base-bone invasion (HR:0.54, 95%CI:0.34–0.85, adjusted P=0.009) were recommended for downstaging to T2 (SBFI_T). The number of MRI-positive lymph nodes was independent prognosticator, supporting an N categorization based on nodal count (LNN_N: N0, 0; N1,1-4; N2, 5-9; N3,≥9). The proposed stage, which integrates SBFI_T and LNN_N, grouped T2N0 and T1N0 as stage Ia, and T1–2N1 as stage Ib.
The proposed SBFI_T,LNN_N and stage systems outperformed the 8th/9th editions, achieving higher C-indices, lower AIC values, and significant risk stratification for OS across all subgroups (all $P < 0.05$).
Conclusion: The proposed staging system outperforms current mainstream systems. It also emphasizes critical MRI features that require clinical attention and highlights their role in accurate prognostic prediction.
Limitations: As only M0 cases were included, the inclusion of metastatic cases is needed in future studies to optimize the M-stage and develop a comprehensive staging framework.

The clinical utility of histogram analysis of time-dependent diffusion MRI in diagnosis and prognostic factors assessment of oropharyngeal carcinoma (6 min)

Fan Yang; Beijing / China

Author Block: F. Yang, H. Wei, M. Lin, H. Zhang; Beijing/CN
Purpose: To evaluate the potential of histogram parameters of time-dependent diffusion MRI (td-dMRI) in differentiating oropharyngeal squamous cell carcinoma (OPSCC) from oropharyngeal lymphoma (OPL) and diagnosing HPV infection.
Methods or Background: Seventy patients with OPSCC and 17 patients with OPL were prospectively included between 2024/01/01 and 2025/06/30. The pathological results were selected as reference, and OPSCC patients with p16 (+++) were categorized into HPV infection group. Two junior radiologists separately delineated the whole tumor slice-by-slice on PGSE imaging (b = 0 s/mm2). Histogram parameters were further acquired. The independent sample t-test or Mann-Whitney U-test was used, as appropriate, and the area under the curve (AUC) was calculated.
Results or Findings: Significant differences were observed in several histogram parameters between OPSCC and OPL, and the representative parameters in each metric were Dex_median (AUC: 0.754), d_entropy (AUC: 0.721), Vin_maximum (AUC: 0.730), Cellularity_maximum (AUC: 0.798), ADC0hz_skewness (AUC: 0.798), ADC30hz_skewness (AUC: 0.748), and ADC55hz_median (AUC: 0.767). Forty-five patients were diagnosed with HPV infection and 25 patients were not. The Cellularity_median (AUC: 0.763), Dex_mean (AUC: 0.761), d_mean (AUC: 0.755), ADC0hz_median (AUC: 0.751), ADC30hz_mean (AUC: 0.756), and ADC55hz_median (AUC: 0.753) were the representative paramaters in each metric.
Conclusion: td-dMRI can be a potential tool in evaluating oropharyngeal mass.
Limitations: Small sample-size carried on single-center is the main limitation for this study.
Funding for this study: None

Ethics committee - additional information: This prospective study was approved by the ethics committee of our hospital and conducted in accordance with the Declaration of Helsinki. Informed consent was obtained from each patient before the MRI examination.

Cascade-penetrating domino-ferroptosis nano inducer synergizes with sonodynamic therapy for anaplastic thyroid cancer (6 min)

Peng Dong; Changchun / China

Author Block: P. Dong; Changchun/CN
Purpose: Ferroptosis has become a new approach for antitumor treatment. However, the insufficient accumulation and poor penetration of ferroptosis inducers deep in tumors greatly limit their therapeutic effects. Herein, we aim to construct a cascade penetrating metal-polyphenol ultrasonic molecular probe, Fe3+Cur-PFP@IR780-LIP (FCIPL). Under ultrasonic stimulation, the nanoparticles can targeted cascade-penetrate deep into tumors, induce domino-ferroptosis reaction, enhance sonodynamic therapy (SDT), and realize multimodal imaging.
Methods or Background: FCIPL were based on the core of FCr consists of ferroptosis inducer curcumin and Fe3+, and co-embedded with PFP in IR780-loaded liposomes. We examined their characterization, basic properties, the safety, uptake capacity, targeting function, cytotoxicity, ferroptosis potentiating SDT effect and mechanism of action, the deep penetration and multimodal imaging capabilities of nanoparticles in vitro and in vivo.
Results or Findings: The FCIPL were regular spherical with uniform size, hydrated particle size of 218.6nm, with good dispersion, stability, and encapsulation rates. Ultrasonic excitation and tumor microenvironment can promote the disassembly of FCIPL, releasing Cur and Fe2+, jointly promotes the domino effect of lipid peroxide accumulation. Vivo and vitro experiments confirmed the good tumor targeting, cascade response and deep penetration ability of the FCIPL with good biosafety, and also verified the ferroptosis potentiating SDT efficacy of the nanoprobe and its mechanism of action, which together effectively demonstrated excellent tumor killing effects. In terms of imaging, FCIPL successfully realizing multi-modal imaging integrating ultrasound, photoacoustic, MRI and fluorescence imaging.
Conclusion: A cascade penetrating metal-polyphenol ultrasonic molecular probe FCIPL was successfully synthesised. Realized multimodal imaging in diagnosis. In terms of treatment, ferroptosis in deep tumors was achieved through targeted osmosis and cascaded response drug delivery system, enhanced sonodynamic therapy, and provide new ideas for integrating ATC diagnosis and treatment.
Limitations: Subsequent clinical transformation.

Quantitative Dual-Layer Spectral CT for Preoperative Prediction of Lymph Node Metastasis in Thyroid Nodules (6 min)

Zhao dong Ai; Changsha, / China

Author Block: Z. d. Ai[1], Z. Huang[2], X. Yu[3]; [1]Changsha,/CN, [2]Guangzhou/CN, [3]Changsha/CN
Purpose: To develop and internally validate a noninvasive prediction model based on quantitative dual-layer spectral CT (DLCT) parameters for identifying metastatic cervical lymph nodes in patients with thyroid nodules.
Methods or Background: This retrospective study included 254 pathologically confirmed lymph nodes (166 metastatic, 88 benign) from 131 patients who underwent preoperative DLCT. Patients were randomly allocated into training (70%) and validation (30%) cohorts. An initial set of DLCT metrics was screened using the Mann–Whitney U test ($p < 0.05$), yielding 26 significant features. Features with poor reproducibility or high redundancy were excluded by interclass correlation coefficient analysis. LASSO regression with 10-fold cross-validation identified five final predictors: enhancement difference (ΔHU), normalized contrast-enhanced CT attenuation, normalized iodine concentration, effective atomic number (Zeff), and 100 keV monoenergetic attenuation. A logistic regression model was constructed to generate a DLCT score. Discrimination and calibration were assessed using ROC analysis and calibration curves, respectively. Feature importance was interpreted via Integrated Gradients.
Results or Findings: The model demonstrated strong discriminatory performance. In the training cohort, it achieved an AUC of 0.873 (95% CI: 0.847–0.925), with 82.0% sensitivity and 87.1% specificity. In the validation cohort, performance remained robust with an AUC of 0.789 (95% CI: 0.702–0.859), 63.0% sensitivity, and 94.0% specificity. Calibration curves indicated satisfactory agreement between predicted and observed outcomes. ΔHU and normalized iodine concentration were identified as the most influential predictors.
Conclusion: A DLCT-based model incorporating five spectral parameters enables noninvasive prediction of lymph node metastasis in thyroid nodules with good discrimination and high specificity, potentially aiding preoperative risk stratification and surgical decision-making.
Limitations: This single-center study lacks external validation and did not incorporate ultrasound or clinical parameters, which may affect generalizability.

Prognostic Value Optimization of T Staging in Nasopharyngeal Carcinoma Based on MRI Grading of Skull Base Structure Invasion (6 min)

Fengze Wu; Guangzhou / China

Author Block: F. Wu, S. Li, D. Cao, H. Ya, H. LI, B. Chen; Guangzhou/CN
Purpose: To explore the prognostic value of the grading of skull base structure (including soft tissue, bone, and skull base foramina) invasion (SBSI) and their potential improvement for the T staging in nasopharyngeal carcinoma (NPC).
Methods or Background: This retrospective study enrolled M0 NPC patients from three medical institutions (1320, 432, and 329, respectively). The primary endpoint was 5-year overall survival (OS). Cluster heatmaps and network analysis were used to explore the grading of SBSI. Univariate and multivariate analyses with Kaplan–Meier method are performed to compare survival outcomes.
Results or Findings: This study included 2001 patients (median age, 46 years [IQR, 39-45]; 1469 males). Multivariate analyses identified invasion of the jugular foramen or foramen ovale (severe skull base foramina invasion, SSBFI) as an independent prognostic factor (HR: 2.24, 95% CI: 1.42-3.54, p=0.001), which conferred a poor prognosis similar to T4 disease(5-year OS: 69.7% vs 75.6%, p=0.421). Conversely, the prognosis of patients with pterygoid and sphenoid base (minor skull base invasion, MSBI) was superior to other T3 skull base involvement (5-year OS: 91% vs 82.4%, p= 0.003), was comparable to that of T2 disease (5-year OS: 91% vs 86.3%, p= 0.267). A proposed T staging(proposed_T) system was created by upstaging SSBFI to T4 and downstaging MSBI to T2. This proposed_T category outperformed the 8th/9th edition and other proposed T staging systems in risk stratification and prognostic prediction.
Conclusion: The grade of SBSI is a critical factor for risk stratification in T3 NPC patients, and its incorporation into T staging leads to a more precise prognostic stratification.
Limitations: The study design was a retrospective analysis and did not include a prospective validation cohort.

Value of Spectral CT in Differentiating Post-Treatment Recurrence or Residual Tumor from Inflammatory Fibrosis in Nasopharyngeal Carcinoma (6 min)

Xiaomin Liu; Guangzhou / China

Author Block: G. Xu, X. Liu, G. Wang; Guangzhou/CN
Purpose: To investigate the potential value of spectral computed tomography (CT) in differentiating post-treatment recurrence/residual tumor from inflammatory fibrosis in patients with nasopharyngeal carcinoma (NPC).
Methods or Background: This prospective study included 44 patients with previously treated NPC who underwent spectral CT either for suspected recurrence or for routine follow-up. Based on pathological or follow-up results, 16 patients were diagnosed with recurrence or residual tumor, 21 were diagnosed with inflammatory fibrosis, and 7 were classified as normal. Quantitative parameters were measured in arterial phase (AP), venous phase (VP), and late delayed phase (LDP). The analyzed parameters included conventional image (CI) CT values, iodine concentration (IC), normalized iodine concentration (NIC), virtual mono-energetic imaging (VMI) with CT values at 40 keV and 100 keV, spectral curve slope (λ HU), extracellular volume (ECV) fraction, arterial enhancement fraction (AEF) and normalizing arterial enhancement fraction (NAEF). Group comparisons were performed with ANOVA or Kruskal–Wallis tests, with post hoc LSD analysis. Diagnostic performance was assessed with ROC analysis.
Results or Findings: LDP-CI, LDP-VMI 40keV, LDP-IC, LDP-λHU, AEF(A/LD), and NAEF(A/LD) performed well in distinguishing between NPC recurrence/ residual tumor and inflammatory fibrosis (all P<.05). AEF(A/LD) and NAEF(A/LD) demonstrated the best performance (P<.001). Their optimal cutoff values were 0.925 for AEF(A/LD) and 0.101 for NAEF(A/LD), with AUCs of 0.818 (sensitivity, 90.5%; specificity, 62.5%), and 0.725 (sensitivity, 68.75%; specificity, 66.67%), respectively. Combining significant parameters further improved diagnostic performance, with an AUC of 0.85 (sensitivity, 68.8%; specificity, 66.7%).
Conclusion: Spectral CT–derived quantitative parameters, particularly AEF(A/LD) and NAEF(A/LD), are valuable for distinguishing post-treatment recurrence/ residual tumor from inflammatory fibrosis in NPC patients.

Federico Collettini; Berlin / Germany

Transarterial Embolization with Ethylene Vinyl Alcohol Copolymer (EVOH) for Unresectable Hepatocellular Carcinoma: Preliminary Results from the TAEVOH Study (6 min)
Costanza Viola; Brescia / Italy

Author Block: C. Viola, F. C. Bodini, M. Graffeo, C. Sallemi; Brescia/IT
Purpose: Hepatocellular carcinoma (HCC) is the most common primary liver malignancy, and transarterial embolization is the standard treatment for intermediate-stage disease. While conventional transarterial chemoembolization (TACE) is widely used, the added value of chemotherapy over bland embolization remains debated, with concerns about increased toxicity and costs. In large tumors, particle-based embolization may result in incomplete coverage, leaving viable tumor tissue. Ethylene-vinyl-alcohol-copolymer (EVOH) is a non-adhesive liquid embolic agent with controlled, progressive delivery that provides durable and uniform vasculature filling. The TAEVOH study aimed to evaluate the feasibility, safety, and oncological outcomes of EVOH embolization in clinical practice.
Methods or Background: This retrospective single-center study included consecutive patients with unresectable HCC treated with EVOH embolization between 2020 and 2025. Eligible patients had BCLC B disease, no portal vein thrombosis or extrahepatic spread, and Child-Pugh A–B liver function. Procedures were performed under conscious sedation with selective or superselective microcatheterization and controlled EVOH injection until complete tumor filling. Primary endpoints were radiologic response (mRECIST) and safety (CIRSE/CTCAE v5.0). Secondary endpoints included AFP reduction and downstaging to curative treatment.
Results or Findings: Forty patients (median age 78 years, 56% male, Child-Pugh A in 82% and B in 18%) underwent 52 procedures with 100% technical success. At first imaging assessment, complete response was observed in 8 of 27 evaluable patients (30%). AFP decreased by >50% in evaluable patients. Eight patients (27%) achieved downstaging and underwent curative therapies. Minor adverse events were limited to post-embolization syndrome and transient grade 1–2 hepatic toxicity, without major complications.
Conclusion: EVOH embolization is a feasible, safe, and effective treatment for unresectable HCC, with encouraging radiologic response and downstaging rates. Prospective studies are warranted to validate these results.
Limitations: Retrospective, single-center design with a limited cohort; long-term follow-up is ongoing.
Funding for this study: No external funding was received for the completion of this study

Real-world breakthrough analysis from the Italian Group of Regenerative and Occlusive Worldwide-used techniques of hepatic Hypertrophy (I GROWtoH) registry (6 min)
Cristina Mosconi; Bologna / Italy

Author Block: M. Serenari[1], F. Ratti[2], M. Cescon[1], G. Ercolani[3], V. Mazzaferro[2], D. Patrono[4], E. Jovine[1], C. Mosconi[1], F. De Cobelli[2]; [1]Bologna/IT, [2]Milan/IT, [3]Forli/IT, [4]Torino/IT
Purpose: To present multicentre real-world data on safety and efficacy of liver hypertrophy-inducing procedures (HIP) aiming to track trends in these approaches in Italy, and support a collaborative multidisciplinary network to reinforce the fundamental synergy between surgeons and radiologists.
Methods or Background: The I GROWtoH registry prospectively collects data on HIPs performed in candidates for major hepatectomy. For this analysis, the retrospective cohort (Jan 2014–Sep 2024) was reviewed. Demographics, indication for surgery, type of hypertrophy technique, imaging-based functional/volumetric assessment and peri-procedural outcomes were analysed.
Results or Findings: A total of 464 patients from 17 centres were included: 169 colorectal liver metastases (36.4%), 97 intrahepatic cholangiocarcinoma (20.9%), 91 perihilar cholangiocarcinoma (19.6%), and 77 hepatocellular carcinoma (16.6%). HIPs performed comprised 224 portal vein embolisations (48.3%; 8% including segment 4), 73 portal vein ligations (15.7%), 44 double vein embolisations/liver venous deprivations (9.5%) and 5 radiation lobectomies (1.1%). Complications occurred in only 3 patients after DVE/LVD. Hepatobiliary scintigraphy was performed in 105 patients after HIP (22.6%) while median increase of future liver remnant volume was 43% (IQR 30–66). Overall, 353 patients (76.1%) underwent curative major hepatectomy; 90-day mortality after HIPs was 5.0%.
Conclusion: Curative hepatectomy was achieved in over three-quarters of patients, underscoring the role of these procedures in expanding surgical options for complex hepatobiliary malignancies and witnessing the need for a shift from a “surgical-based” management to a multidisciplinary approach (from definition of surgical candidates, to choice of hypertrophy techniques, to management of intra and postoperative challenges). This trend reflects the collective effort of the Italian surgical community to build consensus on key aspects of regenerative liver surgery, laying the groundwork for a stable and synergic collaboration between surgeons and radiologists.
Limitations: Retrospective design and heterogeneity of techniques across centres.

Investigating the effectiveness and safety of embolic agents in bronchial artery embolization- A Systematic Review and Meta-aAnalysis (6 min)

David Laczko; Budapest / Hungary

Author Block: D. Laczko, B. Nemes; Budapest/HU
Purpose: Bronchial artery embolization effectively treats severe and recurrent hemoptysis and dramatically reduces mortality rates from 80-90% to less than 10%. Despite its success, no previous meta-analysis has focused on comparing the effectiveness and safety of particle and liquid embolic agents. This study aims to address this gap by comparing the effectiveness and safety of these available embolic agents.
Methods or Background: : We systematically searched MEDLINE, EMBASE, CENTRAL, Scopus, and Web of Science for relevant studies from inception until November 02, 2023. Eligible studies included cohort studies of patients who were treated with either particle or liquid embolic agents. The technical and clinical success, hemoptysis recurrence rates were meta-analyzed. Risk of bias was assessed using MINORS. Forest plots visualized meta-analytical results. The study was registered with PROSPERO (CRD42023480289).
Results or Findings: Of 2,502 studies, 59 met the inclusion criteria, including 4,660 patients. No significant difference between particle and liquid agents was observed in the proportion of immediate clinical success (0.95 vs 0.95, p=0.935). The proportion of 12-month hemoptysis recurrence did not differ between particle and liquid embolic agents (0.14 vs 0.17, p= 0.663). Significantly higher proportions of hemoptysis recurrence were observed between patients with malignant and non-malignant lung disease at all follow-up times (1 month: 0.26 vs 0.05; p<0.001; 3 months: 0.44 vs 0.08; p<0.001; 6 months: 0.56 vs 0.12; p<0.005; 12 months: 0.66 vs 0.11; p<0.001).
Conclusion: Our findings suggest that both particle and liquid embolic agents are effective and safe in treating hemoptysis. Patients with malignant lung diseases had shorter hemoptysis-free periods, highlighting that this subpopulation might benefit from a closer follow-up.
Limitations: The lack of reporting patient level data prevented us from conducting further analyses based on different etiologies and further exploring the high heterogeneity.

Efficacy and Safety of Bronchial Artery Chemoembolization Combined with Chemotherapy and immune checkpoint inhibitors for Advanced Lung Squamous Cell Carcinoma (6 min)

Liyun Zheng; Lishui / China

Author Block: L. Zheng, S. Fang, Z. Zhao, J. Ji; Lishui/CN
Purpose: To evaluate the efficacy and safety of adding bronchial artery chemoembolization (BACE) to chemotherapy in combination with immune checkpoint inhibitors (ICIs) in patients with lung squamous cell carcinoma (LUSC).
Methods or Background: This retrospective study included 71 patients with advanced LUSC between January 2020 and March 2025. Patients received either chemotherapy plus ICIs (Chemo + ICIs group) or chemotherapy plus ICIs combined with BACE (Chemo + ICIs + BACE group). Baseline clinical characteristics were recorded. Tumor response was evaluated. Progression-free survival (PFS) and overall survival (OS) were calculated using the Kaplan–Meier method. Prognostic factors were further explored. Adverse events (AEs) were recorded.
Results or Findings: The objective response rate (ORR) was 59.26% in the Chemo + ICIs + BACE group and 38.64% in the Chemo + ICIs group (p = 0.091). The disease control rate (DCR) was significantly higher in the BACE group (85.19% vs. 61.36%, p = 0.033). Median PFS was significantly longer in the Chemo + ICIs + BACE group (10.8 vs. 5.6 months, p = 0.018). Multivariate Cox analysis identified BACE treatment (HR = 0.53, p = 0.037), number of nodules ≤3 and tumors size ≤5 cm as independent predictors of prolonged PFS. Although the difference in OS was not statistically significant (23.3 vs. 18.4 months, p = 0.139), a favorable trend was observed in the Chemo + ICIs + BACE group. No grade ≥4 adverse events (AEs) were observed, and most AEs were grade 1–2 and manageable with symptomatic treatment
Conclusion: The addition of BACE to chemotherapy and immunotherapy may improve tumor control and prolong progression-free survival in patients with advanced LUSC.
Limitations: This study has limitations inherent to its retrospective design and single-center nature, including potential selection bias and limited generalizability
Funding for this study: This work was supported by the Exploration Project of Zhejiang Natural Science Foundation (LY23H180003); Zhejiang Medicine and Health science and Technology Project (2025KY1958).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was performed in line with the principles of the Declaration of Helsinki. Approval was granted by the Ethics Committee of The Fifth Affiliated Hospital of Wenzhou Medical University (Approval No: 2023-823).

Efficacy and Safety of TACE in Combination with Targeted Therapy and Immunotherapy for Patients with CNLC stage IIb/IIIa Hepatocellular Carcinoma Abstract (6 min)

Zexin Hu; Hangzhou / China

Author Block: Z. Hu; Hangzhou/CN
Purpose: To evaluate the efficacy and safety of first-line transcatheter arterial chemoembolization (TACE) combined with targeted therapy and immunotherapy in patients with stage IIb/IIIa hepatocellular carcinoma (HCC).
Methods or Background: A total of 198 patients who received first-line TACE combined with targeted immunotherapy or TACE alone from January 2015 to December 2022 were selected.
Using propensity score matching, 50 patients were included in both the combination group and the TACE-alone group(Figure 1) . Kaplan-Meier method was used to calculate the median overall survival (mOS) and median progression-free survival (mPFS) with 95% confidence interval (CI). Objective response frate (ORR) and disease control rate (DCR) were assessed based on modified Response Evaluation Criteria in Solid Tumors (mRECIST).
Results or Findings: The mOS in the combination group was 30.1 months (95% CI: 21.9-38.3) compared to 14.5 months (95% CI: 11.0-18.0) in the TACE-alone group, showing a statistically significant difference (P < 0.001). (Figure 2.)
The mPFS in the combination group was 10.3 months (95% CI: 8.8-11.8) compared to 7.1 months (95% CI: 5.8-8.4) in the TACE-alone group, with a statistically significant difference (P < 0.001).
The ORR and DCR in the combination group were 84% and 94% respectively, while in the TACE-alone group, they were 58% and 80% respectively. The differences in ORR and DCR between the two groups were statistically significant (P < 0.05).
The incidence of severe adverse events was 24% in the combination group and 16% in the TACE-alone group(P= 0.317).
Conclusion: Compared to TACE alone, TACE combined with targeted therapy and immunotherapy provides better efficacy without increasing the incidence of severe adverse events in patients with CNLC stage IIb/IIIa HCC.
Limitations: This is a retrospective study with selection bias."

Bronchial artery chemoembolization (BACE) with PD-1 blockades vs. chemotherapy with PD-1 blockades in the treatment of the old adults with non-small cell lung cancer (6 min)

Jianfei Tu; Lishui / China

Author Block: J. Huang, J. Chen, J. Xiang, W. Li, J. Tu, L. Lai; Lishui/CN
Purpose: Chemotherapy combined with immunotherapy is the one of the first-line standard treatment for advanced lung cancer. However, elderly patients typically have comorbidities that tend to limit the use of chemotherapy at standard dosage and frequency. There is a critical need to identify more effective therapeutic interventions.
Methods or Background: This is a retrospective analysis in which we screened elderly lung cancer patients aged 65 years or older (excluding those with driver gene-positive tumors) who were pathologically diagnosed with stage IIIB to IV disease and received immunotherapy combined with BACE or combined with chemotherapy at our hospital between January 2019 and September 2024. The efficacy was evaluated according to the efficacy evaluation criteria for solid tumors (RECIST 1.1). Common Terminology Criteria for Adverse Events (CTCAE) (version 5.0) were used to evaluate adverse drug reactions.
Results or Findings: The final analysis included 81 patients, 39 in the chemotherapy combined with immunotherapy and 42 in the BACE combined with immunotherapy. The median ages of the two patient groups were 71 years and 78 years, respectively. The BACE and chemotherapy arms, respectively, had comparable median PFS (5.5 and 5.2 months; HR 0.95; 95% CI 0.61–1.48) and ORRs (73.8 and 64.1%). BACE cohort showed a numerically better OS of 10.3 months, though this was not statistically significant (10.3 vs 8.7 months; HR 0.98; 95% CI 0.63–1.51). The rate of grade 3 AEs for chemotherapy and BACE arm was 7.7% (3/39) and 4.8% (2/42). No patients occurred treatment-related deaths, hemoptysis or unexpected embolization.
Conclusion: For elderly lung cancer patients, BACE combined with immunotherapy demonstrates comparable efficacy and safety among the two treatment modalities.
Limitations: Since it is a retrospective small-sample study, the level of evidence is limited.

Complication Rates and Effectiveness of Renal Angiomyolipoma Embolisation: A Systematic Review and Meta-Analysis (6 min)

Michael Duffy; Goatstown / Ireland

Author Block: M. Duffy[1], A. Deshwal[1], R. Donnelly[1], M. J. Mullins[2]; [1]Dublin/IE, [2]EAST FREMANTLE/AU
Purpose: To assess the rates of success, complications, and re-interventions of selective arterial embolisation of renal angiomyolipomas
Methods or Background: A systematic review and meta-analysis was conducted, including studies reporting outcomes of selective arterial embolisation for renal angiomyolipomas. Pooled estimates were calculated for technical success, radiological success, clinical success, tumour shrinkage, re-embolisation rates, surgical re-intervention, and complication rates. Heterogeneity was assessed using I^2 statistics. Exploratory regression modelling was performed to assess factors associated with re-intervention.
Results or Findings: Thirteen studies comprising of 478 patients and 542 AMLs were included. Technical success – successful delivery and occlusion of the embolic agent – was achieved in 86.2% of cases (95% CI: 80-89.1%; I^2 = 36.1%). Radiological success, based on CT-assessed tumour shrinkage, was observed in 94% of cases (95% CI:91.2-97.3%; I^2 = 15.6%). Subgroup analysis revealed ethanol-alone embolisation achieved the highest shrinkage (95.8%) and lowest re-intervention rate (3.4%). Pooled re-intervention (re-embolisation or surgery) was required in 19% of cases (95% CI: 10–34%; I^2 = 85.9%). Minor complications occurred in 46% of procedures, predominantly post-embolisation syndrome (PES, 43%; 95% CI: 35–53%, I^2 = 88.8%). Major complications, such as retroperitoneal bleeding, significant haematuria, abscesses or prolonged hospital admission, were rare (pooled rate: 5.7%; 95% CI: 3.9–8.2%), and the pooled rate for surgical re-intervention was 4% (95% CI: 2-7%) with low heterogeneity (I^2 = 9.6%, p = 0.333).
Conclusion: Embolisation is a safe primary treatment option for renal angiomyolipomas with high technical and radiologic success, low major complications, and rates of surgical intervention. Embolic agent choice significantly impacted outcomes in this cohort.
Limitations: Clinical heterogeneity reflects variable techniques, definitions, follow-up, and patient selection. Standardised prospective studies with uniform embolic protocols and eGFR tracking are needed to optimise embolisation strategies and assess long-term renal outcomes.

Effectiveness and Safety of Uterine Artery Embolization in Managing Postpartum Hemorrhage Associated with Placenta Accreta: A Systematic Review and Meta-Analysis (6 min)

Lucas Habiro Alves; São Paulo / Brazil

Author Block: L. Habiro Alves[1], G. Martin[1], A. C. Servidoni[2], H. Provinciatto[3], G. Franceschini Machado[1], K. Miller[4], B. Taneja[5], A. K. Taneja[6], A. Yousif[7]; [1]São Paulo/BR, [2]New Haven, CT/US, [3]Ribeirao Preto/BR, [4]Sao Paulo/BR, [5]Boston, MA/US, [6]Miami, FL/US, [7]El Paso, TX/US
Purpose: Placenta accreta spectrum disorder is a pregnancy complication associated with a substantially increased risk of maternal mortality. With the advancements of interventional radiology, uterine artery embolization has emerged as an effective minimally-invasive alternative to avoid hysterectomy for severe postpartum hemorrhage. The aim of this systematic review and meta-analysis is to evaluate whether uterine artery embolization is an effective and safe method to manage post-partum hemorrhage associated with placenta accreta spectrum.
Methods or Background: PubMed, Embase, and Cochrane Central were systematically searched for studies published from inception until September 2025. A random-effects meta-analysis was conducted through RStudio version 4.4.1 to pool prevalences and rates. The Cochrane Collaboration's Risk Of Bias In Non-randomized Studies of Interventions tool was used for quality assessment.
Results or Findings: Six studies including 215 participants were analyzed. The pooled clinical success rate of uterine artery embolization was 85.0% (95% CI, 77.7–90.2), while the pooled prevalence of hysterectomy after clinical failure was 7.9% (95% CI, 4.9–12.5). Postoperative complications occurred in 19.0% of cases (95% CI, 6.2–45.5) and the pooled mean estimated blood loss was 1825 mL (95% CI, 1116–2533).
Conclusion: Uterine artery embolization is an effective and safe interventional radiology strategy for PPH due to placenta accreta, offering high success rates while preserving uterine function and reducing surgical morbidity.
Limitations: First, there are no published randomized controlled trials on management of PHH secondary to PAS, which restricts the number of studies evaluated and overall statistical power. Second, long-term maternal outcomes, such as subsequent fertility and menstrual function, were not consistently reported, limiting the ability to assess the broader safety profile.

Local intervention with and without embolization in primary and secondary lung tumors: a prospective randomized stuy (6 min)

Thomas J. Vogl; Frankfurt / Germany

Author Block: T. J. Vogl, B. Fischer, T. Gruber-Rouh, H. Adwan; Frankfurt/DE
Purpose: To evaluate unresectable lung metastases of different primary lesions and primary lung cancers treated by transpulmonary chemoperfusion (TPCP) or transpulmonary chemoembolization (TPCE) regarding size and ADC-values.
Methods or Background: In this prospective randomized study 60 patients (30 women, 30 men; mean: 64.5y; range: 29-84y) were included who were treated by TPCP (n=30) and TPCE (n=30). Malignant lesions were from primary lung cancers (n=15), colorectal (n=13), breast cancer (n=10), and other primaries (n=22). All patients were treated via a transfemoral venous approach selectively into the segmental pulmonary artery using Cisplatin and MitomycinC. The TPCE patients received additionally EmboCept®S for the embolization. Follow-up was performed using MRT and CT in 3-month intervals post final therapy session.
Results or Findings: No major side effects were observed. In the TPCE group, mean value in the change of volume was 0.97±0.54, in the TPCP group 1.43±1.14 (p=0.08). Change of the ADC-value was 1.08±0.33 in TPCE and 1.13±0.50 in TPCP (p=0.7). According to RECIST 1.1, TPCE patients showed partial response (PR) in 4 cases and progressive disease (PD) in 4 cases (PR=14.81%, PD=14.81%). The TPCP group showed 1 case of PR and six cases of PD (PR=3.57%, PD=21.43%). The overall survival time in the TPCE group was 732.70±379.41 days, in the TPCP group 552.82±350.23 days (p=0.09). The progression-free time had a p-value of 0.14 (TPCP: 405.36±324.37 days; TPCE: 554.07±397.49 days)
Conclusion: TPCP and TPCE can be safely performed. TPCE resulted in a more stable treatment outcome and a better prognostic trend than TPCP, even though there was no statistically significant difference between TPCP and TPCE concerning overall survival.
Limitations: The number of study participants for each group was very limited.
The groups were not as homogeneous as a statistical evaluation of small groups requires.

Efficacy comparison between endovascular embolization with coils vs coils plus PVA particles in spontaneous soft tissue haemorrhage in anticoagulated patients – a retrospective study (6 min)

Luis Amaral Ferreira; Coimbra / Portugal

Author Block: J. Pereira, L. A. Ferreira, B. Oliveiros, P. Donato; Coimbra/PT
Purpose: To compare different embolic agents' efficacy in the treatment of spontaneous soft tissue haemorrhage in anticoagulated patients.
Methods or Background: Spontaneous soft tissue haemorrhage is a rare but potentially life-threatening condition, affecting anticoagulated patients. Endovascular embolization has emerged as the preferred treatment when conservative management fails.
This retrospective observational study analysed 60 anticoagulated patients treated with transarterial embolization between January 2022 and December 2023. Patients were stratified based on embolic agents used: coils-only versus coils combined with polyvinyl alcohol (PVA) particles. Demographics, clinical presentation, procedural details, and outcomes were collected. Technical and clinical success, post-procedural haemoglobin concentration levels, reintervention rates, and 15-day mortality were assessed.
Results or Findings: Technical success was achieved in all cases with no major complications. No statistically significant differences were found between coils and coils plus PVA groups in terms of haemoglobin concentration variation, transfusion or reintervention need, nor mortality. Mortality at 15 days was 28,6%. Lower systolic and diastolic blood pressures, as well as higher international normalized ratio and prothrombin time, were associated with increased mortality. Higher diastolic blood pressure emerged as a strong predictor of survival.
Although literature suggests possible benefits of combining coils with PVA, our findings did not demonstrate superior outcomes for the combination therapy. Nonetheless, the study supports the safety and efficacy of transarterial embolization in this clinical setting.
Conclusion: Early intervention and haemodynamic stability appear more critical for survival than the choice between coils versus coils plus PVA particles.
Limitations: The main limitation is the retrospective observational nature of the study.
Funding for this study: This study did not receive any funding.

Prophylactic transarterial embolization after endoscopic hemostasis in high-risk patients with non-variceal upper gastrointestinal bleeding - a systematic review (6 min)

Enrico Battiato; Catania / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: E. Battiato, F. Tiralongo, M. D'Urso, G. Vitaliti, D. G. Castiglione, D. Falsaperla, F. Libra, F. Vacirca, A. Basile; Catania/IT
Purpose: To provide a systematic review on prophylactic transarterial embolization (pTAE) after endoscopic hemostasis in high-risk non-variceal upper gastrointestinal bleeding (NVUGIB), focusing on selection criteria, technical conduct by arterial territory and embolic material, clinical outcomes, complications.
Methods or Background: Systematic PubMed and Scopus search (Jan 2010–Sep 2025) included original pTAE studies after successful endoscopic hemostasis and excluded case reports, abstracts, studies focused on variceal bleeding, empiric embolization for angiography-negative bleeding, and systematic reviews/meta-analyses. Finally, 10 studies were included in this review: two randomized clinical trials, three prospective studies, five retrospective studies.
Results or Findings: Randomized evaluation did not show an overall reduction in 30-day rebleeding in intention-to-treat analysis, but suggested benefit in large ulcers (≥15 mm) with lower transfusion needs, and no embolization-related ischemia among treated patients.
Kaminskis et al. reported lower rebleeding and fewer surgery with prophylaxis across matched comparators, also in high-risk profile (Rockall ≥ 7) without excess mortality or ischemic events.
In a series treating duodenal ulcer bleeding, early rebleeding occurred in 11% of cases. Major complications (4%) including hepatic coil migration, highlighting the need for meticulous technique.
Prophylactic TAE showed numerically less rebleeding and 30-day mortality than therapeutic TAE, with comparable complications. Endovascular therapy compared with surgery shows similar mortality rates, higher rebleeding rates, and substantially fewer major complications.
TAE versus surgery after failed endoscopy showed similar 30-day mortality but fewer complications with TAE, with a pTAE subset present but not separately analyzed, underscoring endovascular safety while recognizing rebleeding as the key trade-off in this pathway.
Conclusion: pTAE is feasible, generally safe, and appears to reduce rebleeding and surgical rescue in well-selected patients. Routine application across high-risk presentations is not supported by randomized evidence or guidelines.
Limitations: N/A

Liver Venous Deprivation for Perihilar Cholangiocarcinoma: Safety, Hypertrophic Efficacy, and Impact on Resectability (6 min)

Domenico Santangelo; Milan / Italy

Author Block: D. Santangelo, A. Campisi, D. Palumbo, C. Canevari, F. Ratti, F. Cipriani, A. Chiti, M. Catena, F. De Cobelli; Milan/IT

Purpose: To evaluate the safety and efficacy of liver venous deprivation(LVD) in inducing volumetric and functional hypertrophy, and its impact on resectability in patients with perihilar cholangiocarcinoma(pCCA).

Methods or Background: We retrospectively analyzed 25 patients with histologically confirmed pCCA who underwent LVD between May 2020 and May 2025. LVD was indicated when volumetric future liver remnant (FLR) was <35% or functional FLR was <2.69%/min/m² on 99mTc-mebrofenin hepatobiliary scintigraphy. FLR volumetry was measured at baseline (pre-LVD), 5–15 days post-LVD (time point 1), and 15–30 days post-LVD (time point 2). FLR function was assessed with 99mTc-mebrofenin scintigraphy at baseline and within 30 days after LVD. Primary endpoints were technical success, safety, and post-LVD resection rate. Secondary endpoints included volumetric and functional hypertrophy metrics (degree of hypertrophy (DH) and kinetic growth rate (KGR)) and surgical outcomes, including post-hepatectomy liver failure (PHLF) per ISGLS criteria.

Results or Findings: Baseline median volumetric FLR was 30.0%, and functional FLR was 1.81%/min/m². Biliary drainage was present in 21/25 (84%); median bilirubin was 3.5 mg/dL. Technical success was 100%; one patient (4%) developed a subcapsular hematoma, managed conservatively. At time point 1, median volumetric FLR was 37% (DH 12.7%; KGR 8.1%/week). At time point 2, median volumetric FLR was 41% (DH 16%; KGR 5%/week). In 15 patients with scintigraphy, median post-LVD functional FLR increased to 3.08%/min/m². Surgical resection was performed in 19/25 (76%) at median 40 days post-LVD. Major complications (Clavien–Dindo ≥III) in 14/19 (73.7%). Grade C PHLF in 3/19 (15.8%); 90-day mortality was 15.7%.

Conclusion: LVD was feasible and safe in pCCA, produced substantial volumetric and functional hypertrophy of the FLR, and increased resectability in this cohort. High postoperative morbidity underscores the importance of careful patient selection and perioperative optimization strategies.

Limitations: retrospective. Small sample size.

Accelerated whole-body diffusion-weighted MRI in multiple myeloma patients using deep learning image reconstruction: a retrospective comparison with standard diffusion-weighted imaging (6 min)
Johannes Hofmann; Tübingen / Germany

Author Block: J. Hofmann, S. Afat, K. Nikolaou, J. Herrmann; Tübingen/DE
Purpose: Whole-body MRI (WB-MRI) is routine but time-intensive examination in patients with multiple myeloma. Prolonged scan duration may decrease image quality through motion artifacts, reduce throughput, and increase patient discomfort. This study aimed to evaluate the impact of deep learning–accelerated diffusion-weighted imaging (DWIDL) in 3T WB-MRI on overall and medullary image quality, sharpness, noise, lesion detectability, and diagnostic confidence.
Methods or Background: This retrospective study included 40 patients with multiple myeloma (21 men, 19 women; mean age, 62 ± 11 years; range, 35–82 years) who underwent 3T WB-MRI, including DWI with two b-values (50 and 800 s/mm²) between February 2023 and April 2024. Single-average raw data were processed using a deep learning (DL) image reconstruction algorithm, yielding a simulated acquisition time of 3 minutes 3 seconds for DWIDL compared with 7 minutes 6 seconds for standard DWI (DWIStd) by reducing the number of signal averages. Two experienced radiologists independently evaluated all DWI datasets using a 5-point Likert scale assessing noise level, artifact severity, sharpness, overall image quality, and diagnostic confidence.
Results or Findings: There were no significant differences between DWIDL and DWIStd in artifact severity, sharpness, overall image quality, lesion detectability, or diagnostic confidence. However, DWIDL demonstrated significantly lower noise levels and higher contrast compared with standard DWI ($P < .05$).
Conclusion: Deep learning–based image reconstruction for WB-DWI at 3T is feasible and enables a significant reduction in acquisition time without compromising image quality. Accelerated acquisition particularly benefits multiple myeloma patients by reducing motion artifacts, improving comfort, and potentially enabling MRI instead of CT for better assessment of bone marrow infiltration.
Limitations: This retrospective single-center study with a limited sample size, subjective image quality assessment, and no cost or workflow analysis limits the generalizability and strength of the findings.

Assessment of volumetric and modified Choi MRI response in Desmoid Fibromatosis treatment with Sorafenib versus Nirogacestat (6 min)
Raul Fernando Valenzuela; Houston / United States

Author Block: R. F. Valenzuela, E. Duran-Sierra, M. Antony, J. Espinoza, C. M. Costelloe, J. E. Madewell, W. Murphy, B. Amini, S. Lo; Houston, TX/US
Purpose: Desmoid fibromatosis patients are typically treated with active surveillance and drugs on progression, particularly sorafenib, and most recently, with nirogacestat. This study aimed to determine the signal and volume changes after therapy and over time, comparing both drugs using MRI T2-WI-derived features, including modified Choi (mChoi) and volumetric measurements.
Methods or Background: Retrospective study including 17 patients with single-lesion extremity desmoid fibromatosis and standard-of-care MRI, including T2-WI, from March 2021-February 2024. Volumetric tumor segmentations were created on T2-STIR images. Diameter, mChoi, and volume measurements were computed at four time points across the patient's treatment: Pre-treatment (Pre-Rx), post-treatment 1 (Rx1), post-treatment 2 (Rx2), and post-treatment 3 (Rx3). The percentage change in diameter (RECIST), mChoi, and volume across time were computed with respect to Rx1 and compared in nirogacestat vs. sorafenib patients.
Results or Findings: Eight patients were treated with nirogacestat and nine patients with sorafenib. Nirogacestat-group: 1) mChoi detected two cases of progression not detected by RECIST or volume, 2) from Pre-Rx to Rx3, the average mChoi decreased by 66% over 20 months (-3.3%/month), and 3) from Pre-Rx to Rx3, the average volume reduced by 49% over 20 months (-2.45%/month). Sorafenib group: 1) RECIST, mChoi, and volume detected two progressions. mChoi detected one response not detected by RECIST or volume, 2) from Pre-Rx to Rx3, the average mChoi decreased by 49% over 34 months (-1.44%/month), and 3) from Pre-Rx to Rx3, the average volume decreased by 4% over 34 months (-0.09%/month).
Conclusion: Patients treated with nirogacestat exhibited larger volumetric and mChoi changes, with the fastest response and similar sustained positive treatment effects compared to those treated with sorafenib, indicating the potential of nirogacestat as an effective treatment option for desmoid tumors.
Limitations: Small sample size.

Does Extra-Skeletal Chondrosarcomas manifest distinct MRI radiomics features compared to myxoid liposarcoma and pleomorph sarcoma, and does it have common features with skeletal chondrosarcoma? (6 min)

Roman Perraut-Gattegno; Geneva / Switzerland

Author Block: R. Perraut-Gattegno, J. Stadelmann, P-A. A. Poletti, S. Boudabbous; Geneva/CH
Purpose: The aim of the study was to assess if some features of radiomics are common to extra-skeletal chondrosarcoma and skeletal chondrosarcoma, and to distinguish this rare entity from the most frequent encountered soft tissue sarcoma (myxoid liposarcoma and pleomorphic sarcoma) in MRI imaging.
Methods or Background: Retrospective study on our radiological data base (PACS archive) confronted to data from multidisciplinary sarcoma Concilium, with the evaluation of 150 radiomics features were extracted from volume-of-interest on T1 and T2-weighted spin-echo MRI, from 19 tumor cases (4 ESC, 5 CS, 5 PS and 5 MLS, based on histopathological diagnosis). These radiomics features were then used to train Random Forests to select the best 10 features for the classification of the 4 types of tumors. Then we used a logistic regression to evaluate the best pair of features for dichotomy classification: EOC and OC versus the other types (MLS, PS).
Results or Findings: The visual evaluation of the feature scatter plot confirms the separability of the ESC and SC against the other types of tumours. The evaluation of the logistic regression resulted of a sensitivity of 0.93 specificity of 0.92 for an overall accuracy of 0.92 with the following features: GLCM inverse difference moment normalized (on T2 sequences) and GLCM correlation (on T1 sequences). We consider this preliminary study promising for the use of radiomic features in the differentiation of extra-skeletal and skeletal chondrosarcoma from other soft tissue tumors.
Conclusion: Despite being developed on few cases, 2 radiomics features accurately distinguishes the chondrosarcoma group (ESC + SC) from the MLS and PS on MRI with an overall accuracy of 0.92. We as well evaluated that the chondrosarcoma group had identical profiles on all the radiomic features tested.
Limitations: Small number of cases

Assessment of neoadjuvant therapy response in extremity undifferentiated pleomorphic sarcoma using multiparametric MRI: A comparison between radiation vs consecutive chemotherapy and radiation (6 min)

David Wells; Houston / United States

Author Block: R. F. Valenzuela, E. Duran-Sierra, M. Antony, J. Espinoza, C. M. Costelloe, J. E. Madewell, W. Murphy, D. Wells, B. Amini; Houston, TX/US
Purpose: Undifferentiated pleomorphic sarcoma (UPS) patients are typically treated with either consecutive chemotherapy and radiotherapy (CT-RT) or RT alone. This study aimed to determine the impact of the treatment strategy on imaging and pathology in UPS response assessment based on multiparametric MRI (mp-MRI).
Methods or Background: This retrospective study included 30 extremity UPS patients with preoperative mp-MRI, including contrast-enhanced susceptibility-weighted-imaging (CE-SWI) and perfusion-weighted-imaging with dynamic-contrast-enhancement (PWI/DCE), with surgery performed from February 2021-May 2023. Lesions were visually classified on CE-SWI into one of six morphology patterns. On PWI/DCE, lesions were classified into one of six enhancement patterns. Time-intensity curves (TICs) were classified as types I-V. Patients demonstrating >=90% pathology-assessed-treatment-effect (PATE) on the surgical specimen were labeled as responders (n=15), and those with <90% PATE were labeled as partial/non-responders (n=15).
Results or Findings: 19 patients were treated with presurgical consecutive CT-RT, and 11 with presurgical RT. CT-RT group displayed a higher number of responders (53%) vs. RT (45%). Consecutive CT-RT demonstrated a higher average PATE (78%) compared to the RT group (63%). CT-RT group: 80% of responders displayed a CE-SWI complete-ring pattern (P=1.77x10-5), 90% a PWI/DCE capsular-enhancement (P=3.06x10-6), and 100% a TIC II (P=4.54x10-5). A predictive model combining the PWI/DCE TIC II, PWI/DCE capsular-enhancement, and CE-SWI complete-ring yielded the highest classification performance (AUC = 0.98), discriminating responders from partial/non-responders, outperforming RECIST (AUC = 0.49). RT group: 100% of responders displayed a TIC II (P=0.0253). Perfect classification performance was achieved by a model based on the PWI/DCE TIC II (AUC=1.0).
Conclusion: Predictive models based on PWI/DCE and CE-SWI features can outperform RECIST, predicting pathology-assessed response. Furthermore, classification models that best separate responders from partial/non-responders can vary not only by tumor type but also by treatment regimen.
Limitations: Small sample size.
Funding for this study: The John S. Dunn, Sr. Distinguished Chair in Diagnostic imaging and M.R Evelyn Hudson Foundation Endowed Professorship.

Radiomic Biomarkers from MRI for Predicting Chemotherapy Response in Synovial Sarcoma: A Retrospective Single-Center Study (6 min)

Francesco Pio Papa; Turin / Italy

Author Block: F. P. Papa[1], R. Cuocolo[2], F. Molea[1], L. D'Ambrosio[3], G. Grignani[4], T. Robba[1]; [1]Turin/IT, [2]Naples/IT, [3]Orbassano/IT, [4]Candiolo/IT
Purpose: Synovial sarcoma is an aggressive malignancy that necessitates innovative diagnostic and therapeutic strategies. Predicting chemotherapy response is a pivotal step in the diagnostic-therapeutic pathway, enabling personalized treatment approaches. Radiomics, combined with machine learning, offers a promising avenue to identify imaging biomarkers that predict treatment response.
Methods or Background: In this retrospective, monocentric study, 51 patients diagnosed with synovial sarcoma underwent peri-treatment MRI acquisition. T1-weighted sequences were analyzed to extract 1116 radiomic features, which were subjected to feature selection processes. Machine learning models were developed to predict chemotherapy response. Data were intentionally gathered from heterogeneous MRI scanners to ensure the robustness of the models against clinical variability. Performance metrics included area under the curve (AUC) and accuracy assessments on both training and validation sets.
Results or Findings: The final ExtraTrees model, trained on 20 selected features, showed promising performance on the training set with an accuracy of 0.81 (±0.34), precision of 0.88 (±0.37), recall of 0.87 (±0.42), F1-score of 0.84 (±0.28), and AUC of 0.89 (±0.35), despite high variability.
On the test set (n=17), accuracy was 64.7%, with good sensitivity for non-responders (80%) but lower for responders (58%). Precision was high for responders (0.88) but lower for non-responders (0.44). The test AUC was modest (0.60), while the Precision-Recall Curve (0.72) indicated reasonable precision for the positive class. The Brier score (0.250) suggested moderate model calibration.
Conclusion: This study highlights the potential of radiomics to predict chemotherapy response in synovial sarcoma, despite challenges posed by scanner heterogeneity and intra-reader variability. Further research is required to refine these methods and integrate them into routine clinical practice.
Limitations: This study is limited by single-reader segmentation, small sample size, and lack of external validation.
Funding for this study: No fundings

Delta-Radiomics Based on MRI for Predicting Response to Neoadjuvant Chemotherapy in Osteosarcoma: A Comparative Study with Conventional Imaging Features (6 min)

Ping Yin; Beijing / China

Author Block: P. Yin, N. Hong; Beijing/CN
Purpose: This study evaluates T2-weighted MRI-derived delta-radiomics for predicting histopathological NACT response, comparing efficacy against conventional quantitative imaging features (CQIF) and static radiomics models.
Methods or Background: This retrospective study included 152 patients with histologically confirmed osteosarcoma who underwent MRI before and after neoadjuvant chemotherapy (NACT). Patients were categorized as good responders (n = 57) or poor responders (n = 95) based on postoperative tumor necrosis rate. Quantitative imaging features (diameter, volume, relative signal intensity) and radiomic features were extracted from manually segmented tumor regions on pre- and post-NACT MRI. Delta-radiomics features were calculated as the relative change between the two time points. Feature selection was performed using multivariate stepwise regression. Predictive models were built using selected features from four groups: CQIF, Pre-NACT radiomics, Post-NACT radiomics, and Delta-radiomics. Model performance was evaluated using ROC curves, AUC, accuracy, sensitivity, specificity, and Delong test.
Results or Findings: The Delta-Radiomics model achieved the best predictive performance (AUC = 0.813 training / 0.796 test), significantly outperforming the Post-NACT model (AUC = 0.519 test, $P < 0.05$). It demonstrated high specificity (0.893) and favorable overall accuracy (0.756) in the test cohort. Key predictive features captured dynamic tumor changes in shape, texture complexity, and gray-level spatial relationships. In contrast, the CQIF model retained only the tumor diameter change and showed lower predictive performance (AUC = 0.729 test). No significant differences were found in static Pre- or Post-NACT radiomics features alone.
Conclusion: Delta-radiomics features based on multiparametric MRI offer superior predictive performance in assessing osteosarcoma response to neoadjuvant chemotherapy compared to conventional imaging metrics and static radiomics.
Limitations: Limitations include retrospective design and small sample size affecting generalizability. Future integration of clinical/molecular data could enhance prediction, alongside longitudinal multi-time-point radiomic studies.

Imaging and Epidemiology of the Follow-up of Massive Knee Prostheses (6 min)

Yacine Abdelouahab; Reims / France

Author Block: Y. ABDELOUAHAB, F. Mihoubi Bouvier, J-L. Drape, A. Feydy, P. Anract; Paris/FR
Purpose: Massive knee prostheses are increasingly used after tumor resections or complex revisions. While they allow limb preservation, their imaging follow-up remains poorly standardized, and no dedicated imaging study had previously focused on these implants.
Objectives : (i) To describe physiological and pathological imaging features of massive knee prostheses and propose a surveillance scheme; (ii) to estimate complication rates, implant survival, and associated prognostic factors.
Methods or Background: A retrospective monocentric study was conducted at Cochin Hospital (2010–2022), including 88 patients with distal femoral (n = 71) or proximal tibial (n = 17) prostheses. Over 1,000 imaging examinations were analyzed (radiographs, CT, MRI, EOS, ultrasound). Complications were classified using Henderson's system, expanded with a type VI neuro-functional category.
Results or Findings: Median follow-up was 37 months. Implant survival was 50% at 37 months (mean 58). The complication rate was 73%: infections (30%), aseptic loosening (13.2%), neuro-functional complications (13.2%), and recurrences (15%). Radiography remained central for mechanical issues. Peri-prosthetic ossifications developed around the prosthetic collar: ossification without osteointegration was strongly associated with loosening (61.9% vs 6.9% and 18.2%), while ossification with osteointegration was protective. New calcifications beyond six months, especially in osteosarcoma patients, were highly suggestive of recurrence. Ultrasound proved particularly effective in the popliteal fossa (recurrences, thrombosis, peri-prosthetic changes), while MRI was more useful for soft tissues outside this area.
Conclusion: This first dedicated imaging study on massive knee prostheses establishes peri-collar ossification without osteointegration as a prognostic marker. Above all, it highlights the novel role of ultrasound as a non-invasive, accessible, and highly sensitive modality for surveillance—particularly in the popliteal fossa—offering a decisive new tool to improve early detection and long-term outcomes.
Limitations: Retrospective, single-center design and heterogeneous imaging protocols may limit generalizability.
Funding for this study: This study received no specific funding.

Imaging-based Metastatic Risk Model for Tibial Adamantinoma (6 min)

Paolo Spinnato; Bologna / Italy

Author Block: P. Spinnato[1], M. Colangeli[1], G. Bilancia[1], A. Crombé[2], M. Simonetti[1]; [1]Bologna/IT, [2]Talence/FR
Purpose: Adamantinoma is a primary malignant bone tumor that is extremely uncommon. The categorization of metastatic risk at diagnosis is difficult since there is currently no histological grading. Imaging may therefore be useful in predicting prognosis.
Our goal was to assess baseline imaging characteristics and how they relate to the emergence of metastatic disease.
Methods or Background: We retrospectively collected baseline radiological (CT, MRI, and conventional radiography) and clinical (metastatic disease) data from all consecutive patients with a histological diagnosis of adamantinoma between 2006 and 2022 at our single Sarcoma Center. Lodwick-Madewell grading, periosteal reaction, multifocality, soft-tissue extraskeletal component, tumor location, size, main radiological pattern (lytic, sclerotic, mixed), peritumoral edema, and vascular invasion were all examined. At diagnosis or during follow-up, correlations between the radiological characteristics listed above and metastatic disease were evaluated.
Results or Findings: Twenty-two patients were included (15 female, 7 male - mean age 28.8±13.3 years, range 7-58 years old). Six out of 22 patients (27.3%) developed distant metastases at diagnosis or during follow-up controls (minimum follow-up 24 months). The following radiological features were significantly correlated with the development of metastases at baseline or during follow-up controls: presence of an
extra-skeletal component (p=0.0004), vascular invasion (p=0.0002), and diffuse peritumoral edema (p=0.0004).
A risk model including two of the above mentioned imaging features, provided a sensibility of 100% (54.07%-100%), a specificity of 93.75% (69.67%-99.84%), with an accuracy of 95.45% (77.16%-99.88%) in predicting metastatic disease.
Conclusion: An accurate evaluation of baseline imaging studies in patients affected by adamantinoma may significantly aid in prognosis prediction and the selection of high metastatic-risk patients. For these patients, strict follow-up controls and more aggressive treatments should be suggested after multidisciplinary discussions in sarcoma centers.
Limitations: Retrospective, single-center analysis.
Funding for this study: No funding received.

Quantitative Comparison of Contrast Enhancement Dynamics between Lipid-poor and Lipid-rich Vertebral Hemangiomas on MRI (6 min)

Teresa Barata Rodrigues; Lisbon / Portugal

Author Block: T. B. Rodrigues, C. Rodrigues, A. M. Gaspar, M. Ramalho; Lisbon/PT
Purpose: To quantitatively compare the contrast enhancement dynamics of lipid-poor and lipid-rich vertebral hemangiomas on MRI and assess whether enhancement parameters can reliably distinguish these subtypes.
Methods or Background: Lipid-poor vertebral hemangiomas are rare and diagnostically challenging due to their high T2 signal intensity on fat-suppressed MRI sequences, often mimicking more aggressive lesions. A word-search retrospective analysis included 43 vertebral hemangiomas: 21 lipid-poor (12 females, 9 males; mean age 58.6 ± 13.7 years; mean lesion size 15.5 ± 7.4 mm) and 22 lipid-rich (15 females, 7 males; mean age 57.0 ± 12.6 years; mean size 11.5 ± 5.7 mm). Lesions were confirmed via CT attenuation or MRI follow-up stability. Signal intensity was measured using a fixed region of interest across pre-contrast T1-weighted fat-suppressed, arterial, venous, and delayed (interstitial) phases. Percentage enhancement was calculated relative to pre-contrast signal. Statistical comparisons employed Student's t-test, Mann-Whitney U test, and Chi-square test.
Results or Findings: Lipid-poor hemangiomas exhibited significantly greater enhancement across all post-contrast phases compared to lipid-rich counterparts. In the arterial phase, lipid-poor lesions showed a mean enhancement of 206.8 ± 131.8%, versus 118.0 ± 82% for lipid-rich lesions ($p < 0.05$). Venous phase enhancement was also higher in lipid-poor hemangiomas (278.1 ± 117.0%) than in lipid-rich ones (166.3 ± 97.7%, $p < 0.05$). In the delayed (interstitial) phase, lipid-poor enhancement (267.0 ± 100.2%) remained markedly superior to lipid-rich enhancement (139.4 ± 90.9%, $p < 0.05$). No significant differences were found in age or sex ($p > 0.05$), though lipid-poor lesions trended toward larger size ($p = 0.051$).
Conclusion: Lipid-poor vertebral hemangiomas demonstrate significantly stronger and more persistent enhancement than lipid-rich lesions, suggesting that quantitative enhancement metrics may serve as a valuable tool for subtype differentiation on MRI.
Limitations: Retrospective; Small sample size

Bipolar Radiofrequency Ablation–Assisted Kyphoplasty and Osteoplasty for Malignant Pathological Fractures: Safety and Clinical Outcomes (6 min)

Roberto Marcello; Roma / Italy

Author Block: R. Marcello[1], A. Ciabattoni[1], M. Cuccarelli[2], G. Marcello[2], S. Vitale[1]; [1]Roma/IT, [2]Rome/IT
Purpose: Pathological fractures due to metastatic bone lesions are associated with significant pain and functional impairment. Minimally invasive treatments such as kyphoplasty and osteoplasty offer symptomatic relief, but the risk of cement leakage remains a major concern. This study evaluates the safety and efficacy of bipolar radiofrequency ablation (RFA) prior to cement injection to improve procedural control and patient outcomes.
Methods or Background: We retrospectively reviewed 37 patients with symptomatic malignant pathological fractures who underwent bipolar RFA-assisted kyphoplasty (n=31) or osteoplasty (n=6) between January 2011 and May 2019. Bipolar RFA was performed using the Osteocool RF Ablation System (Medtronic), achieving a constant temperature of 70°C over 7–15 minutes. Cement (PMMA) was then injected into the thermally ablated cavity. Clinical outcomes were assessed via VAS pain scores, and radiological results were evaluated by MR to determine cement distribution and leakage.
Results or Findings: All procedures were technically successful. No peri-procedural morbidity or mortality occurred. Post-procedural VAS scores demonstrated a significant decrease in pain for all patients ($p < 0.05$). MR imaging showed no significant venous or cortical cement leakage. The thermally created cavity facilitated controlled cement deposition.
Conclusion: Bipolar RFA-assisted cementoplasty appears to be a safe and effective technique for managing malignant pathological fractures. This approach reduces the risk of cement leakage while improving pain control and procedural precision. It may serve as a valuable adjunct in interventional strategies for metastatic bone disease. Prospective studies are needed to confirm these findings.
Limitations: Any

Feasibility study of combined diagnosis of multiple functional imaging modalities in the identification of benign and malignant bone tumors (6 min)

Longyao Ma; Zhengzhou / China

Author Block: Y. Li[1], W. Zhang[1], L. Ma[1], L. Liangjie[2], Y. Zhang[1]; [1]Zhengzhou/CN, [2]Beijing/CN
Purpose: Amide proton transfer weighted imaging (APTWI) has been widely explored for tumor evaluation. This study attempted to evaluate the added value of APTWI to multiple model diffusion imaging for differentiating benign and malignant bone tumors.
Methods or Background: This prospective study included 68 patients with pathologically confirmed bone tumors (25 benign and 43 malignant) . All patients underwent MRI examinations including conventional DWI, intravoxel incoherent motion (IVIM), diffusion kurtosis imaging (DKI), and APTWI. The apparent diffusion coefficient (ADC), pure molecular diffusion (D), perfusion fraction (f), pseudo-diffusion (D*), mean kurtosis (MK), and mean diffusivity (MD) were calculated from multiple diffusion models. The magnetization transfer ratio asymmetry at a chemical shift of 3.5 ppm [MTRasym(3.5 ppm)] were derived from APTWI. Mann-Whitney U test or independent samples t-test was used for group comparison between benign and malignant tumors. Logistic regression modeling was used to identify independent predictors and performed combination diagnosis. Receiver operating characteristic (ROC) curve analysis was performed to evaluate the diagnostic performance.
Results or Findings: Malignant tumors showed significantly lower ADC, D, and MD, while significantly higher MK and MTRasym(3.5 ppm) values than those of benign tumors. ROC analysis yielded AUC values of 0.838 (ADC), 0.826 (D), 0.768 (MD), 0.820 (MK), and 0.761 [MTRasym(3.5 ppm)], respectively, for differentiation between benign and malignant bone tumors. Multivariate logistic regression revealed that MTRasym(3.5 ppm) and MK were independent factors for prediction of benign and malignant tumors. The combination of MTRasym(3.5 ppm) and MK showed significant improved diagnostic performance with the AUC of 0.901.
Conclusion: The integration of APTWI and advanced diffusion models provides additional insights into tumor metabolism and microstructure of bone tumors, thus significantly enhancing the diagnostic efficacy.
Limitations: Single-center study, small tumor cohort, and lack of external validation.
Funding for this study: We don't have any funding support.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective investigation was permitted by the Review Committee of the First Affiliated Hospital of Zhengzhou University (2023-KY-0888-003).

Response Patterns During Neoadjuvant Radiation Therapy in Soft Tissue Sarcomas: A Multiparametric MRI Clustering Analysis (6 min)

Balazs Bogner; Freiburg Im Breisgau / Germany

Author Block: B. Bogner, A. Runkel, M. Reisert, T. D. Diallo, P. M. Jungmann, F. Bamberg, M. Jung; Freiburg Im Breisgau/DE
Purpose: To identify distinct treatment response patterns in soft tissue sarcomas (STS) during neoadjuvant radiation therapy (NRT) using multiparametric MRI (mpMRI).
Methods or Background: In this prospective study, 25 STS patients (intermediate or high grade) underwent 3T mpMRI at baseline, mid-treatment (week 3), and post-NRT (week 5). Quantitative parameters were extracted from T2-weighted, diffusion-weighted imaging (DWI), intravoxel incoherent motion (IVIM), and dynamic contrast-enhanced (DCE) sequences following 3D tumor segmentation. Principal component analysis (PCA) and unsupervised k-means clustering identified response patterns based on percentage changes from baseline to post-treatment. Representative whole-mount histology sections were obtained using spatially co-registered in vivo and ex vivo MRI, with necrosis quantified from three representative slices per tumor. Clusters were compared using Mann-Whitney U tests and validated against histopathological necrosis.
Results or Findings: Among 25 patients (mean age 68±14 years, BMI 25.6±5.5 kg/m², 35% female), k-means clustering identified two distinct response patterns. Cluster 1 (n=13) demonstrated variable changes in vascularity/permeability (Ktrans: +32.8±83.5%, Kep: +23.2±27.5%) and perfusion (f: +13.7±35.8%, fD: +10.0±40.1%) with stable cellularity (ADC: +6.2±7.7%, D: +8.4±10.0%). In contrast, cluster 2 (n=12) showed reduced vascularity/permeability (Ktrans: -42.9±30.3%, Kep: -29.8±25.0%, both $p<0.01$ vs. cluster 1) and perfusion (f: -11.4±21.0%, fD: -24.1±25.0%, both $p=0.024$) with reduced cellularity (ADC: +31.7±11.6%, D: +33.9±14.0%, both $p<0.001$). Cluster 2 demonstrated significantly higher post-surgical necrosis (60±30% vs. 30±30%, $p=0.021$), indicating superior treatment response. Notably, volumetric changes did not differ significantly between clusters ($p=0.568$), despite distinct functional imaging patterns and different necrosis levels.
Conclusion: Unsupervised clustering identified two distinct functional response patterns during NRT in STS, independent of volumetric changes. These patterns corresponded to different levels of histopathological necrosis, suggesting that mpMRI could non-invasively identify treatment responders during neoadjuvant therapy.
Limitations: Small sample size.

RPS 2111 - Gliomas: advanced techniques in neuro-oncology imaging

Categories: Imaging Methods, Oncologic Imaging, Neuro
Date: March 7, 2026 | 16:00 - 17:30 CET
CME Credits: 1.5

Moderator:
Pia C Maly Sundgren; Malmö / Sweden

Moderator's introduction (6 min)
Pia C Maly Sundgren; Malmö / Sweden

When Structured Meets Traditional: BT-RADS versus RANO 2.0 in Treated Gliomas with Survival and Decision Impact (6 min)
Akshat hitesh Shah; Kolkata / India

Author Block: A. h. Shah, S. Sen, A. Chandra, A. Gehani; Kolkata/IN
Purpose: RANO 2.0 refines trial-grade response criteria but remains complex and inconsistently applied in routine practice. The Brain Tumor Reporting and Data System (BT-RADS) offers a structured lexicon for follow-up, yet head-to-head outcome-based validation against RANO 2.0 is lacking. We compared diagnostic accuracy, reproducibility, survival stratification, and downstream management impact of BT-RADS versus RANO 2.0 in treated gliomas.
Methods or Background: We retrospectively reviewed 536 patients with treated gliomas (2012–2024; 1,082 follow-up MRIs). Two neuroradiologists independently applied both BT-RADS and RANO 2.0. Truth standards were histopathology, MDT consensus, or ≥12-month follow-up. Endpoints included diagnostic performance, interobserver agreement (κ), Kaplan-Meier progression-free survival (PFS) and overall survival (OS), and concordance with MDT management decisions. Published BT-RADS work confirms feasibility, but survival-based, RANO-anchored validation has not been reported.
Results or Findings: BT-RADS achieved higher diagnostic accuracy (88%) than RANO 2.0 (77%), with better reproducibility (κ = 0.80 vs 0.61). Survival separated cleanly by BT-RADS: median PFS 12 months / OS 22 months for BT-RADS 3, versus PFS 6 months / OS 11 months for BT-RADS 4 (log-rank $p<0.001$). RANO 2.0 categories overlapped substantially, limiting prognostic clarity. BT-RADS also reduced false positives from pseudoprogression, operationalizing RANO's "confirm on repeat scan" rule. Clinical impact was evident: MDT escalation occurred in 78% of BT-RADS 4 and observation in 85% of BT-RADS 2, higher alignment than with RANO 2.0.
Conclusion: In real-world follow-up, BT-RADS is not only more reproducible but also more clinically meaningful than RANO 2.0-cleanly stratifying survival and aligning with actual MDT decisions. This is the first survival-stratified, decision-linked validation of BT-RADS versus RANO, supporting structured lexicons in daily glioma care.
Limitations: Single-center retrospective design; heterogeneous treatment regimen.

Multicentric study on the pre-surgical differentiation of IDH-wildtype glioblastoma and IDH-mutant grade 4 astrocytoma using structured MRI visual assessment (6 min)
Ady Mildred Viveros; Barcelona / Spain

Author Block: A. M. Viveros[1], C. Majós[1], P. Naval-Baudin[1], J. I. García García[1], M. Cos Domingo[1], L. Oleaga[1], M. Smits[2], A. Pons Escoda[1]; [1]Barcelona/ES, [2]Rotterdam/NL
Purpose: This study aims to assess the diagnostic performance of VASARI (Visually Accessible Rembrandt Images) criteria in the pre-surgical differentiation of IDH-mutant-grade-4 astrocytomas(A4-mut) and IDH-wildtype-glioblastomas(Gb-wt), and the potential added-value of incorporating the T2/FLAIRmismatch into the visual evaluation features.
Methods or Background: Histomolecularly confirmed A4-mut or Gb-wt(age-balanced) with available pre-surgical-MRI were recruited retrospectively (2016-2022) from three tertiary hospitals in Spain and The-Netherlands.
Blinded, independent assessments of VASARI_features and T2/FLAIRmismatch were performed by three-experienced-neuroradiologists (5, 10, and >20years of experience), and a final consensus reading was obtained.
Statistical differences(x2-test) and potential discriminatory performance (AUC-ROC) for each VASARI_features were assessed in univariate analysis.
Additionally, two multivariable logistic-regression models were developed: VASARI-only and VASARI+T2/FLAIRmismatch. The discriminative performance of the models was assessed by AUC-ROC values (accuracy, sensitivity and specificity were derived from Youden-index).
All analyses were validated using 5-fold cross-validation.
Results or Findings: A total of 163 patients were included: 43 A4-mut(mean-age 41y.o.,28males) and 120 Gb-wt(mean-age 47y.o.,87males).
Univariate diagnostic performance: The highest AUC-ROC values (>0.70) were T2/FLAIRmismatch, proportion of non-enhancing tumor, definition of enhancing margin, and thickness of enhancing margin (AUC=0.72-0.76). 30% of variables showed AUC=0.60-0.70 and 50% of variables showed AUC<0.60.
The performance of the multivariable models was as follows: the VASARI-only model (three most discriminative features) achieved an AUC=0.82 (accuracy=0.77); whereas the VASARI+T2/FLAIRmismatch model achieved an AUC=0.87 (accuracy=0.88). Expert neuroradiologists' consensus accuracy was 0.83.
Conclusion: A4-mut exhibited higher proportions of non-enhancing-tumor, ill-defined enhancing borders, and thinner enhancing margins as the most prominent radiological differences.
The T2/FLAIRmismatch, present in any proportion (in some cases focal and involving <25% of the total MRI abnormality extent), showed almost perfect specificity for A4-mut.
An accuracy of 0.88 was achieved by the multivariable model (VASARIs plus the T2/FLAIRmismatch), exceeding the neuroradiologists' consensus.

Diffusion-Weighted MRI Radiomics Model in Predicting IDH Status of Non-Enhancing (Low-Grade-Appearing) Adult Diffuse Gliomas (6 min)

Menglin Ge; Beijing / China

Author Block: Y. Liang, Y. Liu, Z. Chen, M. Ge, Y. Wang; Beijing/CN
Purpose: In non-contrast-enhanced (non-CE) adult diffuse gliomas, a significant proportion (19–44%) exhibit aggressive behavior due to high-grade molecular features like IDH wild-type status. Precise preoperative IDH prediction is crucial for optimizing treatment. The 2021 WHO Classification of CNS Tumours designates IDH status as a core determinant for molecular subtyping and grading. IDH wild-type gliomas, even those with low-grade histological appearance, are classified as high-grade and require intensified treatment. Conventional imaging lacks quantitative characterization, whereas radiomics non-invasively reveals tumor heterogeneity by extracting high-throughput quantitative features. This study aims to develop a multimodal MRI radiomics model for preoperative non-invasive prediction of IDH mutation status to guide individualized therapy.
Methods or Background: A retrospective analysis included 151 patients (158 lesions) with pathologically confirmed non-CE adult diffuse gliomas (2016–2023). Based on pathology, patients were stratified into IDH-mutant (44 lesions) and IDH-wild-type (114 lesions) groups and randomly divided into training and validation sets (7:3 ratio). Regions of interest were manually delineated on T2WI, followed by co-registration with ADC and T1CE sequences. A total of 1,132 radiomics features were extracted from T2WI, T1WI, ADC, and T1CE sequences. Feature selection involved ICC (≥0.85), statistical tests, and LASSO regression. Six machine learning models (LR, SVM with RBF/linear kernels, KNN, DT, NB) were evaluated using AUC to assess single-sequence and multi-sequence predictive performance.
Results or Findings: Multi-parametric models combining T2WI, T1CE, and ADC outperformed single-sequence models. The SVM (RBF kernel) classifier with multi-parametric features achieved optimal performance (training AUC = 0.969, sensitivity 88.6%, specificity 100%, accuracy 85.4%; validation AUC = 0.922, sensitivity 82.3%, specificity 90.3%, accuracy 87.3%), significantly surpassing single-sequence models.
Conclusion: The multimodal MRI radiomics model enables accurate, non-invasive IDH status prediction in non-enhancing gliomas (AUC>0.9), assisting surgical planning and advancing imaging-genomic diagnostics.

Benchmarking Advanced Diffusion MRI Models for Preoperative Glioma Characterization: A Multi-Compartment and Zone-Specific Analysis (6 min)

Ivana Jacečková; Prague / Czechia

Author Block: I. Jacečková, V. Sedlák, M. Majovsky, A. Kavkova, D. Netuka, T. Belsan, K. Sichova, E. Stoklasa, M. Nemy; Prague/CZ
Purpose: To benchmark the diagnostic performance of conventional and advanced diffusion MRI models, including ADC, DTI, DKI, SMT, NODDI, and RSI, in predicting histologic grade and IDH mutation status in adult-type diffuse gliomas, and to investigate whether model performance differs between various tumor zones and peritumoral regions.
Methods or Background: A cohort of 200 patients with histologically confirmed adult-type gliomas underwent a standardized 3T MRI protocol including multi-shell diffusion imaging. Quantitative parametric maps were reconstructed from six diffusion models (ADC, DTI, DKI, SMT, NODDI, RSI). Tumoral and peritumoral regions were delineated automatically by a convolutional neural network on structural MRI. Zone-specific diffusion parameters were extracted and evaluated for prediction of histologic grade and IDH mutation. ROC analysis and cross-validation were performed to compare model performance, with ADC serving as the clinical benchmark.
Results or Findings: In addition to significantly increasing diagnostic performance in predicting grade and IDH, advanced multi-compartment models revealed marked spatial heterogeneity not captured by conventional ADC. IDH-wildtype gliomas exhibited elevated cellularity indices in both enhancing tumor and peritumoral regions, whereas IDH-mutant gliomas showed more confined abnormalities. Higher-grade gliomas displayed pronounced microstructural disruption extending into edema and peritumoral tissue.
Conclusion: This study establishes a comparative benchmark of diffusion models for glioma characterization. NODDI, SMT, and RSI outperform conventional ADC and show robust performance across both tumoral and peritumoral compartments. By leveraging automated segmentation and multi-shell diffusion analysis, zone-specific biomarkers can be extracted with minimal human input, supporting precision preoperative assessment and guiding model selection in clinical neuro-oncology practice.
Limitations: The main limitations of this study are its single-center nature and still a relatively small sample size, despite being one of the largest advanced diffusion datasets published. Also, less common models (e.g. CHARMED, VERDICT) were not evaluated.
Funding for this study: Funding was provided by the Ministry of Health of the Czech Republic, grant no. NW25J-08-00023, and by Charles University, project
GA UK no. 222623.

Radiogenomic Signatures of Histological Heterogeneity in H3 K27-Altered Diffuse Midline Gliomas (6 min)

Qianqian Zheng; Chengdu / China

Author Block: Q. Zheng, X. Su, Y. Deng, X. Yang, L. Wang, S. Tang, Y. Jin, Q. Yue; Chengdu, Sichuan Province/CN
Purpose: Diffuse midline gliomas, H3 K27-altered (DMGs) are classified as WHO grade 4 tumors regardless of histopathological appearance. Recent advances reveal substantial heterogeneity among these patients, with some exhibiting histological features resembling lower-grade (LGG, histological grade 2-3) group and others resembling high-grade (HGG, histological grade 4) group. This research aims to identify distinct radiomics and genomics features in LGG and HGG groups with H3 K27-altered and link radiomic signatures with relevant genomic alterations.
Methods or Background: A cohort of 104 H3 K27-altered DMG patients, diagnosed between December 2016 and February 2023, were classified as LGG or HGG by experienced pathologists. Of these, 48 patients comprised the radiomics set from which radiomic features were extracted from preoperative MRI and selected using least absolute shrinkage and selection operator (LASSO) regression. A separate radiogenomics set of 27 patients with both MRI and whole-exome sequencing (WES) data was used to explore associations between radiomic and genomic features. The biological meaning of radiomics-associated key genes was explored using a public glioma dataset from the Chinese Glioma Genome Atlas (CGGA).
Results or Findings: Seven radiomic features were finally selected. Among 35 differential mutation genes, original_glszm_LargeAreaHighGrayLevelEmphasis was associated with AATK, GRIN2A, NEFH and TNK2. In CGGA, GSVA analysis revealed enrichment of pathways related to these radiomics-correlated genes' product. Furthermore, GRIN2A, NEFH and TNK2 emerged as independent prognostic factors for overall survival (OS) in glioma.
Conclusion: Histological grade-specific radiomic features derived from preoperative MRI in H3 K27-altered DMGs are linked to key prognostic genes, offering novel insights into the pathophysiological mechanisms of these tumors and their imaging correlates.
Limitations: This study is limited by its retrospective design and the relatively small sample size. Furthermore, multi-center validation is needed.

Metabolically Active Low-Angiogenic Tumor Habitats Mediate Remote Glymphatic Impairment and Predict Outcome in High-Grade Glioma (6 min)

Hao Wu; Chongqing / China

Author Block: H. Wu[1], T. Xie[2]; [1]Chongqing/CN, [2]Ch/CN
Purpose: To determine whether hypoperfused yet metabolically active tumor regions—termed low-angiogenic tumor (LAT) habitats—impair glymphatic clearance in the contralateral hemisphere and predict clinical outcomes in patients with high-grade glioma (HGG) undergoing standard chemoradiotherapy.
Methods or Background: Materials and methods: This retrospective study included 151 newly diagnosed HGG patients who underwent preoperative multiparametric MRI and received standardized treatment. LAT habitats were delineated from perfusion maps, and their metabolic activity was estimated using a weighted least squares model based on multi-voxel MRS of enhancing tumor regions. Glymphatic function was assessed via the DTI-ALPS index in the anatomically unaffected hemisphere. Partial correlation, single and serial mediation models, and Cox regression were used to evaluate interdependencies among LAT perfusion, metabolism, glymphatic dysfunction, and progression-free survival (PFS), adjusting for IDH mutation status.
Results or Findings: Results□LAT rCBV, Cho/NAA, and ALPS showed strong intercorrelations ($r = 0.763, 0.591, 0.409$; all $p < 0.001$). Mediation revealed a full pathway: LAT perfusion predicted metabolism ($\beta = 1.25$, $p < 0.001$), which predicted glymphatic function ($\beta = 0.06$, $p < 0.001$); only the indirect effect was significant. Cox analysis identified Cho/NAA and IDH—but not ALPS—as independent PFS predictors. Serial mediation confirmed that only metabolism, not glymphatic dysfunction, mediated survival. A multivariable model yielded a C-index of 0.922.
Conclusion: Conclusions: Metabolically active LAT habitats remotely impair glymphatic function and contribute to recurrence. Combined metabolic–glymphatic profiling may offer a mechanistic basis for risk stratification and therapeutic targeting in HGG.
Limitations: LAT metabolism was estimated indirectly, ALPS was measured only contralesionally, and the retrospective design limits causality; moreover, unmeasured solid stress—potentially co-localizing with metabolic tension—may contribute to contralesional glymphatic impairment and warrants prospective multimodal evaluation.

Contra-lesional hippocampus in low grade glioma patients with no hippocampal infiltration - a study of structural remodeling (6 min)

Marcin Radosław Stański; Poznań / Poland

Author Block: M. R. Stański, M. Goralewski, J. Watorek, S. Antczak, J. Moskal, K. Katulska; Poznań/PL
Purpose: Low grade gliomas (LGG) are slowly growing tumours which induce neuroplasticity. It was previously shown that the invasion of hippocampus by LGG may induce enlargement of contra-lesional hippocampus, including its gray matter volume (GMV) and volumes of its subfields. Our goal was to assess if similar changes may occur also in patients with LGG which do not invade hippocampus.
Methods or Background: This was a retrospective study of 3D T1 MRI scans of 30 LGG patients (17 left-, 13 right-sided) without hippocampal invasion and 26 healthy controls. In each case a neuroradiologist drew a 3D volume of interest delineating the tumor. We used virtual brain grafting (VBG) to replace abnormal tissue with a clipping of healthy brain template. Using synthetic images we analyzed GMV with voxel-based morphometry (VBM) and volume of hippocampal subfields with FreeSurfer 6.0. We focused on regions previously reported in the literature to be enlarged in LGG with hippocampal infiltration.
Results or Findings: Contra-lesional hippocampal GMV was significantly larger in left- ($T = 7.78$, $p < 0.05$) and right-sided LGG ($T = 6.39$, $p < 0.05$). A trend towards larger hippocampal-amygdala transitional area (HATA) was seen in both groups, reaching significance in right-sided LGG (Bonferroni corrected $p = 0.04$). In right-sided LGGs, trends for enlargement were also observed in GC-ML-DG head (the granule cell molecular layer of the dentate gyrus head) , CA1 head, and CA3 head.
Conclusion: The hippocampus contralateral to LGG may undergo structural remodeling even when the ipsilateral one is not affected by tumour infiltration.
Limitations: The study had retrospective design. Our cohort size was small due to epidemiology of LGGs and strict inclusion criteria. Groups were heterogenous regarding tumor volumes due to difficulty in adjusting it with small samples.
Funding for this study: The study received no external funding.

The 2025 BraTS MICCAI lighthouse challenge: glioma segmentation on pre- and post-treatment MRI (6 min)

Maria Correia De Verdier; Uppsala / Sweden

Author Block: M. Correia De Verdier[1], R. Saluja[2], L. Gagnon[3], U. Baid[4], M. Astaraki[5], R. Huang[6], S. Bakas[4], E. Calabrese[7], J. D. Rudie[8], B. M. L. G. C. [1]; [1]Uppsala/SE, [2]New York, NY/US, [3]Québec City, QC/CA, [4]Indianapolis, IN/US, [5]Stockholm/SE, [6]Boston, MA/US, [7]Durham, NC/US, [8]La Jolla, CA/US
Purpose: The 2025 Brain Tumor Segmentation (BraTS) challenge on pre- and post-treatment glioma aims to create a large public dataset of annotated diffuse glioma MRIs and a benchmarking environment for developing and evaluating deep learning segmentation models to address challenges in treatment planning and disease monitoring.
Methods or Background: Eighteen institutions on four continents contributed 4401 MRIs of patients with diffuse gliomas, acquired pre- or post-surgery, radiation, or systemic therapy. MRIs included pre-contrast and contrast-enhanced T1-weighted, T2-weighted, and T2-FLAIR sequences. Data preprocessing and annotation followed established BraTS guidelines. Neuroradiologists approved annotations for four sub-regions: enhancing tissue (ET), surrounding non-enhancing FLAIR hyperintensity (SNFH), non-enhancing tumour core (NETC), and resection cavity (RC). Participants used the dataset to develop and evaluate their segmentation models, predicting ET, RC, tumour core (TC = ET + NETC) and whole tumour (WT = TC + SNFH). Forty-four teams participated in the validation phase and 12 teams in the testing phase. Evaluation was performed using lesion-wise Dice Similarity Coefficient (L-DSC) and Normalized Surface Distance (L-NSD).
Results or Findings: The best performing team's L-DSC (mean (median) ± SD) were: ET – 0.81 (0.93) ± 0.26, RC – 0.89 (1.00) ± 0.25, TC – 0.81 (0.94) ± 0.28, WT – 0.88 (0.96) ± 0.18, and L-NSD were: ET – 0.86 (0.96) ± 0.25, RC – 0.89 (1.00) ± 0.25, TC – 0.82 (0.94) ± 0.27 and WT – 0.85 (0.94) ± 0.19.
Conclusion: The 2025 BraTS challenge sets a benchmark for deep learning segmentation models using the largest expert-annotated glioma dataset. The winning team achieved excellent performance with high L-DSC and L-NSD. The developed models may aid objective tumour assessment thought the patient's entire clinical course.
Limitations: The annotator model does not directly take into account inter-observer variability.

Integrating deep learning–derived imaging signatures and intratumoral heterogeneity metrics for prognostic modeling and biological insights in glioblastoma (6 min)

Endong Zhao; Tianjin / China

Author Block: E. Zhao[1], X. Liu[2], Y. Shi[1], X. Gao[1], X. Zheng[1], C. Yang[3], J. Liu[1]; [1]TianJin/CN, [2]Tianjin/CN, [3]Dalian/CN
Purpose: To develop a deep learning–driven model integrating intratumoral and peritumoral features for survival prediction in glioblastoma. Risk stratification was performed by combining a deep learning score (DL score) with an intratumoral heterogeneity score (ITH score) derived from habitat analysis, and their biological underpinnings were explored.
Methods or Background: We retrospectively included 511 pathologically confirmed glioblastoma patients from three hospitals (n=381, model development) and the TCGA cohort (n=130, biological validation). Tumor, peritumoral 10 mm, 20 mm, and edema regions were segmented on contrast-enhanced T1WI and T2WI. Each region was clustered into three habitats using k-means. Multiscale habitat features were quantified to calculate ITH scores. A 3D ResNet101 with Cox partial likelihood loss (DeepSurv) extracted global features to predict survival probabilities. Model performance was evaluated by concordance index (C-index), and DL scores were derived from prediction probability. Patients were dichotomized into high- and low-risk groups by median cutoff, and Kaplan–Meier survival analysis was performed across all DL and ITH scores. Groups with significant stratification (log-rank p<0.001) underwent biological validation in TCGA, including whole-exome sequencing,copy number alterations, tumor mutation burden, RNA-seq, methylation, and proteomics.
Results or Findings: The combined tumor and 10 mm peritumoral model achieved robust prognostic accuracy (validation C-index=0.75; 1- and 2-year AUCs >0.85). Both intratumoral DL score and intratumoral/peritumoral_10mm ITH scores independently stratified survival (p<0.001). High DL scores were linked to oncogenic pathway activation (MAPK, VEGF, focal adhesion) and elevated tumor–stroma ratio, while high ITH scores reflected immune heterogeneity, low tumor mutation burden, and enriched checkpoint expression. Joint stratification (high DL + high ITH) identified the poorest subgroup.
Conclusion: Integrating global deep learning features with intratumoral and peritumoral heterogeneity provides a novel, biologically interpretable basis for risk stratification in glioblastoma prognosis.
Limitations: Validation is biologically indirect, not direct

Molecular versus Histologic Glioblastoma: Tumor Heterogeneity from Multiparametric Physiologic MRI (6 min)

Minseo Choi; Seoul / Korea, Republic of

Author Block: M. Choi[1], Y. Choi[2], J. Lee[1], M. Kim[1], I. Hwang[1], Y. W. Park[1], J. E. Park[1], S. H. Choi[1], K. Choi[1]; [1]Seoul/KR, [2]Pocheon/KR
Purpose: The 2021 WHO classification redefines Grade 2/3 IDH-wildtype diffuse astrocytic tumors with specific molecular alterations as molecular glioblastoma (mol-GBM), grade 4. Since mol-GBM lacks the histological hallmarks of conventional glioblastoma (hist-GBM), it is hypothesized to exhibit a distinct pattern of tumor heterogeneity. This study aimed to explore how mol-GBM differs from hist-GBM in tumor heterogeneity using multi-parametric physiologic MRI and provide novel radiologic insights into the characteristic features of this newly defined subtype.
Methods or Background: In this multi-institutional retrospective study, imaging data were collected from two tertiary centers: 13 mol-GBMs and 39 hist-GBMs from institution 1 (2007–2024) for development, and 9 mol-GBMs from institution 2 (2020–2024) for external validation. Apparent diffusion coefficient (ADC; cellularity), relative cerebral blood volume (rCBV; vascularity), and volume transfer constant (Ktrans; permeability) were binarized into high/low categories, yielding eight spatial habitat clusters (2×2×2) to visualize tumor heterogeneity. Habitat distributions and histogram features (mean, median, 10th, 90th percentile) were compared between groups. Diagnostic performance was assessed by multivariable logistic regression with ROC analysis.
Results or Findings: The tumor volume of high Ktrans clusters was significantly smaller in mol-GBM than hist-GBM (median; 2.5cm³ vs. 14.6cm³, $p<0.001$), particularly for the most malignant cluster (low ADC, high rCBV, high Ktrans; 0.06cm³ vs. 7.0cm³, $p<0.001$). Mol-GBM showed lower mean and 90th percentile values of rCBV ($p=0.013$) and Ktrans ($p<0.001$), whereas no difference was observed for ADC. Consequently, adding rCBV and Ktrans to ADC significantly improved differentiation, increasing the AUC from 0.70 to 0.89 ($p=0.002$).
Conclusion: Non-invasive characterization of tumor heterogeneity using multi-parametric MRI habitat analysis revealed distinct patterns in mol-GBM versus hist-GBM. The most discriminating parameter was tumor permeability (Ktrans), with mol-GBM showing smaller hyperpermeable habitats. In contrast, cellularity (ADC) was comparable across both subtypes.
Limitations: Not applicable.

CBV- vs PSR- optimized MR-DSC-Perfusion sequences for presurgical diagnosis of brain tumors: from demytification to synergy (6 min)

Clemente García; Murcia / Spain

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: C. García[1], I. MARTINEZ-ZALACAIN[2], P. Naval-Baudin[2], A. Camins Simó[2], A. Jareño Badenos[2], M. Cos Domingo[2], C. Majós[2], A. Pons Escoda[2]; [1]Murcia/ES, [2]Hospitalet de Llobregat/ES
Purpose: To compare the diagnostic performance of CBV- and PSR-optimized sequences in the presurgical differentiation of glioblastoma, brain-metastasis, lymphoma, and meningioma, and to assess the additive value of combining both metrics within and across the sequences.
Methods or Background: Retrospective single-center cohort: glioblastoma (n=121), metastasis (n=63), meningioma (n=55), lymphoma (n=13). Each patient underwent two consecutive DSC-acquisitions within the same MR-session: 1st- non-preloaded, high flip-angle (PSR-optimized); and 2nd- full-dose preloaded (using prior contrast), intermediate flip-angle (CBV-optimized, standardized, consensus-compliant). From enhancing tumor masks (plus edema masks for glioblastoma vs. metastasis), we extracted rCBV (NAWM-normalized, leakage-corrected) and PSR statistics. For each tumor-pair we identified the best single-acquisition metric, and trained bivariate logistic models to combine CBV and PSR both within and across both protocols.
Results or Findings: Single-metric AUCs for the 1st DSC-sequence ranged 0.72 (Gb_vs_Metastasis, nrCBVmin_edema)- 0.91 (Meningioma_vs_Lymphoma, PSRp75), average AUC=0.79. For the 2nd, AUCs ranged 0.72 (Gb_vs_Metastasis, PSRmax_edema)- 0.89 (Meningioma_vs_Lymphoma, nrCBV_p75), average AUC=0.80. Overall, CBV and PSR were the best metrics in 50% of comparisons each. Selecting the best-performing protocol per tumor-pair increased average AUC to 0.82. The bivariate intraprotocol models combining nrCBV+PSR in the 1st DSC AUCs ranged 0.76 (Gb_vs_Metastasis, PSRmean_edema+nrCBVmin_edema)- 0.94 (Meningioma_vs_Lymphoma, PSRp75+nrCBVp75), average AUC=0.85. In the 2nd DSC AUCs ranged 0.76 (Gb_vs_Metastasis, PSRmax_edema+nrCBVmax_edema)- 0.93 (Meningioma_vs_Lymphoma, PSRp75+nrCBVp75), average AUC=0.83 The bivariate cross-protocols models combining nrCBV+PSR AUCs ranged 0.8 (Gb_vs_Metastasis, PSRmin_enhancing_2nd+PSR_mean_edema_1st) to 0.94 (Meningioma_vs_Lymphoma, PSRp75_2nd+nrCBVp75_1st), average AUC=0.87.
Conclusion: Both sequences performed similarly in pairwise tumor classification, with CBV and PSR showing no clear predominance in either acquisition. Within each protocol, models combining CBV and PSR outperformed single-metric approaches, with optimal performance achieved when integrating both protocols. Our findings indicate that implementing the dual-DSC protocol in clinical practice could maximize the accuracy of presurgical diagnosis.
Limitations: Single-centre, retrospective design.

Language lateralization in brain tumor patients estimated by resting-state fMRI vs. task-based fMRI (6 min)

Stefan Suvak; Munich / Germany

Author Block: S. Suvak, B. Papazov, E. Schulz, J. Ricke, F. Ringel, S. Stöcklein, V. Stöcklein; Munich/DE
Purpose: Accurate determination of language lateralization is critical for surgical planning in glioma patients, particularly when tumors involve the dominant hemisphere. Task-based fMRI is currently used but is limited by availability and patient compliance. Resting-state fMRI (rs-fMRI) may provide a feasible alternative for identifying the language-dominant hemisphere.
Methods or Background: 22 glioma patients prospectively underwent structural MRI (3D T1w and FLAIR), task-based fMRI (sentence generation), and rs-fMRI (6 min each). Broca's and Wernicke's areas and tumors were semi-automatically segmented. For task-fMRI, activation volumes were determined, while rs-fMRI assessed volumes of regions functionally connected to bilateral Broca seeds ($r = 0.35$). Language lateralization was quantified using the lateralization index ($LI = [L–R]/[L+R]$), with values near ±1 indicating strong lateralization. Task- vs. rs-fMRI-derived LI were compared using paired t-tests and Pearson correlation.
Results or Findings: 22 patients (56 ± 18 yrs) were analyzed; two were excluded due to motion artifacts. Hemispheric lateralization was concordant between task-based and rs-fMRI in 19 patients (95.0%). Rs-fMRI identified left-hemispheric dominance in 17 (mean $LI = 0.28 \pm 0.17$) and right-hemispheric dominance in 3 ($LI = -0.11 \pm 0.15$), while task-fMRI showed left dominance in 18 ($LI = 0.49 \pm 0.22$) and right dominance in 2 ($LI = -0.42 \pm 0.41$). A strong positive correlation was observed between methods ($r = 0.69$, $p = 0.0007$).
Conclusion: Rs-fMRI identified the language-dominant hemisphere in 95% of glioma patients, showing strong concordance with task-based fMRI. As a non-task-dependent, brief, and automatable technique, rs-fMRI may serve as a standardized alternative for preoperative language mapping, facilitating surgical planning and risk assessment.
Limitations: This is a single-center study and intraoperative mapping will be needed to further confirm language lateralization.

MRI-based deep learning system for noninvasive neuropathological profiling of adult-type diffuse glioma (6 min)

Yangyang Li; Beijing / China

Author Block: Y. Li, X. Hong, J. Li, Z. Zhuo, R. Zhang, C. Ye, Y. Liu; Beijing/CN
Purpose: Preoperative neuropathological evaluation of adult-type diffuse gliomas (ADG) is crucial for guiding diagnosis and treatment. We aimed to develop an MRI-based glioma neuropathology prediction (MRI-GNP) deep learning system and assess the ability of deep learning methods to comprehensively predict neuropathology markers of ADGs.
Methods or Background: We utilized 35,616 MR images of 8,844 patients across 22 datasets, along with 39,642 corresponding neuropathology markers. We evaluated various deep learning architectures, input formats, and training strategies to identify the optimal configuration. Model performance was assessed using accuracy and area under the curve (AUC). We evaluated the model's ability to predict 12 tasks. Furthermore, we evaluated MRI-GNP to improve the diagnostic accuracy of neuroradiologists. Finally, to address the challenge of missing contrast-enhanced T1-weighted imaging (T1CE) sequences, we integrated MRI-GNP with generative models.
Results or Findings: Pretrained vision transformers with a 2.5D input configuration were selected. The model achieved high performance (AUC ≥ 0.8) on several prediction tasks, including WHO grade 4 (AUC = 0.852), Ki-67 expression (AUC = 0.817), IDH mutation (AUC = 0.826), and 1p/19q codeletion (AUC = 0.823) based on test sets, whereas for other tasks, such as WHO grade 2/3/4, +7/-10 alteration, CDKN2A/B homozygous deletion, TERT promoter mutation, and EGFR amplification, the model demonstrated moderate performance (AUC ≥ 0.7). The model's performance was poor for MGMT promoter methylation, TP53 mutation, and ATRX mutation. Furthermore, MRI-GNP was validated to significantly improve diagnostic accuracy of neuroradiologists. Finally, incorporating synthetic images enabled MRI-GNP to maintain comparable performance in the absence of T1CE sequences.
Conclusion: MRI-GNP is a robust and generalizable deep learning system for preoperative neuropathology prediction, which has strong potential to enhance precision diagnostics and support clinical decision-making.
Limitations: No limitations were identified.

Liver and spleen elastography (20 min)
Stéphanie Franchi-Abella; Le Kremlin-Bicêtre / France

1. To learn about the technical specificities of liver and spleen elastography in children.
2. To appreciate their diagnostic performance for liver fibrosis and portal hypertension.
3. To understand their pitfalls and limitations and discuss other possible applications.

Contrast-enhanced voiding urosonography (ceVUS) in children - vesicoureteral reflux evaluation and urethral imaging (20 min)
Magdalena Maria Wozniak; Lublin / Poland

1. To understand the present role of ceVUS in the evaluation of vesicoureteral reflux and urethral imaging.
2. To become familiar with the indications and limitations of the technique.
3. To review the examination technique, image interpretation and diagnostic accuracy of ceVUS.

New perfusion US techniques (20 min)
Paul David Humphries; London / United Kingdom

1. To learn about perfusion ultrasound techniques.
2. To appreciate the challenges in paediatrics.
3. To understand what is possible in practice at present.

Abdominal applications of intravascular contrast-enhanced ultrasound (CEUS) (20 min)
Carmelo Sofia; Messina / Italy

1. To understand the safety profile and pharmacokinetics of intravascular microbubble contrast agents.
2. To learn appropriate indications and scanning techniques for CEUS in paediatric abdominal imaging.
3. To appreciate and correctly interpret enhancement patterns in different abdominal organs and pathological conditions in children, correlating them with other imaging modalities for comprehensive diagnosis.

Panel discussion: What is the future for paediatric US? (7 min)

SF 21b - Impact of AI on the radiologist's role within the multidisciplinary team meeting (MDM)

Categories: Artificial Intelligence, Education, Multidisciplinary, Professional Issues

ETC Level: LEVEL II+III

Date: March 7, 2026 | 16:00 - 17:30 CET

CME Credits: 1.5

This session delves into the transformative influence of AI on the radiologist's role within multidisciplinary team meetings (MDMs), exploring how AI-driven tools are enhancing diagnostic accuracy, streamlining workflows, and reshaping collaborative decision-making processes. Attendees will gain insights into the evolving dynamics between radiologists and AI, including the challenges and opportunities presented by automated image analysis, predictive analytics, and the integration of AI-generated insights into patient management discussions. Through real-world case studies and expert perspectives, the session will highlight how radiologists can leverage AI to become pivotal contributors in MDMs, driving more precise, efficient, and patient-centred care in the era of digital medicine.

SF 21c - Understanding visceral (pseudo-)aneurysms: diagnostic and therapeutic approaches

Categories: Imaging Methods, GI Tract, Interventional Radiology, Vascular, Multidisciplinary

ETC Level: LEVEL III

Date: March 7, 2026 | 16:00 - 17:30 CET

CME Credits: 1.5

Visceral (pseudo-) aneurysms (VPAs) demand prompt diagnosis and treatment as they carry a high risk of rupture. This session's learning objectives would focus on diagnosing VPAs on ultrasound, CT, and MRI, principles of interventional treatment, and interventional techniques, including emerging and innovative percutaneous embolisation methods. A panel and interactive discussion will be an ideal platform for learning from the experts.

BS 22 - Rectal cancer staging made simple: TNM classification for radiologists

Categories: Imaging Methods, Abdominal Viscera
ETC Level: LEVEL I+II
Date: March 8, 2026 | 08:00 - 09:00 CET
CME Credits: 1

Moderator:
Regina G.H. Beets-Tan; Amsterdam / Netherlands

Chairperson's introduction (5 min)
Regina G.H. Beets-Tan; Amsterdam / Netherlands

Concept-based learning: understanding TNM staging (15 min)
Ioana Andreea Gheonea; Craiova / Romania

1. To explain the fundamentals of TNM staging.
2. To show how TNM staging impacts surgical planning, neoadjuvant therapy, and prognosis.
3. To discuss the structured templates and AI in TNM staging.

Interactive case-based learning: applying TNM to real cases (20 min)
Ferdinand Bauer; Kaufbeuren / Germany

1. To present anonymised MRI/CT images of rectal cancer cases.
2. To discuss common pitfalls, such as over-/under-staging, and unclear mesorectal involvement.
3. To compare junior radiologists' assessments vs expert reports for self-evaluation.

Gamification: TNM quiz and rapid image review challenge (20 min)
Lucian Mihai Florescu; Craiova / Romania

1. To present 10 rectal MRI images in quick succession and ask participants to classify them within 10 seconds each (TNM Staging Rapid Fire).
2. To show intentionally misclassified TNM reports and ask participants to spot the errors (Staging Error Hunt).
3. To present learning ideas.

RC 2210 - Fat-water and Dixon imaging in musculoskeletal MRI

Categories: Musculoskeletal, Imaging Methods, Physics in Medical Imaging
ETC Level: LEVEL III
Date: March 8, 2026 | 08:00 - 09:00 CET

Ultrasound-guided vacuum-assisted excision: a minimally invasive solution for managing imaging-histological discordant breast lesions after core needle biopsy (6 min)
Elisa D'Ascoli; Rome / Italy

Author Block: E. D'Ascoli, C. Depretto, G. Rossini, G. Irmici, C. De Berardinis, G. Della Pepa, A. Bonanomi, L. Corradini, G. P. Scaperrotta; Milan/IT
Purpose: To evaluate the role of US-guided Vacuum-assisted excision (VAE) in the management of imaging-histological discordant lesions after core needle biopsy (CNB), avoiding unnecessary surgical excision.
Methods or Background: We retrospectively evaluated all patients who underwent US-guided VAE with a 9 G needle at our Institution between January 2015 and August 2023 for imaging-histological discordant lesions after CNB with a 14 G needle. We determined the upgrade rate to malignancy (UR) after VAE and delayed false-negative results after surgery or follow-up. We also assessed the diagnostic performance of the procedure, technical efficacy (TE), technical success (TS), the occurrence of complications and the correlation between upgrade to malignancy and lesion size, BI-RADS category, morphological characteristics, presence of calcifications and history of breast cancer (χ^2 and Mann-Whitney tests).
Results or Findings: We collected data from 334 patients. After VAE, 65.3% (N=218) of the excised lesions were classified as benign, 25% (N=85) were B3 lesions and 9.3% (N=31) were malignant (B5). The upgrade rate to malignancy after VAE was 9.3%. The delayed false negative results were 1.3%. Accuracy was 98.2%, SE was 88.6%, SP was 100%, PPV was 100% and NPV was 97.9%. TE of the procedure was 84.4%; TS was 100%. No major complications were observed. BIRADS category, morphology, margins, and orientation of the lesion were significantly associated with upgrade to malignancy ($p<0.001$).
Conclusion: VAE reduces the risk of underestimation of malignancy in cases of imaging-histological discordance, thus avoiding the need for surgery and reducing patients' stress, overtreatment, complications and costs, without compromising the quality of patient care.
Limitations: Retrospective monocentric study with a limited number of patients.

MINIVAB as a treatment method for small invasive breast cancers – initial results (6 min)
Wendelien Sanderink; Nijmegen / Netherlands

Author Block: W. Sanderink[1], C. Meeuwis[2], S. De Waard[3], A. Zouzos[3], E. E. J. M. Wolters-Van Der Ben[4], F. Van Vliet - Moret[4], R. F. Lim[5], J. Camps Herrero[6], R. Mann[1]; [1]Nijmegen/NL, [2]Arnhem/NL, [3]Stockholm/SE, [4]Nieuwegein/NL, [5]Bergen Op Zoom/NL, [6]Alzira/ES
Purpose: To assess feasibility of complete removal of small breast cancers using Vacuum Assisted Biopsy (VAB) as a therapeutic procedure under ultrasound (US) guidance.
Methods or Background: From August 2021 to May 2025, 35 patients with invasive carcinomas diagnosed by core needle biopsy (CNB), measuring ≤15 mm on US and MRI were enrolled in this international, multicenter, prospective study. One patient withdrew after VAB and was excluded from analysis. All lesions were excised under local anesthesia using a 7G VAB system under US guidance. Three weeks later, breast-conserving surgery excised the VAE cavity. Histopathological findings from VAB were compared with subsequent surgical specimens, and the rate of complete or marginally involved tumor excision by VAB was assessed.
Results or Findings: 34 patients completed the study (mean age, 63.3 years; 13 Netherlands, 20 Spain, 1 Sweden). The mean MRI lesion size was 10.1 mm (range 4-13.7 mm). VAB histopathology identified 33 invasive carcinomas of no special type and 1 with medullary features. Complete excision by VAB was achieved in 12 of 34 patients (35.3%). An additional 6 patients had marginally involved tumor excisions, meeting Dutch guidelines for successful removal (18/34, 52.9%). 13 patients (38.2%) showed more than focal margin involvement (mean residual tumor size, 9.4 mm; range, 5-13 mm). In 3 patients, residual tumor was present in the surgical specimen, though margin involvement >4 mm was unclear.
Conclusion: US-guided VAB achieved complete or marginally adequate excision in a subset of small breast cancers. Residual tumor in several cases indicates that careful patient selection is essential before considering VAB as a standalone treatment.
Limitations: The small sample size and the need for further analysis of patient and procedural variables limit the ability to identify factors that may predict successful VAB excision.
Funding for this study: The study was an investigator initiated study sponsored by an unrestricted grant from BD.

Non-surgical treatment of breast cancer: A comparison of outcomes between cryoablation with hormonal therapy versus cryoablation alone and hormonal therapy alone in patients not eligible for surgery (6 min)

Federica Di Naro; Florence / Italy

Author Block: F. Di Naro, S. E. Baldi Giorgi, F. Pugliese, D. De Benedetto, G. Migliaro, S. Vidali, C. Bellini, T. Amadori, J. Nori; Florence/IT
Purpose: To evaluate the most effective non-surgical treatment for breast cancer in surgery-ineligible patients, comparing ultrasound-guided Cryoablation combined with hormonal therapy (HT) versus Cryoablation and hormonal therapy alone.
Methods or Background: 111 patients (mean age 81.2 years) not-suitable for surgery due to comorbidities or advanced age was enrolled, total of 125 biopsy-confirmed breast cancers. All the lesions were invasive ductal carcinomas (mean size 17.7 mm), hormone-positive and HER2-negative, with no ultrasound-visible lymph-node involvement. Of these, 41 treated with Cryoablation and HT, 36 with Cryoablation and 36 with HT . Locoregional staging was performed with contrast-enhanced-mammography (CEM), followed by CEM and ultrasound follow-up at 12 months post-treatment. Only patients completing follow-up were included. Lesion size was compared at baseline and 12 months after-treatment.
Results or Findings: Of the 125 lesions, 98 completed the 12-months follow-up; 39 in the Cryoablation+HT group, 23 in the Cryoablation-only group, and 36 in the HT-only group. Tumor size reduction was significantly different between the groups (P=0.0005), with greatest reduction in the Cryoablation-with-HT group (83.3%, mean reduction 13.6 mm), followed by Cryoablation-only (61.7%, mean reduction 8.2 mm), and HT-only (42.1%, mean reduction 7.4 mm).Tumors with no CEM-enhancement, suggesting no residual-disease, were most frequent in the Cryoablation-with-HT group (69.2%), followed by Cryoablation-only (60.9%),and HT-only (36.1%). Tumors with complete remission (CR, RECIST 1.1) were similar between the Cryoablation-with-HT and Cryoablation-only groups (74.4% and 78.3%, respectively), followed by the HT-only (36.1%). Pairwise comparisons revealed significant differences between Cryoablation-with- HT and HT-only groups for CEM-enhancement, size reduction, and CR, expressing the added value of Cryoablation (p=0.0041, P<0.0001 and P<0.0001,respectively).
Conclusion: Cryoablation with hormonal-therapy significantly reduces tumor size and residual disease more effectively than therapy alone, making it a promising option for patients not-eligible for surgery.
Limitations: Single-center-retrospective
No-long-term follow-up
Small-cohort

Infection Rate Following Percutaneous Biopsy: A Multicentric Prospective Study (6 min)

Marcella Pasculli; Rome / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: M. Pasculli[1], E. Giannotti[2]; [1]Rome/IT, [2]Cambridge/UK
Purpose: Our primary aim was to compare infection rates between sterile and aseptic technique.
Secondary aims included identifying possible predictors of infection—such as hematoma, diabetes, or immunosuppression—and explore options to reduce environmental impact.
Methods or Background: This prospective multicenter study included 15 centers: 6 using sterile technique (sterile gloves, gel, probe cover, gauze) and 9 using aseptic technique (clean but not fully sterile). Consecutive patients undergoing percutaneous breast biopsy were enrolled over two months (≥50 per center). At 1-month follow-up, patients completed a questionnaire on biopsy type, infection (medical assistance, antibiotics), pain, hematoma, comorbidities, and lesion characteristics. Infection rates were compared between sterile vs aseptic groups and CNB vs VAB using Fisher's exact test, with risk ratios and Wilson 95% CIs. Due to rare events, Firth's penalized logistic regression was applied. Infections were defined as cases requiring antibiotics post-biopsy.
Results or Findings: We analyzed 1,560 biopsies (CNB 1,249; VAB 311), of which 531 were performed under sterile and 1,029 under aseptic conditions. Overall, 9 infections (0.58%) occurred. Infection rates were 0.94% (5/531) in the sterile group and 0.39% (4/1,029) in the aseptic group (risk ratio 2.42, 95% CI 0.65–8.98; p=0.18). No significant differences were observed. Hematoma occurred in 6.4% of CNB and 15.4% of VAB. No infections occurred among patients with diabetes (n=45) or under immunosuppressive therapy (n=18).
Conclusion: Infections after breast biopsy were extremely rare, occurring in less than 1% of procedures. We found no difference between sterile and aseptic technique, or between core biopsy and vacuum-assisted biopsy. The aseptic approach is safe, faster, cheaper, and environmentally friendly. Overall, our results support best practice guidelines that integrate patient safety with sustainability.
Limitations: The low number of infections limited statistical power and led to imprecise estimates in stratified analyses.

Feasibility of Prone Spectral CT in Women with locoregionally advanced breast cancer and Dense Breasts (6 min)

Robin Duteweert; Arnhem / Netherlands

Author Block: R. Duteweert[1], M. Schyns[1], L. Deden[1], C. Meeuwis[1], M. Dorrius[2]; [1]Arnhem/NL, [2]Groningen/NL
Purpose: In women with breast cancer and dense breasts, additional contrast-enhanced imaging modalities are needed to determine the extent of the disease. This study aimed to evaluate the feasibility of spectral CT for breast cancer detection in these women, compared to MRI , using quantitative spectral analysis and qualitative image assessment.
Methods or Background: This single-centre feasibility study prospectively included 12 patients with locoregionally advanced breast cancer and dense breasts (ACR 3–4) between February 2023 and May 2025. All patients underwent breast MRI and 18F-FDG PET/CT as part of routine staging, followed by an additional prone spectral CT on a dual-layer spectral CT scanner. Quantitative analyses included spectral slope (λHU, defined as the attenuation slope between 40 and 70 keV) and iodine concentration in 21 histopathologically confirmed breast lesions (20 malignant and 1 benign), fibroglandular tissue, and pectoral muscle. Three radiologists independently conducted the qualitative image assessment, which comprised evaluation of background enhancement and lesion detection, with outcomes compared to MRI.
Results or Findings: Spectral CT allowed quantitative identification of breast cancer in all patients. Lesions showed a mean λHU of 2.8±1.2, compared to −0.4±0.4 in fibroglandular tissue and 0.7±0.7 in pectoral muscle. Mean iodine concentration was 1.4±0.6mg/mL in lesions, higher than in pectoral muscle (0.4±0.3mg/mL) and fibroglandular tissue (0.0±0.1mg/mL). Background enhancement was scored lower on spectral CT than on MRI across all patients (p=0.07). For lesion detection, spectral CT yielded 56 true positives, 7 false negatives, and 3 false positives, distributed across readers, compared with 55, 8, and 0 on MRI, respectively.
Conclusion: Spectral CT is feasible for breast cancer detection in women with dense breasts, providing quantitative lesion characterization and reader performance comparable to MRI.
Limitations: No pathological proof for all reader-marked lesions, therefore excluded from analysis.

Detectability of breast lesions on conventional and photon-counting computed tomography: an anthropomorphic phantom study (6 min)

Shivaira Joomun; Groningen / Netherlands

Author Block: S. Joomun[1], M. Nicoara[1], L. J. Oostveen[2], I. Sechopoulos[2], G. De Bock[1], M. Greuter[1], M. Dorrius[1]; [1]Groningen/NL, [2]Nijmegen/NL
Purpose: To evaluate influence of dose, reconstruction kernel, matrix size, and virtual monoenergetic imaging (VMI) level on breast lesion detectability on conventional energy integrated (EID) computed tomography (CT) and photon-counting detector (PCD) CT.
Methods or Background: A semi-anthropomorphic breast phantom containing hyperdense masses, calcification clusters, and fibers of different diameters was attached to an anthropomorphic thorax phantom and positioned on a dedicated breast support cushion. Scans were performed in the prone position, with the breast hanging freely, on EID-CT (Somatom Force, Siemens) and PCD-CT (Naeotom Alpha, Siemens). Dose (CTDIvol) and reconstruction kernel were varied on both systems, while matrix size and VMI level were varied on the PCD-CT system. Qualitative analysis was assessed by lesion visibility using a 5-point Likert scale.
Results or Findings: 0.40mm calcification cluster was visible on both systems above 21mGy, whereas 0.29mm cluster was only visible on PCD-CT above 29mGy. 1.80mm mass was not detected on EID-CT but was visible on PCD-CT above 29mGy. On EID-CT, 3.18, 4.76, and 6.32mm masses were visible above 7.4, 1.8, and 0.9mGy, respectively, while on PCD-CT, the 3.18mm mass was detectable above 3.7mGy and the 4.76 and 6.32mm masses above 0.9mGy. Fibers of 0.41 and 0.60mm were visible on EID-CT above 7.4 and 1.8mGy, whereas on PCD-CT, fibers of 0.23, 0.41, and 0.60mm were detected above 29, 7.4, and 0.9mGy, respectively. Optimal visibility was achieved at VMI 70 keV. Sharper kernel enhanced visibility of smaller structures. Use of 1024 matrix on PCD-CT improved detection of smaller structures.
Conclusion: PCD-CT demonstrated higher detectability of breast lesions compared with EID-CT, particularly for small structures.
Limitations: The breast phantom used in this study only contained adipose tissue and no glandular tissue.
Funding for this study: Funding was received from KWF PPS and Siemens Healthineers

Response assessment with 18F-FDG PET/CT after neoadjuvant chemotherapy in breast cancer patients – A review and meta-analysis enclosing axillary, internal mammary, and periclavicular lymph nodes (6 min)

Thiemo Van Nijnatten; Maastricht / Netherlands

Author Block: F. V. Amstel[1], M. Lenaerts[1], F. M. Mottaghy[1], J. Simons[2], M. Smidt[1], T. Van Nijnatten[1]; [1]Maastricht/NL, [2]Rotterdam/NL
Purpose: The diagnostic accuracy and prognostic relevance of 18F-FDG PET/CT for regional nodal response assessment after neoadjuvant chemo-immunotherapy (NAC) in clinically node-positive (cN+) breast cancer remains unclear. Therefore, this review and meta-analysis aims to determine the diagnostic performance of post-NAC 18F-FDG PET/CT for axillary lymph node (ALN) response assessment and to evaluate the prognostic value of post-NAC 18F-FDG PET/CT for internal mammary lymph node (IMLN), and periclavicular lymph node response assessment.
Methods or Background: PubMed, Embase, Cochrane, and Web of Science were searched for studies using post-NAC 18F-FDG PET/CT for nodal response assessment in cN+ patients treated with NAC, up to 17/02/2025. Pooled sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were calculated. For ALNs, surgical pathology served as reference standard. For IMLNs and periclavicular lymph nodes, locoregional or distant recurrence was used as surrogate reference standard.
Results or Findings: Eight studies (574 patients) were included: six (558 patients) on ALNs, two (16 patients) on IMLNs, and one (1 patient) on periclavicular lymph nodes. Regarding ALNs, the overall axillary pathologic complete response rate was 45.2%. The pooled sensitivity, specificity, PPV, and NPV were 52% (95% CI:0.24-0.79), 83% (95% CI:0.72-0.91), 78% (95% CI:0.62-0.89), and 59% (95% CI:0.30-0.82). Regarding IMLNs, the pooled sensitivity, specificity, PPV, and NPV were 40% (95% CI:0.05-0.85), 100% (95% CI:0.72-1.00), 100% (95% CI:0.16-1.00), and 78.6% (95% CI:0.49-0.95). Regarding periclavicular lymph nodes, findings were limited to only one patient.
Conclusion: The diagnostic performance of post-NAC 18F-FDG PET/CT to accurately identify ALN response is limited. Regarding post-NAC 18F-FDG PET/CT in assessing IMLN and periclavicular lymph node response, additional evidence is needed to determine prognostic relevance.
Limitations: For periclavicular lymph nodes, data pooling was not possible given low number of included studies

Utility of the RCR CT Staging Guidelines for Breast Cancer: A Retrospective Observational Study (6 min)

Maiar Elghobashy; Stevenage / United Kingdom

Author Block: M. Elghobashy, P. Fletcher, I. Masroor, F. Peters, S-W. Tan; Stevenage/UK
Purpose: This study aims to demonstrate a centre's experience of the utility of the RCR guidelines for CT staging in breast cancer.
Methods or Background: In the United Kingdom, around 57,000 new cases of breast cancer are diagnosed annually [1]. Early identification of metastatic disease is crucial for improving survival and morbidity. The Royal College of Radiologists (RCR) recommends use of whole-body CT staging for distant metastatic disease in those presenting with T3/T4 cancer, those with 4 or more abnormal lymph nodes at axillary ultrasound and those with symptoms that raise suspicion of metastasis [2].

Despite clear guidelines, patients often undergo CT imaging without fulfilling the aforementioned criteria, thus leading to increased and potentially unnecessary radiation exposure. This study explores the utility of the RCR guidelines in stratifying patients with and without metastasis.
Results or Findings: A retrospective observational study was undertaken with data extracted from a 5-year period. 526 patients were identified who had a breast cancer staging CT. 214 of these studies were excluded from analysis as they represented patients with disease recurrence, known metastatic disease or treatment surveillance. Of the remaining 312 studies, the requests of 187 (60%) did not meet the RCR guidelines. Of these patients, 107 (57%) had no significant findings, 51 (27.3%) had incidental findings requiring further investigations, 25 (13%) had indeterminate findings of possible metastasis (of which only 3 were later proven to be metastasis) and 4 (2%) had CT proven metastasis.
Conclusion: Identifying metastatic disease is key in the management of breast cancer, however, the overuse of CT generates further investigations, and may subject patients to radiation without benefit. The RCR guidelines appear useful in identifying patients who are most likely to benefit from whole body staging CT.
Limitations: N/A

Total-body staging and surgical planning in breast cancer with photon-counting CT (6 min)

Fatemeh Darvizeh; Milan / Italy

Author Block: F. Darvizeh, D. M. G. Bossi, M. Gerli, M. Alì, I. Castiglioni, D. Fazzini; Milan/IT
Purpose: To assess photon counting detector computed tomography (PCD-CT) as a single-session modality for locoregional and systemic total-body staging in breast cancer, aiming to reduce reliance on MRI, lower contrast and radiation dose, and improve patient experience and surgical planning.
Methods or Background: A PCD-CT protocol was developed including virtual non-contrast, arterial (upper abdomen), portal (thorax/abdomen), and delayed phases (abdomen/brain) with spectral reconstruction. Contrast (Iomeron 400 mg/mL) was given at 0.7 mL/kg via the arm contralateral to the tumour. Seventeen consecutive women (mean age 51; range 30–78) with biopsy-proven breast cancer scheduled for neoadjuvant chemotherapy or mastectomy were retrospectively compared with MRI. In mixed benign/malignant cases, an extra thoracic arterial phase was added. Two radiologists independently reviewed tumour, lymph nodes, and extramammary findings.
Results or Findings: PCD-CT enabled accurate detection of the primary tumour and lymphadenopathy, with diagnostic efficacy comparable to MRI. In all cases, findings matched MRI for tumour detection, size, multifocality, lymph node status, and pectoralis muscle involvement. Microcalcifications were seen only on PCD-CT, reflecting superior spatial resolution. Among 17 patients, PCD-CT revealed axillary adenopathy (n=12), internal mammary adenopathy (n=3), pectoralis fascia invasion (n=1), brain metastasis (n=1), and suspicious liver lesions (n=1). Compared with MRI+CT, PCD-CT was faster (10 vs 30 min), required a single contrast injection, and delivered ~35 mSv, ~60% lower than 64-slice CT. Supine positioning was judged more surgically favourable than prone MRI.
Conclusion: PCD-CT provides efficient, accurate locoregional and systemic staging in a single session, reducing contrast, radiation, time, and cost compared with MRI+CT.
Limitations: Small, single-centre cohort.

Pulmonary nodule risk stratification in robotic-assisted bronchoscopy referrals: Can biopsy be avoided? (6 min)
Jonas Kroschke; Zurich / Switzerland

Author Block: J. Kroschke[1], B. J. Kerber[1], J. Happe[1], C. Steinack[2], P. Baumgartner[2], R. Engeli[2], S. Ulrich[2], T. Frauenfelder[1], T. Gaisl[2]; [1]Zürich/CH, [2]Zurich/CH
Purpose: Malignancy risk stratification of pulmonary nodules remains a major challenge in lung cancer screening and incidentally detected nodules. Patients referred for robotic-assisted bronchoscopy with integrated cone-beam CT (RAB+CBCT) at a tertiary hospital represent a distinct, high-risk cohort and it is unclear whether existing stratification tools could reduce biopsy needs. This study evaluated the performance of statistical and deep-learning risk models in this setting.
Methods or Background: We retrospectively analyzed 130 patients (54.5% male, mean age 68.1±9.6 years) with 176 nodules who underwent RAB+CBCT biopsy for suspected lung cancer. Biopsied nodules were visually matched to pre-procedural CT scans using bronchoscopy reports and intraprocedural CBCT. Clinical data were extracted from medical records. Automated segmentation was performed, and a deep learning algorithm (malignancy similarity index, mSI; RevealDx) was applied to CT-based thumbnails including perifocal parenchyma. Brock and Mayo risk scores were calculated.
Results or Findings: Histopathology confirmed lung cancer in 68.8% of nodules. Nodule characteristics were 53.4% solid (62.8% malignant), 21.0% part-solid (56.8% malignant), and 25.6% ground-glass (91.1% malignant). Median nodule size was 12.00mm (IQR 9.00-16.12mm) and volume 670.00mm³ (IQR 290.50-1710.75 mm³). Most nodules (62.5%) were located in upper lobes, without consistent differences in malignancy rate across lobes (e.g. right upper 64.9% vs. right lower 71.4%). ROC analysis demonstrated limited discrimination with Brock (AUC=0.62), Mayo (AUC 0.63), and mSI (AUC=0.50). In patients with prior scans, volumetric growth achieved higher accuracy (AUC=0.75).
Conclusion: Our RAB+CBCT cohort shows a distinct risk profile, especially unexpectedly high malignancy rates in ground-glass nodules. Existing risk models, including deep learning, underperform in this population, making biopsy currently unavoidable. Future research should target tailored stratification models to improve decision-making in high-risk cohorts.
Limitations: Single-center, single-vendor. Limited patient numbers. Selection bias. AI-model not trained for this application.
Funding for this study: No external funding was provided for this study.

Evaluation of pneumothorax predictionability by deep learning method before transtoracic fine needle aspiration biopsy (ttiiab) in lung masses (6 min)
Nilufar Gasimli; Istanbul / Turkey

Author Block: N. Gasimli, V. Mammadlı, H. Ayyildiz, S. M. Ertürk, R. MAMMADZADA; Istanbul/TR
Purpose: Our aim in this study is to evaluate the predictability of pneumothorax, the most common complication of PTB, before TTNAB with deep learning algorithms, and to plan patient management.
Methods or Background: A total of 403 PTB procedures performed under CT guidance in our institution were included in our retrospective study. In our hospital system, images of patients who underwent TTIAB between 2018 and 2023 were downloaded and the data was processed with deep learning algorithms in anonymized form. Control CT images of the patients taken during the PTB planning phase before biopsy and after PTB were used. In our study, a deep learning model was created using the VGG-19 algorithm to classify DICOM images.
Results or Findings: Pneumothorax did not develop in 271 (67%) of the patients who underwent the procedure, while pneumothorax development was observed in 132 cases (33%). 76 of these 132 cases (58%) did not require hospitalization, but 54 cases (42%) required hospitalization. According to the results obtained as a result of the analysis process in our study, the VGG-19 model has 68.7% accuracy and 0.68 AUC values. However, the sensitivity value calculated as 52% as a result of the analysis shows that approximately half of the positive cases are predicted correctly. As a result of the application of the model, 73% of negative cases were classified correctly. This can be attributed to the fact that the chosen method has more effective success on negative cases.
Conclusion: These values, which express the general accuracy rate of the model, show that the selected method has an acceptable success in predicting the risk of pneumothorax.
Limitations: Our study is single-center and one of the limitations is that our sample is not larger.
Funding for this study: None.

Comparison of Fish-hook and Spiral Shaped Wires in CT-guided Pulmonary Nodule Localization: Impact on Complications and Clinical Outcomes (6 min)

Xiaowen Zhang; Groningen / Netherlands

Author Block: X. ZHANG, S. Thom R.G., G. J. De Jonge, M. Van Tuinen, W. Caroline van de, E. Michiel, W. F. A. Den Dunnen, G. De Bock, M. Dorrius; Groningen/NL
Purpose: In December 2020, our center transitioned from using a wire with a fish-hook shape to a wire with a spiral shape for CT-guided pulmonary nodule localization. This study compared the effectiveness and safety of both techniques.
Methods or Background: We retrospectively reviewed 157 consecutive patients who underwent CT-guided wire localization between November 2017 and December 2024 in University Medical Center Groningen (UMCG), Netherlands. Patient demographics, lesion characteristics, procedural and surgical details, and pathological findings were collected. Procedure-related complications were classified as minor (pneumothorax or hemoptysis without clinical consequences) or major (events requiring intervention, including air embolism). Logistic regression was performed to identify factors associated with localization success and procedure-related events.
Results or Findings: Fish-hook shaped wires were used in 79 patients and spiral shaped wires in 78 patients. Technical success was similar between groups (94.9% vs. 96.2%). Minor complications occurred more frequently with fish-hook shape wires (34.2% vs. 21.8%), while major complications were rare and comparable. Pneumothorax rates (minor and major combined) were 31.6% for fish-hook shape wire and 20.5% for spiral shape wires. Pathological representativeness did not differ significantly. In multivariable regression, longer procedure duration and fish-hook shape wire use were independently associated with an increased risk of minor complications.
Conclusion: Both wire types demonstrated high and comparable effectiveness and safety for CT-guided pulmonary nodule localization. However, spiral-shaped wires are associated with fewer minor complications, supporting their preferential use in clinical practice.
Limitations: This is a single-center study with a relatively small sample size, which may limit the generalizability of our findings. In addition, pain scores are not collected, precluding evaluation of this potentially relevant outcome.
Funding for this study: This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

AI Scoring on Chest Radiographs to Guide Biopsy Decisions in Suspected Lung Cancer: Evidence from a Biopsy-Proven Cohort (6 min)

Alper Selver; Izmir / Turkey

Author Block: E. G. KAHRAMAN, Y. VAROL, A. Selver, O. Ozdemir, E. Hasbay, Y. EROL; Izmir/TR
Purpose: To develop and evaluate a novel biopsy-indication scoring system based on TorchXRayVision (TxRV), an open-source deep learning model trained on large chest radiograph datasets, aiming to support clinical decision-making in differentiating malignant from benign lung lesions.
Methods or Background: Chest radiographs of 300 patients were screened; 285 (206 malignant, 79 benign) were eligible after excluding anterior–posterior views and indeterminate pathology. TxRV outputs for 18 radiological findings were extracted. For biopsy indication, six core features (effusion, pneumonia, nodule, mass, lung lesion, opacity) were used to generate three handcrafted scores (simple sum, weighted, maximum). For malignancy prediction, extended 18-feature models were tested: simple sum, weighted sum, logistic regression, and random forest. Statistical analyses included Mann–Whitney U tests, ROC/AUC, confusion matrices, and feature importance mapping.
Results or Findings: Nodule, mass, and lung lesion scores were significantly higher in malignant cases ($p < 0.01$), while opacity showed borderline association ($p = 0.06$). Weighted biopsy scoring yielded the highest discriminatory capacity, with a malignancy prevalence of ~80% above the 75th percentile cut-off. Logistic regression improved interpretability, achieving AUC 0.71 with balanced sensitivity/specificity. Random forest demonstrated superior performance (AUC 0.94, accuracy 90%), but feature importance confirmed that classic oncologic signs (mass, nodule, lesion) remained the strongest predictors. Precision–recall analysis supported these findings, with Random Forest showing F1 = 0.92, PPV 0.94, and NPV 0.85, underscoring robust diagnostic value.
Conclusion: TxRV-derived scoring provides an interpretable, reproducible framework to guide biopsy indication and malignancy risk stratification. Weighted scoring improved diagnostic balance, and logistic regression offered stable performance suitable for clinical translation. Such modeling may help reduce unnecessary lung biopsies.
Limitations: This was a single-center retrospective study with modest sample size. Random forest results suggest possible overfitting, highlighting the need for external validation in larger, multi-center cohorts.

Diagnostic yield, accuracy, and complications following CT guided anterior mediastinal biopsy: a single centre 10-year review (6 min)

Rakesh Ahmed; Dublin / Ireland

Author Block: R. Ahmed, P. Beddy, J. Kavanagh, D. Murphy, V. Young, S. Nicholson, J. F. Meaney; Dublin/IE
Purpose: Anterior mediastinal masses are uncommon, with an estimated prevalence of 0.4-0.9%. Computed tomography (CT) guided core needle biopsy (CNB) facilitates a histological diagnosis and appropriate management. The mediastinum contains several vital structures which must be considered when deciding a trajectory for biopsy. The aim of this study is to review technique, yield, and complications to describe a safe and effective method for biopsy.
Methods or Background: All CT-guided CNB for anterior mediastinal masses (2015 -2025) at a single centre were included. All images were reviewed by two experienced radiologists. Univariable comparisons between the diagnostic yield and non-diagnostic yield groups were performed.
Results or Findings: 52 patients were evaluated. 37 (71.15%) were diagnostic and 15 were (28.85%) non-diagnostic. Of the diagnostic samples, 16 (43.24%) were thymic, 14 (37.85%) lymphomas, and 7 (18.92%) other diagnoses. Minor complications included 6 (11.54%) pneumothoraxes, 6 (11.54%) haematomas, 5 (9.62%) pneumomediastinum, 3 (5.77%) pleural effusions, 2 (3.85%) haemothoraxes, and 1 pulmonary haemorrhage (1.92%). Major complications include 1 (1.92%) haemopericardium requiring pericardiocentesis and 1 (1.92%) fatal pulmonary artery puncture. On univariable analysis, a larger anteroposterior dimension ($p < 0.017$), larger mediolateral dimension ($p < 0.041$), and a greater number of biopsy samples taken ($p < 0.002$) were associated with a lower risk of non-diagnostic yield.
Conclusion: CNB is effective for confirming the nature of anterior mediastinal masses, but complications can arise, particularly from inadvertent puncture of the many vascular structures within this area. To our knowledge, this is the first reported case of a biopsy related fatality. We highlight a method to avoid vascular puncture to ensure safe outcome.
Limitations: Retrospective cohort study.
Small sample size.
Funding for this study: No funding support was available for this study.

CT-guided chest biopsies: impact of operator experience on diagnostic yield and complication rate (6 min)

Helí De Jesús Rueda-Chaparro; Bogotá / Colombia

Author Block: H. D. J. Rueda-Chaparro[1], A. Al Mutairi[2], F. Cadour[3], S. Kandel[3], P. Rogalla[3]; [1]Bogotá/CO, [2]Riad/SA, [3]Toronto, ON/CA
Purpose: To assess the effect of operator experience on diagnostic yield and complication rates in computed tomography (CT)-guided percutaneous chest biopsies.
Methods or Background: This retrospective single-center cohort study included 1,453 consecutive adult patients who underwent CT-guided chest biopsy between July 2022 and June 2024. Exclusion criteria were incomplete clinical/procedural data, ultrasound-guided biopsies, and operators with less than 20 procedures performed during the study period. Eight operators were stratified into three groups based on procedural volume: Group A (<100/year, n=3), Group B (100–200/year, n=3), and Group C (>200/year, n=2). Outcomes included diagnostic yield, complication rates, and predictors of both, assessed using univariable and multivariable logistic regression.
Results or Findings: Adequate tissue for definitive histopathology was obtained in 1,392 cases (96%). Diagnostic yield differed across operator groups: 93% in Group A, 94% in Group B, and 98% in Group C (P=.002). Group C remained independently associated with higher diagnostic yield (OR 2.69; 95%CI 1.26–5.73; P=.011). Complications occurred in 27% of patients, including pneumothorax (20%), chest tube insertion (2%) and other events (5%). Complication rates were highest in Group A (16%) and lowest in Group B (9%), yet operator experience was not independently associated with complications. Independent predictors of higher complication risk included smaller lesion size (OR 0.98 per mm, 95%CI 0.97–0.99; P=.005), use of sedation (OR 1.55; 95%CI 1.09–2.21; P=.016), and lesion location in the right upper lobe (OR 1.73; 95%CI 1.03–2.91; P=.038).
Conclusion: Operator experience was independently associated with higher diagnostic yield in CT-guided chest biopsies, with the most experienced operators achieving superior diagnostic performance. Complication risk related chiefly to lesion size, sedation, and anatomical location.
Limitations: Limitations include the retrospective single-center design, reliance on a two-year procedural volume, and possible dilution of operator-specific effects due to trainee supervision.

Safety of Ultrasound-Guided Pleural Drain Placement in Patients on Dual Antiplatelet Therapy: A Single-Centre Audit (6 min)

Danial Saeed; Durham / United Kingdom

Author Block: D. Saeed[1], N. D. Adroja[1], E. Obasi[1], C. Ridge[2]; [1]London/UK, [2]London/IE
Purpose: Pleural drain insertion is frequently required in patients on dual antiplatelet therapy (DAPT) at our tertiary cardiothoracic centre. Departmental policy advises withholding P2Y12 inhibitors for seven days prior to drain placement, however this is often impractical in urgent settings. Evidence on bleeding risk in this group is limited. This audit evaluated complication rates in DAPT patients undergoing ultrasound (US)-guided pleural drain placement.
Methods or Background: A retrospective review was conducted of all US thorax and interventional radiology guided US drainage procedures from April 2024 to April 2025. Inclusion criteria were documented DAPT use at the time of procedure. Data collected included demographics, antiplatelet regimen, drug-hold duration, procedural details, operator grade, laboratory results, and complications.
Results or Findings: Of 368 drain requests, 33 (9%) were in patients on DAPT (median age 73 years; range 42-81; 64% male). Most received aspirin + clopidogrel (94%), with 70% continuing DAPT without interruption. Drains were predominantly 8 Fr (88%), left-sided (73%), and inserted in the radiology department (73%); 27% were performed in ICU. Operators included consultants (24%), fellows (21%), and registrars (55%). Mean interval from request to insertion was 0.6 days. No major or minor bleeding complications occurred. Two patients received transfusions for unrelated reasons. Referral documentation omitted complete antiplatelet / anticoagulant details in 68% of cases.
Conclusion: In this audit, US-guided small-bore pleural drain placement in patients on uninterrupted DAPT was not associated with bleeding complications, supporting British Society of Interventional Radiology guidance that classifies the procedure as low risk. The findings question the necessity of a seven-day P2Y12 inhibitor hold and highlight the need for improved documentation on referral requests.
Limitations: Small sample size, retrospective design, incomplete documentation, single-centre setting, and lack of long-term follow-up limit generalisability.

Imaging predictors of diagnostic success in Navigational Bronchoscopy (6 min)

Vaishnavi Gnanananthan; Winchester / United Kingdom

Author Block: V. Gnanananthan, M. Morgan, S. Lam, H. Kolajian, A. El-Zeki, A. Metwalli, C. Peebles, A. Alzetani, L. Veres; Southampton/UK
Purpose: Navigational bronchoscopy (NB) is a recognized and increasingly available technique for tissue diagnosis of central pulmonary lesions unamenable to percutaneous CT guided approach. The use of intra-procedural 3D-CT has helped increase diagnostic yield and recent studies have demonstrated good safety profile with fewer complications compared to CT guided biopsy. However, NB remains resource intensive, requiring general anaesthetic and theatre access. Using CT lesion characteristics to predict features favouring diagnostic sampling will allow patient stratification in MDT, avoiding risks of anaesthetic and diagnostic delay.
Methods or Background: This retrospective study included 101 consecutive, eligible patients who underwent NB biopsy at University Hospital Southampton between June 2023 and February 2025. Patients with available histology reports and diagnostic CT imaging preceding NB were included. Diagnostic success was defined as an unequivocal malignant or benign histological diagnosis. Insufficient and equivocal results were classed as non-diagnostic. Pre-NB CT imaging was analysed for lesion characteristics by a team of radiologists.
Results or Findings: NB demonstrated good safety profile with 1% (n=1) post-procedure pneumothorax and no post-procedure haemorrhage . 60% (n=60) of procedures yielded diagnostic sample.
Greater lesion size showed weak but statistically significant correlation with diagnostic sampling rate (r=0.20, p=0.04). Lesions ≥2cm were significantly more likely to yield diagnostic sample (p=0.035) as were lesions adjacent to more central airways (Weibel airway generation ≤4) (p=0.008).
Solid vs subsolid lesions, lobar location and presence of a bronchus sign showed no significant correlation to diagnostic sampling.
Conclusion: CT lesion size cut-off (2cm) and assessment of proximity to central bronchial tree (airway generation ≤4) are significant predictors of success and will help stratify patients referred for NB and streamline cancer diagnostic pathways.
Limitations: Patients with unavailable diagnostic CT imaging were excluded
Funding for this study: No funding was obtained for this study.

Percutaneous CT-guided Lung Core Biopsy - Safety and Diagnostic Adequacy in our hospital (6 min)

Anil Kumar Geetha Virupakshappa; Bedford / United Kingdom

Author Block: A. K. Geetha Virupakshappa; Bedford/UK
Purpose: Aim is to evaluate the histological adequacy and safety of the CT guided percutaneous lung core biopsy done in our radiology department
Methods or Background: Adequacy and safety parameters: (First cycle)
Diagnostic adequacy : 95 % of samples were adequate. Only one sample was inadequate, and this was lesion >2cm, done with an 20G needle and 5 passes obtained.
Sensitivity for malignancy 95% for lesions >2 cm
False positive rate =0%.
Complication rates:
Pneumothorax =20%
Pneumothorax needing drainage= 15% (3cases)
Haemoptysis =0%
Death < 0%

Adequacy and safety parameters (Second cycle):
Diagnostic adequacy : 100 % of samples were adequate.
Sensitivity for malignancy 100% for lesions >2 cm
False positive rate =0%.
Complication rates:
Pneumothorax =40% (10cases)
Pneumothorax needing drainage= 0%
Haemoptysis =16% (4cases)
Death < 0%
Results or Findings: We have a diagnostic accuracy rate of 95% in first cycle and 100% in second cycle, higher than the standard (90%).
We have a pneumothorax rate equal to the standard, 20% in first cycle and 40% in second cycle, but none of them required drainage (0%, standard is 3%).
16% of patients experienced haemoptysis after the procedure (Standard <5%), which were managed conservatively (none of them required hospitalization).
No death resulting from the procedure was recorded.
Conclusion: Documentation of the procedure (mode of imaging, needle size, core samples, number of passes) 100%. Diagnostic adequacy should be >90%. Sensitivity for malignancy > 85%. False positive rate <1%. complication rates: Pneumothorax <20%, pneumothorax requiring drainages <3%, haemoptysis<5%
Limitations: Individual radiologist variation
Funding for this study: No funding for the study

When to validate what: a framework for local performance assessment of AI in radiology (6 min)
Stephan Romeijn; Utrecht / Netherlands

Author Block: K. G. Van Leeuwen, M. Horton, S. Krijgsman, S. Romeijn; Utrecht/NL
Purpose: To present a structured framework that guides decisions on local performance assessment steps needed for safe and efficient AI adoption.
Methods or Background: Local quality assurance is crucial for the responsible implementation of commercially available AI solutions in radiology. A common belief is that every AI tool must always be extensively validated on local data before use. However, this is often impractical, particularly in non-academic hospitals, where resources are limited. To enable responsible yet feasible adoption, we present a framework that aligns the extent of performance validation with the available clinical evidence and the clinical risk of the application.
Results or Findings: The framework starts with an analysis of existing scientific evidence to assess whether sufficient clinical evidence is available on relevant population data. The next step is to consider the clinical risk (low or high). Based on these two factors, different validation types are recommended:
• Low-risk with sufficient evidence: acceptance test and post-deployment monitoring may suffice. E.g. bone age prediction.
• High-risk with sufficient evidence: acceptance test, pilot (shadow-mode or restricted implementation), and post-deployment monitoring are indicated. E.g. breast cancer screening AI.
• Low-risk with limited evidence: retrospective analysis, acceptance test, and post-deployment monitoring are advised. E.g. vertebral fracture detection for opportunistic osteoporosis screening.
• High-risk with limited evidence: retrospective analysis, acceptance test, pilot (shadow-mode or restricted implementation), and post-deployment monitoring are recommended. E.g. stand-alone stroke detection AI.
Conclusion: By tailoring local performance assessment to risk and evidence, this framework balances patient safety with feasibility, supporting responsible AI implementation in both academic and non-academic hospitals.
Limitations: The scope of this framework is limited to commercially available AI systems used in accordance with their intended use and does not address IT or data flow quality assurance.
Funding for this study: No funding was received for this study.

Clinician-Centric Explainable AI: Building Trust in Radiology Diagnosis (6 min)
Tician Schnitzler; Aarau / Switzerland

Author Block: T. Schnitzler[1], H. Zaytoun[1], A. P. Gehret[1], O. E. Oğretmen[2], M. Yavuz[2]; [1]Aarau/CH, [2]Istanbul/TR
Purpose: Artificial intelligence (AI) in radiology continues to face adoption barriers due to opaque decision-making processes that limit clinical trust. Traditional explainable AI (XAI) tools—such as saliency maps or feature importance rankings—rarely align with radiologists' diagnostic reasoning. We propose a Clinician-Centric Explainable AI (CC-XAI) framework to embed clinically meaningful, anatomy- and workflow-rooted explanations directly into radiological decision support.
Methods or Background: A conceptual and applied analysis of CC-XAI was performed, contrasting its interpretability with general-purpose XAI. We developed a five-category taxonomy comprising: (1) Visual (anatomy-aware saliency maps), (2) Textual (clinical language generation), (3) Example-Based (retrieval of annotated similar cases), (4) Quantitative (comparative measurement over time), and (5) Rule-Based (integration of clinical decision logic). A modular CC-XAI system was illustrated using a representative lung nodule case, demonstrating integration of lesion localization, volumetric growth analysis, similar case retrieval, and risk-factor-based reasoning into one cohesive explanation output.
Results or Findings: The proposed CC-XAI framework translates AI predictions into structured, interpretable outputs aligned with clinical workflows and cognitive heuristics. In our example, a spiculated nodule with growth from 8 mm to 15 mm over one year (estimated doubling time of 1119 days) was explained via anatomy-aware localization, growth kinetics, retrieval of two malignant-confirmed prior cases, and rule-based consideration of smoking, cancer history, and pulmonary fibrosis. Each module contributes to a cohesive final interpretation that improves explainability and trust calibration.
Conclusion: Clinician-centric XAI addresses a fundamental barrier to AI adoption in radiology by offering domain-specific, multi-dimensional explanations that mirror radiologists' decision-making processes. Embedding these modules into radiology workflows can facilitate clinically robust, interpretable, and trustworthy AI integration.Its modular design supports integration into clinical workflows for safer, more interpretable, and diagnostically aligned AI usage—especially in high-stakes areas such as lung cancer evaluation.
Limitations: No limitations.

Environmental Impact Reduction through Deep Learning Reconstruction in Clinical CT Imaging: A Hospital-Based Assessment (6 min)

Paolo Niccolò Franco; Monza / Italy

Author Block: P. N. Franco, C. Maino, C. R. G. L. O. M. Talei Franzesi, D. G. Gandola, I. Bianco, R. Corso, D. Ippolito; Monza/IT
Purpose: The healthcare sector accounts for approximately 4.4% of global greenhouse gas (GHG) emissions, with diagnostic imaging being one of the most energy-intensive activities. Computed Tomography (CT) is a major contributor due to high electricity demand and associated emissions. This study aims to evaluate the environmental impact of implementing deep learning-based image reconstruction (DLIR) in CT imaging in a large hospital, focusing on electricity, CO_2 emissions, and iodinated contrast media (ICM).
Methods or Background: Over the course of one year, data were collected from four CT scanners: two newly installed scanners utilizing DLIR technology and two older scanners operating with hybrid and model-based iterative reconstruction algorithms. Energy consumption, CO_2 emissions, and ICM usage were monitored and compared between the two groups. DLIR protocols were introduced with reduced tube voltage (from 120 kV to 80–100 kV) and optimized ICM dose. Energy savings were estimated from the quadratic relationship between kV and power. Emission reduction was quantified in CO_2-equivalent (CO_2e) tons. Water savings were derived from ICM production impact.
Results or Findings: Approximately 28,000 CT exams were performed (54% on iterative scanners, 40% on DLIR). Standard CT scanners consumed ~41,000 kWh/year, equating to ~10.25 tons CO_2/year per device. DLIR implementation allowed for a 30–55% energy reduction depending on scan type. Total annual savings per CT unit were up to 22,550 kWh and 5.6 tons CO_2e. ICM was reduced by 30%, saving ~2,100 liters/year per DLIR scanner and preventing ~81 tons of CO_2e.
Conclusion: Deep learning reconstruction in CT imaging can significantly reduce energy use, CO_2 emissions, and contrast media consumption without compromising diagnostic quality. These results support its implementation as a sustainable innovation in clinical radiology.
Limitations: This study was conducted in a single center, limiting generalizability.
Funding for this study: None.

Algorithmic Fairness Unfolded: Collaborative Ethnography within a Medical Imaging AI Lab for Lung Cancer Screening (6 min)

Michel Vitale; Nijmegen / Netherlands

Author Block: M. Vitale, M. Vegter, C. Jacobs, M. Boenink; Nijmegen/NL
Purpose: This study reports on collaborative efforts within an AI lab developing solutions for lung cancer screening (LCS) to investigate and negotiate how fairness is framed and operationalized in practice, and to develop actionable recommendations for better algorithmic fairness practices in medical imaging AI. It contributes to calls for more context-sensitive, morally robust, and interdisciplinary approaches to algorithmic fairness.
Methods or Background: We draw on a two-year collaboration between engineers and an ethicist in a UMC AI lab, considering fieldnotes and observations from meetings, ethics roundtables, and a six-month project assessing the fairness of AI-based risk models for LCS (Sybil, Venkadesh21, PanCan2b). Leveraging “ethics parallel research” alongside elements of the JustEFAB framework, we reconstruct and critically examine practices, assumptions, and constraints shaping engineers’ approach. We trace how fairness was framed, bias assessed, and explore how fairness practices can be improved. Findings are validated in a follow-up roundtable, informing an agenda for more comprehensive, situated, and auditable fairness practices.
Results or Findings: We observe tensions between comprehensive theoretical frameworks of algorithmic fairness and narrow approaches prevalent in engineering practices, where fairness is often overlooked or reduced to technical optimization. Practical constraints (data availability, timelines, unclear responsibilities, limited resources and interdisciplinary opportunities) foster statistical approaches with limited connection to clinical needs or broader contextual ethical considerations. Bridging this gap requires reflexivity tools, transparent decision-making, interdisciplinary research, and recognition of fairness as a multifaceted ethical issue.
Conclusion: Current fairness assessments insufficiently engage with AI socio-technical and ethical dimensions. Interdisciplinary collaboration can bridge theory and practice, helping developers move beyond technical metrics. Ethics parallel research made these dimensions visible, contextual, and clinically relevant, while highlighting barriers and enablers of better fairness practices.
Limitations: Qualitative, single-center study focused on AI for medical imaging only.
Funding for this study: This research is funded by a public-private project with funding from the Dutch Science Foundation, the Dutch Ministry of Economic Affairs, and MeVis Medical Solutions (Bremen, Germany).

The Influence of Artificial Intelligence on Radiologists’ Diagnostic Performance in Fatigue (6 min)

Mahta Khoobi; Aachen / Germany

Author Block: M. Khoobi, R. Siepmann, S. Nebelung, D. Truhn, C. K. Kuhl; Aachen/DE
Purpose: Night-shift duty can cause fatigue in radiologists, potentially impairing diagnostic performance and compromising patient safety. This study aims to evaluate the impact of night-shift-induced fatigue on radiologists’ diagnostic accuracy and whether artificial intelligence (AI) can mitigate the expected decline in performance.
Methods or Background: This prospective intra-individual reader study (July 2024–March 2025) involved 10 radiology residents (mean clinical experience: 35 months; three women) interpreting three sets of 33 chest radiographs before and after a first-call on-site night shift. Sessions included two pre-shift readings (without AI) and two post-shift readings (with and without AI). Eye tracking captured fixation duration and saccade count, and fatigue was classified as a ≥5% reduction in the slope of the saccadic main sequence between pre- and post-shift sessions. Diagnostic accuracy (Cohen’s κ vs expert majority vote), efficiency (mean reporting time per image), eye-tracking metrics, and surveys were analyzed using generalized linear mixed models with Tukey-adjusted post-hoc comparisons.
Results or Findings: Six of 10 radiologists were classified as fatigued. In fatigued radiologists, diagnostic accuracy declined significantly post-shift (from $\kappa=0.71\pm0.05$ to $\kappa=0.61\pm0.10$; $P<.001$), accompanied by reductions in fixation duration ($P=.010$) and saccade count ($P=.015$). Non-fatigued radiologists showed a smaller decline in accuracy (from $\kappa=0.72\pm0.03$ to $\kappa=0.65\pm0.03$, $P=.037$). Reporting times remained stable pre- and post-shift ($P\geq.463$). AI assistance modestly increased accuracy in both groups ($\Delta\kappa=0.03–0.04$; $P\geq.525$) and reduced reporting times in fatigued ($P=.122$) and non-fatigued radiologists ($P=.031$). User surveys indicated increased mental exhaustion in fatigued radiologists.
Conclusion: Night-shift-induced fatigue impaired diagnostic accuracy without slowing reporting speed, thereby raising concerns about patient safety. AI modestly improved performance but failed to restore pre-shift performance. Institutional fatigue-management strategies are essential, with AI serving as a supportive adjunct.
Limitations: A small sample size and restriction to chest radiographs limited the study.
Funding for this study: The Deutsche Forschungsgemeinschaft supports this research (DFG 701010997, 517243167, 515639690), the German Federal Ministry of Research, Technology, and Space (Transform Liver - 031L0312C, DECIPHER-M, 01KD2420B), and the European Union Research and Innovation Programme (ODELIA - GA 101057091).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Ethical approval was obtained (Medical Faculty, RWTH Aachen University, Germany, reference number 24/376), and informed consent was waived.

RadGame: an AI-powered platform for radiology education (6 min)

Mohammed Baharoon; Jamaica Plain / United States

Author Block: M. Baharoon[1], J. Jun[1], S. Raissi[1], T. Heintz[2], M. Alabbad[3], A. Alburkani[4], M. Mohammed[4], H. R. Alomaish[4], P. Rajpurkar[1]; [1]Boston, MA/US, [2]Maastricht/NL, [3]Hofuf/SA, [4]Riyadh/SA
Purpose: The purpose of this study is to improve radiology education by teaching trainees two essential skills: localizing imaging findings and generating structured clinical reports. Traditional methods often lack interactive feedback and rely on limited datasets, restricting learning opportunities. RadGame addresses these gaps by combining gamification with large-scale datasets and AI-driven feedback to provide scalable, personalized, and engaging training.
Methods or Background: We conducted a prospective, multi-institutional user study with 18 medical students who completed both RadGame modules (Localize and Report) under gamified and traditional learning conditions. Participants were evaluated with pre- and post-tests, and performance was measured using radiologist-verified ground truths, the CRIMSON reporting metric, and efficiency metrics such as time per case.
Results or Findings: Students using RadGame demonstrated significantly greater gains than those in traditional learning, with a 68% improvement in localization accuracy versus 17% and a 31% improvement in report-writing accuracy versus 4%. Additionally, the gamified group showed increased efficiency, completing cases faster over time while maintaining higher diagnostic accuracy.
Conclusion: RadGame demonstrates that AI-powered gamification can significantly enhance radiology training by integrating structured, real-time feedback into localization and report-writing tasks. Compared to traditional passive methods, the platform produced larger improvements in diagnostic accuracy and efficiency among medical trainees. Beyond its educational impact, RadGame also serves as a human-in-the-loop testbed for refining AI evaluation metrics such as CRIMSON, making them more clinically meaningful. These findings highlight the potential for repurposing medical AI resources into scalable, learner-centered educational tools.
Limitations: The limitations of the study are due to a relatively small sample size of 18 students, which reduced the statistical power for some comparisons. Additionally, the gamified module required more interaction time than traditional methods, reflecting trade-offs between active engagement and efficiency.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was reviewed by the Harvard Faculty of Medicine Institutional Review Board (Protocol \#IRB25-0694) and determined to be exempt under 45 CFR 46.104(d)(2)(3).

Economic Evaluations of AI Applications in Radiology: A Systematic Review (6 min)

Federica Zanca; Leuven / Belgium

Author Block: F. Zanca[1], L. Gregory[2], F. Lock[2], H. Harvey[2]; [1]Leuven/BE, [2]Haywards Heath/UK
Purpose: Artificial intelligence (AI) in radiology offers promising applications to enhance clinical and patient outcomes. However, adoption has been slow, partly due to a lack of robust health economic evidence increasingly required for technology integration. While established tools focus on clinical evidence, they often overlook economic impact. This review synthesises literature on economic evaluations of AI in radiology.
Methods or Background: A systematic review of health economic evaluations of radiology AI was conducted and reported following PRISMA guidelines and economic review recommendations. MEDLINE and Cochrane Central were searched using a targeted strategy. Eligible studies were screened, with conflicts resolved by consensus review. Data were extracted into economic, patient, and clinical outcome domains, and reporting quality assessed using CHEERS-AI for evaluations using decision-analytic models.
Results or Findings: Thirty-one studies were included. Reported outcomes varied widely. Most focused on direct costs, cost-effectiveness, and diagnostic accuracy with limited attention to productivity or workflow metrics. Quality-adjusted life years (QALYs) were the predominant outcome, although alternative measures such as cost per patient screened or per correct diagnosis were also used. Half of the studies applied decision-analytic modelling, predominantly in opportunistic imaging contexts, and most originated from the US and UK. Evidence from European settings was scarce.
Conclusion: There is a significant gap between the rapid proliferation of radiology AI tools and the availability of health economic evidence to support their adoption. Economic outcomes and metrics have been largely based on the pharmaceutical best practices. Future studies should broaden outcomes assessed to include productivity, workflow efficiency, and access to care. Cross-disciplinary collaboration and harmonised international guidance are essential to ensure that radiology AI adopted responsibly.
Limitations: Many included studies predated CHEERS-AI. We excluded cardiology and invasive imaging studies. All included studies focused on deep learning.
Funding for this study: This work was supported by the European Innovation Council and SMEs Executive Agency (EISMEA).

AI Act and AI-based radiology software: Implications for clinical use (6 min)

Joel Kohler; Heidelberg / Germany

Author Block: J. Kohler[1], J. Jesser[1], A. Seehafer[2], B. Kohler[3], S. Heiland[1], M. Bendszus[1], J. Kernbach[1], M. Schell[1]; [1]Heidelberg/DE, [2]Berlin/DE, [3]Zurich/CH
Purpose: Hospitals and other healthcare providers increasingly implement AI-based radiology software in their clinical practice. We investigated how the European AI Act (AIA) might affect this usage from 2027 on.
Methods or Background: We applied qualitative and quantitative legal interpretation methods to simulate how the AIA could apply to hospitals. To analyze market effects, we evaluated the landscape of commercial clinical radiology AI applications. We used data provided in the EU Impact Assessment to estimate costs of compliance.
Results or Findings: The AIA intensely regulates 'high-risk' AI systems (assumed 5-15 % of all AI applications). 98.6 % of current products and most future clinical radiology AI-based software will represent such high-risk AI systems. If a hospital uses an AI software as provided by a third-party company, the hospital will act as a 'deployer' (low level of legal duties and moderate costs associated) and the company will be a 'provider' (high level of legal duties). However, not only in case of placing its own AI system on the market but also in certain other scenarios, a hospital might itself become a 'provider' - in some cases unexpectedly and unintentionally. This provider role may lead to roughly 30000 EUR compliance costs per application and up to 330000 EUR one-off and 71000 EUR annual costs on top if a quality management system has to be set up.
Conclusion: Clinical stakeholders should prepare for potentially severe legal and economic implications of AI usage. The AIA might hamper broad innovation adaption and leveraging clinical benefits for providers of AI systems in radiology. Public authorities should consider mitigating these effects.
Limitations: The limitations of the study include legal and economic uncertainties.
Funding for this study: No funding was received for this study.

PAIR: A Framework for Standardized Reporting of Real-World AI Implementation in Hospitals (6 min)

Ramprabananth Sivanandan; Asker / Norway

Author Block: R. Sivanandan[1], W. Grootjans[2]; [1]Asker/NO, [2]Leiden/NL
Purpose: Artificial intelligence (AI) is moving rapidly from development to deployment in radiology. While reporting standards such as CLAIM, CONSORT-AI, DECIDE-AI, STARD-AI, and TRIPOD-AI address validation and trials, they overlook the complex realities of implementation in radiology workflows. This lack of structure hinders comparison, reproducibility, across institutions and potentially limits added value of AI solutions.
Methods or Background: We developed the Protocol for AI Implementation Reporting (PAIR) to provide a standardized, practice-oriented framework for documenting and guiding AI implementation in hospitals. PAIR integrates and extends existing reporting guidelines, and it is organized around four domains. The first domain, problem and purpose, describes the clinical need, clarifies the value proposition, and supports application selection. The second is the AI system, which details the technical specifications, regulatory status, and intended use. The third domain addresses implementation, including governance, workflow integration, interoperability, user training, and change management. The fourth domain, results and sustainability, encompasses safety monitoring, drift and bias control, equity, cost-effectiveness, adoption, and retirement criteria.
Results or Findings: PAIR includes a reporting checklist, manuscript template, and workflow diagram to support transparent documentation and knowledge sharing. Beyond reporting, it also functions as a practical guide for hospitals to structure AI adoption and assess whether an application adds measurable value to radiological practice.
Conclusion: PAIR fills an existing gap between reporting standards and enables transparent and reproducible reporting while guiding safe, equitable, and value-driven AI implementation in clinical practice. Its adoption will accelerate the adoption of trustworthy AI in radiology and beyond.
Limitations: At present, PAIR remains conceptual and awaits empirical validation
Funding for this study: No funding

Photon-Counting CT in Spinal Implants: Artifacts Reduction and Image Quality Improvement (6 min)
Luca Alessandro Cappellini; Meda / Italy

Author Block: L. A. Cappellini[1], G. Ressa[1], M. De robertis[1], G. Savini[1], R. Levi[1], C. Brembilla[2], M. Fornari[2], L. S. Politi[1]; [1]Pieve Emanuele/IT, [2]Rozzano/IT
Purpose: The aim of this study was to qualitatively and quantitatively determine whether Photon-Counting CT (PCCT) with Virtual Monoenergetic Imaging (VMI) improves postoperative assessment of spinal implants by reducing metallic artifacts, enhancing diagnostic confidence, and better evaluating postoperative complications, in comparison with conventional CT.
Methods or Background: A total of 16 subjects who underwent PCCT (NAEOTOM Alpha, Siemens) for postoperative evaluation following anterior, posterior, or combined spinal fixation were included. Scans were performed at 120 or 140 kVp, with and without IMAR.
Images were evaluated using VMI (60–190 keV). For each examination, 13 ROIs were placed to calculate Artifact Index (AIx), HU values, and Standard Deviation (SD). Subjective evaluation was performed by three radiologists using a Likert scale (1–5) at different energy levels. Where available PCCT was compared to conventional CT.
Results or Findings: PCCT proved effective in reducing soft tissue artifacts, with optimal performance between 110 and 140 keV. At energies above 150 keV, loss of contrast were observed impairing tissue differentiation.
Images at 0.2 mm with Br76 kernel showed higher SD and AIx but were subjectively superior for evaluating screws, bone contours, and metal-bone interfaces, compared to IMAR and VMI, due to overcorrection bands, shading, and native software limitations.
The subjectively selected optimal reconstruction did not always correspond to the image with the lowest AIx. Compared to available conventional CT scans, monoenergetic PCCT images achieved higher Likert scores and lower AIx values.
Conclusion: PCCT provides high subjective and objective image quality in patients with spinal metallic implants. For the evaluation of periprosthetic bone changes, ultra-high-resolution reconstructions with bone kernel images are preferred. Virtual Monoenergetic Imaging (VMI) improves soft tissue assessment, particularly in the setting of postoperative complications.
Limitations: Sample size, Comparison with conventional CT was limited

Impact of Deep Learning-Based Denoising on Image Quality and Diagnostic Confidence in Neurovascular Ultrahigh-Resolution Photon-Counting CT Angiography (6 min)
Adrienn Toth; Charleston / United States

Author Block: A. Toth, M. T. Hagar, M. Silbergleit, J. Y. Cho, M. Vecsey-Nagy, A. Varga-Szemes, M. V. Spampinato; Charleston, SC/US
Purpose: Ultra-high-resolution (UHR) photon-counting detector (PCD)-CT angiography with sharp neurovascular kernels (Hv72) and high-level quantum iterative reconstruction (QIR-4) yields excellent intracranial image quality but often suffers from elevated image noise in the lower neck. This study evaluated the added value of a post-hoc convolutional neural network (CNN) denoising algorithm on quantitative image quality metrics in head and neck UHR PCD-CTA.
Methods or Background: In this retrospective study, head and neck UHR PCD-CTA datasets were reconstructed using a sharp neurvascular kernel (Hv72) and iterative reconstruction (QIR-4), with and without post-hoc CNN–denoising. Image noise, intraluminal attenuation, signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR) were measured at the 'lower–neck' (CCA and vertebral artery segment V1), 'mid–neck' (carotid bifurcation and V2), 'intracranially' (ICA and V4), and compared using paired t-test.
Results or Findings: 25 consecutive patients were enrolled. CNN-denoising reduced image noise at all vascular levels ($p<0.001$), with the largest absolute reduction in the 'lower-neck' (–28.6 HU; 43.3%, $p<0.001$). Mean intraluminal attenuation was preserved across all vascular levels with only minimal differences (<3 HU), and signal variability (SD) remained unchanged. SNR and CNR improved significantly throughout the vasculature. In the 'lower-neck', CNR increased by 79.4% (6.3 ± 5.8 vs 11.3 ± 9.2; $p<0.001$). In the 'mid-neck', SNR and CNR increased from 35.8 ± 11.3 to 74.8 ± 72.5 ($p<0.001$). 'Intracranially', SNR rose from 27.8 ± 6.4 to 51.4 ± 11.6 and CNR from 25.1 ± 6.3 to 46.5 ± 11.2 ($p<0.001$).
Conclusion: CNN–denoising selectively suppressed image noise without altering vessel attenuation, providing SNR and CNR improvements across all vascular levels. Improvements were most pronounced in the mid neck, while intracranial regions demonstrated stable and reproducible enhancement. While lower neck values improved, variability remained higher due to artifact-prone anatomy.
Limitations: No limitations.
Funding for this study: No funding was received for this study.

Performance of Photon-Counting Detector CT artifact reduction algorithms in post-embolization evaluation of intracranial aneurysm (6 min)

Limin Lei; Zhengzhou / China

Author Block: L. Lei, Y. Zhou, X. Guo, Z. Wang, L. Tao; Zhengzhou/CN
Purpose: To evaluate the image quality and diagnostic confidence of the Metal Artifact Reduction (MAR) algorithm for photon counting detector CT (PCD-CT) in follow-up of cerebral aneurysm embolization coils.
Methods or Background: CTA data of the head and neck of 38 patients with intracranial aneurysms after embolization were prospectively collected. All examinations were performed on photon-counting detector CT. The scan data were reconstructed with two different slice thicknesses (0.8 mm and 0.2 mm), with or without MAR, respectively. Objective parameters such as CT value and standard deviation (SD) were recorded, and artifact index (AI), signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR) were calculated. Subjective evaluation was assessed according to the Likert scale scoring method. The post-embolization therapeutic efficacy was assessed by the aneurysm neck, parent artery, and postprocedural complications.
Results or Findings: The subjective and objective image quality evaluation of MAR groups were better than those of non-MAR groups ($P<0.05$). The noise of 0.2mm image was slightly higher, but the display of blood vessels and brain tissue near artifacts was better than that of 0.8mm group. Compared with DSA, the differences in aneurysm neck length and bilateral parent artery diameter in MAR groups were significantly smaller than those in MAR groups ($P<0.05$). Importantly, MAR group with 0.8mm showed 1 aneurysm recurrence, 1 residual filling, 4 parent artery stenosis and 2 aneurysm ruptures, while the 0.2 mm MAR group showed 5 filling defects, but non-MAR group showed none.
Conclusion: PCD-CT combined with MAR can improve image quality, improve visualization of cerebral arteries, reduce metal artifacts, significantly improve outcome assessment and complication detection of aneurysms after embolization, especially on 0.2 mm images.
Limitations: Number of cases is small, we need more patients to be included to verify this result.
Funding for this study: None.

Put an eye on the brachial plexs: initial experience with Photon Counting CT (6 min)

Gennaro D'Anna; Legnano / Italy

Author Block: G. D'Anna, S. Barazzetta, M. Alì, A. Licata, M. Gerli, F. Darvizeh, L. Di Palma, I. Castiglioni, D. Fazzini; Milan/IT
Purpose: To evaluate the possibility to detect brachial plexus on Total Body PCCT. We evaluated post-contrast images looking for the divisions and relations with surrounding structures.
Methods or Background: We retrospectively analyzed the first 11 patients scanned at our Institution with photon-counting CT (Siemens Naetom Alpha), comparing similar patients evaluated with our other scanner (Siemens Magnetom Flash). We established as “well-visible” a case with good delineation of roots and trunks, “medium visible” a case with weak delineation of roots and trunks, “poor visible” a case with poor delineation of the structures.
Results or Findings: In the reprocessed images at 70 keV, based on the acquisition made with Photon-Counting technology scanner, out of a total of 11 patients the brachial plexus anatomy is clearly visible in 4 patients (36.36%). In 5 patients it is moderately visible (45.45%) while in 2 cases (18.18%) it is not possible to discern the anatomical structures reliably. In images reprocessed at 140 keV brachial plexus anatomy is clearly visible in 3 patients (27.27%). In 3 patients it is moderately visible (27.27%) while in 5 cases (45.45%) it is not possible to discern the anatomical structures reliably. Aat 70 keV (No. 4), only No. 3 is also clearly visible in the reworks at 140 keV. (75%). Cases with average brachial plexus anatomy visible at 70 keV are No. 5, while at 140 keV they turn out to be No. 3 (60%). All the cases evaluated on Somatom Flash showed poor delineation of brachial plexus.
Conclusion: PCCT may evaluate anatomical structures of brachial plexus, allowing more precise and effective diagnosis and patient management.
Limitations: Small sample size

3D Volume Rendering of Ultra-High-Resolution Photon-Counting CTA: A Useful Tool for Neurosurgical Evaluation of Intracranial Aneurysms (6 min)

Adrienn Toth; Charleston / United States

Author Block: A. Toth, S. Al Kasab, K. Kicielinski, M. Silbergleit, J. Y. Cho, M. T. Hagar, M. Vecsey-Nagy, A. Varga-Szemes, M. V. Spampinato; Charleston, SC/US
Purpose: Three-dimensional (3D) volume rendering (VR) reconstructions offer comprehensive illustration of anatomy and pathology. We hypothesized that combining the high spatial resolution of ultra-high-resolution (UHR) photon-counting detector (PCD)-CTA with 3D VR post-processing could provide significant benefits for the neurosurgical evaluation and management of intracranial aneurysms.
Methods or Background: In this IRB-approved retrospective study, consecutive patients with diagnosed intracranial aneurysms were included. Image acquisition was performed using a clinical PCD-CT scanner in UHR mode. Two neurosurgeons independently evaluated both conventional 2D images and 3D VR reconstructions. A 13-item questionnaire was used to assess image quality, aneurysm characterization, and the clinical usefulness of the 3D VR datasets. Aneurysm neck and dome dimensions were measured on both 2D source images and 3D VR reconstructions to determine inter-reader agreement.
Results or Findings: 21 patients with 32 aneurysms were enrolled. Image quality and clinical usefulness of 3D VR images were rated as excellent, with percentage agreement ranging from 58% to 100%, primarily differing between ratings of 4 and 5. Inter-reader reliability for aneurysm size measurements on 3D VR reconstructions was good for dome size (ICC=0.74) and moderate for neck size (ICC=0.55). Bland–Altman analysis showed measurement differences were generally minor, with a few larger discrepancies for bigger aneurysms.
Conclusion: UHR CTA-based 3D VR reconstructions provided high subjective image quality, allowing for the precise depiction of aneurysm morphology and reproducible size measurements with good inter-reader agreement. UHR CTA-based 3D VR reconstructions may complement or potentially replace confirmatory invasive angiography in selected cases by providing reliable morphological information, streamlining preoperative workflows, and supporting surgical or endovascular planning.
Limitations: Digital subtraction angiography (DSA), MR angiography, or surgical records were not used as reference standard, precluding direct confirmation of aneurysm size and morphology.
Funding for this study: No funding was received for this study.

The Evaluation of Intracranial Stents and Flow Diverters Patency with Photon-Counting Detector CT: Comparison with Digital Subtraction Angiography (6 min)

Lianpei Yang; Zhengzhou / China

Author Block: L. Yang[1], Z. Xu[2]; [1]Zhengzhou/CN, [2]Beijing/CN
Purpose: This study aimed to evaluate the diagnostic accuracy of ultra-high-resolution (UHR) scanning mode in photon-counting detector computed tomography angiography (PCD-CTA) for evaluating the patency of intracranial stents and flow diverters, with comparison to results from digital subtraction angiography (DSA) for in-stent stenosis.
Methods or Background: A retrospective analysis was conducted on patients with previously implanted intracranial stents or flow diverters who were admitted for CT examination between January 2025 and August 2025. All patients underwent CT scanning on PCD-CT with UHR mode (collimator specification: 120×0.2 mm). Images were reconstructed in both UHR (slice thickness 0.2 mm, kernel Hv72) and standard resolution mode（SR ,slice thickness 0.6 mm, kernel Hv40). Radiologists conducted both objective and subjective assessments of the reconstructed images, quantitatively measured the degree of stenosis, and performed comparative analyses with digital subtraction angiography (DSA) as the reference standard.
Results or Findings: 37 patients (60.3±8.6 years[standard deviation]; 24males) with 39 stents and three flow diverters were evaluated.The UHR images had a higher sharpness than SR images($p<0.001$).The subjective scores demonstrated that UHR images had a better pronounced effect than SR images on reducing blooming artifacts, showcasing in-stent lumen and stent demonstration, and diagnostic confidence ($p < 0.001$) .Furthermore, the UHR images of reader 1 and reader 2 both showed a diagnostic accuracy of 97.6% (95%CI:87.4%, 99.9%), compared to those of were 85.7% (95% CI: 71.5%, 94.6%) for reader1 and 81.0%(95% CI: 65.9%, 91.4%) for reader 2 .There was a high consistency of readers'evaluation with a kappa of 1 for UHR images and 0.767 for SR images .
Conclusion: UHR PCD-CTA enables non-invasive assessment of intracranial stents and flow diverters patency with superior image quality and diagnostic accuracy.
Limitations: The high-resolution images are not directly compared with EID-CT.
Funding for this study: No funding was obtained for this study.

Ethics committee - additional information: The study was approved by the Drug (Device) Clinical Trial Ethics Committee of Henan Provincial People's Hospital, with approval number (2024-285-02).

Advances in glioblastoma and various grade glioma using Photon-Counting CT (6 min)

Ilaria Conti; Sassari / Italy

Author Block: I. Conti, G. De Paula, D. Turilli, L. Piscopo, E. Solinas, L. M. Fattacciu, M. Pedde, M. Scaglione, S. A. Masala; Sassari/IT
Purpose: This study aims to develop autonomous Generative AI agents capable of integrating entropy maps derived from Photon-Counting Computed Tomography (PCCT), magnetic resonance imaging (MRI), and, when available, histopathological data, to enable personalized diagnostic profiling of brain tumors (specifically glioblastomas and high-grade gliomas) thereby facilitating advanced preoperative planning and intraoperative guidance.
Methods or Background: A prospective analysis was conducted on 25 patients affected by glioblastoma or various grade glioma who underwent PCCT brain imaging at our Radiology Department. A dedicated angiographic protocol was applied to assess perilesional vascularization, in addition to generating iodine concentration maps and entropy maps for lesion characterization and perfusion analysis. Imaging datasets underwent radiomic feature extraction and were co-registered with multiparametric MRI, including MR spectroscopy and, when available, with histopathological results.
Results or Findings: This study demonstrated that the use of PCCT provides enhanced spatial resolution and allows evaluation of post-treatment tumor activity using entropy and iodine maps, while achieving significant reduction in both radiation dose and intravenous contrast medium volume.
integrating traditional AI with advanced radiological imaging significantly enhances the quality of care for patients with glioblastoma and high-grade gliomas. The use of multimodal imaging and AI-driven interpretation enables advanced diagnosis and personalized treatment planning, resulting in increased survival rates, fewer re-interventions, and overall cost-effectiveness.
Conclusion: Since clinicians often struggle to integrate complex, heterogeneous, and large-scale data into a comprehensive view of oncologic patient management, the assistance of an autonomous Generative AI agents play a pivotal role to fully leverage all available data.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study

Establishing Diagnostic Reference Levels (DRLs) for Neurointerventional Procedures in Malta (6 min)
Marvin Grech; Ghaxaq / Malta

Author Block: M. Grech, F. Zarb, R. Grech, P. Bezzina; Msida/MT
Purpose: Interventional neuroradiology procedures are vital for managing neurological conditions but expose patients to ionising radiation. The aim of the study was to assess the level of radiation doses during diagnostic and therapeutic Neurointerventional procedures in Malta and to establish and compare local Dose Reference Levels (DRLs) with international standards.
Methods or Background: Retrospective data were collected from DoseWatch for the period January 2020 to May 2025, focusing on Air Kerma Area Product (PKA), Reference Air Kerma (RAK), and Fluoroscopy Time (FT) for the following procedures: Cerebral Angiography (CA), Stroke Thrombectomy (ST), Aneurysm Coiling (AC), and AVM/AVF embolization. DRLs were calculated as the 3rd quartile (75th percentile) of the dose distributions.
Results or Findings: In Malta, the 3rd quartile values for CA were considerably lower than those reported in the literature, with PKA at 58 Gycm², RAK at 330 mGy, and FT at 9 minutes. ST revealed radiation doses approximately half of those reported in the literature (PKA: 70 Gycm²; RAK: 372 mGy; FT: 23 minutes). For AC, the doses were comparable to international standards (PKA: 182 Gycm²; RAK: 3384 mGy; FT: 45 minutes). Conversely, radiation doses for AVM/AVF embolisation were considerably higher (PKA: 1463 Gycm²; RAK: 7900 mGy; FT: 168 minutes).
Conclusion: The findings emphasise the importance of understanding radiation exposure to enhance patient safety. Establishing local DRLs will provide benchmarks for practitioners in Malta, while enabling continuous monitoring and development of optimisation strategies to mitigate risks associated with ionising radiation.
Limitations: This was a single center study establishing local DRLs and comparing these to literature findings. The center where study took place is however the only center providing neurological services in Malta.
Funding for this study: No funding required

Saving lives and preventing harm in Jersey: Radiographer-Led Nasogastric Tube Position Check Pathway Pilot (6 min)
Gavin Cain; St. Helier / United Kingdom

Author Block: G. Cain[1], N. Aslam[1], D. J. M. Tolan[2], G. Roe[2], L. Horder[3], A. Gill[4]; [1]St. Helier, Jersey (Channel Islands)/UK, [2]Leeds/UK, [3]London/UK, [4]Oxford/UK
Purpose: To evaluate the safety, timeliness, and accuracy of a radiographer-led nasogastric (NG) tube position check pathway pre- and post-implementation.
Methods or Background: A collaborative initiative involving professional bodies, including the Society and College of Radiographers and the Royal College of Radiologists, launched a national radiographer-led NG tube pathway. This empowers radiographers to assess NG tube placement on chest X-rays and take corrective action if tubes are misplaced. It's a response to repeated safety alerts related to the inadvertent use of misplaced NG tubes—classified as 'Never Events' by the NHS. On 30th June 2025, Jersey General Hospital became the first pilot site in the UK and Channel Islands to implement the pathway.

A retrospective audit compared the first 12 weeks post-implementation (radiographers performing first-line placement checks) with a pre-implementation period (radiologist-only X-ray reporting). Metrics assessed included time from image acquisition to clinical evaluation, misplacement detection rate, corrective action on misplaced tubes, and concordance between radiographer evaluations and the definitive radiology report. Radiographers completed a national competency-based e-learning programme supported by governance and a Standard Operating Procedure.
Results or Findings: Median turnaround time for clinical evaluation was reduced from 242.2 hours (10.1 days) to 12 minutes post-implementation. Radiographers detected 100% of misplaced NG tubes (12/12) and took corrective action on all misplaced tubes identified in the department (6/6). Concordance with the definitive radiology report was 96.8% (60/62).
Conclusion: The radiographer-led pathway is safe and effective, significantly reducing delays and minimising the risk of Never Events. The Jersey pilot reinforces evidence that with appropriate training and governance, radiographers can enhance NG tube safety through assessment and action at the point of image acquisition.
Limitations: Small sample size; focused on radiographer accuracy rather than patient outcome.
Funding for this study: No

Enhanced Arterial Imaging with Reduced Contrast Load: A Longitudinal Study of Weight-Based CTA Protocol Implementation (6 min)

Hortência De Jesus Ferreira; Campinas / Brazil

Author Block: J. T. d. S. d. Castro, H. d. J. Ferreira, D. C. Novais da Silva, D. Yamada, S. San Juan Dertkigil, F. Reis; Campinas - Sao Paulo/BR
Purpose: Weight-based personalisation of contrast media in CTA can maintain or increase arterial enhancement while reducing contrast load; longitudinal real-world evidence remains scarce. The aim is to quantify the impact of weight-stratified CTA protocols on arterial enhancement and iodine use in a real-world setting.
Methods or Background: Single-centre retrospective longitudinal study within ANGIO-MONITOR. Consecutive angiographic CTAs were analysed across two periods: pre-implementation (fixed protocols; N=1,626) and post-implementation (from 01-Jun-2025; weight-based volumes/flows and PSI ceilings; N=558). Primary endpoint: arterial attenuation (HU) in the target vessel per exam. Secondary endpoints: proportion of "optimal" studies (≥350 HU), contrast volume (mL/exam; mL/kg), and repeat-acquisition rate. Statistical tests: Welch's test for means, proportion comparisons with 95% CIs; exam-level analyses with temporal stratification.
Results or Findings: Arterial enhancement increased from 315.5 HU (95% CI 311.1–319.9) to 484.4 HU (469.8–499.1); $p=7.1\times10^{-79}$. Mean contrast volume decreased from 79.5 mL (78.3–80.7) to 67.9 mL (65.8–69.9); $p=1.1\times10^{-20}$. mL/kg fell from 1.09 (1.07–1.11) to 0.91 (0.88–0.94); $p=5.8\times10^{-25}$. The proportion of optimal studies rose from 30.0% to 76.5% (absolute Δ +46.6 pp; RR 2.55; $p<10^{-16}$). Repeat-acquisition rates were low and similar (1.91% vs 2.15%; p=0.72). Effects were observed across angiographic indications in routine operations.
Conclusion: Weight-based CTA protocols, implemented under technologist-led governance and injector/CT synchronisation, substantially increased arterial enhancement while reducing contrast exposure in real-world practice. Findings support institutional scale-up, underpin iodine stewardship and cost savings, and provide a foundation for indication-specific analyses and prospective predictive modelling.
Limitations: The study is a single-center retrospective analysis, which may limit the generalizability of the findings.
Funding for this study: Not Applicable
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The work has been submitted to the university's Research Ethics Committee (CEP) and is currently under review for evaluation and final opinion.

Predictive Modeling and Image Quality Metrics for Dose Reduction in CT-Guided Liver Ablation (6 min)

Tim Antheunis; Veenendaal / Netherlands

Author Block: T. Antheunis[1], M. Hakkert[2], B. Vermolen[1]; [1]Ede/NL, [2]Haarlem/NL
Purpose: CT-guided liver ablation is a minimally invasive procedure associated with substantial radiation exposure for both patients and staff. Current protocols are not optimized, resulting in unnecessary dose. This study aimed to achieve dose reduction through protocol optimization, validated by a predictive model correcting for clinical factors.
Methods or Background: A single-center interventional study was conducted at Ziekenhuis Gelderse Vallei. Group A (n=76) underwent ablation before protocol adjustment; Group B (n=7) after implementation. A linear regression model was developed from Group A to predict dose-length product (DLP) based on significant clinical factors (patient size, number of lesions). In parallel, a phantom study evaluated the impact of slice thickness, tube current, and reconstruction technique (hybrid iterative reconstruction vs. model based reconstruction) on task-based image quality using the detectability index (d'). The optimized protocol was applied to Group B and validated against model predictions.
Results or Findings: Patient size ($r=0.76$; $p<0.001$) and number of lesions ($p=0.016$) were the strongest dose determinants. The model explained 59% of DLP variance (RMSE=532 mGy·cm). Phantom analysis showed model based reconstructions maintained higher d' at low dose compared to iDose (at 2 mGy: IMR=4.71 vs. iDose=1.66). The new protocol reduced CTDIvol for spiral scans to 2–4 mGy and differentiated between planning and control scans. Group B achieved a 40–70% DLP reduction versus predicted values, with clinically acceptable image quality.
Conclusion: Task-based image quality analysis combined with predictive modeling enables substantial radiation dose reduction without compromising diagnostic utility. The integration of IMR, reduced tube current, and adjusted slice thickness was key. This approach provides a robust framework for task-specific CT protocol optimization and is transferable to other interventional procedures.
Limitations: The limitations of the study are single centre study and

Expanding radiographers' knowledge and skills through Virtual Reality (VR): A bridging role in preoperative assessment. A pilot experience (6 min)

Andrea Masperi; Abbiategrasso / Italy

Author Block: A. Masperi, G. Di Stefano, C. Gallotta, M. Vertemati; Milan/IT
Purpose: To evaluate the value of 3D CT reconstructions visualised in VR for preoperative planning in paediatric and adult thoracic surgery, and to assess through a pilot study the role of radiographers as key professionals in the workflow, from image acquisition to VR scenario creation and clinical collaboration.
Methods or Background: We conducted a feasibility study including eight patients, five paediatric and three adults, selected in collaboration with the surgical team to represent different anatomical and pathological scenarios.
CT datasets were processed into patient-specific 3D models and integrated into immersive VR environments. The workflow included: 1) segmentation with 3D Slicer, 2) rendering optimisation in Blender, 3) VR development in Unity, and 4) deployment on Meta Quest 3. Models were validated with surgeons through a mixed assessment: a seven-item Likert survey (1–5) and open-ended feedback on anatomical accuracy and surgical planning.
Results or Findings: In paediatric cases, VR improved vascular and bronchial assessment, supporting thoracoscopic or conservative strategies. In adults, it enhanced anatomical understanding and team communication, with limited impact on surgical choices. All models scored highly (4–5/5) for accuracy and clinical value.
Conclusion: Radiographers demonstrated the ability to manage the full workflow from imaging to VR, enhancing data optimisation, 3D modelling, and teamwork to support surgical planning. By streamlining processes and reinforcing clinical decision-making, they establish themselves as key professionals in precision surgery.
Limitations: This study involved a small and heterogeneous cohort without a control group and relied on qualitative data. Model accuracy depended on CT quality, while the VR workflow required specific skills that were progressively acquired during the process. Nevertheless, it represents the first Italian experience of VR-based surgical planning led by radiographers.
Funding for this study: This study is based on the ongoing agreement for the provision of virtual 3D models between PRINTMED-3D (Integrated Platform for Three-Dimensional Medical Technologies), awarded in 2019 under the "Call Hub Research and Innovation" program by Regione Lombardia, supported within the MUSA (Multilayered Urban Sustainability Action) project funded in 2022 by the National Recovery and Resilience Plan (PNRR), and the Vittore Buzzi Children's Hospital, part of ASST FBF-Sacco.

Evaluation of Needle Artefact Reduction Techniques in CT-Guided Biopsy Imaging (6 min)

Clare Rainey; Cork / Ireland

Author Block: S. Toomey, B. Normoyle, A. England, C. Rainey, N. Moore, L. McLaughlin, M. F. Mcentee, M. Maher; Cork/IE
Purpose: CT-guided lung biopsy plays an important role in diagnosing malignant lung lesions. However, the presence of biopsy needle containing metal components introduces unwanted streak artefact that can obscure needle tip visualisation. This study aims to evaluate the impact of various protocols and needle size on axial streak artefacts.
Methods or Background: Two needles 18G and 20G with and without stylets were imaged in a watermelon using protocols at 70,80,100,120 kV with multiple reconstruction techniques including ASIR, DLIR and MAR. Signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR) were calculated across multiple ROIs to objectively compare image quality. Line plot profiles were used to calculate the artefact width for each protocol.
Results or Findings: The Interventional Protocol produced the highest SNR values for 18G and 20G biopsy needle. In line plot profile analysis, less streak artefact from the biopsy needle was produced in the Interventional Protocol. In the 20G smaller gauge needle, produced less streak artefact with the stylet out compared to the 18G. The higher tube voltages particularly in 100 and 120 kV reduced streak artefact for both biopsy needles.
Conclusion: The Interventional Protocol demonstrated consistent metal artefact reduction generated by 18G and 20G biopsy needle. This reduction may lead to a better depiction of the needle tip inside the nodule of interest.
Limitations: Study acquisitions were based on imaging a watermelon, watermelons have been used in similar experiments but are not necessarily a valid substitute for humans,.

Shaping Radiography Education: Radiographers Designing Modular 3D-Printed Angiographic Simulators (6 min)

Andrea Masperi; Abbiategrasso / Italy

Author Block: A. Masperi, F. Cavaliere, S. Boniardi, M. Vertemati, F. Pezzotta; Milan/IT
Purpose: To pioneer a shift in radiographer education by moving beyond traditional lectures toward immersive, practice-based learning through simulation. Within the specialized field of interventional and angiographic radiology, radiography students conceived and built a modular 3D-printed angiographic simulator.
Methods or Background: A modular 3D-printed angiographic simulator was developed from angio-CT datasets extending from femoral to supra-aortic arteries. The workflow included: 1) image segmentation with 3D Slicer, 2) mesh refinement in Meshmixer, 3) modeling and support design with Fusion, 4) resin-based additive printing of vascular structures, and 5) post-processing and casting to assemble the simulator. Validation was conducted by radiographers and interventional radiologists using a 5-point Likert scale to assess anatomical fidelity and suitability for practice.
Results or Findings: Five radiographers and three interventional radiologists evaluated the 1:1 scale simulator, reporting high anatomical fidelity (median rating ≥4/5) and strong suitability for practicing catheter navigation and angiographic techniques, highlighting its potential as a safe and reproducible training tool.
Conclusion: This project established an innovative educational paradigm in interventional radiology through the creation of a modular 3D-printed angiographic simulator, designed by radiographers for radiographers. Beyond enhancing technical competence, critical reasoning, and professional autonomy, the simulator represents a scalable and reproducible model that can transform radiographer education internationally, fostering a new generation of professionals equipped for the evolving challenges of interventional practice.
Limitations: This study has some limitations. High production and assembly costs may hinder broader implementation, while radiographers' skills in 3D printing and post-processing are still developing. Moreover, the simulator has not yet undergone structured testing with students, and its educational effectiveness requires further validation.

Radiation Dose Monitoring in Interventional Cardiology: Patient, Occupational, and Pediatric Perspectives from Latin America (6 min)

Marcus Vinicius Linhares Oliveira; Salvador / Brazil

Author Block: M. V. L. Oliveira[1], J. Ferreira[1], I. Modesto[1], E. Matos[1], D. Andrade[1], L. Santana[1], C. Ubeda[2], M. Navarro[1]; [1]Salvador/BR, [2]Arica/CL
Purpose: To review and synthesize recent Latin American research strategies on dose monitoring in fluoroscopy-guided and cardiology procedures, highlighting patient, occupational, and quality-assessment perspectives.
Methods or Background: A PubMed search was conducted using the terms Diagnostic reference level OR Radiation dose monitoring AND (fluoroscopy OR cardiology OR fluoroscopy guided interventional procedures) AND ("Latin America" OR Brazil OR Argentina OR Chile OR Colombia OR Peru OR Venezuela OR Ecuador OR Uruguay OR Paraguay OR Bolivia) for studies published between 2010and 2025. A thematic synthesis was applied to group studies into patient monitoring, risk assessment, pediatric DRLs, and occupational exposure.
Results or Findings: Twenty-two articles were selected. Brazilian institutions reported comprehensive patient dose registries, with one multicenter database covering over 10,000 cardiology procedures and identifying patients reaching substantial radiation dose levels (SRDLs), triggering dermatological follow-up. The MARP (Modelo de Avaliação de Risco Potencial) model compiled more than 200,000 records across 121 institutions, providing structured indicators for quality evaluation. Pediatric studies proposed initial DRLs using age- and weight-based criteria, addressing a critical gap in radiation protection for children. Occupational assessments revealed lens doses averaging 25–47 µSv/procedure, with estimated annual exposures of 6–11 mSv, and frequent extremity overexposures due to hand positioning.
Conclusion: Brazil's initiatives illustrate the feasibility of structured dose monitoring and DRL implementation in interventional cardiology. Expanding these models through regional collaboration, standardized protocols, and occupational protection strategies is essential to strengthening radiation safety across Latin America.
Limitations: Coverage across Latin America remains limited, and gaps persist in multinational registries, prospective interventions, and long-term patient outcomes.

Personalized Weight-Tiered Protocols in Angiotomography: The Synergy Between Canon Prime SP and Stellant SmartFlow Injector in Improving Diagnostic Quality (6 min)

José Thiago De Souza De Castro; Campinas / Brazil

Author Block: J. T. d. S. d. Castro, D. C. Novais da Silva, H. d. J. Ferreira, D. Yamada, S. San Juan Dertkigil, F. Reis; Campinas/BR
Purpose: Diagnostic quality in angiotomography relies on adequate vascular opacification (arterial Hounsfield Units, HU). Even with advanced technologies, standardized protocols ignoring patient weight often lead to suboptimal contrast. A study at HC-UNICAMP with 1,082 CTAs confirmed significant influence of weight, venous access type/caliber, contrast flow on arterial density. These findings informed personalized, weight-tiered protocols starting June 1, 2025.
Methods or Background: Retrospective analysis included 1,082 CTA exams performed with a Canon Prime SP 80-channel CT, Stellant SmartFlow injector (Bayer), and 300 mg/mL iodinated contrast. Variables collected included weight, age, venous access type/caliber, contrast flow, and arterial HU. Exams were quality-classified per ACR criteria: <250 HU (poor), 251–349 HU (average), and ≥350 HU (excellent). Following this analysis, new personalized weight-tiered protocols were implemented from June 2025, adjusting kVp, flow, contrast volume, and dose modulation for specific weight ranges (e.g., PE protocol for weights up to >100kg), with tailored parameters for each.
Results or Findings: Preliminary data shows significant improvement in contrast opacification: the percentage of exams >350 HU increased from 30% to 70%. An approximate 15% reduction in effective radiation dose was also observed. These are partial results from over 140 exams performed up to June 25, 2025, indicating that the personalized angiotomography protocols are extremely promising.
Conclusion: The implementation of personalized weight-tiered protocols in angiotomography at HC-UNICAMP marks a data-driven shift, optimizing diagnostic quality while reducing radiation dose and contrast volume. The synergy between the Canon Prime SP CT and Stellant SmartFlow injector, coupled with the radiology team's input, was crucial. This project serves as a model for other institutions, with prospective monitoring and full results to be presented at ESR2026.
Limitations: Results are being updated according to the new protocol's implementation, with ongoing data collection.
Funding for this study: Not applicable.

Preoperative Contrast-Enhanced Magnetic Resonance Angiography for Perforator Mapping in Free Flap Reconstruction after Oncological Head and Neck Surgery: Protocol Optimization and Clinical Feasibility (6 min)
Fleur De Geer; Amsterdam / Netherlands

Author Block: F. De Geer[1], L. C. ter Beek[1], A. Te Boekhorst[1], B. Plakke[1], L. Karssemakers[1], R. Dirven[1], F. Siepel[2], M. Van Alphen[1], W. Schreuder[1]; [1]Amsterdam/NL, [2]Enschede/NL
Purpose: Large head and neck defects following oncological resection are often reconstructed using free vascularized tissue flaps such as the anterolateral thigh flap (ALT) and fibula free flap (FFF). These flaps depend on small perforator vessels for perfusion. Preoperative Magnetic Resonance Angiography (MRA) could offer detailed insights into perforator course, caliber, origin and main pedicle length and could aid in successful surgical flap design and elevation. This study presents an optimized MRA protocol for head and neck cancer patients scheduled for oncological resection with ALT or FFF reconstruction.
Methods or Background: Using a 3.0-T Philips MRI system (dStream Achieva), T1-weighted 3D gradient echo DIXON sequences are acquired: pre-contrast, arterial, and early venous phases after gadolinium-based contrast injection. Scans are fluoroscopically triggered with centra k-space acquisition initiated two seconds post-trigger. Post-contrast axial slices are analyzed for perforator identification. Vascular structures and surrounding anatomy are segmented and rendered into 3D models. Based on the MRA-based 3D models, a surgical plan is created and translated into the operating room with 3D printed perforator marking guides.
Results or Findings: Nineteen patients underwent surgery using this protocol. In all cases, intraoperative perforators matched those visualized on MRA. Seventeen surgeries followed the preoperative plan; two required intraoperative adjustments. The mean System Usability Score (SUS) for the 3D models as evaluated by the operating surgeons was 73.7 (SD 9.0), indicating the clinical utility of this method.
Conclusion: Preoperative MRA combined with 3D modeling enables accurate perforator mapping and enhances surgical planning for head and neck reconstruction using lower extremity perforator flaps.
Limitations: The current protocol requires gadolinium-based contrast agents, though MRI offers potential for non-contrast-enhanced vascular imaging. Research in our institute is ongoing to optimize such sequences and preliminary results will be presented at ECR.
Funding for this study: Not applicable.

Unique aortic remodeling and device-related complications after PETTICOAT endovascular repair (6 min)
Nina Kerschbaumer; Palo Alto / United States

Author Block: N. Kerschbaumer[1], A. Fereydooni[1], D. Vigneault[1], K. Bäumler[1], G. Mistelbauer[1], D. Mastrodicasa[2], E. George[1], D. Fleischmann[1]; [1]Stanford, CA/US, [2]Seattle, WA/US
Purpose: To identify anatomic and device-related factors associated with aortic remodeling and complications following PETTICOAT(Provisional-Extension-To-Induce-Complete-Attachment).
Methods or Background: The concept of scaffolding the aortic true lumen (TL) with bare-stent distal to standard TEVAR has become valuable in dissection treatment. However, anatomical and technical factors associated with treatment outcomes have not been established.
In this observational, single-center study two cardiovascular radiologists reviewed a retrospective cohort of 64 patients with complicated type-B-dissection or residual descending dissection after type-A-repair, treated with distal bare-stent extension. Available pre-/postoperative and follow-up (median 15 months) CT-angiograms were assessed.
Results or Findings: We identified four distinct, PETTICOAT-specific phenomena:
First, small contrast jets into the false lumen (FL) through dissection flap fenestrations corresponding to intercostal arteries were observed at several bare-stent levels, typically thrombosing throughout follow-up.
Second, in contrast to covered endografts, the aortic TL can fully re-expand, even beyond the diameter of the bare-stent, with gradual complete absorption of the FL thrombus (n=1).
Third, we observed new focal contrast outpouchings in the dissection flap separating the TL from the thrombosed FL (proposed term: 'junctional SINE') at the junction between covered and uncovered stents (n=2). These can be explained as intimal erosions caused by protruding bare-stent wires, associated with abrupt caliber changes and 'telescoping' where the bare-stent exits the endograft.
Fourth, all cases of bare-stent migration (n=3), were associated with junctional SINEs. Predisposing factors for migration were short device overlaps within angulated aortic segments.
Conclusion: Temporary intercostal fenestrations and TL re-expansion beyond device diameter may be part of normal healing. The prognosis of 'junctional SINEs' and their association with aortic angulation and device migration may impact patient selection and device design.
Limitations: This study identified unique imaging features, but is underpowered to establish prognostic significance of these observations.

70 kVp with deep learning image reconstruction in aortic CTA: Halving radiation and contrast dose while maintaining endoleak detection post-TEVAR (6 min)

Ping Hou; Zhengzhou / China

Author Block: P. Hou; Zhengzhou/CN
Purpose: To evaluate the feasibility of reducing radiation dose and contrast medium (CM) volume in aortic CT angiography following thoracic endovascular aortic repair (TEVAR) using 70 kVp and deep learning image reconstruction (DLIR), and to assess its capability in detecting subtle endoleaks.
Methods or Background: Sixty-five patients undergoing post-TEVAR aortic CTA were prospectively enrolled and divided into two protocols: Group A (100 kVp, 60 mL CM) reconstructed with 50% ASIR-V, and Group B (double-low: 70 kVp, weight-adapted CM [0.5 mL/kg]) with four reconstruction subgroups: filtered back projection (B1), 50% ASIR-V (B2) and DLIR-H (B3). Objective metrics (CT values, noise, contrast-to-noise ratio [CNR], figure of merit for CNR [FOMCNR]) and subjective image quality (noise, sharpness, overall quality) were evaluated by two blinded radiologists. Endoleak detection rates were compared across groups.
Results or Findings: Group B3 demonstrated the lowest noise, with a 23.49% reduction versus Group A ($P < 0.001$), while aortic CT values, CNR, and subjective scores remained comparable ($P > 0.05$). FOMCNR in B3 was significantly higher than in A ($P < 0.001$). Group B achieved a 52.38% reduction in radiation dose ($P < 0.001$), alongside 39% and 33.6% reductions in CM volume and injection flow rate, respectively ($P < 0.001$). For endoleak detection, Group B3 achieved 100% sensitivity, matching Group A. Subgroups B1 and B2 showed lower detection rates (76.3% and 81.5%, $P < 0.05$).
Conclusion: 70 kVp combined with DLIR-H enables substantial reductions in radiation dose and CM volume without compromising image quality or diagnostic accuracy for detecting subtle endoleaks post-TEVAR.
Limitations: Not applicable.
Funding for this study: No funding was received for this study.

Imaging role in diagnosing and monitoring Takayasu arteritis in pediatric patients (6 min)

Shreyosi Santra; Vellore / India

Author Block: S. Santra, L. K. B P, E. Joseph, A. IRODI, L. Robinson Vimala ; Vellore/IN
Purpose: To highlight the significance of radiological imaging in evaluating disease progression and guiding immunomodulation in pediatric patients with Takayasu arteritis.
To develop an optimal workflow of radiological techniques to minimise radiation exposure in this vulnerable age group.
Methods or Background: A retrospective analysis of fifteen pediatric patients diagnosed with Takayasu arteritis at our institute between 2014 and 2024 was conducted.
The study evaluated the role of Computed Tomography (CT) angiography, Magnetic Resonance angiography (MRA), and Positron Emission Tomography-Computed Tomography (PET-CT) in diagnosis and follow-up in pediatric patients with Takayasu arteritis. Radiological findings were compared with clinical presentation and lab parameters- ESR & CRP.
Results or Findings: Wall thickening, stenosis, dilation, aneurysm, signs of organ damage, such as a contracted kidney in renal artery stenosis, and collateral vessel formation were the observed imaging features.
The majority of patients underwent CT angiography for diagnosis. Dose-limiting techniques such as high pitch, iterative reconstructions, body-adapted protocols, and shielding for thyroid and gonads should be included in the workflow of evaluation of pediatric patients with Takayasu arteritis.

The CARDS score can be used to assess the disease severity. On comparing the CARDS score with laboratory parameters –CRP & ESR in follow-up patients, no definitive pattern was found, thus making imaging crucial for disease assessment.
Conclusion: Radiological investigations are crucial for evaluating disease activity and progression, as the accuracy of lab parameters for Takayasu arteritis is limited in diagnosis and disease progression. However, due to significant concerns regarding radiation exposure to this age group requiring repeated follow-up examinations, judicious use of radiation and non-radiation-emitting techniques is highly recommended in managing these patients.
Limitations: No limitations

CE-Boost Delayed-Phase CTA for Type II Endoleaks after EVAR: Improved Detection and Feeding Vessel Identification (6 min)

Huasong Cai; Guangzhou / China

Author Block: R. Xu, D. Xie, Z. Lai, H. Ma, H. Cai; Guangzhou/CN
Purpose: Type II endoleaks are the most common complication after endovascular aneurysm repair (EVAR) and often require secondary embolization. Conventional delayed-phase CTA may miss low-flow leaks and inadequately depict feeding vessels. We assessed whether post-processing with contrast enhancement boost (CE-boost) improves detection of type II endoleaks and feeding-vessel identification compared with conventional CTA, using DSA as reference.
Methods or Background: This retrospective study included 26 EVAR patients (mean age 72 ± 6.5 years; 19 men) with suspected type II endoleaks. All underwent arterial- and delayed-phase CTA; delayed-phase images were further processed with CE-boost. Endoleak attenuation (HU), signal-to-noise ratio (SNR), contrast-to-noise ratio (CNR), and endoleak area (mm^2) were measured. Two blinded radiologists scored endoleak visibility and feeding-vessel delineation on a 4-point scale. Sensitivity, specificity, and accuracy for feeding-vessel identification were determined against DSA.
Results or Findings: CE-boost increased endoleak attenuation (159 vs. 113 HU), SNR (26.0 vs. 9.0), and CNR (17.3 vs. 5.1) compared with conventional delayed-phase CTA (all $p < 0.001$), and yielded a larger measured endoleak area (168 vs. 122 mm^2, $p = 0.002$). Median visibility scores improved (4 vs. 3, $p < 0.001$), as did delineation of feeding vessels (3.5 vs. 2.2, $p < 0.001$). Against DSA, conventional CTA achieved sensitivity 80%, specificity 95%, and accuracy 88%; CE-boost improved sensitivity to 95%, specificity to 96%, and accuracy to 95% ($p < 0.01$ vs. conventional).
Conclusion: CE-boost applied to delayed-phase CTA significantly enhances visualization of type II endoleaks and improves diagnostic accuracy for feeding-vessel identification. This technique supports more confident diagnosis and treatment planning, though validation in larger, multicenter cohorts is needed.
Limitations: This single-center retrospective study with a small sample size may be subject to selection bias, and further multicenter validation with larger cohorts is required

Dual-Energy CT in the Follow-Up of endovascular treated Visceral Aneurysms: Overcoming the Metal Artifact Challenge (6 min)

Giangabriele Francavilla; San Giovanni Rotondo / Italy

Author Block: G. Francavilla, L. M. Cacioppa, M. Rosati, P. Boscarato, N. Rossini, S. Ielpo, R. Candelari, C. Floridi, A. Giovagnoni; Ancona/IT
Purpose: Follow-up of visceral aneurysms treated with metallic coils remains challenging for conventional CT due to metal artifacts that limit evaluation of the aneurysm sac and adjacent vessels. Dual-Energy CT (DECT), through virtual monoenergetic images (VMI) and iodine maps, may improve diagnostic accuracy and reduce the need for confirmatory angiography.
Methods or Background: Seventeen patients with true visceral aneurysms (splenic, hepatic, renal, and mesenteric) treated by coil embolization were retrospectively analyzed. All underwent DECT follow-up between 1 and 6 months. High-keV VMI (100–140 keV) were evaluated for artifact reduction and morphological assessment of the aneurysm sac and surrounding tissues, while low-keV VMI (40–60 keV) and iodine maps were used for detection of in/out arterial feeders and residual perfusion.
The analysis was performed both qualitatively and quantitatively: qualitative assessment was conducted using a 5-point Likert scale for image quality and diagnostic confidence, while quantitative evaluation included placement of circular regions of interest (ROIs) to measure attenuation values and image noise.
Findings were compared with conventional CT reconstructed at 120 kVp and, when available, with angiography as the reference standard.
Results or Findings: High-keV VMI significantly reduced coil-related artifacts, improving diagnostic readability ($p < 0.05$). Low-keV VMI increased sensitivity for intravascular contrast, allowing identification of feeders and residual perfusion not visible on conventional CT. Iodine maps confirmed these findings, helping to differentiate true enhancement from artifacts.
Conclusion: DECT provides clear advantages over conventional CT in the follow-up of coil-embolized visceral aneurysms. High-keV VMI reduce metallic artifacts, while low-keV VMI and iodine maps enhance detection of feeders and residual flow. DECT may become the reference imaging tool for post-procedural monitoring, improving patient management and reducing the need for angiographic confirmation.
Limitations: The limited number of cases

Analysis of Factors Influencing the Efficacy of Ovarian Vein Embolization for Pelvic Venous Insufficiency and Construction of and Performance Evaluation of a Short-Term Efficacy Prediction Model (6 min)

Binyu Zheng; Beijing / China

Author Block: B. Zheng; Beijing/CN
Purpose: The study aims to elucidate the related factors of short-term efficacy of Ovarian Vein Embolization (OVE) in the treatment of pelvic venous insufficiency (PVI), constructs a predictive model for short-term efficacy of OVE, and evaluates its predictive efficacy.
Methods or Background: Clinical and ultrasound data were retrospectively collected from female patients with PVI who underwent OVE at Shijitan Hospital. This study was the first to apply the Minimal Clinically Important Difference to define symptomatic improvement in the Pelvic Venous Clinical Severity Score. Symptomatic improvement was the evaluation standard, and factors affecting short-term efficacy were analyzed. The ROC curve assessed predictive efficacy. Internal validation used k-fold cross-validation to evaluate discrimination, calibration, and clinical utility.
Results or Findings: (1) The study included 82 patients: 43 in the remission group and 39 in the non-remission group. (2)There were significant differences between the two groups in the duration of abdominal discomfort, the diameters of the left ovarian and parametrial veins, and the presence of internal iliac vein reflux..(3) Logistic regression revealed that longer abdominal discomfort, smaller left ovarian vein diameter, and internal iliac vein reflux were independent risk factors for poor short-term efficacy of OVE. The ROC curve AUC was 0.807, with a best cut-off value of 0.453. Sensitivity and specificity for predicting efficacy were 82.1% and 74.4%. Internal validation showed discrimination (AUC=0.779), a Brier score of 0.176 indicating accuracy, reasonable calibration, and positive net clinical benefit in decision curve analysis.
Conclusion: (1) The duration of lower abdominal discomfort, ovarian vein diameter and internal iliac vein reflux are independent predictors of the short-term efficacy of OVE for PVI. (2) The prediction model of short-term efficacy of OVE for PVI in this study has satisfactory validity.
Limitations: No external validation

PAD-RADS: A Novel Comprehensive Reporting System for Peripheral Artery Disease (6 min)

Andreea-Emilia Iacobut; Basel / Switzerland

Author Block: A-E. Iacobut[1], P. J. Kettnaker[2], R. W. Huegli[1], D. Bilecen[2]; [1]Bruderholz/CH, [2]Liestal/CH
Purpose: To introduce PAD-RADS, a novel, comprehensive Peripheral Artery Disease Reporting and Data System for standardizing computed tomography angiography (CTA) reporting in patients with known peripheral artery disease (PAD).
Methods or Background: Despite advances in CTA technology and increasing use for PAD assessment, there is currently no standardized reporting system equivalent to CAD-RADS for coronary CTA. The lack of structured reporting hinders effective communication between interpreting and referring physicians, limits multicenter research, and creates inconsistencies in patient management recommendations. PAD-RADS was developed to address these gaps by categorizing lesion severity, quantifying overall atherosclerotic burden, and incorporating key modifiers relevant for clinical decision making.
Results or Findings: PAD-RADS assigns a grade (0–5) based on the most severe arterial lesion per limb, with 0 indicating no stenosis and 5 representing total occlusion. The system is complemented by a plaque burden score (P0–P4) and a set of clinical modifiers (e.g., non-diagnostic segments, stents, grafts, collateralization, uncalcified plaques etc.). Case-based application demonstrates enhanced reproducibility, clarity in identifying culprit and incidental lesions, and improved reporting quality in both outpatient and acute care settings. The proposed system serves as a framework for quality assurance and education.
Conclusion: PAD-RADS offers a structured, reproducible method for reporting peripheral artery imaging that has the potential to improve communication, research, and clinical care in PAD. Prospective studies are needed to validate its utility and impact on patient outcomes.
Limitations: PAD-RADS may oversimplify complex clinical scenarios and requires careful integration with clinical context. Its applicability in diverse populations, interobserver reliability, and effectiveness across different healthcare settings require further investigation. Adoption will necessitate prospective validation, multidisciplinary education and consensus building.
Funding for this study: No funding was received for the present study.

Radiation protection: Safety measures and knowledge among interventional radiologists – a UK-based analysis of current practices and recommendations for improvement (6 min)

Rayhan Yousef Gasiea; Blackburn / United Kingdom

Author Block: R. Y. Gasiea[1], A. T. Rogers[2], R. Lakshminarayan[3], M. Hamady[4], B. Huasen[5]; [1]Blackburn/UK, [2]Nottingham/UK, [3]Hull/UK, [4]London/UK, [5]Manchester/UK
Purpose: Minimally invasive procedures using X-rays have been taken over many traditional surgical techniques, less focus has been placed on the complications faced by primary operators compared to achieving better success rates and outcomes for procedures. The major focus has always been on patient safety and patient dose, which is important. However, there is no doubt that radiation exposure also poses risks to staff working in Interventional Radiology (IR). Over the years, protection for staff has improved, although this progress has unfortunately been driven by first-hand complications observed in healthcare providers.
Methods or Background: Together with the British Society of Interventional Radiology (BSIR), a survey was conducted to better understand current practice and availability to operators who use ionising radiation for their vascular and non-vascular practice. This was sent out to members over the 2023-2024 period.
Results or Findings: 112 respondents received across 22 vascular centres in the UK, including pregnant female members, helped gauge an understanding of current practice. We review and discuss the results obtained from the 30 questions asked.
Conclusion: The survey demonstrates some concern and also positive findings in terms of awareness. Clinicians are innovators and problem solvers. With the increased use of ionising radiation in clinical practice, radiation from scatter and strain from garments.
Limitations: N/A

1. To understand how ultrasound contrast media enhance imaging and their role in diagnosis.
2. To assess patient suitability: recognise the importance of patient screening for contraindications before administering contrast.
3. To learn key steps to safely administer ultrasound contrast and monitor for potential adverse effects.

Individualised contrast injection in CT: from protocols to practice (10 min)
Svea Deppe Moerup; Middelfart / Denmark

1. To understand personalised contrast protocols by recognising the need for individualised contrast injection strategies in CT imaging based on patient factors.
2. To assess patient characteristics: Learn how to evaluate factors such as renal function, body weight, and medical history to tailor contrast doses and injection techniques.
3. To identify best practices for ensuring patient safety and optimising imaging quality through personalised contrast administration in CT.

Contrast in mammography: technical protocols and safety standards (10 min)
Cristina Poggi; Sesto Fiorentino (FIRENZE) / Italy

1. To understand the contrast role in mammography, recognising how contrast media improve visualisation of breast tissue and the detection of subtle lesions.
2. To identify indications for contrast in mammography, such as for dense breast tissue or inconclusive mammograms.
3. To apply safety measures for mammography contrast, ensuring proper contrast administration, minimising risks unique to mammography.

Panel discussion: Safer contrast use, what else can we do? (15 min)

RPS 2305 - How AI is redefining prostate cancer detection, risk stratification and prognosis: from promising research to clinical impact

Evaluating AI assistance in clinically significant prostate cancer diagnosis using MRI (6 min)
Ying Hou; Nanjing / China

Author Block: Y. HOU; Nanjing/CN
Purpose: Artificial intelligence (AI) is potential as an assistant in support of human in diagnosing clinically significant prostate cancer (csPC) with MRI. We aimed to test the noninferiority and superiority of human-AI collaboration to human stand-alone review in csPC diagnosis with MRI.
Methods or Background: This observer study was conducted in four randomized cohorts (n = 1,305) who initially underwent MRI for csPC from two medical centers. A clinically available AI system was implemented as an assistant or not to stand-alone double reading in 21 readers to flag cases for further arbitration review among MRI-screened men with suspicious csPC. The secondary outcome was the clinically insignificant prostate cancer (ciPC) diagnosis.
Results or Findings: In four observer groups, except for junior readers in center 1, Human-AI collaboration was equal to human-alone (AUROC, 0.87 vs 0.82; P = .069), regardless of experience, readers with human-AI collaboration were superior to readers with human-alone (AUROC, 0.86 ~ 0.94 vs 0.70 ~ 0.86; all P-values < .001) in patient-level csPC diagnosis. Using PI-RADS ≥ 3 as diagnosing indication, human-AI collaboration achieved higher sensitivity (92.9% [688/740] vs 87.6% [617/704]; Odds ratio [OR], 1.86 [1.30- 2.67], P = .0007), higher specificity (66.2% [408/616] vs 46.7% [257/550]; OR, 2.23 [1.76- 2.83], P < .0001) than human-alone for csPC diagnosis. For ciPC, human-AI collaboration did not increase risk for over cancer detection rate (6.2% [38/616] vs 4.7% [26/550], OR, 1.30 [0.80- 2.21], P = .276), while achieved higher specificity (68.9% [376/546] vs 46.4% [231/498], OR, 2.56 [1.99-3.29], P < .0.001) than human-alone review.
Conclusion: Human-AI collaboration is noninferior and superior to human-alone review regarding improvement of accuracy in csPC diagnosis and not increase risk for ciPC overdiagnosis at MRI.
Limitations: Further prospective validation

Automated MRI-based segmentation of the prostate, prostatic zones, periprostatic space, urethra and seminal vesicles using Convolutional Neural Networks trained on expert-annotated data (6 min)
Szilvia Tótin; Dunaújváros / Hungary

Author Block: S. Tótin[1], W. Holmlund[2], A. T. Simkó[2], T. Z. Kincses[1], E. Koós[1], P. Palásti[1], Z. Fejes[1]; [1]Szeged/HU, [2]Umeå/SE
Purpose: Accurate delineation of prostate zones and adjacent structures is essential for diagnosis, radiotherapy planning and surgical decision-making in prostate cancer. Manual contouring is time consuming and prone to variability. This study aimed to develop and validate convolutional neural networks (CNNs) for automated segmentation of the prostate zones, urethra, periprostatic neurovascular bundle and seminal vesicles on MRI, using a large expert-annotated dataset.
Methods or Background: We used T2-weighted multiparametric MRI scans from 200 PROSTATEx patients. Manual segmentations of the peripheral, central and transitional zones, anterior fibromuscular stroma were performed in 3D Slicer following PI-RADS v2.1 supplemented by the urethra, seminal vesicles and periprostatic bundle. 40 cases were independently annotated by two radiologists to provide inter-reader variability. The CNNs were trained on 160 cases and validated on 40 test cases. Performance was assessed using Dice Similarity Coefficient (DSC), Surface Dice Measurement (SDM) at multiple tolerance levels and Center Line Distance (CLD) for urethral evaluation, using Hero Imaging software.
Results or Findings: The CNNs achieved segmentation accuracy comparable to expert readers. For the prostate, the mean DSC value exceeded 0.90, matching inter-reader variability (0.913±0.0027). Urethral delineation achieved CLD values of 3.0 mm, similar to radiologist agreement (3.6 mm). The CNNs extended reliable segmentations to the central, peripheral and transitional zones, anterior fibromuscular stroma, periprostatic bundle and seminal vesicles, reaching agreement levels comparable to experienced radiologists.
Conclusion: Our CNN framework enables realiable, automated MRI segmentation of the prostate zones, urethra, periprostatic space and seminal vesicles. By reducing workload it has the potential to support standardized diagnosis, precise radiotherapy with urethral and periprostatic sparing and informed surgical planning.
Limitations: Partial external validation (performed on the prostate zones only).
Some regions showed high inter-reader variability, which may indicate the need to harmonize image interpretation.
Funding for this study: No funding was provided for this study.

Integrating Automated Neurovascular Bundle Segmentation and Radiomics Biomarkers for Diagnostic and Prognostic Modeling in Prostate Cancer (6 min)

Gemma Urbanos; Madrid / Spain

Author Block: G. Urbanos, A. Jimenez-Pastor, A. Nogue, G. Ribas, F. J. E. Higa, C. Fontenla Martínez, V. Belloch Ripollés, L. Marti-Bonmati, A. Alberich-Bayarri; Valencia/ES
Purpose: Accurate evaluation of the prostatic neurovascular bundles (NVBs) in prostate cancer (PCa) informs staging and treatment but remains difficult to standardize. This study developed an automated pipeline for NVB segmentation, tumor–NVB invasion risk stratification, and radiomics-based prediction of biochemical recurrence (BCR), perineural invasion (PNI), and extraprostatic extension (EPE).
Methods or Background: We collected 807 PCa MRI real-world exams from three sources. Apparent Diffusion Coefficient (ADC) maps and prostate/lesion segmentations were obtained with QP-Prostate®. Experts manually annotated NVBs in 470 T2-weighted (T2w) series, used to train a nnU-Net 3D full-resolution model. Data were split into 80% training/validation and 20% testing. In patients with peripheral zone (PZ) lesions (N=65), minimum lesion–NVB distance was computed and categorized as high (<2 mm), intermediate (2–5 mm), or low (>5 mm) risk.

The trained model was applied to 280 diagnostic cases with PZ lesions and clinical data. Radiomic features from lesions and NVBs (ADC and T2w), extended with PSA and age, were used to predict PNI (185-, 91+), EPE (131-, 64+), and BCR (35-, 43+). Pipelines included normalization, feature selection, outlier removal, and class balancing. Different classification models were trained with 5-fold cross-validation.
Results or Findings: The results were assessed on the test set. NVB segmentation showed a mean surface distance of 1.02 (0.58–1.93) mm and volume difference of 0.41 (0.23–0.76) cc. Tumor–NVB invasion risk classification achieved accuracy of 0.89. Prediction AUCs were 0.73±0.07 for BCR, 0.80±0.05 for PNI, and 0.80±0.05 for EPE. Models combining NVB and lesion radiomics outperformed either region alone.
Conclusion: Automated NVB segmentation enables accurate invasion risk classification and improves prediction of BCR, PNI, and EPE, supporting integration into clinical risk stratification.
Limitations: Retrospective design, moderate segmentation overlap, and limited BCR prediction performance require external validation.

DeepSector-PI: Automated PI-RADS-Compliant Lesion-to-Sector Mapping (6 min)

Rafał Janusz Jóźwiak; Warsaw / Poland

Author Block: R. J. Jóźwiak[1], J. Mycka[1], M. Gonet[1], I. Mykhalevych[1], T. Lorenc[1], A. Zacharzewska-Gondek[2], J. Dołowy[2], K. Tupikowski[2]; [1]Warsaw/PL, [2]Wrocław/PL
Purpose: The PI-RADS 2.1 sector map is a standardized 39-sector grid of the prostate that enables unambiguous lesion localization on mpMRI. We aimed to train a DL-based model for automatic prostate sector mapping and to evaluate its performance on real-world data drawn from an expert-curated mpMRI reference dataset.
Methods or Background: DeepSector-PI is built on a DenseNet-based classification network. To evaluate its performance, we assembled data from 321 mpMRI cases with identified suspicious lesions that were independently reported by three expert radiologists, who annotated all lesions and completed structured reports (SR) including the PI-RADS 2.1 sector map. In total, 845 lesion–sector pairs were used for training, and 106 pairs were reserved for validation. Model performance was stratified by zonal location (PZ/TZ/both), anatomical level (base/mid/apex), and lesion size quantified by the number of sectors involved.
Results or Findings: F1 scores and balanced accuracy were computed across all stratifications. By lesion size, F1 was 0.65 / 0.78 / 0.86 for lesions involving <4, 4–6, and ≥7 sectors, respectively; by zonal location, F1 was 0.77 / 0.73 / 0.67 for lesions confined to PZ, TZ, and both zones, respectively. Balanced accuracy for the same stratifications was 0.90 / 0.87 / 0.91 (size) and 0.92 / 0.91 / 0.84 (zone). We also remapped predictions to a simplified 24-sector scheme, yielding F1 of 0.72 / 0.84 / 0.86 (size) and 0.83 / 0.75 / 0.77 (zone), with corresponding balanced accuracy of 0.91 / 0.90 / 0.90 (size) and 0.94 / 0.92 / 0.86 (zone).
Conclusion: DeepSector-PI provides robust classification of lesion-involved prostate sectors, supporting standardized reporting and targeted biopsy planning. DeepSector-PI performance depends on lesion extent and zonal/anatomical level.
Limitations: Classification requires sector-labeled data from experts or another AI model.

Intralesional and perilesional radiomics strategy based on different machine learning for the prediction of international society of urological pathology grade group in prostate cancer (6 min)

Yongsheng Zhang; Hangzhou / China

Author Block: Y. Zhang, Z. Li; Hangzhou/CN
Purpose: To develop and evaluate a intralesional and perilesional radiomics strategy based on different machine learning model to differentiate International Society of Urological Pathology (ISUP) grade > 2 group and ISUP ≤ 2 prostate cancers (PCa).
Methods or Background: 340 case of PCa patients confirmed by radical prostatectomy pathology were obtained from two hospitals. The patients were divided into training, internal validation, and external validation groups. Radiomic features were extracted from T2-weighted imaging, and four distinct radiomic feature models were constructed: intralesional, perilesional, combined tumoral and perilesional, and intralesional and perilesional image fusion. Four machine learning classifiers logistic regression (LR), random forest (RF), extra trees (ET), and multilayer perceptron (MLP) were employed for model training and evaluation to select the optimal model.
Results or Findings: The AUCs for the RF classifier were higher than that of LR, ET, and MLP, and was selected as the final radiomic model. The nomogram model integrating perilesional, combined intralesional and perilesional, and intralesional and perilesional image fusion had an AUC of 0.929, 0.734, 0.743 for the training, internal, and external validation cohorts, respectively, which was higher than that of the individual intralesional, perilesional, combined intralesional and perilesional, and intralesional and perilesional image fusion models.
Conclusion: The proposed nomogram established from perilesional, combined intralesional and perilesional, and intralesional and perilesional image fusion radiomic has the potential to predict the differentiation degree of ISUP PCa patients.
Limitations: Its retrospective design and limited case number may introduce selection bias. Notably, only patients who underwent radical prostatectomy were included, potentially excluding patients with the most aggressive cancers not suitable for surgery, thus limiting generalizability.
Funding for this study: This study was supported by Zhejiang Traditional Medicine and Technology Program (2024ZL688, 2024ZL668).

From Imaging to Outcomes: A PI-RADS–Driven Radiomics and Clinical Machine Learning Model for Detecting Clinically Significant Prostate Cancer (6 min)

Dimitrios Samaras; Larissa / Greece

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: D. Samaras[1], G. Agrotis[2], M. Vakalopoulou[3], M. Vlychou[1], I. Tsougos[1]; [1]Larissa/GR, [2]Amsterdam/NL, [3]Paris/FR
Purpose: This study aimed to develop and evaluate a machine-learning (ML) framework based on the PI-RADS protocol for detecting clinically significant prostate cancer (csPCa) using multiparametric MRI (mpMRI), simulating radiologists' decision-making.
Methods or Background: The publicly available PI-CAI (Prostate Imaging Cancer AI) dataset was employed, comprising 1,500 cases from 1,476 patients across 11 centers using seven MRI scanners. Among these, 1,075 cases were benign or clinically insignificant prostate cancer (cinsPCa), while 425 represented csPCa, defined as Gleason score (GS) ≥ 3+4. Ground truth labels were derived from biopsy results conducted by urologists, radiologists, or trained medical personnel under supervision. The ML framework followed a two-branch architecture: T2-weighted (T2W) images for the transition zone, and diffusion-weighted imaging (DWI) with apparent diffusion coefficient (ADC) maps for the peripheral zone. In addition to a radiomics-only model, a combined radiomics + clinical model was developed incorporating PSA, age, and prostate volume. Feature extraction was performed using Pyradiomics, including shape and texture features from original and filtered images. Feature space dimensionality was progressively reduced through a multi-stage pipeline: low-variance filtering (threshold 0.01), Pearson correlation pruning ($\rho \geq 0.85$), and Wilcoxon rank-sum testing ($p \leq 0.1$), followed by supervised feature selection restricted to training folds. The dataset was split into 80% training/validation and 20% testing, with five-fold cross-validation. Performance metrics included AUC, sensitivity, specificity, accuracy, balanced accuracy, and F1-score.
Results or Findings: The combined model (radiomics+clinical) outperformed the radiomics-only model, achieving higher AUC in both training (0.79±0.02 vs. 0.76±0.02) and testing set (0.78 vs. 0.73).
Conclusion: Our approach demonstrates strong potential for improving csPCa detection, supporting biopsy decisions, and enhancing patient outcomes.
Limitations: The modest external test set and absence of deep learning benchmarks limit generalizability. Validation on larger, multicenter cohorts and integration into clinical workflows are warranted.
Funding for this study: This work has been partially supported by project MIS 5154714 of the National Recovery and Resilience Plan Greece 2.0 funded by the European Union under the NextGenerationEU Program.

Cross-Sequence Consistency Deep Learning for Detecting Clinically Significant Prostate Cancer in PI-RADS 1–3 Lesions at MRI (6 min)

Lu Bai; Xi'an / China

Author Block: L. Bai, L. Luo, H. Han, W. Wang, J. Yang; Xi'an/CN
Purpose: To develop and validate a deep learning model with a cross-sequence consistency module (CSCM) for improving csPCa detection in bpMRI among PI-RADS 1–3 lesions.
Methods or Background: To develop and validate a deep learning model with a cross-sequence consistency module (CSCM) for improving csPCa detection in bpMRI among PI-RADS 1–3 lesions.This retrospective multicenter study included patients who underwent biparametric MRI (bpMRI) including T2WI, DWI, and ADC sequences. A deep learning framework integrating three 3D ResNet-18 streams for feature extraction and a transformer-based fusion module was developed, with additional CSCM to enhance feature alignment across sequences. The model was tested using two external test sets. Model performance was evaluated using AUC, accuracy, sensitivity, and specificity using histopathologic outcomes as standard.
Results or Findings: A total of 1050 patients with PI-RADS 1-3 lesions were divided into a training set (n=332), internal test set (n=83), external test set one (n=281) and external test set two (n=354). At histopathologic analysis, 22% (230/1050) of patients had csPCa lesions. The DL framework showed AUCs of 0.825, 0.851 and 0.821 for in internal test set, external test set one and two, with corresponding accuracy of 0.907, 0.786 and 0.771, respectively.
Conclusion: A CSCM-based deep learning model with improved identification of csPCa in PI-RADS 1–3 lesions using bpMRI, demonstrating strong generalizability and potential to reduce diagnostic variability and unnecessary biopsies.
Limitations: It is a retrospective study, it carries inherent selection bias,and the analysis did not include dynamic contrast-enhanced (DCE) sequences.
Funding for this study: None.

AI-Assisted Prostate Cancer Detection with MRI: A Clinical Routine Simulation Study (6 min)

Lorenzo Pinto; Naples / Italy

Author Block: L. Pinto[1], G. Di Costanzo[1], C. Riccio[2], A. G. Tucci[1], L. Palumbo[1], R. Cuocolo[3], A. R. R. Padhani[4], M. Imbriaco[2], A. Ponsiglione[2]; [1]Pozzuoli/IT, [2]Napoli/IT, [3]Salerno/IT, [4]Northwood/UK
Purpose: Interest in AI-driven detection of clinically significant prostate cancer (PCa) on MRI is growing. We evaluated a commercial AI system as a concurrent decision-support tool, assessing its impact on radiologists of varying expertise.
Methods or Background: In our retrospective study, consecutive patients underwent multiparametric MRI (mpMRI) for clinical suspicion of PCa. Scans were reviewed by six readers with different expertise, with and without AI assistance. Intra- and inter-reader agreements and the impacts of AI-assisted on patient-level csPCa scores were assessed. Diagnostic performance metrics at patient level and benefit-to-harm ratios were evaluated.
Results or Findings: The study included 100 patients (26% with csPCa). There was no improvement in inter-reader agreement with AI readings (0.584 vs 0.573). Residents were most likely to change PI-RADS scores with AI assistance compared to basic and expert readers (19, 9, and 7 changes, respectively). Overall, there was no significant difference in AUROC between AI-assisted and unassisted readings (0.87 vs 0.86; p = 0.734). At a PI-RADS ≥3 threshold, sensitivity was slightly lower with AI (0.87 vs 0.89), while specificity (0.73), PPV (0.53–0.54), and NPV (0.94–0.95) remained similar. Subgroup analyses showed no significant differences in diagnostic performance. A slight increase in grade selectivity and selective biopsy avoidance was observed among experts and residents, respectively, with AI-assisted readings when applying a PI-RADS cut-off of 3 or PSA density ≥0.15.
Conclusion: AI decision support does not significantly improve diagnostic accuracy for csPCa detection across readers of varying expertise, with minor impacts on benefit-to-harm ratios.
Limitations: We did not fully account for MRI-negative patients who avoided biopsies, so accuracy metrics should be interpreted relative to the evaluated cohort. Lack of per-lesion analysis.

Artificial Intelligence as a Gatekeeper in Prostate Cancer Imaging: Can We Avoid Unnecessary Biopsies? (6 min)

Karen Andreina Bolivar Gil; Buenos Aires / Argentina

Author Block: K. A. Bolivar Gil, F. D. Losada Lopez, J. Camean, L. A. MIQUELINI; Buenos Aires/AR
Purpose: Detecting suspicious lesions suggestive of clinically significant cancer which require biopsy for diagnosis, remains an imaging challenge. The aim of this study is to evaluate the added value of artificial intelligence in radiology reports, in order to avoid unnecessary biopsies.
Methods or Background: This retrospective study analysed a cohort of 141 patients who underwent prostate mpMRI between 2022 and 2025 with the assistance of an AI-based diagnostic tool. All examinations were initially interpreted by an experienced radiologist. Subsequently, patients underwent transperineal cognitive fusion biopsy (MRI–US) targeting between one and four lesions per patient, resulting in a total of 163 lesions. Histopathological evaluation of the biopsy specimens served as the reference standard.
Results or Findings: Diagnostic concordance between expert radiologists and the AI program was observed in 85 cases (60.3%); of these, 68 (80.0%) were positive for clinically significant prostate cancer (Gleason score ≥7) and 17 (20.0%) negative.
On independent analysis, expert radiologists reported 81/141 positive cases (57.4%) and 60/141 negative cases (42.6%). The AI, when limited to concordant cases, identified 68 positives (80.0%) and 17 negatives (20.0%).
AI detected suspicious lesions in 104/141 patients (73.8%). Among the 37 patients without AI-reported lesions (26.2%), histopathology was also negative in 30 (81.1%) and positive for clinically significant prostate cancer in 7 (18.9%). The AI system achieved a sensitivity of 90.7% and specificity of 45.5% for detecting clinically significant prostate cancer, with a PPV of 65.4%, NPV of 81.1%, and overall accuracy of 69.5%.
AI improved the NPV to 85% in low to intermediate risk lesions.
Conclusion: The AI system demonstrated a high NPV, enhancing triage of low to intermediate risk lesions and potentially helping to avoid unnecessary prostate biopsies.
Limitations: Due to the retrospective design, not all AI-reported positive cases underwent biopsy.
Funding for this study: No funding was provided for this study.

Adapting Generative Cross-Modality Image Translation Models for Prostate Magnetic Resonance Imaging (MRI) Denoising: A Large-Scale Study on T2-Weighted Imaging (6 min)

Rafael Moreno Calatayud; Silla / Spain

Author Block: R. Moreno Calatayud, P. Rodríguez Belenguer, J. Gómez-Martínez, J. Aquerreta-Escribano, G. Ribas, A. Galiana-Bordera, L. Cerda Alberich, L. Marti-Bonmati; Valencia/ES
Purpose: Image quality is critical in prostate MRI, as noise and artifacts can obscure anatomical structures, reduce diagnostic confidence, and compromise the performance of downstream automated algorithms. This study evaluated translation-inspired generative models for denoising prostate T2-weighted MRI, aiming to improve image quality while preserving anatomical fidelity.
Methods or Background: This retrospective study included a cohort of 805 patients (>18 years old), divided into a training set and a validation set of 700 and 105 patients respectively, with a confirmed pathology diagnosis of prostate cancer who underwent T2-weighted MRI volumes at Hospital Universitari i Politècnic La Fe from January-2015 to December-2022. Synthetic low-quality images were generated by adding Gaussian noise, bias field inhomogeneities, blurring, and ghosting, while the original scans were used as high-quality ground truths. Two state-of-the-art generative models were adapted to this framework: Biting et al.'s edge-aware GANs (Ea-GAN) and Kim et al.'s adaptive latent diffusion model (ALDM VQGAN). These models were developed for brain MRI to translate T1-weighted images into T1ce, T2, and FLAIR sequences but were repurposed to denoise prostate T2-weighted MRI.
Results or Findings: Quantitative image quality metrics calculated on the model output resulted in a peak signal-to-noise ratio (PSNR), structural similarity index (SSIM) and normalized mean square error (NMSE) of 29.5, 0.86 and 0.04 respectively with the high-quality ground truth image. These values indicate a strong resemblance between the reconstructed and reference images, highlighting the model's ability to reduce noise while preserving underlying anatomical structures.
Conclusion: This pilot study showed generative models can improve image quality of prostate T2-weighted MRI, highlighting potential clinical utility in the early diagnosis of prostate cancer when dealing with noisy acquisitions. Further research is required to validate the model in larger cohorts.
Limitations: No limitations were identified.
Funding for this study: Funding was provided by the Instituto de Salud Carlos III call for Research, Development, and Innovation (R&D&i) Projects related to Personalized Medicine and Advanced Therapies (Transmissions Initiative), co-financed by the European Union-NextGenerationEU /Recovery Plan, transformation and Resilence (RPTR).

Integrating Radiomics and CNN-Based Approaches for Automated PI-RADS 3–5 Classification in Prostate MRI (6 min)

Saman Fouladi; Milan / Italy

Author Block: S. Fouladi, F. Darvizeh, R. Di Meo, L. Di Palma, A. Maiocchi, E. Damiani, M. Alì, D. Fazzini, G. Gianini; Milan/IT
Purpose: Accurate classification of clinically significant prostate cancer remains challenging, particularly in distinguishing aggressive tumors from indolent ones. Although multiparametric MRI (mpMRI) has enhanced lesion detection, effective categorization using the Prostate Imaging Reporting and Data System (PI-RADS) remains complex. This study aims to develop and evaluate complementary automated approaches for PI-RADS classification, focusing on categories 3, 4, and 5, using ADC, DWI, and T2W sequences.
Methods or Background: Three approaches were investigated. First, hand-crafted radiomic features were extracted from manually segmented lesions using the PyRadiomics library. Second, we extended this approach by incorporating fully automated lesion and zonal segmentation to simulate a practical, manual-free pipeline. Third, a custom convolutional neural network (CNN) was trained on ADC images and lesion masks to learn high-level features directly. These features were subsequently used to train multiple machine learning models for multi-class PI-RADS classification.
Results or Findings: Features derived from ADC consistently achieved superior performance, with one ensemble model reaching an accuracy of 0.77 and an AUC of 0.83. Combining features from all sequences further improved robustness (accuracy = 0.73, AUC = 0.84). PI-RADS 5 classification proved most reliable (AUC ≥ 0.94), whereas PI-RADS 3 remained the most challenging to distinguish.
Conclusion: ADC-derived features are highly effective for PI-RADS classification, and integrating automated radiomic extraction with deep learning enhances robustness and practical applicability. Combining multi-sequence information and learning-based approaches offers a promising pathway for automated risk stratification in prostate cancer.
Limitations: The study is limited by the dataset size and the reliance on manually segmented lesions in some approaches, which is time-consuming. Nevertheless, the results are promising, and performance is expected to improve further with larger datasets and fully automated pipelines.
Funding for this study: Funding The work was partially supported by the MUSA-Multilayered Urban Sustainability Action project, funded by the European Union-NextGenerationEU, under the Mission 4 Component 2 Investment Line of the National Recovery and Resilience Plan (NRRP) Mission 4 Component 2 Investment Line 1.5: Strengthening of research structures and creation of R&D "innovation ecosystems", set up of "territorial leaders in R&D" (CUP G43C22001370007, Code ECS00000037); Program "piano sostegno alla ricerca" PSR and the PSR-GSA-Linea 6; Project ReGAInS (code 2023-NAZ-0207/DIP-ECC-DISCO-23), funded by the Italian University and Research Ministry, within the Excellence Departments program 2023-2027 (law 232/2016).

Diagnostic Pitfalls of AI-Assisted Multiparametric MRI in Prostate Cancer Detection: When AI Gets It Wrong (6 min)

Antonella Borrelli; Rome / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: A. Borrelli, L. Laschena, M. Pecoraro, S. Lucciola, E. Messina, V. Panebianco; Rome/IT

Purpose: To evaluate the diagnostic pitfalls of AI-assisted mpMRI in prostate cancer detection

Methods or Background: Artificial Intelligence (AI) applied to mpMRI is increasingly integrated into prostate cancer (PCa) workflows. Its potential in PCa detection has been investigated, but limitations remain underexplored. MRI pitfalls are a major source of false positives. Prostate mpMRI, although accurate, is influenced by anatomical, clinical, and technical factors that can mimic cancer. In this retrospective single-center study, 458 mpMRI scans were reviewed: 150 biopsy-proven PCa, 156 true negatives, and 152 scans previously identified as Pitfalls. After exclusions, 362 cases were processed with AI software.Diagnostic performance was compared with expert radiologist reports and histopathology when available.Errors were classified as false positives and recurring misclassification patterns.

Results or Findings: In the overall cohort of 458 patients (150 cancers, 152 pitfalls, 156 negatives), AI demonstrated a sensitivity of 92.0%, but specificity was only 70.5%, leading to an accuracy of 77.5% and an AUC of 0.66. In the restricted cohort of 306 patients (150 cancers and 156 negatives, excluding pitfalls),sensitivity remained stable at 92.0%,while specificity improved to 93.6%,yielding an accuracy of 92.8% and an AUC of 0.93 in line with literature.

BPH caused the largest number of AI errors, DWI artifacts and ectopic BPH showed the highest misclassificatio rate resembling novice reader challenges and confirming that AI currently mirrors known interpretative limitations.

Conclusion: These results highlight the current limitations of AI tools in prostate imaging, particularly in differentiating cancer from benign mimics, reinforcing the need for expert radiologist oversight in clinical practice.

Limitations: Single-center retrospective study.

The tested AI software may not represent other platforms.

Our Cohort intentionally enriched with pitfalls and challenging cases making it less comparable to everyday practice

The Incidence of High-Frequency Sensorineural Hearing Loss (HF-SNHL) in Patients with Endolymphatic Hydrops (EH) Depicted on Meniere's Disease-MRI (MD-MRI) (6 min)
Siti Nurfarhana Mohd Arif; London / United Kingdom

Author Block: S. N. Mohd Arif, S. Mendis, J. Abdulla, S. Jawad; London/UK
Purpose: According to the 2015 Bárány Society Criteria, definite MD requires audiometrically documented low-to-middle frequency SNHL time-locked with vertigo. It is recognised that low/all frequencies can be affected as the condition becomes chronic.

EH, the anatomical hallmark of MD can be detected on MD-MRI.

The prevalence of EH associated with HF-SNHL and, its relationship with disease duration and age of onset, is unknown.

We aimed to study the incidence of high versus low frequency SNHL in patients with MD-MRI proven EH, with a particular emphasis on age of onset and symptom duration.
Methods or Background: Retrospective analysis of the clinical history and pure tone audiometry results of patients who underwent MD-MRI over a one-year period (N=166), with emphasis on the pattern of SNHL when EH is depicted on MD-MRI.
Results or Findings: 65% of patients with radiologically confirmed EH exhibited HF-SNHL—a pattern that challenges the conventional emphasis on LF-SNHL in MD.

HF-SNHL and non-low-frequency SNHL (NLF-SNHL) presentations were more common in younger patients. In our cohort, 33.3% of patients with HF-SNHL were under the age of 50, and 66.7% reported symptom duration of less than two years. This subset of patients, while demonstrating clear clinical and radiological features of MD, often do not meet the Bárány Society's criteria. These findings support the notion that HF-SNHL may present an early disease stage, which could later evolve into the classical LF-SNHL pattern. Therefore, age and symptom duration, although not formally included in current diagnostic frameworks, may serve as important clinical indicators in evaluating patients with atypical presentations.
Conclusion: We highlight HF-SNHL as a clinically relevant audiometric pattern in early phase MD, including in younger patients, supported by its correlation with findings on MD-MRI.
Limitations: Low patient numbers. N = 166.

Photon-Counting CT Provides Superior Qualitative Evaluation of Otologic Diseases Compared to Conventional CT: Analysis of 32 Ear Sections (6 min)
Gaia Ressa; Milan / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: G. Ressa, L. A. Cappellini, R. Levi, G. Savini, S. Aimola, A. Spinello, D. Villari, G. Spriano, L. S. Politi; Milan/IT
Purpose: Compare Photon Counting CT (PCCT) with conventional CT in detecting pathological alterations in fine anatomical ear structures, also evaluating potential radiation dose reduction with PCCT.
Methods or Background: In this prospective, single-center study, patients with otolaryngological clinical indications (e.g., hearing loss, otorrhea, tinnitus) underwent PCCT (NAEOTOM Alpha, Siemens Healthineers). PCCT imaging employed an Ultra High Resolution Mode protocol (120 × 0.2 mm collimation), Hr92 kernel, 0.2 mm slice thickness, tube voltage of 120 or 140 kV with Sn filter, pitch 0.55, rotation time 1s, and IQ level 150. Images were reconstructed axially and coronally with 0.2 mm slices bilaterally. All patients had prior conventional CT scans (100–140 kV, 0.4–0.7 mm slice thickness). Three neuroradiologists (3, 4, and >25 years experience) independently reviewed PCCT and conventional CT images for 15 otologic pathologies, scoring likelihood via a 5-point Likert scale after a 3-month washout. Interobserver agreement was assessed with Spearman's correlation, and diagnostic improvement with linear regression. Radiation doses (DLP) were compared using Mann–Whitney U test.
Results or Findings: Thirty-two ears sections from 16 patients (mean age 55, 8 women) were evaluated. PCCT demonstrated superior detection of otospongiotic foci (OR 1.56; p=0.006), tegmen tympani erosion (OR 1.79; p=0.004), ossicular erosion (ORs 1.72–2.15; p<0.05), tympanic membrane thickening/retraction (ORs 2.21, 2.72; p=0.001) and facial canal erosion (OR 1.5; p=0.01) compared to conventional CT.
PCCT reduced mean DLP by 60% (236 ± 23 vs. 525 ± 277 mGy*cm; p=0.004).
Conclusion: PCCT improves detection of otologic pathology while significantly reducing radiation dose compared to conventional CT.
Limitations: Small sample size

MRI Predictors of Baseline Vestibular Function in Vestibular Schwannoma (6 min)

Sophie Neveu; Geneva / Switzerland

Author Block: S. Neveu, D. Daskalou, N. Guinand, P. Senn, M. Becker; Geneva/CH
Purpose: Vestibular dysfunction is frequent in vestibular schwannoma (VS) and has a major impact on quality of life. We aimed to determine whether MRI-derived features are associated with baseline vestibular function as measured by objective testing.
Methods or Background: We retrospectively studied untreated, unilateral VS patients evaluated between 2014 and 2021 at a tertiary center. Vestibular function was assessed using bithermal bilateral caloric testing, video head impulse testing (vHIT), and ocular and cervical vestibular evoked myogenic potentials (oVEMP; cVEMP). MRI predictors included tumor volume (small 0–100 mm^3, medium 101–1000 mm^3, large >1000 mm^3), Koos grade, and fundal contact.
Results or Findings: A total of 149 patients were included (median age 58 years). Large tumours showed markedly greater caloric weakness compared with small tumours (median 52% vs 10%, p<0.0001). For the lateral canal, vHIT gain was significantly lower in large than in small tumours (0.77 vs 0.98, p<0.0001), with significant reductions also observed in the anterior (p<0.0001) and posterior (p=0.004) canals. Fundal contact was associated with greater caloric weakness (median 39% vs 24%, p=0.003) and predicted reduced anterior (p=0.04) and lateral (p=0.03) canal vHIT gains. In multivariable analysis, tumour volume, Koos grade and fundal contact emerged as independent predictors of caloric weakness and vHIT gain of the lateral canal. Absent oVEMP and cVEMP responses were observed predominantly in large tumours and Koos 4 lesions and were not associated with fundal contact.
Conclusion: Tumor volume, Koos grade, and fundal contact are independent MRI predictors of vestibular dysfunction in untreated VS. Recognizing these imaging markers at diagnosis can prompt targeted vestibular testing, inform counselling and treatment planning, and lay the groundwork for predictive models of functional decline.
Limitations: Not applicable.

The Use of Gadopiclenol For Meniere's MRI (6 min)

Susan Jawad; London / United Kingdom

Author Block: S. Jawad; London/UK
Purpose: Gadopiclenol is a new MRI contrast agent that can be administered at half the usual dose of established MRI contrast agents. At a lower dose (0.05mmol/kg), gadopiclenol has been shown to be non-inferior to gadobutrol (adminstered at 0.1mmol/kg) for body imaging and neuroimaging.

Meniere's protocol MRI is utilised to identify the presence of endolymphatic hydrops, the anatomical hallmark of Meniere's disease. Some centres administer single dose of older macrocyclic gadolinium based contrast agents and some administer double dose of these older agents to achieve satisfactory contrast in the perilymph.

No studies exist that assess the efficacy and safety of gadpiclenol given at lower doses of gadolinium than older macrocyclic gadolinium based contrast agents.
Methods or Background: Prospective study assessing the diagnostic efficacy and safety profile of gadopiclenol given at 0.05mmol/kg in patients undergoing Meniere's MRI.
Results or Findings: Six months worth of data of gadopiclenol usage in Meniere's MRI at four times less dose than the macrocyclic agent used previously will be presented at the time of the ECR meeting in March 2026. A calculation of the environmental/sustainability impact of this will be provided.
Conclusion: Gadopiclenol is a safe and effective gadolinium based agent that can be used at lower doses than older macrocyclic gadolinium based contrast agents for the MRI investigation of Meniere's disease. This has a positive impact on dose of gadolinium patients are exposed to as well as well as impact on sustainability, as gadolinium has been identified as an emerging pollutant.
Limitations: Case numbers around 120.
Funding for this study: None.

Comparative Study of Non-Enhanced 3D-FLAIR and Contrast-Enhanced 3D-FLAIR Sequences in the Diagnosis of Endolymphatic Hydrops Using 5T MRI (6 min)

Meng Qiu Liu; Hefei / China

Author Block: M. q. Liu[1], Y. Liu[1], X. Song[2]; [1]Hefei/CN, [2]Shanghai/CN
Purpose: To evaluate the diagnostic value of non-enhanced 5T MRI 3D-FLAIR sequences for endolymphatic hydrops.
Methods or Background: Fourteen patients (7 males, 7 females; mean age 59.05±8.04 years) clinically suspected of Meniere's disease underwent 5T inner ear MRI with gadolinium contrast. All patients underwent pre-contrast conventional inner ear MRI, internal auditory canal hydrography, and 3D-FLAIR sequences (parameters: TR: 10000.00 ms, TI: 2500.00 ms, TE: 455.40 ms, slice thickness: 0.5 mm, flip angle: 54.00°). Four hours after double-dose contrast injection, contrast-enhanced 3D-FLAIR and thin-slice T1WI fat-suppressed sequences were performed. Two head and neck radiologists with 10 years of experience independently reviewed the images; discrepancies were resolved by consensus.
Results or Findings: Using contrast-enhanced 3D-FLAIR as the reference standard, all 14 patients exhibited varying degrees of endolymphatic hydrops: 7 had vestibular hydrops, 14 had cochlear hydrops, 2 had concurrent vestibular neuritis, and 2 had labyrinthitis. Non-enhanced 3D-FLAIR detected 7 cases of vestibular hydrops, 13 cases of cochlear hydrops, and hyperintensity in 1 vestibular neuritis case but failed to visualize labyrinthitis. The diagnostic concordance rates for non-enhanced 3D-FLAIR were 100% for vestibular hydrops and 92.9% (13/14) for cochlear hydrops.
Conclusion: Non-enhanced 5T 3D-FLAIR demonstrates high diagnostic accuracy for endolymphatic hydrops and may partially replace contrast-enhanced sequences. For patients suspected of Meniere's disease without hydrops on non-enhanced 3D-FLAIR, contrast-enhanced imaging is recommended to exclude labyrinthitis or vestibular neuritis.
Limitations: The sample is small

Comparison of CT with and without artefact removal algorithms and CBCT in postoperative cochlear implant imaging – a temporal bone study (6 min)

Henri Viitanen; Turku / Finland

Author Block: H. Viitanen[1], J. Hakumäki[1], H. P. Matikka[1], S. M. Kaartinen[1], A-P. Ronkainen[1], J. Koivisto[2], S. Sipari[1], A. Dietz[1], M. Iso-Mustajärvi[1]; [1]Kuopio/FI, [2]Helsinki/FI
Purpose: Artefact removal algorithms (ARA) for pacemakers (PM) and neurostimulators (NS) are available but the use of ARAs haven't been reported in cochlear implant (CI) imaging, where metal artefacts obscure the evaluation of electrode placement. Additionally, cone-beam computed tomography (CBCT) has been shown to be superior in postoperative CI imaging regarding metallic artefacts. The aim of the present study is to evaluate computed tomography (CT) images with and without ARA in comparison with CBCT images to determine the most suitable postoperative imaging modality for clinical use.
Methods or Background: Three SlimJ electrodes and three MidScala electrodes (Advanced Bionics) were inserted into six freshly frozen temporal bones (TB), which were scanned with CT (Siemens Somatom) and CBCT (Promax Planmeca) with our institution's clinical protocols with and without ARAs (PM and NS). Images were evaluated by two neuroradiologists and two ENT specialists. Scores (1-5) were given to the overall image quality (OIQ), suitability for trauma evaluation (TE), and for blooming, ring, and streak artifacts.
Results or Findings: The CBCT protocols were ranked best in OIQ (means 4.12 and 4.08), TE (means 4.42 and 4.08) and blooming (means 4.04 and 4.21). The difference between CBCT protocols was not statistically significant ($p=0.775$) in a pairwise comparison. The results were mixed with ring and streak artifacts. CT protocols without ARA had a mean OIQ of 2.92 and 3 and with NC of 1.29 and PM of 2.92. CBCT protocols were better than CT protocols in OIQ, TE and blooming ($p<0.001$).
Conclusion: CBCT was better than CT in postoperative CI imaging of TBs, and ARAs did not provide any benefit. No specific ARA exists for CI imaging and the use of ARAs developed for other regions/implants cannot be recommended.
Limitations: Cadaver study, limited sample size.
Funding for this study: None.

Temporal Bone Pneumatization and Its Relationship with Mastoiditis: A CT-Based Case-Control Radiologic Study (6 min)

Fatemeh Azizi; Istanbul / Turkey

Author Block: F. Azizi; Istanbul/TR
Purpose: To evaluate temporal bone pneumatization patterns in adult patients with mastoiditis using a sigmoid sinus-based classification system and to investigate the association between limited mastoid pneumatization and susceptibility to mastoid infection, through comparison with a control group.
Methods or Background: This retrospective case–control study included 250 adult patients (aged 20–45 years) with radiologically confirmed mastoiditis and 200 age-matched control subjects without mastoiditis who underwent high-resolution computed tomography (HRCT) of the temporal bone for other clinical indications. Pneumatization patterns were assessed on axial CT images and classified into four groups—hypopneumatization, moderate, good, and hyperpneumatization—based on their extent relative to the sigmoid sinus. The distribution of pneumatization types was compared between the mastoiditis and control groups using descriptive and inferential statistics.
Results or Findings: In the mastoiditis group, hypopneumatization (58.4%) and moderate pneumatization (39.2%) were predominant, while good (2.4%) and hyperpneumatization (1.2%) patterns were rare. In contrast, the control group exhibited a significantly higher prevalence of good (37.0%) and hyperpneumatization (20.5%) patterns. Chi-square analysis confirmed a statistically significant association between limited pneumatization and mastoiditis ($p < 0.001$).
Conclusion: Limited mastoid pneumatization is strongly associated with the presence of mastoiditis and may serve as a radiologic marker of increased disease susceptibility. The sigmoid sinus-based classification system provides a practical and reproducible method for assessing pneumatization and may assist in clinical risk stratification, diagnosis, and surgical planning.
Limitations: This retrospective study is limited by potential selection bias and the qualitative assessment of pneumatization rather than volumetric analysis. Clinical outcomes were not evaluated, and the restricted age range (20–45 years) limits generalizability to other populations. Future prospective studies with broader age groups, clinical follow-up, and advanced imaging are needed.

Comparative evaluation of neurography sequences for facial nerve visualisation across 3T MR scanners (6 min)

Manon M.M. Moll; Amsterdam / Netherlands

Author Block: M. M. Moll, L. Karssemakers, B. Plakke, A. Te Boekhorst, L. C. ter Beek, M. Valstar, M. Van Alphen, L. Braun; Amsterdam/NL
Purpose: Facial nerve injury is a concerning complication in parotid tumour surgery, affecting the patient's quality of life. A tool that facilitates preoperative visualisation of the facial nerve and its spatial relationship to parotid tumours may complement intraoperative facial nerve monitoring. Due to advances in high-resolution MR, especially in the field of neurography, the development of such a tool is more feasible. This study aims to evaluate and compare various neurography sequences for facial nerve imaging across different sequences from different MR manufacturers.
Methods or Background: We scanned fifteen healthy volunteers to compare four promising 3D sequences described in the literature: Philips NerveVIEW (turbo spin echo sequence with motion sensitised driven equilibrium pulse), Siemens CISS (Constructive Interference in Steady State), Siemens DESS-WE (double-echo steady-state water-excitation), and Siemens SPACE (Sampling Perfection with Application optimised Contrast using different flip angle Evolution). Sequences were compared based on qualitative (radiologist assessment) and quantitative assessments (signal-to-noise ratio and signal-to-contrast ratio).
Results or Findings: Preliminary observations indicate that different neurography sequences yield distinct signal characteristics for the intraparotid facial nerve, with hypointense visualisation in CISS and SPACE, and hyperintense visualisation in DESS-WE and NerveVIEW. Complete qualitative and quantitative analyses are currently underway.
Conclusion: The neurography sequences exhibit distinct signal characteristics in visualising the intraparotid facial nerve. Ongoing comprehensive qualitative and quantitative analyses will provide further insight into the optimal imaging approach for preoperative visualisation in parotid gland surgery.
Limitations: As the scans were performed on volunteers, no contrast was administered.
Funding for this study: No funding was provided for this study.

Specific anatomical characteristics of the styloid process as risk factors for internal carotid artery dissections: a systematic review and meta-analysis of controlled trials (6 min)

Tomas Klail; Münsterlingen / Switzerland

Author Block: T. Klail[1], E. Kalioras[2], M. Von Gernler[2], R. Giger[2], A. K. Exadaktylos[2], M. Müller[2], F. Wagner[3]; [1]Münsterlingen/CH, [2]Bern/CH, [3]Aarau/CH
Purpose: Internal carotid artery dissection (ICA-D) is a cause of stroke in adults. The styloid process may be a risk factor for ICA-D due to potential (micro)trauma from its proximity to the ICA. This systematic review with meta-analysis investigates the association between SP characteristics, particularly SP-ICA distance, and ICA-D.
Methods or Background: A systematic review was conducted across six databases to identify observational studies comparing ICA-D patients to controls. The primary association of interest was SP-ICA distance and ICA-D. Secondary studied associations were ICA-D with SP length and angulation. Random-effects meta-analysis evaluated associations, with a subgroup analysis of moderate/high-quality studies with standardised mean difference (SMD, Hedges' g) as an effect size.
Results or Findings: Six studies were included. Subgroup analysis of moderate/high-quality studies with measurement of the SP-ICA distance ipsilateral to the ICA-D (4 studies) showed a negative SMD -0.29, $p = 0.047$ indicating shorter SP-ICA distance in ICA-D cases. Moderate heterogeneity ($I^2 = 63\%$) existed. A pooled meta-analysis of all five case-control studies (270 ICA-D patients, 377 controls) showed no significant difference in SP-ICA distance (SMD = -0.92, $p = 0.143$) with high degree of heterogeneity. SP length meta-analysis (3 studies) found no significant differences (SMD 0.24, $p = 0.139$) and two studies found no significant association between ICA-D and SP angulation.
Conclusion: Shorter SP-ICA distance might be a risk factor for ICA-D. SP-ICA distance seems to be a more reliable parameter than SP length for risk stratification in evaluating potential underlying cause in ICA-D.
Limitations: Despite excluding studies with significant methodological differences to address heterogeneity, inconsistencies in SP-ICA distance measurement persist and may obscure a true association. Furthermore, the inclusion of studies utilizing adjusted SP-ICA distances could have influenced the overall results.
Funding for this study: The authors declare no financial support for the present study.

Development and Multicenter Validation of a Spectral CT-Based Model for Identifying Eosinophilic Chronic Rhinosinusitis with Nasal Polyps (6 min)

Zixuan Ma; Beijing / China

Author Block: Z. Ma, X. Lu; Beijing/CN
Purpose: Eosinophilic and non-eosinophilic subtypes of chronic rhinosinusitis (CRS) differ in immunological characteristics, clinical manifestations, and treatment responses.This study aims to develop and validate machine learning models using energy CT data to accurately distinguish between eosinophilic and non-eosinophilic CRS.
Methods or Background: A total of 293 CRS patients were included and randomly divided into a training set (n = 232) and a validation set (n = 61). All patients underwent spectral CT scanning, with the reconstruction of conventional image, virtual monoenergetic images (VMI) (40, 70, 100 keV), electron density (ED), and effective atomic number (Z_eff). Regions of interest were manually segmented, and radiomic features were extracted for machine learning modeling. Four predictive models were developed: (1) conventional; (2) conventional + VMI; (3) conventional + ED + Z_eff ; and (4) conventional + VMI + ED + Z_eff. Model performance was evaluated by the area under the receiver operating characteristic curve (AUC), with pairwise comparisons using the DeLong test and multiple-comparison correction to control overall significance.
Results or Findings: The AUC values for the training and validation sets were as follows: conventional, 0.79/0.74; conventional + VMI, 0.85/0.84; conventional + ED + Z_eff, 0.90/0.88; and conventional + VMI + ED + Z_eff , 0.95/0.92. The fusion model combining conventional CT, VMI, ED, and Z_eff significantly outperformed the other models in distinguishing eosinophilic from non-eosinophilic CRS ($p < 0.008$ after multiple-comparison correction).
Conclusion: A fusion model based on Spectral CT, integrating conventional, VMI, ED, and Z_eff maps, can effectively differentiate eosinophilic and non-eosinophilic CRS, demonstrating high diagnostic accuracy and potential clinical application value.
Limitations: This study is limited by its single-center design, which may limit the generalizability of the findings to other populations
Funding for this study: None

Onset and Development of Chronic Rhinosinusitis from Infancy through Adolescence in Primary Ciliary Dyskinesia Detected by Longitudinal Magnetic Resonance Imaging (6 min)

Lena Wucherpfennig; Heidelberg / Germany

Author Block: L. Wucherpfennig[1], M. Lulay[1], A. Seitz[1], I. Baumann[1], M. Stahl[2], H-U. Kauczor[1], M. A. Mall[2], O. Sommerburg[1], M. O. Wielpütz[3]; [1]Heidelberg/DE, [2]Berlin/DE, [3]Greifswald/DE
Purpose: Previous cross-sectional study employing magnetic resonance imaging (MRI) of paranasal sinuses showed a high extent of chronic rhinosinusitis (CRS) in children with primary ciliary dyskinesia (PCD). However, longitudinal imaging data on CRS onset and progression is lacking. The aim of this study is to longitudinally assess CRS in PCD from infancy through adolescence with MRI.
Methods or Background: 22 children with PCD (mean baseline age 7.6±5.7yr, range 0-18yr) underwent a mean of 2.8±1.8 (range 1-9) annual standardised paranasal sinus MRI examinations. MRI were assessed using the previously evaluated CRS-MRI score by two readers.
Results or Findings: At infancy (0yr), 83-100% of paranasal sinuses and mastoid cells were opacified. Mucosal swelling was the most prevalent (83-100%) and dominant abnormality (50-100%). At preschool age (1-5yr), the prevalence of opacified sphenoid sinus (83% vs. 100%, $p<0.01$) as well as mastoid cells increased ($p=0.567$-0.999 vs. infancy). Mucosal swelling remained the most prevalent (100%) and dominant abnormality (47-100%), while the prevalence and subscore of mucopyoceles increased (81% vs. 13% and 2.0 ± 1.6 vs. 4.1 ± 2.1, respectively; $p<0.05$). At school age (≥6yr), almost all maxillary, sphenoid and ethmoid sinuses (91-100%), and 87% of mastoid cells were opacified ($p=0.122$-0.999 vs. preschool age). The prevalence of mucopyoceles, polyps and sinus deformation decreased (60% vs. 81%, 40% vs. 70% and 51% vs. 78%, respectively; $p<0.05$ vs. preschool age), especially in maxillary sinuses. The CRS-MRI sum score averaged 27.8±4.9 at infancy, tended to increase at preschool age (31.9±5.6, $P>0.999$) and decreased at school age to 25.6±8.3 ($p<0.01$).
Conclusion: Longitudinal paranasal sinus MRI detects high prevalence and extent of paranasal sinuses abnormalities from infancy. Our data support its role for comprehensive non-invasive monitoring of CRS in PCD.
Limitations: The number of patients was only moderate.

Radiological Phenotypes in Rhinogenic Contact Point Headache: A Novel Prognostic Classification (6 min)

Salvatore Lavalle; Enna / Italy

Author Block: S. Lavalle[1], E. Masiello[2], P. Romeo[3], A. Maniaci[1], A. Lo Casto[4]; [1]Enna/IT, [2]Milan/IT, [3]Catania/IT, [4]Palermo/IT
Purpose: Rhinogenic contact point headache (RCPH) is still an unsolved diagnostic problem in routine medical practice. In this prospective study, we sought to create and validate a complete radiologic classification system built on anatomic phenotypes, to standardize
the diagnosis and inform treatment.
Methods or Background: A prospective observational study of 120 patients with suspected RCPH was performed from January 2023 to June 2025. All the patients received high-resolution CT scans and clinical data were retrieved. Five radiological anatomical features (CP, CI, SD,
CB, ME, TH, and AV) were evaluated.
Results or Findings: In our cohort (42.7±13.5 years and 58.3% female), CP-I (septum-middle turbinate contact) was the most frequent contact type (37.5%), followed by CP-II (22.5%), CP-III (18.3%), CP-IV (12.5%), and CP-V (9.2%). Moderate contact intensity (CI-2) was observed in 45.8% of cases. Septal deviation was categorised as mild (SD-A) in 28.3%, 1.7%, moderate in 41.7% (SD-B) and severe (SD-C) in 30.0% of patients.
Concha bullosa was observed in 54.2% of patients and the bulbous type (CB-B) was most frequent (26.7%). Mucosal oedema at contact point (ME-1) was significantly correlated with higher pain scores (p=0.003). Mild and moderate turbinate hypertrophy (TH-I and TH-II) were found in 10% and 40.8% of subjects, respectively. Paradoxical middle turbinate (AV-P) was the most common anatomical variation (22.5%) followed by Haller cells (18.3%).
Conclusion: Based on the radiological phenotype, a standardized diagnostic method can guide targeted therapies. The importance of anatomical variants is crucial for proper management.
Limitations: Validation in larger series is warranted. It is could be useful to evaluate the inter-reader agreement on larger shorts

Structural imaging findings of costovertebral joints by low dose spine CT-scan in patients suspected of axial spondyloarthritis (6 min)
Mies A Korteweg; Amsterdam / Netherlands

Author Block: M. A. Korteweg, M. Wessels, B. Bartels, M. Gerritsen, W. Van der Heijden, C. Van der Laken; Amsterdam/NL
Purpose: Axial spondyloarthritis (axSpA) affects costovertebral joints (CVJs). Radiographs visualize CVJs poorly. Advancements in low-dose (ld)CT facilitate spine imaging with 2-7 fold lower effective dose (ED) than radiography (1.4mSv). This study describes structural CVJ changes in suspected axSpA patients.
Methods or Background: Between 1/8/24-30/11/24 consecutive suspected axSpA patients were included. Final clinical diagnosis (axSpA, diffuse idiopathic skeletal hyperostosis (DISH), rheumatoid arthritis (RA), osteoarthritis (OA)), was outcome variable. Two radiologists, blinded for diagnosis, evaluated ldCTs. 24 medial (M), 20 lateral (L) CVJs were scored per patient using Kellgren-Lawrence OA-classification; 0-4 (no pathology-complete ankyloses)- as no CVJ-scoring system is known.
Joints scored 3-4 were rated as significant pathology; and reported as 1 for final analyses. These were compared per level between axSpA and other diagnosis groups using Student's t-test for independent samples, assuming equal variance, with two-tailed distribution (p-value ≤0.05 = statistically significant). Erosions were assessed visually. Interobserver agreement and ED were determined.
Results or Findings: 77 patients (48 female, mean age 45y; range 19-74y) were included with clinical diagnosis: axSpA (n=26); DISH (n=6); RA (n=5), OA (n=40). Structural changes occur at different levels in all groups. Average number of significantly affected CVJs/patient in axSpA, DISH, RA, OA: 8.5; 12; 6; 8.5. Most prevalent is; axSpA at CVJ4L (p=0.05), DISH at CVJ10L (p=0.02).
Mean ED; 1.3 mSv (± SD 0.4). 1 patient had erosions (20 CVJs); diagnosed axSpA. Interobserver agreement; kappa 0.86 (95% CI 0.73-1.00).
Conclusion: LdCT detects structural CVJ changes at low ED. AxSpA structural abnormalities overlap in amount and number with; DISH, RA, OA. RA shows the least and DISH the most changes- mainly caudally. Erosions are scarce and only in axSpA. Potential differential features in structural imaging findings at affected sites warrant further investigation.
Limitations: No major limitations.

Novel Source-Separated QSM for Improved Hemosiderin Assessment in Hemophilic Arthropathy (6 min)
Sam Sedaghat; Heidelberg / Germany

Author Block: S. Sedaghat[1], J. Park[2], E. Fu[2], M. Grözinger[1], H-U. Kauczor[1], H. Jang[2]; [1]Heidelberg/DE, [2]Davis/US
Purpose: To evaluate a novel source-separated quantitative susceptibility mapping (QSM) technique integrated with ultrashort echo time (UTE) for accurate detection and quantification of hemosiderin in hemophilic arthropathy (HA), and to compare it with conventional QSM methods.
Methods or Background: This prospective, multicenter study included 10 MRI scans at 3T of knee and ankle joints (5 HA patients and 5 healthy controls). A validation phantom containing calcium carbonate (diamagnetic) and iron oxide (paramagnetic) was used. Three susceptibility mapping approaches were compared: (1) the novel multi-step source-separated UTE-QSM, (2) a non-source-separated UTE-QSM, and (3) a conventional non-UTE QSM. Susceptibility values were quantified in the phantom, and in vivo image quality was assessed by two musculoskeletal radiologists using a 5-point Likert scale.
Results or Findings: In the phantom, conventional QSM underestimated susceptibility (up to 0.236 ppm), whereas source-separated UTE-QSM yielded distinct diamagnetic (–0.704 to –0.410 ppm) and paramagnetic (0.484 to 0.857 ppm) values, strongly correlating with true concentrations ($R = –0.99 / 0.95$, $p < 0.05$). In vivo, visual Likert-scale ratings confirmed that source-separated UTE-QSM maps provided the highest image quality and diagnostic confidence. They consistently detected hemosiderin deposits in all HA patients, delineating both subtle focal accumulations and extensive joint involvement. These findings were underestimated on conventional QSM and only partially visible on non-source-separated UTE-QSM, particularly in regions with mixed tissue composition. Lesion conspicuity and boundary sharpness were superior on source-separated maps, facilitating reliable tissue differentiation. No false-positive paramagnetic signals were observed in healthy controls, underscoring the technique's specificity.
Conclusion: Source-separated UTE-QSM enables superior quantification and visualization of hemosiderin in hemophilic arthropathy compared with conventional approaches, supporting its potential as a valuable tool for diagnosis and longitudinal monitoring in HA.
Limitations: Small cohort and specialized post-processing requirements limit immediate clinical implementation.

Imaging of polymyalgia rheumatica: A comparison between contrast-enhanced whole-body MRI and (18F)-FDG-PET (6 min)

Suela Mema; Dresden / Germany

Author Block: S. Mema, R-T. Hoffmann, R. Winzer, M. Miederer, I. Platzek; Dresden/DE
Purpose: The aim of the present study is to assess the agreement between contrast-enhanced whole-body MRI and FDG-PET in the detection of joint and entheses involvement in patients with polymyalgia rheumatica.
Methods or Background: The current retrospective study included 26 (15 women and 11 men, mean age 70.4 y, SD 8.1) with polymyalgia rheumatica who received a contrast-enhanced FDG-PET-MRI in the period between 2013 and 2023.
10 anatomical structures per patient (glenohumeral, acromioclavicular and hip joints, greater trochanters and ischial tuberosities) were evaluated independently by two nuclear medicine physicians and two radiologists. A total of 155 joints and 102 tendon insertions were evaluated.
A four-point Likert scale was used to rate the signs of inflammation (0 = no signs of inflammation ....up to 3 = pronounced signs of inflammation). Differing results were resolved in consensus.
Weighted kappa (k) was used to quantify the agreement between methods (MRI and FDG-PET) as well as the interrater agreement.
Results or Findings: Scores based on FDG-PET and MRI were identical for 90 anatomical sites and differed for 167 sites. The resulting weighted kappa was k = 0.45, indicating moderate agreement according to Landis and Koch´s criteria.
Conclusion: Whole-body MRI revealed bilateral symmetric synovitis and enthesitis in the majority of patients. The agreement between MRI and FDG-PET regarding the extent of inflammation of the synovium and entheses was moderate. A substantial number of joints and entheses identified as inflamed on FDG-PET were interpreted as normal on MRI. These findings suggest that whole-body MRI may underestimate inflammatory activity in PMR compared to FDG-PET.
Limitations: Limitations include the small patient cohort and the fact that many patients had already initiated treatment at the time of FDG-PET/MRI.

Development and Validation of a Deep Learning Model for Diagnosing Axial Spondyloarthritis Using Radiographs and Clinical Risk Factors (6 min)

Qingqing Zhang; Guangzhou / China

Author Block: Q. Zhang, J. Liu, L. Ruifeng, Y. Chen, X. Chen, W. Lin, X. Xia, X. Liu, M. Li; Guangzhou/CN
Purpose: To develop and validate a deep convolutional neural network (CNN) that analyzes radiographic images and incorporates clinical risk factors (age and sex) to enhance the diagnostic accuracy of axial spondyloarthritis (axSpA) in patients with chronic lower back pain.
Methods or Background: Clinical and radiographic data were retrospectively collected from patients presenting with chronic lower back pain. A total of 34178 pelvic radiographs were included and split into a training cohort (n = 31015; 1891 axSpA, 29124 non-axSpA) and a validation cohort (n = 3164; 181 axSpA, 2983 non-axSpA). A deep CNN model was trained to detect radiographic features indicative of axSpA. Additionally, a combined model integrating clinical risk factors (age and sex) with imaging data (radio-clinical model) was developed. Model performance was evaluated using the area under the receiver operating characteristic curve (AUC), accuracy (ACC), sensitivity, and specificity. Calibration curves and decision curve analysis (DCA) were also performed to assess clinical utility.
Results or Findings: The CNN model achieved an AUC of 0.906, accuracy of 0.836, sensitivity of 0.836, and specificity of 0.837 in the training cohort. In the validation cohort, it reached an AUC of 0.928, accuracy of 0.855, sensitivity of 0.839, and specificity of 0.840. The radio-clinical model demonstrated improved diagnostic performance, with an AUC of 0.993 (95% CI: 0.989–0.995) in the training cohort and 0.941 (95% CI: 0.897–0.968) in the validation cohort. Calibration curves indicated good agreement between predicted and observed outcomes, and DCA confirmed the model's added value in clinical decision-making.
Conclusion: A deep CNN can accurately distinguish between axSpA and non-axSpA cases based on radiographs. The incorporation of clinical risk factors further enhances diagnostic performance, offering a promising tool for supporting early and accurate diagnosis of axSpA.

To X-ray or not to X-ray - Preliminary results of a comparative study on first-line imaging in suspected axial Spondyloarthritis (axSpA) (6 min)

Dominik Deppe; Berlin / Germany

Author Block: D. Deppe, S. T. Ulas, M. Koka, F. N. Proft, V. Rios Rodriguez, M. Protopopov, J. Rademacher, D. Poddubnyy, T. Diekhoff; Berlin/DE
Purpose: In routine practice, patients with suspected axial Spondyloarthritis (axSpA) usually undergo sacroiliac joint radiography, followed by MRI if negative. However, X-rays (XR) are limited by low sensitivity and specificity. Computed tomography (CT) is gold standard for detecting structural lesions and can now be performed with ultra-low-dose (uld) techniques at radiation exposure comparable to or lower than XR. This study evaluates the diagnostic efficacy of XR-, MRI-, and uld-CT -based pathways in suspected axSpA.
Methods or Background: 231 patients with suspected axSpA were randomized into three arms:
1. Standard (XR first, followed by MRI if negative; followed by uld-CT if negative)
2. MRI-first (followed by uld-CT if MRI was negative)
3. CT-first (followed by MRI if CT was negative).
Positive imaging was defined by the unambiguous identification of active inflammatory (according to updated ASAS definition) or structural lesions (e.g. extensive erosions), rated in consensus reading by two radiologist specialists in musculoskeletal imaging.
Results or Findings: In the standard-imaging Arm (42 patients), XR was positive in 4/42 patients (9.52%). Subsequent MRI was positive in three patients (3/38; 7.89%) and negative in the other 35 patients. All 35 patients who underwent further subsequent CT had negative results. In the MRI-first arm (97 patients), MRI was positive in 21/97 (21.65%) patients. Subsequent CT in 76 patients showed no positive results (0/76). In the CT-first arm (92 patients), initial CT was positive in 23/92 (25 %). Subsequent MRI, performed in 69 patients, was positive in two patients (2.9%).
Conclusion: The standard imaging pathway demonstrated the lowest diagnostic efficacy compared to the MRI-first and CT-first approaches, raising the question of whether the current imaging pathway should be updated.
Limitations: This is an ongoing study and clinical final diagnosis as the gold standard is missing.
Funding for this study: No funding was provided for this study.

Predicting total knee arthroplasty in osteoarthritis: comparative performance of radiomics, clinical, and combined models (6 min)

Atefe Pooyan; Philadelphia / United States

Author Block: A. Pooyan[1], E. Alipour[2], M. Nyflot[2], M. Chalian[2]; [1]Philadelphia, PA/US, [2]Seattle, WA/US
Purpose: Knee osteoarthritis (OA) is a prevalent disabling disease. Total knee arthroplasty (TKA) treats end-stage OA. Early identification of patients at high risk for TKA may improve understanding of disease progression. This study aimed to find the features associated with TKA and compared the performance of clinical, radiomics, and combined models for predicting TKA in OA patients.
Methods or Background: We analyzed 507 knees from the OAI-ZIB dataset with manually segmented baseline MRIs. The outcome was TKA within 9 years in the segmented knee. Radiomics features (n=400) were extracted from femoral bone, femoral cartilage, tibial bone, and tibial cartilage using PyRadiomics. Clinical variables (n=13) included demographics, comorbidities, medication use, and baseline WOMAC scores. Univariate logistic regression with Benjamini-Hochberg correction identified significant features. Three model types: logistic regression, Least Absolute Shrinkage and Selection Operator (LASSO), and Extreme Gradient Boosting (XGBoost), were trained on three feature sets: radiomics only, clinical only, and combined. Performance was assessed by AUC-ROC, AUC-PR, and F1-score with 95% confidence intervals. Feature importance for XGBoost was evaluated using SHAP values.
Results or Findings: 45 radiomics features and three clinical variables (WOMAC pain, disability, stiffness) were significantly associated with TKA in univariate analysis. The combined XGBoost model performed best, achieving an AUC-ROC of 0.95 (95% CI: 0.92-0.97), AUC-PR of 0.72 (0.58-0.82), and F1 of 0.56 (0.46-0.64) in cross-validation, and an AUC-ROC of 0.72 (0.57-0.84), AUC-PR of 0.30 (0.16-0.47), and F1 of 0.48 (0.31-0.63) on the test set. Final model included 38 of 413 features, with femoral bone sphericity, WOMAC disability, and WOMAC pain as top predictors.
Conclusion: Combining radiomics with clinical features improves TKA prediction in OA, with XGBoost showing the strongest performance.
Limitations: Study was limited by using TKA as a surrogate outcome influenced by non-disease factors.
Funding for this study: No funding was received for this study.

Long-Term Impact of Intralesional Bony Overgrowth on Opposing Cartilage Integrity: Five-Year Results Following Cartilage Repair (6 min)

Felix Ragnar Merlin König; Vienna / Austria

Author Block: F. R. M. König, M. W. Raudner, G. Wollner, V. Juras, P. Szomolanyi, V. Vetchy, J. Leitner, V. Schmidbauer, S. Trattnig; Vienna/AT
Purpose: This study aimed to assess the impact of intralesional bony overgrowth (ILBO) after cartilage repair on the integrity of opposing articulating cartilage (OpaC) using T2 mapping and to correlate these findings with clinical outcomes in a five year follow up.
Methods or Background: In this multicenter study, MRI examinations were conducted in 45 patients up to 5 years after cartilage repair (Microfracturing [MFX] and Matrix-induced Autologous Chondrocyte Implantation [MACI]). ILBO was classified into <50% and ≥50% of the transplant thickness. T2 values of the opposing articulating cartilage (OpAC) were measured at 3, 12, and 60 months post-surgery in patients with and without ILBO at 60 months, together with clinical assessments using the International Knee Documentation Committee (IKDC) and Knee injury and Osteoarthritis Outcome Score (KOOS).
Results or Findings: At 60 months post-surgery, 44.4% of patients had ILBO, associated with significantly higher OpAC T2 values (P = 0.004). A trend toward increased T2 values at 12 months was observed but was not statistically significant (P = 0.06). No significant differences in clinical outcomes were found between patients with or without ILBO, nor between those with higher or lower OpAC T2 values. Notably, even small ILBO (<50%) significantly elevated OpAC T2 ratios.
Conclusion: Even small ILBO (<50% or ≥50% of transplant thickness) significantly alters the biophysical MRI properties of OpAC, shown as higher T2 values after 60 months. Although these changes are not yet reflected in clinical scores, they may indicate early cartilage degeneration and could guide future monitoring strategies after cartilage repair.
Limitations: ILBO was categorized as <50% or ≥50% overgrowth. While useful, finer 25% intervals could clarify ossification effects on OpAC. Additionally, a 60-month follow-up may be too short to reveal long-term clinical implications.
Funding for this study: This study has received funding from FWF Der Wissenschaftsfonds (grant no. KLI917) and the Slovak Research and Development Agency (grant no. APVV-21-0299)
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Approval was obtained from the local ethics committees and federal authorities at each participating site prior to patient enrollment. The study was conducted from May 2013 to June 2023 to compare the outcomes after MFX and MACI. This trial was registered under EudraCT number 2011-005798-22 and ClinicalTrials.gov identifier NCT01656902.

Prediction of Rheumatoid Arthritis Disease Activity by Integrating Photoacoustic Imaging, Ultrasound, and Clinical Parameters (6 min)

Zhibin Huang; Shenzhen / China

Author Block: Z. Huang, Y. Yin, S. Mo, F. Dong; Shenzhen/CN
Purpose: This study aimed to develop and validate a predictive model for assessing disease activity in patients with rheumatoid arthritis (RA) by integrating clinicopathological data, conventional ultrasound features, and photoacoustic imaging-derived SO_2 measurements. The goal was to improve diagnostic accuracy and provide comprehensive clinical insights.
Methods or Background: A total of 182 patients diagnosed with RA were enrolled and randomly divided into a training cohort (70%) and a testing cohort (30%). Univariate and multivariate logistic regression analyses were conducted to identify independent predictors. Three models were constructed: ModA (clinical parameters only), ModB (clinical and ultrasound features), and ModC (clinical, ultrasound, and photoacoustic SO_2 measurements). The diagnostic performance of each model was assessed and compared using receiver operating characteristic curve analysis and the DeLong test.
Results or Findings: Multivariate analysis identified disease duration, age, pain score, grayscale ultrasound score, power Doppler score, and joint SO_2 levels measured by photoacoustic imaging as significant predictors of RA disease activity. In the testing cohort, ModA achieved an AUC of 0.646 , ModB improved to 0.773, and ModC achieved the highest AUC of 0.801. These findings indicate that the integrated model combining clinical, ultrasound, and photoacoustic imaging features (ModC) provides superior predictive accuracy for RA disease activity.
Conclusion: Combining photoacoustic SO_2 measurements with conventional clinical and ultrasound features significantly enhances the accuracy of disease activity prediction in patients with RA. The proposed integrated model offers a comprehensive, reliable, and reproducible tool for clinical decision support and individualized disease monitoring.
Limitations: Although the sample size was adequate for preliminary validation, it may limit the generalizability of our findings. Furthermore, while photoacoustic imaging has shown considerable promise in experimental and early clinical settings, its widespread adoption in routine clinical practice remains limited.
Funding for this study: No
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study strictly adhered to the ethical standards set forth in the Declaration of Helsinki and received approval from the Medical Ethics Committee of Shenzhen People's Hospital (Approval No.: SYL-202161-02). Written informed consent was obtained from all participants.

Impact of type II lunate morphology on hamatolunate joint impingement and wrist osteoarthritis in patients with wrist pain (6 min)

Melisa Aslan; Antalya / Turkey

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESSR

Author Block: M. Aslan, T. Pınarbaşılı, I. Erdem Toslak; Antalya/TR
Purpose: The aim of the study is to evaluate hamatolunate facet morphology and association with cartilage lesions using magnetic resonance imaging(MRI) in patients with wrist pain
Methods or Background: From January to December 2024 wrist MRI of patients with Type II lunate were retrospectively evaluated.Geometric characteristics of the hamate(tapered/round) and lunate facet(concave/straight) was decided.Maximum diameter of the facet of the lunate and hamate, the angle between the ulnar and radial margins of the hamate were measured from coronal images. Ulnar variance was evaluated from X-Rays. On MRI, triangularfibrocartilage complex lesions were noted and cartilage surface of the hamatolunate facet was subjectively graded as 0;normal, 1;partial thickness, 2; full thickness cartilage defect, 3; full thickness cartilage defects with signal changes in the subchondral bone.Data was statistically analyzed.
Results or Findings: We included 137 wrists of 127 patients. The mean coronal sizes of the lunate and hamate facet were 2.99(±0,92) and 3.55(±1.2) mm respectively. The mean angle between margins of the hamate was 43.8°(±9.3). %36.5 of the patients had positive, %36.5 had negative ulnar variance. 46.7% of patients had grade o, 20.4% had grade 1 , 21.9% had grade 2, 10.9 % had grade 3 cartilage lesions. There was not any correlation between the measurements or geometrical analysis of hamate,TFCC lesions or ulnar variance with the cartilage lesions.
Logistic regression analysis revealed a trend towards presence of cartilage lesions as the lunate transverse diameter decreases (p=0.083).There was a statistically significant correlation between age and grade 3 lesions (p=0.047)
Conclusion: In patients with type II lunate, age is an important contributor factor for grade 3 cartilage lesions, Patients with shorter lunate facet are more likely to have cartilage lesions.
Limitations: Small sample size and retrospective nature of the study are the limitations.
Funding for this study: No funding was received.

A new approach to whole body-MRI for rheumatological imaging in psoriatic arthritis using dixon fat fraction and water fraction mapping (6 min)

Salvatore Lavalle; Enna / Italy

Author Block: S. Lavalle[1], A. MONTANA[2], F. Aiello[1], G. Privitera[2], R. Foti[2], R. Foti[2], P. Romeo[2]; [1]Enna/IT, [2]Catania/IT
Purpose: Whole-body MRI (wbMRI) is an advanced scan modality which provides high-contrast resolution images of the entire body and it's a valuable tool for diagnosing and monitoring systemic arthritides by virtue of its comprehensive coverage . We aim to investigate how quantification of DIXON fat fraction (FF) mapping and water fraction (WF) mapping on diagnostic accuracy and how it change in relaction to sex and age.
Methods or Background: In this prospective imaging study, we enrolled 67 patients with confirmed or suspected rheumatologic disease, with possible axial involvement, who underwent whole-body MRI. We assessed both sacroiliac joints at four sites. Differences in fat fraction and water fraction were observed and correlated. To obtain robust and accurate confidence intervals, we performed all analyses with the nonparametric Mann-Whitney and Kruscal-Wallis tests.
Results or Findings: There is a significant correlation between age and FF values, in particular as age increases, FF values increase and older subjects present lower WF values. Sex does not determine significant differences in the mappings. Furthermore, patients with psoriatic arthritis have higher FF values than other rheumatological patients (p value 0.008).
Conclusion: These preliminary data suggest that age and the presence of psoriatic arthritis are correlated with elevated FF values. Larger studies may help identify the optimal cutoff for predicting disease activity and progression.
Limitations: Small simple size, inter-reader agreement
Funding for this study: No funding

Ultrasound Detection of Synovitis in Immune Checkpoint Inhibitor Therapy: Prevalence and Clinical Correlates (6 min)

Aamir Shah; Anantnag / India

Author Block: A. Shah, M. H. Mir, N. A. Choh; Srinagar/IN
Purpose: The primary objective was to estimate the prevalence of ultrasound-detected synovitis in patients receiving ICIs(Immune checkpoint inhibitors). Secondary objectives were to evaluate correlations between ultrasound findings and musculoskeletal symptoms, to assess associations with laboratory biomarkers, and to describe the joint distribution.
Methods or Background: In this prospective cohort, 120 patients starting ICI therapy were screened and 110 enrolled. All underwent clinical evaluation, laboratory testing(ESR, CRP, RF, anti-CCP, ANA), and standardized US of wrists, MCP(metacarpals), and knees three months after ICI initiation. Synovitis was defined as gray-scale (GS) ≥1 and/or power Doppler (PD) ≥1 using OMERACT scoring. Prevalence was estimated with 95% CIs(Confidence Intervals), and predictors were assessed using logistic regression.
Results or Findings: US-detected synovitis was present in 62/110 patients (56.4%, 95% CI 47.0–65.3%). PD activity was seen in 19%, and effusion in 71%. Wrists were most often affected (52%), followed by MCP joints (38%) and knees (24%). Prevalence did not differ by cancer type or ICI regimen. Synovitis was far more frequent in symptomatic patients (84%) than in asymptomatic patients (28%). Inflammatory markers and autoantibodies showed no significant association. On multivariable analysis, musculoskeletal symptoms were the only independent predictor (OR 3.1, 95% CI 1.4–7.8).
Conclusion: This study revealed a high prevalence of US detected synovitis in ICI-treated patients, including many without joint symptoms. Conventional biomarkers were unhelpful, highlighting US as a valuable tool for early detection and monitoring of musculoskeletal irAEs.
Limitations: This was a single-centre study with a modest sample size, restricting subgroup analyses by cancer type and ICI regimen. Patients were evaluated only at a three-month time point, so the prognostic significance of subclinical synovitis remains uncertain. Longitudinal follow-up is needed to establish whether subclinical synovitis predicts clinical progression or necessitates treatment modification.
Funding for this study: No funding was provided for this study

A Comparison of T2 Relaxometry, ADC Imaging& Diffusion Tensor Imaging in assessment of early onset Articular Cartilage damage of the knee (6 min)

Rajeshwar Balaji Venkatasubramanian; Chennai / India

Author Block: R. B. Venkatasubramanian[1], R. Sivakumar[1], G. MURUGAN[1], L. Murali[2], V. Sai[1], R. Ramachandran[1], B. Dev[1], R. Rangasami[1], G. Ilangovan[2]; [1]Chennai/IN, [2]Tirupattur/IN
Purpose: To compare&evaluate T2 Relaxometry, ADC /DWI and Diffusion Tensor Imaging in assessment of early-onset articular cartilage damage of knee in young adults.
Methods or Background: Certain routine sequences in MRI knee protocol like T2,GRE can help in assessing cartilage damage once macrostructural damage had already occured. However special sequences like T2 Relaxometry, ADC and DTI/FA are increasingly used in cases with high suspiscion of microstructural /impending cartilage damage, especially in athletes and trauma victims.
T2 relaxometry is sensitive to collagen integrity and water content.
ADC/diffusion weighted sequence can identify early stages of inflammation.
Diffusion Tensor Imaging sensitively depicts proteoglycan content and collagen structure in cartilage.
40 adults(18-30 years age) who presented for knee MRI for indications other than trauma/pain and without gross signal changes in T2/PDFS were chosen.
Additional primary sequences of T2 Relaxometry, ADC/DWI and DTI centered for cartilage and derivative sequences like T2*, R2*, AvDC and Fractional anisometry were obtained.
Qualitative&quantitative assessment of cartilage was done with these sequences to establish the more sensitive/specific sequence which can help to detect cartilage damage earlier than conventional sequences.
Results or Findings: T2 relaxometry showed qualitative signal changes in articular cartilage earlier than ADC&DTI, predominantly in tibiofemoral joint surface.
Healthy controls had mean T2 values 29.1 +/- 3.2 msec, while early-onset cartilage damage had 35.2+/- 3.3 [$p<0.05$] in affected areas.
ADC values in healthy controls were 1.81 +/- 0.44 x 10−3mm2/s compared to 1.21 +/- 0.89 x 10-3mm2/s.[$p<0.05$].FA values showed minimal difference even in cartilage damage identified in other 2 sequences.
Conclusion: T2 relaxometry is a sensitive sequence for cartilage microstructural damage.
T2 relaxometry and ADC mapping can be done routine in athletes and young adults for early detection of cartilage damage.
Limitations: Limited sample size can be increased.

Quantitative Elastography of the Achilles Tendon Detects Subclinical Enthesopathy in Psoriatic Arthritis (6 min)

Aysun Gündüz Uslu; Malatya / Turkey

Author Block: V. Burulday, A. Gündüz Uslu, S. Yolbaş; Malatya/TR
Purpose: To compare Achilles tendon elasticity, measured by shear wave elastography (SWE), between asymptomatic psoriatic arthritis (PsA) patients and healthy controls. PsA frequently involves entheseal structures, but subclinical changes often escape clinical detection. SWE provides a non-invasive, quantitative method to assess tendon stiffness and may reveal early abnormalities.
Methods or Background: This prospective case–control study was conducted at Inonu University (Oct 2024–Feb 2025). Thirty-four PsA patients (≥2 years disease duration, 18–65 years, no Achilles symptoms) and 34 age- and sex-matched healthy volunteers were enrolled. Exclusion criteria included diabetes, rheumatoid arthritis, ankylosing spondylitis, tendinopathy, systemic steroids or biologics, recent ankle trauma or surgery. Ultrasound and SWE were performed with a Mindray Resona I9, L14-3Ws probe. Participants lay prone with feet relaxed. Achilles thickness was measured 3 cm proximal to the calcaneal insertion. SWE was performed longitudinally with a 3 mm ROI; six measurements per tendon were averaged. Values were recorded in m/s and kPa. Only high-quality images (M-STB = 5) were analyzed.
Results or Findings: Demographics did not differ between groups. Tendon thickness was similar bilaterally ($p>0.5$). SWE values were significantly higher in PsA patients. Left tendon: 4.89 ± 2.52 m/s vs 3.23 ± 0.41 m/s ($p<0.001$). Right tendon: 4.88 ± 1.94 m/s vs 3.12 ± 0.30 m/s ($p<0.001$). kPa values showed the same pattern, indicating subclinical stiffening in PsA.
Conclusion: SWE demonstrated increased Achilles tendon stiffness in asymptomatic PsA patients despite normal thickness. Elastography may serve as a sensitive imaging biomarker for early detection and monitoring of enthesopathy. Larger, multicentre studies are needed.
Limitations: Single-centre design, modest sample, no EMG or histopathology, and no treatment-based analysis.
Funding for this study: Supported by Inonu University Scientific Research Projects Coordination Unit (BAP). No external funding.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Approved by Inonu University Clinical Research Ethics Committee (protocol 2024/119). Written informed consent was obtained from all participants.

RPS 2312 - Future directions of paediatric neuroradiology

Categories: Neuro, Paediatric, Foetal

Sadness-induced cognitive control deficits in adolescents with bipolar disorder: a pilot fMRI study (6 min)
Xiaoping Yi; Chongqing / China

Author Block: X. Yi[1], B. T. Chen[2]; [1]Chongqing/CN, [2]Duarte, CA/US
Purpose: To examine how sad emotional stimuli affected cognitive control especially response inhibition and its underlying neural mechanism in aBD, using a task-based functional magnetic resonance imaging (fMRI) with the Go/No-Go task.
Methods or Background: Bipolar disorder (BD) is characterized by intense mood swings including maniac and depressive episodes. Adolescents with BD (aBD) often experience impaired cognitive control when processing sad stimuli, particularly response inhibition. We hypothesized that aBD may have altered brain activation in response to sad emotional stimuli, which would be related to cognitive control ability. A total of 43 adolescents diagnosed with BD and 18 healthy control (HC) participants performed an emotional Go/No-Go task during brain fMRI. Brain activation during sad No-Go versus neutral No-Go trials was compared between the two groups (FDR-corrected, $p<0.05$), which was correlated separately with behavioral performance and with clinical questionnaires scores.
Results or Findings: Compared to the HC, the aBD group showed significantly increased activity in hippocampus, parahippocampal gyrus, thalamus, caudate nucleus, insula, temporal lobe and cerebellum ($p < 0.05$) when exposed to sad emotional stimuli. The activity of thalamus and caudate nucleus was positively correlated with false response errors ($r = 0.328$, $p = 0.004$), while temporal and insular activity was correlated with neutral targets omission errors ($r = 0.037$, $p = 0.026$). The cerebellar activity was negatively correlated with reaction time (emotional: $r = -0.408$, $p = 0.008$).
Conclusion: This study identified key neural mechanisms involving the limbic system, temporal lobe, insula, and cerebellum underlying cognitive control in aBD. These finding may help guide future treatment approaches focusing on emotional regulation and cognitive function in the aBD.
Limitations: The sample size was relatively small, and this was a cross-sectional study.

Melatonin alleviates lactate and promotes neurogenesis via the JAK2/STAT3 pathway in hypoxic-ischemic neonatal rats (6 min)
Shen Gui; Wuhan / China

Author Block: X. Wang[1], Y. Wang[1], M. Yu[1], Y. Li[1], S. Gui[2], X. Zhang[1], Y. Qin[1], N. Xue[1], Y. Zeng[1]; [1]Weifang/CN, [2]Shanghai/CN
Purpose: Multimodal magnetic resonance imaging (MRI) combined with multiple histological techniques was employed to investigate the effects of melatonin (Mel) treatment on endogenous neural stem cells (NSCs) regeneration and metabolic conditions in the hippocampal dentate gyrus, and explore the potential neuroprotective effect via the JAK2/STAT3 pathway in neonatal rats with hypoxic-ischemic brain damage (HIBD).
Methods or Background: Cerebral blood flow was dynamically monitored by laser speckle imaging. Multimodal MRI was applied in vivo to assess metabolic alterations in the cerebral microenvironment. Multiple histological techniques were employed to evaluate the effect of endogenous neurogenesis in the dentate gyrus (DG). 28 days post-modeling, the Morris water maze (MWM) was used to assess behavioral and cognitive function.
Results or Findings: Laser speckle imaging revealed that cerebral blood flow decreased most significantly at 24 h after HIBD . T2WI demonstrated a marked reduction in infarct volume following Mel treatment, accompanied by decreased abnormal DWI signals and significantly increased rADC values. Both Amide-CEST and NOE-CEST showed reduced abnormal signals in the injured hemisphere after Mel treatment, with LD-Amide and LD-NOE values significantly elevated MRS indicated a reduction in lactate levels in the Mel group. EdU/Nestin and EdU/DCX immunofluorescence staining revealed that Mel promoted the proliferation and migration of endogenous NSCs. The JAK2 inhibitor (WP1066) and agonist (C-A1) were used and results demonstrated that Mel exerts protective effects by inhibiting the JAK2/STAT3 pathway. MWM further confirmed that Mel improved memory function in neonatal rats with HIBD.
Conclusion: Multimodal MRI offers a visual basis for monitoring metabolic changes and reveals that Mel treatment can improve cerebral microenvironmental metabolism in HIBD neonatal rats. Moreover, Mel promotes endogenous NSC proliferation and migration by inhibiting the JAK2/STAT3 pathway.
Limitations: We recommend conducting further clinical studies.

Glymphatic system dysfunction in children with MRI-Negative focal epilepsy and relationship to cognitive impairment: A multimodal MRI study (6 min)

Haifeng Ran; Zunyi / China

Author Block: H. Ran, T. Zhang, K. Huang; Zunyi/CN
Purpose: Epilepsy is a common pediatric disease that often leads to cognitive and intellectual impairments, but the relationship between glymphatic system function and cognitive performance in children with focal epilepsy(FE) remains unclear. This study investigated the association between glymphatic system markers and cognitive outcomes in childhood FE.
Methods or Background: 80 FE children and 87 healthy controls(HC) were recruited, all subjects underwent multimodal MRI scan and cognitive performance assessment. And the glymphatic markers were acquired based on MRI data, including choroid plexus(CP) volume, cerebrospinal fluid(CSF) volume, diffusivity along perivascular spaces(ALPS), blood-oxygen-level-dependent(BOLD) signals, and CSF(BOLD-CSF) coupling. Comparisons of glymphatic markers were conducted between the FE and HC groups. The correlation analysis was performed to assess the association between glymphatic markers and cognitive function scores and clinical variables.
Results or Findings: The ratio of CP, CSF volume to intracranial volume was significantly higher in children with FE compared to HC($p<0.05$). Additionally, the BOLD-CSF coupling in the whole and middle cortical regions and the left hemisphere and global ALPS index were significantly lower in FE children compared to HC($p<0.05$). the ratio of CP volume changes were negatively correlated with PRI and onset age($p<0.05$), the ratio of CSF volume changes were negatively correlated with PRI and FSIQ($p<0.05$), and the BOLD-CSF coupling in the whole and middle cortical regions were negatively correlated with the age($p<0.05$) , while the left hemisphere ALPS index was positively correlated with VCI, PRI, WMI, PSI, FSIQ, respectively($p<0.05$), the global ALPS index was positively correlated with VCI, WMI, PSI, FSIQ, respectively($p<0.05$) and negatively correlated with the disease duration($p<0.05$).
Conclusion: These findings identify an association between glymphatic system dysfunction and cognitive impairment in children with FE.
Limitations: The cross-sectional design limits the ability to track spatiotemporal changes in glymphatic dysfunction.
Funding for this study: This research was supported by the National Natural Science Foundation of China (Grant Nos .82171919) and Intelligent Medical Imaging Engineering Research Center of Guizhou Higher Education Institutions project (Grant No. Qianjiaoji [2023] 038)

Glymphatic system dysfunction in children with focal epilepsy evidenced by DKI-ALPS and DTI-ALPS index (6 min)

Haifeng Ran; Zunyi / China

Author Block: H. Ran, T. Zhang, K. Huang; Zunyi/CN
Purpose: The diffusion tensor imaging analysis along the perivascular space(DTI-ALPS) method has been used to evaluate glymphatic system function in patients with epilepsy. However, since the diffusion tensor model may fail to describe the diffusion coefficient of the nerve fibre crossing region accurately. Thus, this study aimed to combined diffusion kurtosis imaging ALPS(DKI-ALPS) and DTI-ALPS methods to evaluate glymphatic system function in children with focal epilepsy(FE).
Methods or Background: The study finally included 63 children with FE and 58 healthy controls (HC).All participants underwent MRI scans to acquire DKI and DTI data, and they also received a cognitive assessment on the same day as their MRI scan. We calculated the DTI-ALPS and DKI-ALPS indices for the left brain, the right brain and the whole brain. A two-sample t-test was then used to compare the DTI-ALPS and DKI-ALPS indices of the two groups. We examined the correlation between the DTI-ALPS and DKI-ALPS indices and clinical variables. The statistical threshold was set at $P < 0.05$.
Results or Findings: Both groups were matched for age, sex, and education. Compared to HC, FE children showed decreased DTI-ALPS and DKI-ALPS indices. However, both left, right, mean DKI-ALPS index and only mean DTI-ALPS index was significantly decreased($P < 0.05$). Correlation analysis revealed a significant positive correlation between the decreased DTI-ALPS index and the VCI, PRI, WMI, PSI and FSIQ ($P < 0.05$). Regrettably, there was no significant correlation between DKI-ALPS indices and clinical variables.
Conclusion: This study demonstrates that abnormal glymphatic function in children with FE and associated with cognitive impairment. DKI-ALPS index showed higher sensitivity than DTI-ALPS in detecting group differences, and DTI-ALPS index may be a potential biomarker for cognitive impairment.
Limitations: Due to its cross-sectional design, causal relationships cannot be established.
Funding for this study: This study was supported by National Natural Science Foundation of China (grant No. 82171919), Intelligent Medical Imaging Engineering Research Center of Guizhou Higher Education Institutions project (grant No. Qianjiaoji [2023] 038), and Construction of Scientific and Technological Innovation Talent Team of Functional Imaging and Artificial Intelligence Application Research in Guizhou Province (grant No. QianKeHeRenCai CXTD [2025] 047).

Impact of intrauterine fetoscopic spina bifida repair on foetal brain edema (6 min)

Maximilian Schulze; Marburg / Germany

Author Block: M. Schulze[1], P. J. Orbán[2], C. Keil[1], S. Köhler[1], R. Axt-Fliedner[2], G. Kasprian[3], I. Bedei[2]; [1]Marburg/DE, [2]Giessen/DE, [3]Vienna/AT
Purpose: Neural tube defects such as myelomeningocele (MMC) and rachischisis are frequently associated with secondary central nervous system alterations including hindbrain herniation, edema, and aqueductal obstruction. Surgical repair aims to reduce these sequelae, but postoperative radiological outcomes remain incompletely characterized.
Methods or Background: A retrospective cohort of 31 patients with MMC (n=18) or rachischisis/myelocele (n=13) was analyzed using pre- and postoperative foetal MRI. Parameters included atlanto-occipital membrane bulging, extracerebral space size, brain edema, aqueductal patency, and cavum septum pellucidum (CSP) perforation. Statistical methods comprised descriptive analysis, correlation tests, and McNemar's test for paired pre/post comparisons.
Results or Findings: Preoperatively, 71% of patients demonstrated atlanto-occipital bulging, 68% brain edema, and 74% aqueductal stenosis; mean extracerebral space was 3.1 mm. Postoperatively, bulging decreased to 16%, edema to 16% (McNemar $p < 0.001$), and extracerebral space increased to 8.2 mm. However, aqueductal obstruction was observed in 39% of cases postoperatively, and CSP findings remained unchanged or worsened in some patients. A very strong correlation was detected between postoperative hindbrain herniation and postoperative brain edema ($r \approx 0.94$; Chi^2 $p = 0.0005$).
Conclusion: Surgical repair significantly improves edema and hindbrain bulging, with clear enlargement of the extracerebral space. Nevertheless, aqueductal obstruction and CSP changes persist as postoperative risks. The close association between hindbrain herniation and postoperative edema highlights the need for vigilant MRI follow-up and may inform tailored therapeutic strategies.
Limitations: Retrospective design. Clinical endpoints such as neurological function or developmental milestones were not evaluated.

Abnormalities present on MRI in monochorionic twin pregnancies with demise of 1 twin (6 min)

Phua Hwee Tang; Singapore / Singapore

Author Block: P. H. Tang, W. C. Tan, A. Bhatia, G. Y. H. Ng, J. Y. Kong, A. J. Anand, P. L. Tan, C. L. Ong; Singapore/SG
Purpose: Monochorionic twin pregnancies with single intrauterine foetal demise are reported as having highest risk of cerebral injury. Objective is to review our institution's foetal MRI cases in the past decade to determine abnormalities seen in monochorionic twin pregnancies with demise of 1 twin.
Methods or Background: Retrospective review of foetal MRI brain performed for monochorionic twin pregnancies for foetal demise / post in utero intervention from 1 Jan 2014 to 31 Dec 2024 was performed. Indication for MRI, gestational age at imaging, type of intervention performed (cord coagulation, ligation of vessel, radiofrequency ablation) were obtained from the radiology report.
Results or Findings: There were 54 MRI done for monochorionic twin pregnancies for foetal demise / post in utero intervention from 1 Jan 2014 to 31 Dec 2024.
MRI was performed at an average 23.0 weeks of gestation (range from 21.0 to 31.1 weeks.)
There were 11 pairs of live twins post intervention with 2 foetuses having mild ventriculomegaly.
Only 1 pregnancy being investigated for demise of 1 twin showed demise of both twins, both showing acute brain infarcts. Of the other 42 pregnancies having demise of 1 twin, 36 (85.7%) of the live twins were normal, 5 (11.9%) live twins had brain abnormalities, 1(2.3%) live twin had isolated pericardial effusion.
Brain abnormalities were acute infarcts in 2 foetuses, smaller cerebral hemisphere in 1 foetus, thin bilateral cerebral parenchyma in 2 foetuses, possible subependymal heterotopia in 1 foetus, giving cerebral abnormality rate of 13.9% (6/43).
Conclusion: Cerebral abnormalities are seen in 13.9% of monochorionic twin pregnancies with demise of 1 twin.
Limitations: Postnatal follow up not available at the time of preparation of this abstract.

Morphometric similarity mapping in pediatric migraine without aura: unravelling the role of sex (6 min)

Alessia Guarnera; Rome / Italy

Author Block: A. Guarnera[1], A. Napolitano[2], F. Dellepiane[2], A. Carboni[2], M. C. Rossi Espagnet[2], G. Moltoni[1], C. Gandolfo[2], D. Longo[2]; [1]Rome/IT, [2]Vatican City/VA
Purpose: Pediatric migraine without aura (pmwa) is suspected to cause structural and functional alterations in the brain connectome. MSM (morphometric similarity mapping), which has never been applied to pmwa, is an advanced technique which identifies anomalies of the cerebral cortex and connectivity. The paper aims to: a) identify differences in morphometric similarity networks (MSNs) in pediatric patients affected by mwa compared to controls and in subgroups of patients; and b) correlate these differences in MSNs with patients' demographic and clinical characteristics.
Methods or Background: 83 patients (6-18 years), and 81 controls were retrospectively recruited from our Institution's archive if the subjects showed: normal MRI exams and neurological examination, and no comorbidities. 3D T1 MPRAGE and DWI were pre-processed to obtain eleven cortical parameters for the MSN analysis. The global and regional mean morphometric similarities were calculated. We performed separate linear regression models, followed by an ANOVA with an FDR correction and a p-value threshold of 0.05 for all subjects and subgroups of patients in the global and regional models. For significant predictors, a post hoc analysis using the Benjamini-Hochberg method was performed.
Results or Findings: MSM identified significant differences in MSNs in patients based on clinical and demographic parameters, particularly biological sex. The cerebral pathways that showed the most significant alterations encompassed the executive function pathway, the nociceptive pathway, and the default mode network ($p<0.001$).
Conclusion: Differences in MSNs in the executive function pathway, the nociceptive pathway, and the default mode network demonstrated that migraine shapes the cerebral connectome and favours neuronal plasticity and may lead to chronicity of migraine symptoms. Biological sex is confirmed as a paramount parameter in migraine, supporting the hypothesis of a "sex-specific phenotype".
Limitations: The key limitation is the retrospective design of the study.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Not applicable
Ethics committee - additional information: The study is retrospective.

Elevated hippocampal lactate levels in MR Spectroscopy - A diagnostic tool to predict the laterality of Mesial Temporal Sclerosis in a setting of childhood afebrile seizures with adenoid hypertrophy (6 min)

Gowtham Krishna Jasti; Visakhapatnam / India

Author Block: G. K. Jasti, B. Suryarekha; Visakhapatnam/IN
Purpose: To establish relation between post seizure elevation of lactate in hippocampi and evolution of Mesial Temporal Sclerosis (MTS) in children with Hypertrophic Adenoids (HA)
Methods or Background: We conducted analysis of 60 children with afebrile seizures and no obvious positive findings in MRI Brain Epilepsy Protocol. 20 Children between the age range of 5 – 15 years with grade III /IV HA and associated afebrile seizures were included in this study.
The study was performed in 1.5 Tesla Philips Ingenia system at two radiology units in separate cities. Single voxel high TE (135 ms) MR Spectroscopy(MRS) was performed in bilateral hippocampi.
Study was performed between 01.01.2023 to 01.09.2025 and subjects showing elevated lactate peak were revaluated after 18 months for detection of features of MTS.
Results or Findings: Out of the 20 patients 60% had elevated lactate peaks in hippocampi. 40% patients had elevated lactate peaks in only one of the hippocampus. Left hippocampus showed unilateral elevation of lactate in 50% cases out of the total positive studies and right hippocampus showed unilateral lactate elevation in 25% cases. Rest of cases showed lactate elevation in both hippocampi. Cases with unilateral elevation of lactate in hippocampus showed mild reduction of corresponding hippocampal volume in repeat MRI Study 18 months after the first study with associated subtle T2/FLAIR hyperintensity suggesting evolution of MTS. Elevated lactate could be secondary to seizure acitvity or chronic obstructive sleep apnea in severe adenoid hypertrophy which increases neuronal excitability.
Conclusion: MRS shows promising results in predicting laterality of MTS in children with epilepsy and adenoid hypertrophy. It is helpful in assessment of other neuronal metabolites such as altered glutamate/glutamine and choline levels secondary to abnormal energy metabolisms in epilepsy.
Limitations: Limited sample size.

MRI findings in pediatric idiopathic intracranial hypertension: evaluating the oculomotor nerve cistern as a potential new diagnostic marker (6 min)

Bilgesu Arıkan Ergün; Ankara / Turkey

Author Block: B. Arıkan Ergün, S. Yilmaz, H. Bulut, B. Uçan, S. Seçer, S. Celik, D. Yüksel, Ç. Üner; Ankara/TR
Purpose: Idiopathic intracranial hypertension (IIH) is characterized by elevated intracranial pressure without an identifiable cause. Although headache is the most common symptom, prepubertal children often present with ocular motor nerve involvement, differing from older patients. This study aimed to assess the diagnostic value of oculomotor cistern (OMC) enlargement in pediatric IIH, compare it with established MRI findings, and propose it as a potential biomarker.
Methods or Background: Brain MRI and contrast-enhanced MR venography of patients under 18 years with clinical signs of increased intracranial pressure were retrospectively reviewed independently by two blinded radiologists. Pituitary morphology, perioptic CSF space, optic nerve tortuosity, posterior scleral flattening, Meckel's cave dimensions, OMC CSF space, and venous sinus narrowing were evaluated. Demographic data, ophthalmologic findings, and CSF pressure measured by lumbar puncture were recorded. Patients with elevated CSF pressure were compared with those with normal pressure.
Results or Findings: A total of 76 children with suspected IIH were evaluated, 10 of whom were excluded due to secondary causes. Among the remaining 66, 44 (67%) had elevated and 22 (33%) normal CSF pressure. In addition to established imaging findings—such as increased perioptic CSF, posterior scleral flattening, and optic nerve tortuosity—increased CSF space in the OMC was also statistically significant.
Conclusion: Neuroimaging is essential in IIH evaluation. Alongside recognized findings such as perioptic CSF widening, optic nerve tortuosity, posterior globe flattening, sellar changes, and venous sinus stenosis, increased OMC CSF space may serve as a novel imaging marker for diagnosing pediatric IIH.
Limitations: The limitations of the study are its retrospective and single-center design, which may limit generalizability, the small sample size, non-homogeneous patient age distribution, and the lack of long-term clinical correlation of oculomotor cistern enlargement with visual outcomes or disease progression.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes

Spectrum of MRI Signatures in Pediatric Infectious Encephalitis: Towards a Pattern-Based Diagnostic Framework (6 min)

Priya Behl; Chandigarh / India

Author Block: P. Behl; Chandigarh/IN
Purpose: Magnetic resonance imaging (MRI) plays a pivotal role in evaluating brain infections in children presenting with acute infectious encephalitis. Interpretation can be challenging, as a single pathogen may lead to diverse imaging appearances, while similar MRI patterns may arise from different infectious agents. Establishing recognisable imaging patterns can aid radiologists in refining differential diagnoses and guiding clinical management.
Methods or Background: This prospective study included 27 microbiologically confirmed cases of acute infectious encephalitis admitted between November 2023 and April 2025. MRI scans were systematically assessed for the predominant signal abnormality (restricted diffusion versus T2 hyperintensity) and the distribution of lesions. Based on these criteria, key imaging patterns of paediatric brain infection were identified.
Results or Findings: Six principal MRI patterns were delineated: (1) restricted diffusion in supratentorial white matter (adenovirus, rotavirus, enterovirus, chikungunya, herpes simplex virus), (2) restricted diffusion in supratentorial grey matter (herpes simplex virus, varicella, Epstein–Barr virus, enterovirus), (3) restricted diffusion in the corpus callosum (influenza, rotavirus, Escherichia coli, Salmonella), (4) T2 hyperintensity in supratentorial white matter (TORCH group: toxoplasma, rubella, cytomegalovirus, herpes simplex virus), (5) T2 hyperintensity in the basal ganglia or thalami (Epstein–Barr virus, varicella zoster, dengue, Japanese encephalitis virus), and (6) T2 hyperintensity in the posterior fossa (enterovirus). Recognition of these imaging spectra facilitated pathogen-directed differential diagnosis.
Conclusion: A structured, pattern-based framework enables consistent interpretation of MRI findings in paediatric brain infections. Integrating these imaging insights into clinical practice may improve diagnostic accuracy and expedite management decisions.
Limitations: The limitations of the study are the relatively small cohort size and the absence of long-term imaging follow-up.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes

The Value of 3D arterial spin labeling in early diagnosis and short-term prognostic grouping of Full-Term neonatal hypoxic-ischemic encephalopathy (6 min)

Liu Chang; Hefei / China

Author Block: L. Chang; Hefei/CN
Purpose: To investigate the value of 3D arterial spin labeling(ASL) perfusion imaging and DWI for the early diagnosis of hypoxic-ischemic encephalopathy(HIE) in term neonates and the predictive value of 3D ASL for patient prognosis.
Methods or Background: A total of 60 full-term neonates clinically diagnosed with HIE were divided into favourable outcome and adverse outcome groups according to their prognosis,and all subjects underwent 3D ASL and DWI simultaneously.The areas of interest included bilateral basal ganglia, thalamus, and frontal white matter, and the final average was bilaterally taken.To investigate the correlation between CBF value of HIE in neonates and neonatal behavioral neurological assessment (NBNA).
Results or Findings: The CBF values of basal ganglia and thalamus in the adverse outcome group were higher than those in the favourable outcome group, and the difference was statistically significant ($P<0.01$); the CBF value of frontal white matter in the adverse outcome group and the favourable outcome group were statistically significant ($P<0.01$); the CBF values in the basal ganglia and thalamus of neonates in the HIE group were greater than those of normal controls, and the differences were statistically significant ($P<0.01$); respectively CBF values in the basal ganglia region were highly correlated with NBNA scores ($r=-0.8196, p<0.01$) and negatively correlated; thalamic CBF values were highly correlated with NBNA scores ($r=-0.8504, p<0.01$) .
Conclusion: ASL findings within 1 day after birth in full-term neonates were highly correlated with NBNA scores. It can diagnose HIE early and predict the outcome of functional brain damage with better diagnostic efficacy than DWI.
Limitations: Clinical application in the early diagnosis of children with HIE, for the prognosis of children in the near future prediction, children after treatment review, to understand the cerebral tissue perfusion, with no radiation, convenient examination
Funding for this study: This study was supported by grants from The National Natural Science Foundation of China (32071054).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the medical ethics committee of affiliated hospital of University of Science and Technology of China (2021-RE-118). Parents of the neonates gave informed consent and signed the informed consent form.

Transient brain injury in utero imaging among surviving and recipient co-twins in demised, TTTS, or monochorionic pregnancy evaluations in second and third trimester (6 min)

Jason Michael Johnson; New Haven / United States

Author Block: S. Babapour, A. Demiray, J. M. Johnson; New Haven, CT/US
Purpose: There is an increased risk of neurologic damage, 20- 40%, in the surviving twin if one twin dies in utero. This single-institution retrospective study evaluated the effects of co-twin demise and twin-twin transfusion syndrome (TTTS) on fetal brain and vasculature in monochorionic twin pregnancies.
Methods or Background: Using fetal brain MRI and ultrasound imaging, 16 defects were identified among 53 in utero twins. The study focused on cases within the first 30 days after a demise during the second and third trimesters. The average gestational age at initial MRI evaluation and based on LMP was 23 weeks and 4 days.
Results or Findings: 24 (48%) pregnancies involved a demised twin, most frequently associated with advanced TTTS (stage 3-4) or following radiofrequency ablation. Maternal demographic data were generally unremarkable except for two cases of maternal obesity. The imaging findings of the surviving co-twins, using both ultrasound and MRI, were largely consistent and indicated normal neurodevelopmental growth and cerebral vascular flow. The demise of donor twins occurred within three days post-procedure. In most cases, no evidence of acute brain injury, asymmetric development, or compensatory vascular overflow was detected in the surviving or recipient twins within one month following the co-twin's demise. Notable exceptions included single cases of asymmetric biometry and increased corpus callosum length.
Other observed abnormalities among co-existing twins with early-stage TTTS included heart enlargement, ventriculomegaly, and Dandy-Walker malformation, although five cases demonstrated intact brain and vascular flow. There was a high concordance (95.35%) between ultrasound and MRI findings.
Conclusion: After advanced TTTS and fetal demise, surviving co-twins generally do not exhibit early brain injury or abnormal vascular compensation within one month; however, comprehensive soft tissue evaluation remains essential.
Limitations: A lack of long-term follow-up beyond one month post-demise.

Evaluation of fetal brain changes between fetal growth restricted and small-for-gestional age pregnancies using T1 mapping sequence (6 min)

Liangyu Ji; Nanjing / China

Author Block: L. Ji, X. Zhang, M. Zhao; Nanjing/CN
Purpose: Fetal growth restriction (FGR) poses challenges in both the timing and detection of altered brain development, particularly in distinguishing pathological FGR from small for gestational age (SGA) fetuses. This study aimed to investigate differences in T1 relaxation times in the fetal brain between FGR and SGA cases.
Methods or Background: STAGE data were collected using two flip angles(15°and 60°, with a TR=600ms) at 1.5T. T1app maps of the fetal brain were generated from the STAGE data. T1 values were measured and compared in the following regions: frontal white matter (FWM), occipital white matter (OWM), centrum semiovale (CSO), thalami (T), cerebellar hemisphere (HC), basal ganglia (BG), and brainstem. T1 values among FGR, SGA, and AGA groups were compared using independent or Welch's t-tests, as appropriate. A p-value < 0.05 was considered statistically significant.
Results or Findings: Among 50 cases (16 SGA, 13 FGR, 21 AGA), FGR fetuses exhibited significantly higher T1 values in FWM, OWM and CSO compared to the other two groups. FGR showed differences in the BG(1593.21±205.60ms vs 1368.92±233.12ms P=0.006) and brainstem(1315.11±263.57ms vs 1142.69±217.58ms P=0.039) compared to AGA fetuses. The T1 values of AGA fetuses showed negative correlations with gestational weeks in BG (r=-0.660), brainstem (r=-0.603), HC (r=-0.469), FWM (r=-0.646), OWM (r=-0.540) and thalami (r =-0.513).
Conclusion: T1 mapping offers a sensitive, non-invasive method for detecting microstructural brain alterations in FGR fetuses, especially in white matter and subcortical regions.
Limitations: First, some images were of suboptimal quality due to a small gestational age or polyhydramnios. Second, the study did not assess long-term neurodevelopmental outcomes, so the clinical relevance of the observed differences in T1 values remains uncertain.

Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: It was approved by the institutional ethics committee of The First Affiliated Hospital of Nanjing Medical University.

Prenatal Corpus-Callosum Abnormalities: Maternal, Gestational and Brain-Biometric Profiles in a 61-Case MRI Cohort (6 min)

Jason Michael Johnson; New Haven / United States

Author Block: S. Babapour, J. Pearce, L. Ment, M. Bahtiyar, K. Kohari, E. Dave, J. M. Johnson; New Haven, CT/US
Purpose: To characterize maternal and fetal features quantitatively with a standardized panel of brain MRI biometrics among referrals with suspected corpus callosum (CC) anomalies.
Methods or Background: In this single-center retrospective evaluation of 61 consecutive fetal MRIs (2013-2025) reported as CC abnormality, morphometric variables were reviewed: bilateral ventricular-atria (VA) diameters, CC length, cerebral and bone biparietal diameters (BPD), vermis antero-posterior (AP) diameter & height, coronal cerebellar diameter and pons AP diameter (table 1). Gestational age (GA) was taken from ultrasound dating or, if absent, last menstrual period.
Results or Findings: Mean maternal age at MRI was 31.8 ± 4.7 years (22–42). Median GA was 25 weeks (IQR 22–28).
• CC morphology: complete agenesis in 42 (69 %), partial agenesis or hypoplasia in 10 (16 %), dysgenesis in 9 (15 %).
• CC length (non-agenesis, n = 32): 29.7 ± 6.1 mm (-1.8 SD vs normative medians).
• VA diameters: dilatation ≥ 10 mm in 34/55 measurable cases (62 %). VA_mean inversely correlated with CC length ($r = -0.58$, $p < 0.001$).
• Posterior fossa: vermis height < 5th percentile in 10/43 (23 %), predominating in complete agenesis (8/10).
• Parenchyma–skull discordance: cerebral BPD lagged behind bone BPD by ≥ 5 mm in 28/50 (56 %).
No significant association was found between maternal age tier (< 30 vs ≥ 30 yr) and degree of VA dilatation or CC subtype ($p > 0.3$).
Conclusion: In this in utero second and early third trimester MRI series, CC malformations were assessed in mothers of reproductive age. Ventriculomegaly and posterior-fossa under-development were common co-findings and showed quantifiable relationships to CC size. Routine extraction of these biometric signatures may refine prenatal counselling and prognostication in CC anomaly.
Limitations: Further multicenter validation and collaboration are required.

Frank Volker Bensch; Helsinki / Finland

Improved Detection of Bowel Ischemia in Emergency CT: Diagnostic Value of Spectral Reconstructions Across DECT and PCCT Platforms (6 min)
Fiona Karola Elisabeth Mankertz; Tübingen / Germany

Author Block: F. K. E. Mankertz, N. Maalouf, J. Berger, J. Herrmann, R. Dehdab, K. Nikolaou, S. Afat; Tübingen/DE
Purpose: To assess whether spectral CT reconstructions improve diagnostic accuracy of bowel ischemia detection compared with blended images and stratified by dual energy CT and photon counting CT platforms.
Methods or Background: This retrospective single centre study included 378 emergency spectral CT examinations for suspected bowel ischemia between January 2023 and July 2025, with 265 dual energy CT and 113 photon counting CT. Exclusions were absent spectral data, non diagnostic image quality, incomplete bowel coverage, no reference standard within 72 hours, or age <18 years. Two abdominal radiologists with four years subspecialty experience independently reviewed examinations first with blended images and after a four week washout with spectral reconstructions. Readers assigned 1 to 5 suspicion scores per examination and duplicate cases assessed intra reader repeatability. Outcomes were analysed with generalized linear mixed models with random intercepts for reader and case and with DeLong testing.
Results or Findings: Bowel ischemia was present in 126/378 examinations (33%). Sensitivity increased from 75% with blended images to 87% with spectral reconstructions ($p = 0.008$) and specificity from 72% to 86% ($p < 0.001$). Per reader AUC rose from 0.81 and 0.82 to 0.91 and 0.92, both $p < 0.001$. Diagnostic confidence improved from 3 to 5 on a 7 point scale. Inter reader agreement rose from kappa 0.56 to 0.71 and intra reader repeatability was high at 0.82. Platform stratified analysis showed significantly greater gains with photon counting CT than with dual energy CT (interaction $p = 0.03$).
Conclusion: Spectral reconstructions improved diagnostic accuracy, confidence and agreement for bowel ischemia detection. Gains were greater with photon counting CT. Integrating spectral reconstructions into emergency CT workflows may improve reliability without added contrast or radiation.
Limitations: Single-centre design and reader pool may limit generalisability.

Difficult abdominal closure after emergency laparotomy: predictive role of morphometric abdominal indices on CT imaging (6 min)
Francesco Rizzetto; Milan / Italy

Author Block: F. Rizzetto, R. Bini, P. Chiara, T. Pilia, F. Cammarata, C. B. Monti, S. P. B. Cioffi, D. Albano, A. Vanzulli; Milan/IT
Purpose: Predicting difficult abdominal closure after emergency laparotomy remains a clinical challenge. This study aimed to assess whether morphometric abdominal indices derived from preoperative CT can predict the need for multiple surgical procedures to achieve definitive closure.
Methods or Background: We retrospectively reviewed emergency abdominal CT scans performed between 2010 and 2024 in patients who subsequently underwent open abdominal surgery. Morphometric measurements included maximum latero–lateral diameters of the rib cage, abdomen, and pelvis; maximum anteroposterior and cranio–caudal abdominal diameters; and total abdominal cavity volume. Thickness of the anterolateral abdominal wall muscles, rectus abdominis, and length of the linea semilunaris were also recorded. Demographic data and surgical indication were also collected. The primary endpoint was difficult abdominal closure, defined as requiring more than one surgical procedure for closure. Variables with $p<0.10$ at univariate analysis were entered into multivariate logistic regression (significance $p<0.05$), reporting odds ratios (ORs) and 95% confidence intervals (CIs).
Results or Findings: A total of 144 patients (105 males, 72%; mean age 47±21 years) were included. Difficult closure occurred in 35 patients (24%). These patients were more frequently male (86% vs. 69%; $p=0.063$) and more often underwent surgery for trauma (83% vs. 43%; $p<0.001$). Among morphometric parameters, only abdominal cavity volume ($p=0.002$) and the minimum thickness measured among the rectus abdominis muscle bellies ($p=0.063$) were associated with difficult closure. In multivariate analysis, abdominal cavity volume (OR=1.45; 95%CI: 1.12–1.91; $p=0.006$) and trauma (OR=5.22; 95%CI: 1.77–18.4; $p=0.005$) remained independent predictors.
Conclusion: Total abdominal cavity volume was the only independent morphometric predictor of difficult closure, together with trauma as the surgical indication. Incorporating this parameter into preoperative assessment may improve risk stratification and guide surgical management in emergency patients.
Limitations: Retrospective design and variability in surgical decision-making could limit generalizability.

Enhancing Adherence to Imaging Guidelines in Acute Pancreatitis: Impact of a Two-Cycle Quality Improvement Audit (6 min)

Minouche Maki; Leicester / United Kingdom

Author Block: M. Maki; Leicester/UK
Purpose: The general objective of the audit, through local data utilization, was to support the continued quality enhancement by reassessing the imaging practice of AP across two audit cycles
Methods or Background: 619 inpatient patients were retrospectively followed between 2023 and 2025. The first audit cycle involved thirty patients and the second audit cycle involved fifty patients. Intervention activities were comprised of electronic reminding of imaging request and posters in high-traffic zones, and training for clinicians. The imaging conducted within 72 hours of the request was termed to be compliant, and the modality choice or the use of needless premature CT used as additional
Results or Findings: The compliance rate was 85 percent and the compliance rates in cycle one and cycle two were elevated by 20.3 percent (66.7 percent) and 20.3 percent respectively. The use of ultrasound increased by 70-90 percent at admission and decreased by 30-10 percent in the unnecessary use of CT
Conclusion: The two- cycle audit carried out within the University Hospitals of Leicester (UHL) Trust shows the appropriateness of continuous quality improvement in the alignment of clinical practice with evidence-based suggestions in imaging of acute pancreatitis (AP). It has been discovered that the overall compliance rates regarding the use of the 600 patients 72-hour-long imaging standard were higher than the 66.7% of the first cycle to 96% of the second cycle. Notably, the percentage of the unnecessary premature scan CT minimized (30 to 10), and the percentage of admission ultrasounds rose 70 to 90
Limitations: Despite the huge improvements, delays were only in two patients in the second round, both of which had issues related to the patient such as imaging intolerance, but 15% of all the patients in the dataset still had delays.
Funding for this study: I do not need funding for this audit, I just need an opportunity to present my audit either orally or by eposter.

Provision of Emergency Non-Traumatic Abdominal Imaging in the UK: A National Snapshot Audit (6 min)

Naren Govindarajah; Milton Keynes / United Kingdom

Author Block: N. Govindarajah, J. K. C. Mak, S. Qadri, K. Drinkwater, H. Roach, R. Greenhalgh, G. Retnasingam, H. Addley; London/UK
Purpose: To evaluate the provision of emergency non-traumatic abdominal imaging in the United Kingdom.
Methods or Background: Prompt abdominal imaging is central to the diagnosis and management of acute surgical emergencies. The Royal College of Radiologists (RCR) led a national audit to assess the availability, organisation, and reporting practices of emergency non-traumatic abdominal CT imaging across United Kingdom (UK) hospitals.

A structured online survey was distributed to radiology departments nationwide. Data were collected from 103 hospitals which included tertiary and district-general (DGH) institutions. Questions addressed service provision, vetting processes, reporting responsibilities and radiologist–clinician communication.
Results or Findings: Only 37% of centres recorded a dedicated National Emergency Laparotomy Audit (NELA) Radiology lead at their institutions. All centres (100%) provided both in and out-of-hours CT scanning for acute abdominal emergencies. Only 51% had a standardised flagging system to prioritise patients in-hours, falling to 49% out-of-hours. Acute abdominal imaging pathways were available in 41% of hospitals in-hours and 39% out-of-hours. Vetting of CT requests was primarily undertaken by on-site radiology consultants during in-hours (98%), but responsibility shifted largely to teleradiology providers out-of-hours (74%).

On-site consultants almost universally provided the first report in-hours (97%), whereas out-of-hours this was delivered by teleradiology (76%). Documentation of radiologist–clinician communication was inconsistent, with 56% of departments recording formal discussion in-hours and a similar proportion (56%) out-of-hours.
Conclusion: This audit demonstrates that although universal CT access exists for emergency non-traumatic abdominal imaging in the UK, significant variation persists in pathways, request vetting, reporting practices, and documentation. This audit has highlighted the reliance on off-site and teleradiology reporting out-of-hours nationally. The findings support the need for clearer national standards and improved consistency in pathways to ensure effective imaging provision for acutely unwell patients.
Limitations: Snapshot audit
Funding for this study: No funding.

The use of imaging in patients with a necrotising soft tissue infection (6 min)

Lidewij M.F.H. Neeter; Maastricht / Netherlands

Author Block: L. M. Neeter, J. Suijker, M. De Lijster, A. Pijpe, A. Meij - de Vries; Beverwijk/NL
Purpose: Necrotising soft tissue infections (NSTIs) are infections of the deeper tissues; necrotising fasciitis and Fournier's disease being the most well-known. Due to the rapid progressive destruction of tissue and systemic toxicity, time is of the essence for successful treatment. However, recognition of NSTIs, which predominantly relies on symptom recognition combined with surgical inspection, is challenging and patients are often misdiagnosed. We describe the use of imaging in a Dutch cohort of NSTI patients.
Methods or Background: The database of a Dutch multicentre retrospective cohort on 271 NSTI patients from 11 hospitals treated between 2013 and 2017, was accessed for information on the location of NSTI, the imaging performed, and its outcomes.
Results or Findings: Imaging was performed in 152 (56.1%) patients. Sixty-three patients underwent ultrasound (41.4%), 28 x-ray (18.4%), 89 CT (58.6%), and 12 MRI (7.9%). In 56 patients, NSTI was considered as potential diagnosis before the imaging examination was performed. In those patients, the ultrasound was suggestive for NSTI in seven patients (70.0%), x-ray in two patients (50.0%), CT in 37 patients (88.1%), and MRI in two patients (66.7%). CT supported the diagnosis of NSTI in the head/neck, arm/thorax, leg, anogenital/gluteal, and abdominal region in two (50.0%), six (100.0%), seven (100.0%), seventeen (94.4%), and eight patients (75.0%), respectively.
Conclusion: In this retrospective cohort, imaging was performed in the majority of NSTI patients. CT was most commonly used in case of suspected NSTI and seems able to recognise NSTI in the vast majority of cases. However, the benefits of imaging and potential disadvantages caused by imaging, such as delay in surgical inspection, remains a challenging and debatable trade-off.
Limitations: Acquiring diagnostic accuracy was not possible; the cohort consisted solely of NSTI patients.

Diagnostic Failures in Abdominal Parenchymal Trauma: The Mistake Just Around the Corner (6 min)

Maria Cristina Firetto; Milan / Italy

Author Block: M. C. Firetto, G. Carrafiello; Milan/IT
Purpose: Trauma causes 9% of global deaths (case fatality 4.6%–10.1%), and whole-body CT reduces mortality by 13%. Yet diagnostic failures—seen in up to 12.9% of scans—contribute to 11% of trauma deaths. This study aims to characterize both technical/methodological and interpretative errors in detecting parenchymal injuries of abdominal organs (lacerations, hematomas, infarctions, and associated vascular lesions such as active bleeding, pseudoaneurysms, and arteriovenous fistulae) on emergency CT, and to propose targeted strategies for error reduction.
Methods or Background: A structured narrative review of published series on parenchymal injuries was performed. Diagnostic failure rates were analyzed for abdominal parenchymal and associated vascular injuries. Errors were classified as:
- Technical/methodological: incomplete multiphase protocols, motion artifacts, beam-hardening, streak artifacts.
- Interpretative: false positives (overcalls of congenital clefts, normal variants, artifacts), false negatives (missed pseudoaneurysms, subtle hematomas, delayed bleeds).
Representative cases illustrate common diagnostic pitfalls.
Results or Findings: Technical errors accounted for ~60% of failures. Monophasic protocols missed: 10%–15% of splenic/hepatic injuries, 5%–20% of vascular lesions, 8%–10% of renal parenchymal injuries, up to 50% of ureteropelvic junction injuries. Artifacts masked both parenchymal and vascular lesions. Pancreatic and adrenal injuries were described qualitatively; quantitative data on missed diagnoses are lacking in the available series. Interpretative errors (~40%) included overcalls due to enhancement heterogeneity and undercalls of vascular injuries and delayed hemorrhage. Dual-/multiphase CT, orthogonal reconstructions, structured reporting, and systematic search patterns improved detection and reduced delays.
Conclusion: Optimizing acquisition protocols, interpretative training, structured reporting, and multidisciplinary review can reduce diagnostic errors and improve trauma outcomes.
Limitations: The narrative review design and heterogeneity of published protocols limit quantitative synthesis; data on pancreatic and adrenal parenchymal injuries remain insufficient, and the proposed error-reduction strategies lack prospective validation.

Reducing ct overuse in minor head injury: a local campaign (6 min)

Karanvir Singh Chhabra; Jalandhar / India

Author Block: K. S. Chhabra, T. Sehgal, D. B. Dahiphale, B. Patel; AURANGABAD/IN
Purpose: To evaluate the impact of a local awareness and guideline-based campaign on reducing unnecessary CT brain scans in patients with minor head injury at a tertiary care centre in India.
Methods or Background: Background
CT brain is often overused in cases of minor head injury, exposing patients to unnecessary radiation, increasing costs, and burdening radiology services. International guidelines such as the Canadian CT Head Rule (CCHR) and NICE criteria provide evidence-based thresholds for imaging. However, adherence in busy emergency settings remains inconsistent.
Methods or Approach
A baseline audit was performed of 120 consecutive patients with Glasgow Coma Scale (GCS) 13–15 presenting with head injury between January and March 2025. The proportion of CT scans meeting CCHR criteria was calculated. A local campaign was then implemented, including educational sessions for emergency physicians, pocket guideline cards, and posters displayed in the emergency department. A re-audit of 100 patients was conducted three months later.
Results or Findings: At baseline, 62% of CT scans were performed without meeting guideline criteria. Following the campaign, inappropriate CT utilisation decreased to 32%, reflecting a 30% improvement. No clinically significant injuries were missed during the re-audit period. Emergency physicians reported improved confidence in applying CCHR criteria, and turnaround time in the CT suite improved due to reduced scan load.
Conclusion: A simple, low-cost educational campaign significantly reduced inappropriate CT brain scans for minor head injury without compromising patient safety. Sustained adherence to clinical decision rules can improve resource utilisation, reduce radiation exposure, and optimise emergency imaging services.
Limitations: Single-centre data.

Incidental Findings on Head CT: What to Report, What to Ignore (6 min)

El Mehdi Rajali; Casablanca / Morocco

Author Block: E. M. Rajali; Casablanca/MA
Purpose: To guide radiologists through the growing challenge of incidental findings on head CT, providing a practical framework for distinguishing harmless variants from clinically significant lesions.
Methods or Background: Head CT is the first-line exam in trauma and emergency neurology. Its systematic use in high-volume, time-sensitive settings frequently reveals incidental abnormalities. While some are benign and can be ignored, others require recognition and follow-up. The core challenge lies in balancing thoroughness with clinical relevance, avoiding both unnecessary investigations and missed diagnoses.
Results or Findings: In daily practice, radiologists often struggle with this balance: over-reporting benign variants such as physiologic calcifications, cavum septum pellucidum, or mild sinus changes may create anxiety and lead to unwarranted work-up. On the other hand, subtle but significant findings — such as silent infarcts, meningiomas, or hydrocephalus — may be overlooked, with important clinical consequences. Age-related atrophy further illustrates this dilemma, requiring correlation with patient age and symptoms before deciding on its significance. The key is a structured, context-driven approach supported by clear reporting recommendations.
Conclusion: The challenge of incidental findings is not to see “more,” but to know what truly matters. By applying a systematic approach, radiologists can remain consistent, provide reassurance to clinicians, and avoid sending patients into unnecessary diagnostic odysseys, while still capturing findings with real clinical impact.
Limitations: May not encompass all potential incidental findings
Funding for this study: No funding

Single-Energy Metal Artifact Reduction Improves Carotid CTA Quality in Patients with Fixed Dentures (6 min)

Huasong Cai; Guangzhou / China

Author Block: R. Xu, D. Xie, Z. Lai, H. Ma, H. Cai; Guangzhou/CN
Purpose: To evaluate the effectiveness of single-energy metal artifact reduction (SEMAR) in improving image quality of emergency carotid CT angiography (CTA) in patients with fixed metal dentures at different intraoral positions.
Methods or Background: We retrospectively reviewed 103 emergency patients (mean age 65 ± 12 years; 62 men) who underwent carotid CTA on a 320-detector CT scanner. Images were reconstructed conventionally and with SEMAR. Patients were stratified by denture position: unilateral (n=48), bilateral (n=33), and anterior (n=22). Objective metrics included vessel attenuation (HU), signal-to-noise ratio (SNR), and contrast-to-noise ratio (CNR). Two neuroradiologists independently scored image quality on a 5-point scale. Statistical tests included paired t-test, Wilcoxon signed-rank test, ANOVA with Bonferroni correction, and κ statistics.
Results or Findings: Interobserver agreement was excellent (κ=0.95–0.97). In unilateral and bilateral groups, SEMAR significantly increased attenuation, SNR, and CNR of arteries adjacent to dentures (all $p<0.001$). For unilateral dentures, ipsilateral internal carotid attenuation rose from 347 ± 79 HU to 370 ± 87 HU, SNR from 34.9 ± 14.7 to 37.0 ± 15.9, and CNR from 29.3 ± 12.9 to 31.5 ± 13.7. In bilateral cases, attenuation increased from 361 ± 107 HU to 404 ± 106 HU, SNR from 34.8 ± 9.2 to 38.4 ± 9.6, and CNR from 32.7 ± 17.2 to 37.8 ± 17.8 (all $p<0.001$). No significant objective differences were observed in anterior-denture cases. SEMAR improved median subjective quality scores from 2 to 4 overall (all $p<0.001$), with marked gains in unilateral and bilateral positions, but not anterior.
Conclusion: SEMAR substantially reduces denture-related artifacts and improves both objective and subjective image quality in emergency carotid CTA, enhancing diagnostic confidence without additional scan time or radiation.
Limitations: This single-center retrospective study with a relatively small sample size.

CT and MRI predictors of early myelopathy after spinal trauma: a preliminary study (6 min)

Irem Ceren Koc; Samsun / Turkey

Author Block: I. C. Koc, K. Aslan, B. Genç; Samsun/TR
Purpose: The purpose of this study is to determine the CT parameters that can predict myelopathy risk in spinal trauma patients, to investigate the MRI parameter differences between patients with and without myelopathy and compare the spinal cord changes between these groups during early trauma period (120 days).
Methods or Background: 115 patients who suffered spinal trauma, had CT taken within 24 hours and spinal MRI taken within first 48 hours were included in this retrospective single-center study. 76 patients had myelopathy while 39 patients didn't. Paraspinal muscle area (PMA) and density (PMD), bone density (BD), subcutaneous fat thickness (SFT) at the level of trauma, spinal canal AP diameter measured in CT and spinal cord area, spinal canal area, cord compression ratio measured in MRI were compared between groups. Nine patients without myelopathy and 14 patients with myelopathy had control MRI within 120 days after trauma. Longitudinal comparisons were made between groups.
Results or Findings: There were no statistically significant differences between groups for PMA, PMD, bone density, SFT. Spinal canal AP diameter below the trauma level (SCAPBTL) showed significant difference (p=0.037). Spinal cord area at trauma level and spinal canal area below the trauma level (SCABTL) showed significant difference (p=0.026; p=0.024). AUC of 0.624 was determined for SCA-BTL through ROC analysis to distinguish myelopathy (75% sensitivity, 56.41% specificity). In longitudinal analysis there were no significant differences for SCA-TL neither within nor between groups (p=0.26; p=0.975; p=0.45).
Conclusion: Our study shows only SCAPBTL was meaningful in CT. SCA-BTL can be used to differentiate myelopathy. Spinal cord doesn't show significant change both within and between groups in early trauma period.
Limitations: Small sample size. Since data regarding spinal injury impairment scale wasn't available, a clinical correlation couldn't be analyzed.
Funding for this study: No funding was received for this study.

Acute low back pain of extra-axial non-traumatic origin: clinical and radiological overview from a high-load tertiary emergency department (6 min)

Pietro Andrea Bonaffini; Monza / Italy

Author Block: P. A. Bonaffini[1], E. Piccin[1], C. Preti[2], R. Cosentini[2], C. Valle[1], P. Marra[1], S. Sironi[1]; [1]Monza/IT, [2]Bergamo/IT
Purpose: To report prevalence and etiologies of acute extra-axial non-traumatic low back pain (ALBP, <3 months onset), in patients admitted in a high-load tertiary emergency department (ED) over 2-year (2018-2020). To review radiological features and imaging contribution in ALBP, using discharge or ward admittance diagnosis as reference.
Methods or Background: Patients admitted to ED were retrospectively divided according to back pain onset (chronic/acute) and origin (traumatic/non-traumatic, axial/extra-axial): chronic pain, trauma-related and axial causes were excluded. Clinical evaluation during admittance was checked; then, abdominal, genitourinary, gynecological, infectious, rheumatological and cardio-pulmonary etiologies were categorized by final diagnosis at discharge or ward admittance. Then imaging results (plain radiography, US, CT) for each category were reviewed and reported.
Results or Findings: Among 46.449 patients, 2024 (23%) were admitted for lumbar pain: in 78.6% chronic-traumatic-musculoskeletal, in 21,4% extra-axial non-traumatic (ALBP). In ALBP final diagnosis was: 212 patients(49,5%) with urinary disease (kidney stones, pyelonephritis, cystitis), 95(22,2%) abdominal (constipation, biliary cholic), 67(15,6%) gynecologic (including pregnancy), 24(5,6%) infectious (influenza, fever), 21(4,9%) cardio-pulmonary (pneumonia, pericarditis), 7(1,6%) rheumatologic (polyarthritis) and 1(0,2%) vascular (dissection). US was the most employed technique (26,9%; 31,6% patients with urinary, 24,2% abdominal, 14,9% gynecological, 28,9% infectious diseases and for aortic dissection). Plain radiography was used to exclude perforation/occlusion (13,4%). CT used was in 9 patients (2,1%) as completion (inconclusive US/plain radiography), including aortic dissection. In 264 patients (61,7%) imaging was not performed: diagnosis was gained through clinical/laboratory data.
Conclusion: ALBP is a relevant cause of access to ED. In 20% of cases origin is related to abdominal causes, being urinary diseases the most common. With inconclusive clinical-laboratory evaluation (40%) imaging can aid in confirming pain origin. US is essential for kidney-abdominal evaluation, CT could be reserved to selected cases, sparing unnecessary radiation exposure.
Limitations: Retrospective

Economic potential of optimizing mobile stroke unit implementation in Germany : A markov model based analysis (6 min)

Noah Castioni; Mannheim / Germany

Author Block: N. Castioni, J. S. Rink; Mannheim/DE
Purpose: To assess the economic and health system impact of optimized mobile stroke unit (MSU) care in Germany, specifically incorporating a newly developed mobile head CT scanner that delivers high-quality imaging directly in the prehospital setting. This study also highlights, for the first time, the impact of (1) dispatcher sensitivity as a dominant driver of MSU case capture and cost-effectiveness and (2) explicit modeling of endovascular therapy (EVT) workflow acceleration—two aspects not fully captured in prior MSU cost-effectiveness studies.
Methods or Background: Expanding on and going beyond prior CEAs, the Markov model included both intravenous thrombolysis (IVT) and, for the first time, EVT care pathways, incorporating time and outcome data from recent clinical registries. Dispatcher sensitivity was systematically varied and analyzed for its effect on case capture, improving on the previous static approach. Model scenarios compared EMS with MSU services for different catchment areas, schedules, and resource-sharing settings, capturing system-level effects of greater dispatch precision and faster EVT.
Results or Findings: Improved dispatcher sensitivity yielded a more substantial reduction in incremental cost-effectiveness ratios (ICERs) than adjustments in hardware or staffing costs. Explicit inclusion of EVT workflow improvements led to a higher rate of good outcomes (29.6% mRS 0–2 with MSU vs. 27.5% EMS in EVT-eligible patients), with superior QALYs and costs. While cost-effectiveness was achieved in large catchment areas, scenarios with high dispatcher sensitivity achieved economic viability even at a more modest scale, unlike prior findings.
Conclusion: Focusing on dispatcher performance and system-wide EVT optimization enables a broader range of MSU designs to achieve cost-effectiveness, going beyond previous reviews that emphasized only scale. These innovations maximize health and economic benefit.
Limitations: Model outcomes rely on estimated EVT gains and dispatch characteristics; real-world validation remains needed.

Radiation Exposure from Paediatric Head CT and CT Angiography in Trauma Care (6 min)

Daniel Rosok; Essen / Germany

Author Block: D. Rosok, M. Opitz, D. Bos, Y. L. Thal, J. Haubold, B. Schweiger, M. Forsting, C. Deuschl, S. Zensen; Essen/DE
Purpose: Head CT and CT angiography (CTA) of the craniocervical vessels are essential in emergency diagnostics in children, despite their heightened sensitivity to ionising radiation. This study evaluates the radiation exposure associated with head CT and CTA in paediatric patients examined in the trauma resuscitation unit (TRU).
Methods or Background: Patients aged 0–15 years undergoing head CT and CTA in the TRU between 04/2020 and 08/2023 were included. Volume-weighted CT dose index (CTDIvol), dose-length product (DLP), and effective dose (ED) were analysed for three age groups according to national diagnostic reference levels (DRL): I (0–<5 years), II (5–<10 years), III (10–<15 years). ED was derived using conversion factors and organ doses were estimated via Monte Carlo simulation.
Results or Findings: Of 212 children treated in the TRU, 62.7% (133/212) had CT, and 72.2% (96/133) underwent both head CT and CTA. Median CTDIvol, DLP, and ED (IQR) by age group were: head CT: I: 18.9mGy (17.5–20.1mGy), 282mGycm (253–301mGycm), 3.9mSv (3.6–4.5mSv); II: 23.9mGy (22.3–26.2mGy), 381mGycm (351–413mGycm), 2.7mSv (2.5–2.9mSv); III: 29.4mGy (27.1–32.5mGy), 460mGycm (430–533mGycm), 1.8mSv (1.7–2.1mSv); CTA: I: 1.4mGy (1.4–1.5mGy), 40mGycm (37– 43mGycm), 5.7mSv (5.5–6.2mSv); II: 2.0mGy (1.5–2.1mGy), 68mGycm (50–72mGycm), 5.4mSv (4.0–5.7mSv); III: 2.2mGy (2.2–2.3mGy), 83mGycm (75–88mGycm), 2.8mSv (2.5–3.0mSv). All doses were below national DRLs across age groups.
Conclusion: Head CT and CTA in paediatric trauma care can be performed at moderate radiation levels. Continued dose optimisation is vital to further reduce long-term risks such as radiation-induced malignancy.
Limitations: The limitations of the study are its single-centre design and use of a specific scan protocol, which may limit the generalisability of our findings. Nevertheless, this setting also allows for a detailed analysis of the protocol and its effects on radiation doses in children.

RC 2414 - Interventional imaging: technological progress and new frontiers

Categories: Radiographers, Interventional Radiology, Nuclear Medicine, Vascular
Date: March 8, 2026 | 11:30 - 12:30 CET
CME Credits: 1

Moderators:
Nejc Mekis; Ljubljana / Slovenia
Alessandro Posa; Roma / Italy

Chairpersons' introduction (5 min)
Nejc Mekis; Ljubljana / Slovenia
Alessandro Posa; Roma / Italy

Radiographers and radiologists' collaboration in interventional mammography (10 min)
Noelle Frances Clerkin; Belfast / United Kingdom

1. To explore new technologies: recognise advancements like DBT and CEDM in interventional mammography.
2. To identify improved techniques: learn about new biopsy and localisation methods.
3. To enhance patient outcomes: understand how advancements improve safety and comfort in procedures.

Interventional procedures guided by nuclear medicine imaging (10 min)
Jelena Perić; Ljubljana / Slovenia

1. To understand PET-guided biopsy.
2. To identify focal therapy delivery techniques.
3. To explore additional techniques in radio-guided surgery.

New techniques in cardiovascular interventional procedures (10 min)
Irene Nieri; Paris / France

1. To explore new techniques by understanding innovations like robotic assistance and advanced imaging in cardiovascular procedures.
2. To recognise patient benefits with new methods that allow improved outcomes and accuracy.
3. To apply best practices: learn to safely incorporate these techniques into clinical practice.

Interventional techniques in radiation therapy (10 min)
Patrizia Cornacchione; Rome / Italy

1. To explore cutting-edge techniques like stereotactic radiosurgery and brachytherapy.
2. To enhance treatment precision: improvements in tumour targeting, minimising damage.
3. To prioritise safety through the implementation of accurate procedures in innovative radiation therapies.

Panel discussion: A collaborative outlook on the future of interventional imaging (15 min)

RPS 2401 - Pancreas cancers and high-risk pancreatic lesions

ML radiomics diagnostic model for differential diagnosis of small Solid Pseudopapillary Epithelial Neoplasm of the pancreas (6 min)

Anastasiia Igorevna Baeva; Moscow / Russia

Author Block: A. I. Baeva, A. Ustalov, S. A. Shmeleva, I. Gruzdev, V. Struchkov, E. V. Kondratyev, A. Pokshubina; Moscow/RU
Purpose: The five-year survival rate for patients with solid pseudopapillary epithelial neoplasm (SPEN) after surgery exceeds 98%, whereas pancreatic ductal carcinoma (PDAC) is highly aggressive, characterized by invasive growth and early metastasis. Differential diagnosis of small SPEN and PDAC is challenging. The aim of the present study was to develop and evaluate a ML-radiomic model for distinguishing SPEN from PDAC to improve diagnosis in pancreatic cancer.
Methods or Background: A cohort of 97 patients was retrospectively analyzed, including 39 with SPEN under 30 mm in diameter without local invasive growth and 58 with PDAC, all undergoing contrast-enhanced CT scans and histopathological examination of tumor tissues between 2022 and 2025. Tumor segmentation was manually performed on arterial and venous images using a 3D ROI. Radiomic features were extracted with the "Radiomics" extension in 3D-Slicer. Seven machine learning (ML) models were developed based on these features, and their performance was evaluated using ROC AUC to identify the best classifier.
Results or Findings: The AutoML_Stacking model achieved the highest ROC-AUC of 0.971, demonstrating excellent discriminatory ability. Similar results were obtained for the LGBM and LR models (ROC-AUC of 0.965). All models had ROC-AUC values between 0.920 and 0.971, indicating robustness of the radiomic features. Sensitivity ranged from 0.972 to 1.0, reflecting good SPEN detection.
Conclusion: ML-radiomics diagnostic models for distinguishing SPEN from PDAC were developed. The AutoML_Stacking and LightGBM models exhibit high diagnostic efficiency, highlighting the potential of radiomics for differentiating small SPEN from PDAC, aiding early diagnosis in pancreatic cancer.
Limitations: Not applicable.

Relationships of Fat Infiltration and R2* with Hepato-pancreatic Diffusion Metrics: A Quantitative MRI Study Using the Spleen as Reference (6 min)

Zeynep Nazli Doghramachi; Ankara / Turkey

Author Block: Z. N. Doghramachi, T. Cankurtaran, D. KALEMCİ, M. ALIYEV, Z. N. DAYICAN, O. Kayık, B. Yavuz Sarsam, A. Isik; Ankara/TR
Purpose: To investigate the independent effects of fat infiltration (Proton Density Fat Fraction, PDFF) and iron overload (R2∗) on quantitative diffusion-weighted imaging (DWI) metrics in the liver and pancreas, using the spleen as a parenchymal reference tissue.
Methods or Background: This cross-sectional study included 102 adults (55.8 ± 11.3 years). Abdominal quantitative MRI comprised multi-echo gradient-echo acquisitions for PDFF and R2∗ mapping, and multi-b-value DWI (b=0–2500 s/mm2) for diffusion analysis (monoexponential ADC, logarithmic ADC, and biexponential fast/slow components). Statistical analyses included partial correlation (adjusted for R2∗) and multivariable linear regression (adjusted for age, sex, and BMI) to assess associations between PDFF, R2∗, and diffusion metrics in the liver and pancreas, as well as their ratio to spleen values.
Results or Findings: In the liver, Fat Fraction (FF) showed positive associations with the biexponential fast component ($r=0.280$, $p=0.004$) and the ratio of fast/slow components ($r=0.293$, $p=0.003$). No independent associations were found for monoexponential or logarithmic ADC. In the pancreas, R2∗ was independently and positively related to monoexponential ADC ($\beta=0.380$, $p<0.001$) and negatively to logarithmic ADC ($\beta=-0.293$, $p=0.003$). The association between pancreatic FF and logarithmic ADC lost significance after R2∗ adjustment. Ratio-based analysis (Pancreas/Spleen) further demonstrated an independent effect of pancreatic FF on the biexponential slow ADC component.
Conclusion: Hepatopancreatic fat infiltration (PDFF) and R2∗ showed independent, albeit weak, associations with specific DWI metrics. These findings suggest that the effects of both fat and iron need to be considered when interpreting quantitative diffusion measurements in the liver and pancreas.
Limitations: This study was limited by the relatively small sample size, the absence of participants with high-grade steatosis, and the lack of voxel by voxel analysis, as all measurements were ROI-based.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes

Refining baseline staging in the era of neoadjuvant chemotherapy for resectable and borderline resectable pancreatic cancer: the role of FDG-PET and EOB-MRI (6 min)

Francesco Prato; Milan / Italy

Author Block: F. Prato, D. Palumbo, G. Orsi, M. Macchini, C. Carconi, A. Chiti, M. Falconi, M. Reni, F. De Cobelli; Milan/IT
Purpose: Neoadjuvant chemotherapy (NAT) is becoming the treatment of choice for pancreatic ductal adenocarcinoma (PDAC). In this scenario, the traditional classification of borderline-resectable and anatomically resectable disease—based mainly on CT—appears progressively outdated, also due to inter-observer variability. Although upfront surgery is rare, accurate baseline staging remains crucial to define prognosis and guide therapy, while avoiding futile surgery in patients with occult systemic disease. Advanced imaging such as FDG-PET and MRI with liver-specific contrast media (EOB-MRI) may provide incremental value over CT.
Methods or Background: In this prospective study, patients with a resectable or borderline resectable (according to CT scan), were screened using both FDG-PET and 3T-EOB-MRI before the initiation of NAT.
Results or Findings: Of 154 screened patients, 124 were enrolled (upfront resectable = 71, borderline = 53); one patient was later reclassified as locally advanced. Additional imaging excluded 24 patients (18.8%) due to previously undetected metastases, while 5 (3.3%) were excluded for protocol deviations. After a median follow-up of 20 months, 18/154 (11.6%) were considered true positives ("screening failures"), while 117/154 (76%) were true negatives (correctly classified as resectable/borderline). False negatives occurred in 8/154 cases (5.2%) and false positives in 6/154 (3.9%), mostly related to PET overestimation. Retrospective analysis suggested that MRI alone, particularly when interpreted by expert radiologists, could further reduce both false positives and negatives. In upfront resectable patients, predictors of occult metastases (on baseline CT scan) included tumor necrosis (p=0.009), dilated Wirsung duct (p=0.04), and CA19.9 ≥200 U/mL (p<0.001).
Conclusion: EOB-MRI proved more effective than FDG-PET in identifying occult metastases, especially in the liver and peritoneum, thereby reducing futile surgeries. These findings support prioritizing EOB-MRI in baseline staging protocols for PDAC, particularly in high-risk patients, to optimize therapeutic strategies and patient selection.
Limitations: Monocentric

Contrast-enhanced ultrasound combined with percutaneous ultrasound-guide core needle biopsies in the diagnosis of pancreatic lesions (6 min)

Quan Dai; Chengdu / China

Author Block: Q. DAI, M. Lu; Chengdu, China/CN
Purpose: To compare the diagnostic performance of pancreatic lesions using percutaneous ultrasound (US)-guided core needle biopsy (CNB) with and without contrast-enhanced ultrasound (CEUS).
Methods or Background: The patients were divided into two groups, US and CEUS group, based on whether CEUS was performed prior to biopsy. Before and after propensity score matching (PSM), the CNB-relevant characteristics of the two groups, including the first puncture success rate, the number of sampling, complication rate, type of complications, and degree of abdominal pain, were compared. The accuracy, sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV), and area under the curve (AUC) of percutaneous US-guided CNB were compared between the groups.
Results or Findings: This study included 277 patients with pancreatic lesions who underwent percutaneous CNB before PSM. After controlling for potential biases using PSM, significant differences were observed in the first puncture success rate and the number of sampling (P<0.05). Importantly, before and after PSM, the CEUS group achieved a higher first-puncture success rate while obtaining a lower number of sampling (P<0.05). Furthermore, the significant difference was observed in the AUC for diagnostic performance between the two groups when compared using DeLong's test (P=0.043).
Conclusion: Performing CEUS before percutaneous CNB for pancreatic lesions can help achieve better biopsy results, reduce the number of punctures samples, increase the success rate of biopsies, and avoid the need for repeat biopsies.
Limitations: First, the sample size was derived from a single center, and the percutaneous CNB technique for pancreatic lesions requires radiologists with extensive experience in US intervention, which may have affected the generalizability of our findings. Second, as a retrospective study, there remains a potential for selection bias despite conducting a PSM analysis.

Prospective evaluation of MR elastography for pancreatic cancer characterization and treatment response (6 min)

Vitali Koch; Frankfurt / Germany

Author Block: V. Koch[1], L. D. Grünewald[1], K. Eichler[1], R. Hammerstingl[1], O. Darwish[2], J. Gotta[1], T. Vogl[1], R. Sinkus[2]; [1]Frankfurt/DE, [2]Paris/FR
Purpose: The aim of this study was to evaluate magnetic resonance elastography (MRE) using the acoustic (2D) and gravitational transducer (2D/3D) concept for detecting pancreatic cancer and assessing its potential as a marker of chemotherapy response.
Methods or Background: In this prospective study, 51 patients with confirmed pancreatic cancer undergoing upper abdominal MRI were enrolled between June 2023 and April 2024. An additional 15 healthy volunteers were included as a reference standard. All participants underwent two examinations at 40 Hz (Aera, 1.5 T, Siemens Healthineers, Germany): first with a commercial MRE system (Resoundant, 2D-MRE, SE-EPI sequence, 11 s breath-hold), and subsequently with the gravitational transducer approach (2D- and 3D-MRE, GRE sequence, TE = 9.2 ms [in-phase], fractional motion encoding at 30 mT/m, 14 s breath-hold). Data were independently analyzed by three experienced readers. To assess potential biases in 2D/3D stiffness reconstruction, analytic plane waves with known wavelength and absorption were superimposed at varying amplitudes and temporal noise levels, and used to derive quality indices for 2D and 3D MRE.
Results or Findings: Significant differences in stiffness, shear wave speed, and phase angle were observed between healthy volunteers and pancreatic cancer patients ($p < .05$). Subtype-specific signatures enabled differentiation between ductal adenocarcinoma and neuroendocrine tumors ($p < .05$). Stiffness changes tracked chemotherapy response ($p < .05$), while higher baseline values correlated with longer hospitalization. 2D-MRE systematically overestimated stiffness, whereas proposed 3D-MRE Quality Indices improved reliability.
Conclusion: Gravitational MRE enables accurate, noninvasive characterization of pancreatic tissue. Both approaches correlated well with the commercial standard, while 3D-MRE uniquely delivered functional imaging markers, opening new avenues in abdominal imaging.
Limitations: Limited study population. Prospective validation in larger patient cohorts needed.
Funding for this study: No funding.

Nomogram for Predicting Tumor-Stroma Ratio in Pancreatic Ductal Adenocarcinoma Using Dual-Energy Computed Tomography (6 min)

Weiyue Chen; Lishui / China

Author Block: W. Chen, G. Lin, M. Chen, J. Ji; Lishui/CN
Purpose: This study aimed to develop and validate a nomogram to predict both the tumor-stroma ratio (TSR) and the overall survival (OS) of patients with pancreatic ductal adenocarcinoma (PDAC) using preoperative dual-energy computed tomography (DECT) parameters.
Methods or Background: 153 patients with histopathologically confirmed PDAC who underwent preoperative DECT scans were retrospectively reviewed and divided into high- and low-TSR groups based on histological analyses of surgical specimens. Several DECT parameters of the primary tumor were measured, including the normalized iodine concentration (NIC), effective atomic number, slope of the energy spectrum attenuation curve (K), CT values (40–100 keV), and extracellular volume fraction (ECVf), and analyzed alongside clinical and radiological data. Univariate and multivariate logistic regression models were used to identify independent predictors, which were then incorporated into radiology, DECT, and nomogram models. The association of the nomograms with OS was assessed using Kaplan–Meier curves and Cox regression analysis.
Results or Findings: CT-reported lymph node status, NICvenous, Kvenous, and ECVf were identified as independent predictors of the TSR and included in the nomogram model. The nomogram demonstrated high predictive accuracy with an area under the receiver operating characteristic curve of 0.934 in the training set and 0.891 in the validation set, outperforming the radiology model (0.715 and 0.692, respectively). Patients with a high predicted TSR exhibited worse OS than those with a low predicted TSR.
Conclusion: The DECT-based nomogram model provides a noninvasive and accurate preoperative prediction of the TSR and prognosis of patients with PDAC and may assist in individualized risk stratification and treatment planning.
Limitations: First, its retrospective, single-center design may introduce bias and limit external validity. Second, the TSR was evaluated using whole-tumor histological slides, which might result in an overestimation compared to conventional assessment techniques.
Funding for this study: This study was approved by the Ethics Committee of the Fifth Affiliated Hospital of Wenzhou Medical University (approval no. 2024-508).

Prognostic Value of the Node Reporting and Data System (Node-RADS) in Patients with Pancreatic Ductal Adenocarcinoma Undergoing Pancreatoduodenectomy (6 min)

Yuqi Wang; Chengdu / China

Author Block: Y. Wang, Y. Li, H. Yu, Z. Huang, B. Song; Chengdu/CN
Purpose: To compare the prognostic performance of pathological (pN) and clinical N staging (cN) with Node-RADS for recurrence-free survival (RFS) in patients with pancreatic ductal adenocarcinoma (PDAC) following pancreatoduodenectomy.
Methods or Background: This retrospective study included patients with pathologically confirmed PDAC underwent pancreatoduodenectomy between June 2018 and January 2023 and had preoperative contrast-enhanced abdominal CT. Two observers independently assessed lymph nodes ≥0.4 cm in short-axis diameter on venous-phase images using conventional CT criteria and Node-RADS, with a 4-week interval. Node-RADS scores ≥3 were defined as positive. For each patient, total and station-based Node-RADS scores were calculated. Prognostic performance was evaluated using time-dependent ROC curves and Cox regression. Interobserver agreement was assessed with intraclass correlation coefficients (ICC).
Results or Findings: 220 patients (median age, 63 years; 138 men) were analyzed. Median RFS was 10 months. The AUCs of pN for 12-, 24-, and 36-month prediction were 0.546, 0.560, and 0.581, while cN yielded 0.541, 0.501, and 0.538. Node-RADS total scores showed AUCs of 0.581, 0.654, and 0.605. The number of positive stations achieved higher performance (0.611, 0.717, 0.695). Station 16a2 scores showed prognostic value (AUCs 0.533, 0.653, 0.631). Node-RADS total score (p=0.0368), positive station number (p=0.00163), and stations 16a2 (p=0.0312) and 17 (p<0.001) as adverse prognostic factors. Interobserver agreement was moderate (ICC = 0.528).
Conclusion: Node-RADS outperformed pN and cN in predicting RFS after pancreatoduodenectomy. Positive station number and stations 16a2 and 17 provided additional prognostic value, supporting Node-RADS as a practical tool for preoperative risk stratification in PDAC.
Limitations: This retrospective single-center study lacks external validation, which may restrict generalizability. Additionally, CT images obtained over four years may have been affected by inter-scanner and technical variability, potentially influencing Node-RADS assessment.
Funding for this study: This study received no external funding.

Baseline dual-layer spectral CT-based habitat analysis for predicting postoperative recurrence in pancreatic ductal adenocarcinoma and the association with tumor-stroma ratio (6 min)

Cai Wei; Beijing / China

Author Block: C. Wei, Y. Zhu, X. Zhao; Beijing/CN
Purpose: To investigate the value of habitat imaging employing baseline dual-layer spectral CT (DLCT) in predicting recurrence of pancreatic ductal adenocarcinoma (PDAC) after radical resection, and explore the relationship with pathological tumor-stroma ratio (TSR).
Methods or Background: we retrospectively enrolled 136 resected PDAC patients who underwent multiphase DLCT and randomly assigned them to training and validation cohorts. Extracellular volume (ECV) fraction and arterial enhancement fraction (AEF) were generated from spectral images. Tumor voxels were clustered into habitats via K-means, and quantitative habitat parameters were extracted. Cox regression was used to build clinical-radiological, habitat, and combined models for recurrence-free survival (RFS). Model performance was assessed by concordance index (c-index) and time-dependent ROC, and recurrence risk was compared by Kaplan–Meier analysis. Spearman correlation and multivariable linear regression evaluated the relationship between TSR and habitat metrics.
Results or Findings: The combined model integrating fraction of habitat-1 (f1), fraction of habitat-4 (f4), CA19-9 >180 U/mL, and rim-enhancement achieved c-indices of 0.912 and 0.899 in training and validation cohorts, respectively, outperforming the clinical-radiological model. Time-dependent ROC showed AUCs >0.85 for RFS prediction. Patients predicted as high-risk had significantly shorter RFS than low-risk (p < 0.001). f1 and f4 correlated with TSR and enabled quantitative prediction of TSR.
Conclusion: The combined model, integrating habitat quantitative parameters, CA19-9 and rim-enhancement, providing a noninvasive approach for predicting the risk of recurrence in PDAC preoperatively. Habitat quantitative parameters could be used to quantitative predict pathological TSR.
Limitations: This retrospective design might introduce selection bias, as the analysis was limited to resectable PDAC, which only accounts for a small part of all PDAC. Furthermore, although a validation cohort was used, external validation from multi-center with larger sample size was still needed to further confirm the stability of the results.
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective study was conducted in accordance with the Declaration of Helsinki. The study protocol was approved by the Institutional Review Board of the National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College (Approval #21/241-4521; November 10, 2021).

Targeting Inflammation: A Biologically Justified MRI Fat-Fraction-Enhanced Tool for High-Risk IPMN Prediction (6 min)

Diego Palumbo; Milan / Italy

Author Block: D. Palumbo, F. Prato, G. Belfiori, P. CAMISA, B. Ferrara, L. Piemonti, M. Falconi, S. Crippa, F. De Cobelli; Milan/IT
Purpose: Intraductal papillary mucinous neoplasms (IPMNs) are established precursors of pancreatic ductal adenocarcinoma (PDAC). Current guidelines recommend surgery based on high-risk stigmata (HRS) and worrisome features (WF), yet these criteria lack accuracy and no reliable non-invasive biomarker of malignancy is available. We aimed to identify preoperative radiological biomarkers to distinguish low-grade from high-grade/invasive IPMNs.
Methods or Background: Between June 2020 and January 2025, 206 patients undergoing surgical resection for suspected pancreatic cystic neoplasms were prospectively enrolled. Final pathology showed 49 low-grade dysplasias (LGD), 42 high-grade dysplasias (HGD), and 40 invasive carcinomas (IPMC). For the present analysis, IPMN were stratified into low-risk (LGD) and high-risk (HGD + IPMC) groups. Preoperative imaging included CE-MRI with dedicated MRCP incorporating mDixon Quant Fat Fraction sequences and contrast-enhanced CT. Inter-modality agreement between CT and MRI for WF/HRS was evaluated. A composite risk score was constructed by summing WF and HRS, weighted according to hazard ratios reported in the literature. Biological samples (peripheral/portal blood, cyst fluid) were systematically collected intraoperatively and analyzed for inflammatory and metabolic markers.
Results or Findings: Pancreatic fat fraction (assessed on non-atrophic parenchima) was significantly higher in high-risk vs low-risk IPMN (15.7% ± 13.8 vs 6.9% ± 5.0, p=0.023), but showed no correlation with molecular variables. Distal pancreatic atrophy showed a trend toward significance (p=0.062). Individual WF/HRS performed poorly, with wide inter-modality variability (K-Cohen 0.02 to 0.87). Conversely, their additive integration into a risk score significantly predicted high-risk IPMN and correlated with inflammatory markers on cyst-fluid samples, particularly TNF-α (p=0.005).
Conclusion: Pancreatic fat fraction on MRI emerges as a promising non-invasive biomarker for stratifying IPMN. WF/HRS are inconsistent as isolated criteria, but their cumulative integration into a risk score enhances predictive accuracy and correlates with local inflammatory mediators.

Date: March 8, 2026 | 11:30 - 12:30 CET
CME Credits: 1

Moderator:
Matthias Eberhard; Zurich / Switzerland

Dosimetric study on cardiac photon counting CT (6 min)
Pietro Levoni; Pieve Emanuele / Italy

Author Block: P. Levoni[1], F. Catapano[1], C. Lisi[1], A. Laghi[1], M. Francone[2], L. S. Politi[1]; [1]via Rita Levi Montalcini 4, 20072 Pieve Emanuele, Milan/IT, [2]Sant'Andrea Hospital, via di Grottarossa 1035-1039, 00189 Rome/IT
Purpose: Photon-counting detector CT (PCD-CT) has been proposed to reduce radiation exposure compared with energy-integrating detector CT (EID-CT). Nonetheless, data on patients' radiation dose in cardiac applications are still limited. The aim of the present study is to quantify and analyse radiation dose across three cardiac PCD-CT protocols, and to compare the results with a standard cardiac EID-CT protocol.
Methods or Background: A cohort of 268 patients who underwent coronary CT angiography between December 2024 and July 2025 was retrospectively included. Each patient underwent one of four acquisition protocols: three PCD-CT protocols - Spectral; Ultra-High Resolution (UHR); UHR Spectral - and one EID-CT protocol. For each acquisition volume, CT dose index (CTDIvol), dose length product (DLP), and size-specific dose estimate (SSDE), were retrieved, and total DLP was calculated. Statistical analysis included descriptive assessment and Kruskal–Wallis H-tests to compare dose distributions across protocols.
Results or Findings: Mean±SD total DLP values were 653±192 mGy·cm for the Spectral protocol, 947±233 mGy·cm for the UHR protocol, 1373±316 mGy·cm for the UHR Spectral protocol, and 390±114 mGy·cm for the EID-CT protocol. Kruskal-Wallis H-tests showed that each pair of distributions is different with statistical relevance. The median value of total DLP for the UHR Spectral protocol (1356 mGy·cm) results greater than the corresponding Italian Dose Reference Level (1200 mGy·cm).
Conclusion: Cardiac PCD-CT protocols resulted in higher radiation doses compared with a conventional cardiac EID-CT protocol. Among PCD-CT protocols, UHR Spectral acquisitions frequently exceeded national reference limits. These findings suggest that PCD-CT protocols with default high-dose settings should be reserved for cases where maximal image quality is strictly required.
Limitations: The patient cohort undergoing the UHR protocol included a limited number of 20 patients.

Coronary Artery Calcium Score calculated on Photon Counting Computer Tomography scans: comparison of different reconstruction algorithms and scan protocols for measurement and risk stratification (6 min)
Emanuele Muscogiuri; Leuven / Belgium

Author Block: E. Muscogiuri, T. Busselot, E. Di Dedda, S. Dymarkowski, H. Bosmans; Leuven/BE
Purpose: Compare coronary artery calcium score (CACS) from Photon Counting Computed Tomography (PCCT) images, acquired with contrast-enhanced ECG-gated and non-contrast, non-gated scan protocols, and reconstructed with different algorithms: “Pure Calcium” (PC) and “Virtual non-contrast” (VNC).
Methods or Background: Patients undergoing a PCCT scan before Transcatheter Aortic Valve Implantation were included. For each patient, CACS was measured in five datasets with dedicated software: “true” non-contrast ECG-scan (TNC, reference); PC and VNC reconstructions of the ECG-gated (PCGATED, VNCGATED) and non-gated contrast-enhanced scans (PCNON-GATED, VNCNON-GATED). Statistical pairwise comparisons per patient and per vessel (LM+LAD, LCX, RCA) were made using a Friedman test and Dunn’s multiple comparison test. Additionally, CACS was classified in risk categories (0; 0-10; 10-100; 100-400; >400) and compared using weighted Cohen's κ.
Results or Findings: Sixty-one patients were included (25 males, mean age 78,4 years). The analysis per patient showed that TNC CACS was not significantly different ($p<0.05$) from PCGATED, while it was significantly different from PCNON-GATED and VNC reconstructions. The analysis per vessel showed that CACS of LM+LAD calculated on PC reconstructions were not significantly different from TNC, while all the CACS of LCX were different from TNC. CACS of RCA calculated on PCGATED images were not significantly different from TNC. Classification comparison per CACS thresholds showed excellent agreement for PCGATED and PC-NONGATED (0.86 and 0.83, respectively) and a moderate to good agreement for VNCGATED and VNC-NONGATED (0.64 and 0.59, respectively).
Conclusion: The CACS measurements performed on PC reconstructions (particularly with ECG-gating) proved more reliable than those obtained from VNC reconstructions. However, it has to be noted that significant differences persist in the evaluation of CACS per vessel and in the risk stratification of patients among the different reconstructions.
Limitations: Small study population with the same disease.

Dual-layer spectral CTA: assessment of coronary vessels using 35mL of high concentration iodinated contrast agent and comparison with standard techniques (6 min)

Silvia Tamietti; Biella / Italy

Author Block: S. Tamietti[1], F. Piacentino[2], F. Fontana[3], A. Gnesutta[2], M. Venturini[4], C. Beltramini[5], E. Macchi[2]; [1]Biella, BI/IT, [2]Varese/IT, [3]Vergiate/IT, [4]Segrate/IT, [5]Golasecca/IT
Purpose: To evaluated the image quality and plaque characterization in coronary CT angiography (CCTA) using dual-layer spectral CT (DL-SCT) with a reduced iodinated contrast bolus (35 mL) compared to the standard dose (70 mL). We focused on the role of virtual monoenergetic imaging (VMI) and Z-effective reconstructions.
Methods or Background: A cohort of 40 patients, with low-to-intermediate cardiovascular risk who underwent CCTA with DL-SCT (IQon Spectral CT Philips, Amsterdam, The Netherlands) were retrospectively divided in two groups based on contrast dose (70mL vs. 35mL of iomeron 400mg/mL). Quantitative parameters (contrast attenuation, signal-to-noise ratio [SNR], contrast-to-noise ratio [CNR]) were measured. Qualitative image analysis was performed by two radiologists. Plaque characterization was compared across conventional, VMI, and Z-effective reconstructions.
Results or Findings: In the reduced-contrast group, VMI at 50 keV achieved attenuation values comparable to standard acquisitions, while SNR and CNR were significantly higher ($p < 0.05$). Qualitative image scores were similar between groups; however, stenosis evaluation improved in the reduced-dose group due to fewer blooming artifacts in spectral reconstructions. Plaque analysis showed significant reduction in calcified plaque area and stenosis with VMI at 200 keV and Z-effective images, while VMI at 50 keV improved delineation of fibro-lipidic plaques and stenosis assessment ($p < 0.05$).
Conclusion: DL-SCT allows a 50% reduction in iodine load without compromising diagnostic quality. Low-energy VMI reconstructions maintain contrast enhancement, while VMI and Z-effective images enhance plaque characterization, supporting more accurate clinical management.
Limitations: The limitations of the study are the requirement for additional research on large, multicenter cohorts employing intra-patient protocols, in order to validate and improve future clinical practice.

Contrast Dose Reduction in infants and children with Complex Congenital Heart Disease Using Virtual Monoenergetic Imaging on Dual-Layer Spectral Detector CT (6 min)

Xiaomin Liu; Guangzhou / China

Author Block: X. Cao, J. Li, X. Zhong, X. Liu; Guangzhou/CN
Purpose: To investigate the feasibility of reducing the contrast dose and the optimal keV of virtual monoenergetic images (VMIs) on dual layer spectral detector CT (DLCT) in infants and children with complex congenital heart disease (CHD).
Methods or Background: Prospectively enrolled 80 infants and children with complex CHD and underwent preoperative DLCT. Patients were randomly divided into two groups: group A (N=36, standard dose, 1.5~2 ml/kg) and group B (N=44, low dose, 1ml/kg). Conventional image (CI) and VMIs in range of 40-85 keV were reconstructed in group B while only CI was reconstructed in group A. Image quality was evaluated using qualitative scores and objective metrics including CT value, standard deviation (SD), signal-to noise ratio (SNR), and contrast-to-noise ratio (CNR) for the pulmonary artery and ascending aorta.
Results or Findings: Group B received 24% less contrast than group A [8.00 (5.00;11.00) ml vs 10.50 (8.00;21.00) ml, P<0.05]. VMI 40 keV in group B yielded the highest CT value, SNR, CNR of pulmonary artery and ascending aorta among different VIMs, and significantly outperformed CI in group A (P<0.05). Subjective evaluation score on VMI 40-50 keV of group B was significantly higher than CI of group A (P<0.05). Diagnostic accuracy for CHD at 40-50 keV in group B was 97.73%, significantly higher than group A (93.40%, P<0.05), while no significant difference in sensitivity and specificity.
Conclusion: VMI 40-50 keV in DLCT can significantly improve image quality, allowing contrast dose reduction in infants and children with complex CHD without compromising diagnostic performance.

Clinical feasibility and safety of low-iodine-concentration contrast media in low-tube-voltage, low-dose coronary CT angiography for suspected coronary artery disease (6 min)

Chul Hwan Park; Seoul / Korea, Republic of

Author Block: C. H. Park, S. Lee, J. W. Kim, J. E. Nam, E-Y. Choi, T. H. Kim; Seoul/KR
Purpose: Recent advances in low-kVp coronary CT angiography (CCTA) allow reduced iodine use, enabling the use of low-concentration iodine contrast media (ICM) while lowering radiation exposure. This study compared image quality and radiation dose between high- and low-concentration ICM in low-kVp, low-dose CCTA.
Methods or Background: 120 patients with suspected coronary artery disease were prospectively randomized to receive either high-concentration (Optiray, 350 mgI/mL) or low-concentration (Visipaque, 270 mgI/mL) contrast media. All CCTAs were performed using a 64-slice CT scanner with tube voltage and contrast volume adjusted to BMI. Quantitative (attenuation, noise, SNR, CNR) and qualitative (4-point scale) image quality were assessed. Acute and delayed adverse effects were monitored. Radiation dose was measured as dose-length product (DLP).
Results or Findings: No significant differences were found in demographic data, including heart rate. Attenuation (408.0 ± 67.9 HU vs. 424.5 ± 64.4 HU, p = 0.174), image noise, SNR, CNR, and qualitative image quality (mean scores: 3.34 vs. 3.46, p = 0.075) were comparable between groups. No acute adverse reactions occurred. Delayed adverse reactions were rare and non-severe, and resolved without sequelae. The radiation dose was not significantly different between the two groups (p = 0.842).
Conclusion: ICM dose reduction using low-concentration ICM is clinically feasible and provides comparable qualitative image quality in CCTA when using BMI-adapted low-kVp protocols in patients with suspected coronary artery disease.
Limitations: In this study, both groups used a low radiation dose protocol of either 100 kVp or 80 kVp. Subjects were randomly assigned to the two groups, resulting in no difference in body mass index. Tube voltage was determined by body mass index. Therefore, the radiation doses for both groups were similar, making it difficult to emphasize

Reducing Contrast Dose In Pulmonary Vein CT Imaging With Spectral Dual-Layer CT (6 min)

Philip Martin Tetteroo; Utrecht / Netherlands

Author Block: P. M. Tetteroo[1], C. Grinwis[1], L. R. Koetzier[1], D. Suchá[1], E. Langzam[2], N. R. van der Werf[3], B. K. Velthuis[1]; [1]Utrecht/NL, [2]Haifa/IL, [3]Best/NL
Purpose: To evaluate whether contrast-medium (CM)-dose in a pulmonary vein CT protocol can be safely reduced while maintaining diagnostic image quality using injection protocol adjustments and mono-energetic 55 keV reconstructions (MonoE55) on a dual-layer spectral CT (Philips CT7500).
Methods or Background: Sixty-eight patients were scanned with CM-dose concentrations progressively reduced from 100%, to 86%, 72%, 58% (N=17/group) with weight-adjusted (<80/≥80 kg) dual-phase contrast-injection protocols. Baseline contrast was 108/120 mL for <80/≥80 kg. Timing thresholds and injection speeds were modified from 200 HU in the descending aorta with 6/6.7 mL/s (<80/≥80 kg) for both 100%/86% CM-doses to 100 HU in the ascending aorta with 5/5.7 and 4.5/5.5 mL/s for 72%/58% CM-doses to optimize contrast timing. Subjective image quality (SIQ) was scored on MonoE55 and conventional images by one experienced, blinded cardiovascular radiologist using a 5-point Likert-scale for noise, contrast, attenuation, overall, and 3D volume. Objective image quality (OIQ) >200 HU was considered diagnostic and was assessed using 25 mm² regions-of-interest in four pulmonary veins, left atrial appendage, left atrium, and descending aorta. Data were compared to conventional 100% CM-dose images (reference) using Wilcoxon signed-rank or Mann–Whitney U tests for OIQ, and Wilcoxon signed-rank or chi-squared tests for SIQ.
Results or Findings: MonoE55 significantly improved SIQ across all CM-doses (p≤.026) compared with the reference, regardless of body weight, except for noise at 86% CM-dose, which was not significantly different (p=.295). MonoE55 significantly increased OIQ across all locations and for all CM-dose groups (p<.001). No MonoE55 attenuation measurements fell <200 HU.
Conclusion: CM-dose for pulmonary vein CT protocols can safely be reduced by 42% without compromising SIQ and OIQ when using spectral dual-layer MonoE55 reconstructions in combination with adjusted contrast timing and injection speed.
Limitations: Small sample size and single-reader design.
Funding for this study: No funding was received for this study.

Free-breathing isotropic cardiovascular 3D cine MRI without contrast agent - comparison to clinical standard (6 min)

Ruixin Chen; Leiden / Netherlands

Author Block: R. Chen[1], H. Lu[2], A. Cernicanu[3], J. Westenberg[1], M. Sevenster[4], J. Keupp[4], J. Meineke[4], H. J. Lamb[1]; [1]Leiden/NL, [2]Amsterdam/NL, [3]Eindhoven/NL, [4]Hamburg/DE
Purpose: To develop and evaluate a free-breathing isotropic cardiovascular 3D cine MRI 1.5T framework that can assess cardiovascular anatomy and function without using contrast agent.
Methods or Background: A cartesian spiral(CASPR) bSSFP continuous k-space acquisition with 3D sagittal coverage of the whole heart and thoracic aorta was acquired twice, with 2.5mm and 2mm isotropic resolution. GPU-based reconstruction included retrospective binning of k-space profiles with respect to ECG and respiratory self-gating using a 1D feet-head projection. Conventional breath-hold 2D cine and 3D mDixon MR angiography sequences were acquired for comparison. Cardiovascular measurements were compared with Bland-Altman analysis and Intraclass Correlation Coefficient(ICC) for observer agreement(p<0.05).
Results or Findings: 24 volunteers were evaluated. Acquisition took 5-7minutes, with reconstruction about 5minutes per sequence. Compared to 2D cine, 3D cine demonstrated accurate measurement of left-ventricle ejection fraction, with a bias of 1.38% and limits of agreement(LoA) from −2.85% to 5.61% at 2.5mm, and a bias of 1.39% with LoA from −1.53% to 4.30% at 2.0mm. Aorta root sizes measured by 2D and 3D cine were comparable, showing a mean difference of 0.28mm2 with 95% LoA from -0.33mm2 to 0.89mm2 at 2.5mm, and a mean difference of 0.25mm2 with 95% LoA from -0.24mm2 to 0.74mm2 at 2.0mm. Other measurements showed strong agreement between 2D and 3D cine, with minimal mean differences and narrow limits of agreement. Intra- and interobserver for all the measurements showed at least moderate agreement, with ICC of 0.75 to 0.998.
Conclusion: Free-breathing isotropic cardiovascular 3D cine MRI using cartesian spiral sampling, without contrast agents, enables a simplified and time-efficient assessment of cardiovascular anatomy and function compared to 2D cine at 1.5T.
Limitations: There is a lack of studies including patients with arrhythmias and irregular breathing to validate image quality and quantification.

Contrast-free postoperative imaging of the pulmonary artery vasculature: Comparison of Relaxation-Enhanced Angiography without Contrast and Triggering (REACT) and time-resolved contrast-enhanced MRA (6 min)

Vanessa Schmidt; Cologne / Germany

Author Block: V. Schmidt, L. Goertz, J. Tristram, R. A. Terzis, K. Kaya, D. Maintz, C. H. Gietzen, L. Pennig, J. P. Janssen; Köln/DE
Purpose: To compare REACT, a flow-independent 3D isotropic non-contrast MRA, with time-resolved contrast-enhanced MRA (4D CE-MRA) for postoperative assessment of the pulmonary arteries and right ventricular outflow tract, with emphasis on different implant types.
Methods or Background: In this retrospective single-center study, 53 patients with congenital heart disease underwent both 4D CE-MRA and REACT at 1.5 T. Three radiologists independently scored image quality (IQ), motion, and susceptibility on 5-point Likert scales for MPA, LPA, and RPA; diameters were measured and stenosis/dilatation recorded. Subgroup analyses were performed for stents, conduit/patch/valve (CPV), and no implant.
Results or Findings: REACT achieved higher overall IQ than 4D CE-MRA and significantly better motion scores in all vessels (all $p < 0.001$), while susceptibility scores were comparable (ns). The proportion of fully diagnostic studies (3/3 segments) was similar (REACT 77.4%, 41/53; 4D CE-MRA 83.0%, 44/53; McNemar ns). Diameter measurements showed excellent inter-reader agreement (ICC ≈ 0.89–0.95) and minimal bias between techniques; only the RPA was slightly smaller with REACT (mean difference –0.85 mm, $p < 0.001$), with Bland-Altman limits around ± 4 mm. In subgroup analyses, stented segments exhibited no IQ advantage of REACT and remained limited by susceptibility; motion scores remained superior with REACT, and diagnostic yield differences were not significant. In CPV and no-implant groups, REACT provided about +1 median IQ and motion score, with high diagnostic rates for both techniques.
Conclusion: REACT enables robust, contrast-free postoperative imaging of the pulmonary arteries with superior image quality and reduced motion artifacts compared to 4D CE-MRA, while maintaining highly reproducible diameter measurements. Stent segments remain a shared limitation; neither technique reliably evaluates stent lumen, and alternative modalities should be considered for targeted stent assessment.

RPS 2407 - Female pelvic cancer imaging: what's new?

Categories: Imaging Methods, Oncologic Imaging, Interventional Oncologic Radiology, Genitourinary
Date: March 8, 2026 | 11:30 - 12:30 CET
CME Credits: 1

Moderator:
Elisabeth Hedlund; Uppsala / Sweden

Immersive imaging for gynecologic oncology: planning beyond slices (6 min)
Roberta Chianura; Rome / Italy

Author Block: R. Chianura, P. P. Azzaro, C. Panico, B. Gui, E. Sala, G. Avesani, A. Fagotti, A. Rosati, D. Arrigo; Rome/IT
Purpose: To assess the usefulness of three-dimensional reconstructions (3DR) and virtual reality (VR) derived from CT/MRI datasets in complex gynecologic malignancies, with a focus on multidisciplinary decision-making and surgical planning.
Methods or Background: In this single-center pilot study, 40 patients undergoing highly challenging surgery (e.g., pelvic exenteration; recurrences involving muscle, vessels, or bone; tumors at difficult sites such as the hepatic hilum) were included. CT (n = 24) and multiparametric MRI (n = 16) datasets were segmented and converted into interactive 3D models; VR simulations were generated from the same meshes. Four gynecologic oncology surgeons, assisted by a urogenital radiologist, evaluated each case first with standard imaging and then with 3DR/VR. After review, they completed a 5-point Likert questionnaire (1 = no benefit, 5 = maximum benefit) covering patient counseling, tumor board decisions (surgery vs. alternative therapy) and surgical planning. Pre-processing time was recorded.
Results or Findings: Mean usefulness scores increased from 3.0 ± 0.5 with standard imaging to 3.8 ± 0.3 for 3DR ($p < 0.01$) and 4.6 ± 0.5 for VR ($p < 0.001$). Consensus on surgical strategy during multidisciplinary discussions was achieved in 34/40 cases, with VR prompting management-related questions in 14 cases. Surgeons reported improved spatial understanding in 63% of cases and predicted safer resection planes. Median preparation time was 120 minutes (IQR 100–130), representing the main barrier to daily practice.
Conclusion: Immersive 3D visualization significantly improves surgical planning and decision-making in complex gynecologic oncology. Streamlining segmentation and workflow processes will be essential for clinical implementation. In future phases, intraoperative augmented reality (AR) will be tested, with early results showing stable hologram registration and promising integration into surgical practice.
Limitations: The small sample size and reliance on simulated MDT limit the generalizability of the findings

Transarterial Chemoperfusion (TACP) and Transarterial Chemoembolization (TACE) in the Treatment of Advanced Pelvic Gynecological Cancer: Tumor Response and Survival (6 min)
Thomas J. Vogl; Frankfurt / Germany

Author Block: T. J. Vogl, A-I. Nica, L. S. Alizadeh, I. Yel, C. Wolfram, H. Adwan; Frankfurt/DE
Purpose: To retrospectively evaluate the efficacy of transarterial chemoperfusion (TACP) and transarterial chemoembolization (TACE) in the treatment of locally recurrent, unresectable gynecologic cancer regarding local tumor response and survival outcome.
Methods or Background: Between January 2000 and October 2023, 75 female patients diagnosed with locally recurrent, unresectable gynecologic tumors (cervical cancer, ovarian cancer) underwent 213 TACP and 154 TACE procedures. Among these, 33 underwent TACP, 20 received TACE, and 22 a combination of both therapies. Local tumor response was evaluated using the RECIST criteria and survival rates were determined with the Kaplan-Meier estimator.
Results or Findings: 50 patients (66.67%) maintained stable disease until completing therapy, while 10 patients (13.33%) exhibited partial response, 2 patients (2.67%) achieved complete response and 13 (17.33%) experienced progressive disease. Thus, 62 of 75 patients (87%) were classified as therapy responders. Overall, we observed a decrease of 5.53% in tumor size and 7.71% in tumor volume compared to baseline measurements. The median overall survival for all patients was 16.05 months, the median progression-free survival 13.5 months. The patients treated with TACP had the highest therapy response (90.91%) vs 81.92% of patients treated with both therapies and 70% of patients treated with TACE.
Conclusion: TACP and TACE are minimally invasive treatment options for patients with recurrent unresectable cervical and ovarian cancer. These therapies are particularly beneficial for patients who do not tolerate, refuse or do not respond to conventional treatment like chemo- or radiotherapy. However, further studies are still necessary
Limitations: -Retrospective and single-center study design
-Varying follow-up intervals and, in many cases, short follow-up period.
-Heterogeneous cohort, encompassing numerous tumor types with varying numbers of patients.
-Heterogeneous treatment strategy with transarterial therapies for both palliative and neoadjuvant purposes.

AI-driven Prognostication in High-Grade Serous Ovarian Cancer: An LLM-Guided System Fusing CT Imaging and Clinical Data after Neoadjuvant Chemotherapy (6 min)

Junjun Li; Hefei / China

Author Block: J. Li, J. Xu; Hefei/CN
Purpose: High-grade serous ovarian cancer (HGSOC) is characterized by extensive peritoneal and omental dissemination. Sensitivity to neoadjuvant chemotherapy (NACT) critically determines progression-free survival (PFS) and the likelihood of achieving R0 cytoreduction, yet robust preoperative prognostic tools are lacking. We developed GPCC, a GPT-5–Prompted CT–Clinical multimodal fusion system, to predict individualized PFS and R0 probability while providing interpretable decision support.
Methods or Background: In this multicenter retrospective study, 320 patients with HGSOC were enrolled and divided into a training cohort (n=220) and an external validation cohort (n=100). Baseline contrast-enhanced abdominopelvic CT scans focusing on omental metastases were processed using a Vision Transformer (ViT) model, which performed patching, feature extraction, and attention-based aggregation to derive patient-level imaging representations. Clinical variables, including the peritoneal cancer index (cPCI) and CA-125, were standardized and embedded. Large language model(GPT5)–generated clinical prompts guided cross-modal attention for targeted retrieval and deep fusion of imaging and clinical features. Model development employed five-fold stratified cross-validation with multitask outputs for PFS risk prediction and binary R0 classification.
Results or Findings: In the external validation cohort, GPCC achieved a concordance index of 0.81 for PFS prediction (95% CI, 0.77–0.85) and an AUROC of 0.95 for R0 prediction (95% CI, 0.89–0.99), significantly outperforming clinical-only, imaging-only, and conventional fusion baselines (PFS C-index relative improvement 28.9%, $p<0.0001$). Attention maps highlighted hallmark omental findings, including caking and cord-like infiltration, while SHAP analysis identified CT features and cPCI as dominant contributors, supporting interpretability.
Conclusion: GPCC integrates CT imaging and clinical data through a clinical-prompt–guided paradigm, delivering accurate and interpretable predictions of PFS and R0 outcomes in NACT-treated HGSOC. This system offers actionable perioperative decision support and demonstrates strong potential for clinical translation.
Limitations: Retrospective study with moderate sample size; requires larger prospective validation before clinical implementation.
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The Ethics Committee of the First Affiliated Hospital of the University of Science and Technology of China approved this study (approval No. 2024KY261), and the requirement for informed consent was waived due to its retrospective design.

The added value of the O-RADS score to clinical and imaging features in predicting malignancy risk in ovarian tumors (6 min)

Fengqiao Zhao; Ordos / China

Author Block: F. Zhao; Ordos/CN
Purpose: To evaluate the additional diagnostic value of integrating the O-RADS MRI scoring system with conventional clinical and radiological features for predicting ovarian malignancy.
Methods or Background: This retrospective study analysed data from 187 patients (215 lesions) at Ordos Central Hospital (2015–2025). Patients were divided into training (144 patients/166 lesions) and test sets (43 patients/49 lesions). All pathological results were confirmed by two senior pathologists. Clinical and MRI features were collected, and lesions were scored using O-RADS criteria. Predictive models with and without O-RADS were developed using ten machine learning algorithms and evaluated via ROC analysis, calibration curves, DCA, and SHAP.
Results or Findings: O-RADS scores showed significant correlations with CA125 levels, tumour boundaries, solid components, and septa (all $q < 0.001$). Multivariate analysis identified tumour boundary (OR = 26.207, p= 0.008) and septa (OR = 1.987, p = 0.042) as independent predictors. Incorporating O-RADS improved model performance, increasing test set AUC from 0.920–0.943 to 0.969–0.998. Specificity and PPV reached 100% in some models. SHAP analysis confirmed O-RADS as the most influential predictive feature.
Conclusion: The O-RADS score significantly enhances the diagnostic accuracy of machine learning models for ovarian tumour classification when combined with conventional clinical and imaging features.
Limitations: First, as a single-center retrospective investigation, the constrained sample size—particularly the limited number of malignant cases—may hinder the models' generalizability; future multicenter collaborations are essential to expand the cohort for external validation. Second, despite standardized processing, variations in MRI equipment (1.5T and 3.0T) and scanning protocols over the decade-long period could still impact the consistency of imaging features (27). Moreover, this study omitted dynamic contrast-enhanced MRI (DCE-MRI) and textural analyses; subsequent work might integrate multiparametric MRI and deep learning methods to further refine model efficacy.
Funding for this study: No funding was provided for this study.

Prediction of Lymphovascular Invasion in Cervical Cancer Through MRI Radiomics and Machine Learning Approaches (6 min)

Fatih Eroglu; Karabuk / United States

Author Block: A. Sözeri[1], F. Eroglu[1], N. Gokmen[2], C. Karagoz[3], E. Kayali[3], Z. Firat Cuylan[3]; [1]Karabuk/TR, [2]Istanbul/TR, [3]Ankara/TR
Purpose: Lymphovascular space involvement (LVSI) is a major prognostic factor in cervical cancer, yet its preoperative assessment remains challenging. According to NCCN guidelines, adjuvant radiotherapy is recommended for cervical cancer (CC) patients with postoperative risk factors. As combined surgery and radiotherapy increase complication risk, accurate preoperative identification of prognostic factors is crucial. LVSI—the presence of tumor cells within lymphatic or blood vessels—is an independent prognostic marker, particularly in node-negative CC. Although adjuvant radiotherapy can reduce recurrence by nearly 47% in LVSI-positive patients, existing detection methods remain insufficiently accurate.
Methods or Background: A cohort of 62 female patients diagnosed with cervical cancer was retrospectively analyzed. Patient ages ranged from 29 to 78 years, with a mean age of 50 years. Among them, 46 patients presented with histologically confirmed lymphovascular space involvement (LVSI). Radiomics features were extracted from axial and sagittal T2-weighted (T2W) sequences and diffusion-weighted imaging (DWI-B=1000), enabling quantitative characterization of tumor from mpMRI.
Results or Findings: All machine learning classifiers trained on LASSO-selected radiomics features from the DWI, axial and sagittal T2-weighted (T2W) images show high discriminative ability. The Gradient Boosting model classifed the LVSI and non-LVSI groups very perfectly, achieving the largest area under the curve (AUC = 0.65) and 0.762 accuracy. With an AUC of 0.63, the Random Forest models came in second in concatenated sequences with 0.710 accuracy showing strong classification accuracy with little loss of sensitivity or specificity.
Conclusion: In conclusion, this study demonstrates that mpMRI-based radiomics shows strong potential for preoperative prediction of LVSI in cervical cancer, potentially enabling personalized treatment planning; however, further multicentre validation is required before clinical adoption.
Limitations: Not applicable.

Assessment of adherence to ESUR guidelines in MRI acquisition for uterine cancers and its impact on multidisciplinary tumour boards (MDTs) management decisions: preliminary results (6 min)

Guido Imbemba; Frattamaggiore / Italy

Author Block: G. Imbemba, S. Bottazzi, V. Celli, E. S. Trogu, F. L. Lia, M. Dolciami, L. D'Erme, E. Sala, B. Gui; Rome/IT
Purpose: To systematically evaluate the adherence of external pelvic MRI studies to ESUR guidelines in patients referred to the uterine MDTs at our tertiary centre, identifying the most frequent protocol deviations, assessing their impact on patient's management.
Methods or Background: This retrospective, observational, single-centre study includes patients with cervical cancer (CC) and endometrial cancer (EC) discussed at the uterine MDTs between September 2024 and September 2025, whose external pelvic MRI scans are reviewed by a dedicated GYN radiologist.
Results or Findings: Between September 2024 and September 2025, 1820 cases were discussed and 607 required imaging revision. Of these, 277/607 were acquired at our Institution, while 330/607 were not and 110/330 (33%) were deemed non-compliant to ESUR guidelines (84 CC and 26 EC cases).
Among CC MRIs, the main causes of non-adherence were absence of axial-oblique T2-WI in 68/84, absence of axial-oblique DWI in 68/84, absence of DWI images in 14/84, slice thickness >4mm in 19/84 cases. Also, contrast media was administered in 72/84 cases (86%). 24/84 patients required repeating MRI. Among those who did not: in 38 cases the necessary information was obtained through PET/CT and in 22 cases MRI was deemed sufficient to exclude locally-advanced CC and proceed directly to surgery.
Among EC MRIs, the main non-adherence causes were: absence of axial-oblique DWI in 24/26 (92%), absence of axial-oblique T2-WI in 22/26 (85%), absence of axial-oblique post-contrast images in 25/26 (96%). Five patients required repeat MRI to assess the suitability for fertility-sparing procedures.
Conclusion: Adherence to ESUR guidelines for CC and EC MRI varies across institutions, missing recommended sequences and including non-recommended ones. This may reduce diagnostic accuracy, delay treatment initiation, and increase economic and environmental burden due to the unnecessary use of contrast agents.
Limitations: Na

Radiologic–Pathologic Correlation of Ovarian Masses: Use of Diffusion, DCE and Radiomics (6 min)

Farook Abubacker Sulaiman; Chennai / India

Author Block: F. Abubacker Sulaiman, R. Praveenkumar, S. Zainamb Begum, M. Nivitha, J. Lydia, A. Raashid Ibrahim; Chennai/IN
Purpose: To assess the diagnostic performance of diffusion-weighted imaging (DWI), dynamic contrast-enhanced MRI (DCE-MRI), and radiomics features in differentiating benign and malignant ovarian masses, and to correlate imaging biomarkers with histopathological findings.
Methods or Background: A prospective study was conducted on 80 patients presenting with ovarian masses who underwent multiparametric MRI prior to surgery or biopsy. MRI protocol included T1- and T2-weighted sequences, DWI (b-values 0, 800 s/mm²), and DCE-MRI with quantitative perfusion analysis. Apparent diffusion coefficient (ADC) values, enhancement curve types, and radiomics features (first-order, texture, and shape-based metrics) were extracted from tumor regions using semi-automated segmentation. Histopathological diagnosis served as the reference standard. Statistical analysis included ROC curve evaluation and logistic regression to identify the best predictive model.
Results or Findings: Malignant lesions demonstrated significantly lower mean ADC values ($0.89 \pm 0.17 \times 10^{-3}$ mm²/s) and higher K^trans values on DCE compared to benign lesions ($1.45 \pm 0.24 \times 10^{-3}$ mm²/s, $p < 0.001$). Radiomics parameters such as gray-level entropy and surface irregularity showed strong correlation with tumor grade ($r = 0.71$, $p < 0.001$). The combined model integrating ADC, DCE kinetics, and key radiomics features achieved an AUC of 0.94 for malignancy prediction, outperforming any single parameter. Imaging patterns corresponded well with histopathologic features such as cellular density, necrosis, and stromal vascularity.
Conclusion: Multiparametric MRI incorporating diffusion, perfusion, and radiomics analysis enhances non-invasive characterization of ovarian masses and correlates strongly with histopathologic aggressiveness. This integrated approach may improve preoperative risk stratification and treatment planning.
Limitations: Single-center design, modest sample size, and absence of external radiomics validation restrict generalizability. Larger multicentric datasets and standardized acquisition protocols are needed for clinical translation.
Funding for this study: No external funding was received for this study.

The added value of ADC in multiparametric MRI for uterine smooth muscle tumor characterization (6 min)

Federica Masino; Bari / Italy

Author Block: F. Masino[1], C. Locorotondo[2], A. Torrente[2], M. Montatore[1], M. Balbino[1], V. Buonocore[2], M. Morgillo[2], G. Guglielmi[1], E. Muscogiuri[2]; [1]Foggia (FG)/IT, [2]Brindisi/IT

Purpose: To evaluate the added diagnostic value of integrating ADC with conventional MRI features in the differentiation of uterine smooth muscle tumors.

Methods or Background: Preoperative distinction between leiomyomas, STUMP, and leiomyosarcomas is critical due to radically different therapeutic implications. While MRI represents the reference imaging technique, morphology alone is insufficient to ensure accuracy. In this retrospective single-center cohort of 27 surgically confirmed cases, both qualitative MRI features (shape, margins, necrosis, T1/T2 signal, contrast enhancement, DWI) and quantitative ADC values were systematically assessed. Logistic regression and ROC analysis tested the incremental value of ADC.

Results or Findings: Among 27 patients, 22 had benign lesions and 5 had non-benign tumors. Morphological features such as irregular margins, necrosis, and hemorrhagic T1 foci correlated significantly with malignancy ($p<0.05$), but showed partial overlap with atypical leiomyomas. The ADC alone yielded excellent discrimination (AUC 0.995). Importantly, when ADC was combined with morphological parameters, diagnostic performance improved from an AUC of 0.982 (morphology alone) to 1.000 (integrated model). This integration enhanced risk stratification, supporting accurate identification of leiomyosarcomas while avoiding unnecessary radical surgery in benign cases.

Conclusion: A multiparametric MRI approach integrating ADC with morphological features achieves nearly ideal accuracy in differentiating uterine smooth muscle tumors, providing radiologists with a powerful tool to optimize patient management.

Limitations: No limitations were identified.

Funding for this study: No funding was received for this study.

Advancing Patient-Specific Dosimetry for Synchrotron Phase-Contrast Breast CT: A Monte Carlo Framework for Clinical Translation at the Australian Synchrotron (6 min)

Amir Entezam; Notting Hill / Australia

Author Block: A. Entezam[1], A. Pakzad[1], A. Maksimenko[1], C. Hall[1], M. John Cameron[1], P. Brennan[2], D. Hausermann[1], T. Gureyev[1], H. M. Quiney[1]; [1]Melbourne/AU, [2]Sydney/AU
Purpose: To develop and validate a patient-specific Monte Carlo (MC) dosimetry framework for propagation-based X-ray phase-contrast breast computed tomography (BCT) at the Imaging and Medical Beamline (IMBL) of the Australian Synchrotron, enabling accurate estimation of mean glandular dose (MGD) for clinical translation.
Methods or Background: BCT provides 3D imaging without breast compression, improving comfort and enhancing visualization of internal structures—crucial for accurate cancer detection. Propagation-based phase-contrast BCT offers superior soft-tissue contrast at equal resolution and comparable or lower doses than conventional absorption-based BCT. Accurate radiation dosimetry is vital for patient safety and optimal imaging performance. Most existing MC-based MGD studies use homogeneous phantoms, neglecting patient-specific anatomy that affects dose distribution. To overcome this, a voxel-based MC dosimetry framework was developed using EGSnrc to calculate MGD in realistic anthropomorphic breast phantoms derived from synchrotron BCT images, tailored to IMBL beam properties. Corresponding homogeneous phantoms were also generated, and air kerma–to–MGD conversion factors were obtained and compared with heterogeneous phantom results. Simulations were performed for varying breast densities, dimensions, and skin thicknesses across 28–38 keV.
Results or Findings: Breast anatomy and beam energy strongly influenced MGD. Higher glandular density and larger breasts increased MGD, while a 2 mm thicker skin layer reduced it by about 10% at equal air kerma. MGDs decreased with rising beam energy, though less markedly in larger breasts. Comparisons between heterogeneous and homogeneous phantoms showed clear differences in conversion coefficients, underscoring the need to include anatomical heterogeneity in dosimetric modelling.
Conclusion: The voxel-based MC framework offers an anatomically accurate, patient-specific approach to dosimetry in synchrotron phase-contrast BCT, enabling precise dose estimation and supporting safe, effective clinical implementation at the Australian Synchrotron..
Limitations: This study focused on simulations performed using only EGSnrc MC code.
Funding for this study: Funding was provided by Australian National Health and Medical Research Council (NHMRC) Synergy Grant (APP2011204).

3D-printed anthropomorphic breast phantoms with iodinated resin disks to evaluate the performance of Contrast-Enhanced Mammography (6 min)

Adrián Belarra; Madrid / Spain

Author Block: A. Belarra[1], M. Castillo[1], I. Hernandez-Giron[2], N. Amallal El Ouahabi[1], A. Tejerina[1], P. Homolka[3], M. Chevalier[1]; [1]Madrid/ES, [2]Dublin/IE, [3]Vienna/AT
Purpose: Contrast-enhanced mammography (CEM) is a widespread imaging modality to improve lesion detection. In this study, a 3D-printed anthropomorphic phantom including iodinated resin disks is employed to evaluate CEM performance.
Methods or Background: A breast-CT volume segmented into gland/skin and fat and further compressed (thickness: 4.8 cm) was used to generate four 1.2cm-thick slices, which were 3D-printed (BambuLab X1C, 0.2 mm nozzle, 0.14 mm layer height, 100% infill-lines) selecting PLA for glandular tissue/skin and ABS for fat. One of the intermediate slices included five cylindrical recesses (8mm diameter, 0.8mm height) located over different backgrounds. Three sets of four resin iodinated disks (Iomeron400) were SLA-printed with varying concentrations (0.50, 0.75, 1.00 mg/cm²). A fifth disk was PLA-printed as a control. Three CEM phantom images were acquired (Hologic-3Dimensions)for each set of resins+PLA disks. On the images, the difference (S) between MPV of a 7mm-circular-ROI inside each disk and MPV of a 1mm-band-ROI on the background were computed. For each set, the average S was obtained across images (and all disks for resins ones).
Results or Findings: The phantom background was successfully removed in CEM images. S values were [average□SD(range)]: [0±2(-2,1) for the PLA disk] and for iodinated disks: [23±5(17,28); 0.50mg/cm2], [30±7(24,39); 0.75mg/cm2] and [44±4(40,49); 1.00mg/cm2]. S value and iodine concentration were linearly dependent (43.1 slope; R2=0.998).
Conclusion: In CEM images, both PLA (glandular tissue) and background (parenchyma) were successfully removed, whereas resin-disk signals remained visible. As expected, S values increased with iodine concentration. These results support the use of 3D-printed anthropomorphic phantoms for evaluating the CEM performance under conditions that better mimic the clinical scenario.
Limitations: A wider range of concentrations must be evaluated and a better recess-disk fitting achieved to reduce the air artefact on the disk borders.
Funding for this study: This work was supported by the Spanish Ministry of Science and Innovation under grants PID2021-123390OB-C22 and PID2021-123390OB-C22.

Manufacturing and validation of part-solid pulmonary nodule phantoms with realistic morphology and multiple densities using stereolithography-based 3D-printing (6 min)

Louise D'Hondt; Ghent / Belgium

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: L. D'Hondt[1], D. Buytaert[1], P-J. Kellens[1], A. Snoeckx[2], K. Bacher[1]; [1]Gent/BE, [2]Antwerp/BE
Purpose: While phantoms support objective CT image quality and dose evaluations, off-the-shelf models insufficiently reflect complex morphologies and radiodensity heterogeneities, thereby limiting clinical translation of results. Part-solid pulmonary nodules exemplify intricate structures inadequately represented by generic models. Adaptation of 3D-printing in research could improve phantoms. This study aimed to 3D-print part-solid nodule phantoms that mimic patient nodules, as validated by a human reader study.
Methods or Background: Seven part-solid pulmonary nodules on patient-derived CT series were segmented and solid core and ground glass densities were measured through Hounsfield Unit (HU) thresholding. Four target radiodensity ranges were defined and stereolithography-based 3D-printing parameters were optimised towards 3D-designs of nodules with a solid core (>0HU) and three gradients mimicking ground glass opacity ([0; -300HU[, [-300; -500HU[, [-500; -750HU]). Low-dose CT acquisitions of 3D-prints incorporated in a Lungman phantom were randomised with patient scans. A multicentre, single-blinded reader study, involving seventeen radiologists, assessed whether 3D-printed nodules were distinguishable from real part-solid nodules using $\chi 2$ goodness-of-fit testing.
Results or Findings: Final 3D-printed nodule models consisted of the four target radiodensities measured on CT-images of clinical nodules. Overall accuracy of all scored nodules was 53.50%. Importantly, the false negative rate indicates that, across all radiologists, 47.50% of 3D-printed nodules was incorrectly classified as a real patient nodule, while 44.54% of patient nodules were thought to be 3D-prints. There was significant evidence ($\chi 2$= 136.13; p= 1.864e-31; 5% confidence level) against readers reliably distinguishing patient nodules from our 3D-printed phantoms.
Conclusion: We were able to manufacture nodule phantom models with morphological and radiological properties that are highly customisable, relatively inexpensive and indistinguishable from real clinical examples. As such, this study demonstrates that adaptation of 3D-printing can enhance clinical relevance of phantom research.
Limitations: No limitations were identified.
Funding for this study: Funding was provided by the FWO “Kom op tegen Kanker”-project for lung cancer screening research in Belgium. (Project number: G0B1922N).

Ethics committee - additional information: The retrospective use of patient CT series was approved by the Antwerp University Hospital Ethics Committee (Approval Number: EC/PM/eva/2024.048).

Deep Learning-Based Anatomical Segmentation for Beam Hardening Correction in Clinical Dark-Field Chest Radiography (6 min)

Lennard Kaster; Munich / Germany

Author Block: L. Kaster[1], M. Lochschmidt[1], A. M. Bauer[1], T. Dorosti[1], S. Demianova[1], T. Koehler[2], D. Pfeiffer[1], F. Pfeiffer[1]; [1]Munich/DE, [2]Hamburg/DE
Purpose: Dark-field chest radiography has demonstrated superiority over conventional radiography for diagnosing and staging pulmonary diseases by visualising microstructural lung changes. However, rib- and clavicle-induced beam hardening artefacts generate false dark-field signals that impair diagnostic accuracy. This study introduces an AI-based segmentation framework for anatomically adaptive beam hardening correction (BHC) in clinical dark-field radiographs.
Methods or Background: Rib and clavicle segmentations were obtained using U-Net models trained on the VinDr-RibCXR dataset and clinical attenuation images. Masks were refined into anterior and posterior rib components and combined with attenuation-contribution weights derived from dual-energy CT material decomposition (aluminium and water as surrogates for bone and soft tissue). Patient-specific correction maps were generated and subtracted from raw dark-field images. The method was evaluated on 174 radiographs (healthy, COPD, COVID-19) using qualitative assessment and quantitative measures of signal homogeneity and diagnostic separability.
Results or Findings: Uncorrected dark-field radiographs showed elevated signals at rib and clavicle locations, obscuring the lung parenchyma and reducing interpretability. The proposed segmentation-based BHC suppressed these artefacts, yielding a more homogeneous dark-field signal and improved visualisation of pulmonary structures. Improvements were consistently observed across all cohorts. Quantitatively, intra-pulmonary signal variability decreased (coefficient of variation −16%, $p < 0.001$), and diagnostic separability improved, with overlap between healthy and diseased lungs reduced by up to 18.8%.
Conclusion: AI-segmentation-based BHC enables regionally adaptive correction of bone-induced artefacts in dark-field chest radiography, improving image homogeneity and visual differentiation of pathological changes. This addresses a key limitation of the modality and strengthens its clinical potential for pulmonary disease assessment.
Limitations: The limitations of the study are that correction performance depends on segmentation accuracy and on contribution weights derived from limited spectral CT datasets. Patients with atypical anatomy or metallic implants may still exhibit residual artefacts.

Characterization of a Deep Learning CT Reconstruction Algorithm and Comparison with Iterative Reconstruction Algorithms (6 min)

Raffaele Villa; Monza / Italy

Author Block: R. Villa, N. Paruccini, E. De Ponti; Monza/IT
Purpose: To characterize the image quality performance of a deep learning-based (DL) reconstruction algorithm, Philips Precise Image, and compare it with iterative reconstruction (IR) algorithms (iDose 4 and IMR) under clinically relevant conditions. The goal is to evaluate its potential in optimizing CT protocols.
Methods or Background: Two phantoms were used for this study: an anthropomorphic abdomen phantom (PhantomX, Germany) and a Catphan phantom (The Phantom Laboratory, USA). Both phantoms were acquired at five dose levels (1.7-6.8 mGy), with each acquisition repeated five times. Two CT scanners were used: one with Philips iDose 4 and IMR, and another with Philips iDose 4 and Precise Image. Image quality was evaluated in terms of noise, spatial resolution, blur, visual artifacts, and detectability index with a channelized Hotelling observer.
Results or Findings: Precise Image significantly improved all image quality parameters compared to iDose 4. Furthermore, noise reduction was up to 70%, spatial resolution improved by up to 20%, and CHO scoring increased by up to 90%. The improvement was less pronounced with IMR; however, Precise Image demonstrated behaviour more similar to filtered back projection (FBP) than IMR, with less dependency of image quality on contrast. This similarity makes it easier to optimize CT protocols. Additionally, Precise Image produced fewer visual artifacts than IMR, resulting in images that were much more similar in appearance to FBP images and reducing the synthetic texture typically associated with iterative reconstruction techniques.
Conclusion: The DL reconstruction algorithm demonstrates superior image quality performance compared to conventional iterative reconstruction methods. Its image characteristics, which closely resemble those of FBP, suggest it could be a valuable tool for simplifying and improving CT protocol optimization.
Limitations: Phantom size, small size compared to an adult patient.

Assessment of Low-Contrast Lesion Detectability in CT: Evaluation of Super Resolution Deep-Learning Reconstruction Using 3D-Printed Lifelike Abdominal Phantoms (6 min)

Leening Liu; Philadelphia / United States

Author Block: D. W. Shin[1], J. Im[2], L. Liu[2], B. E. Hoppel[1], T. Hagio[3], A. Dhanantwari[1], K. Boedeker[3], P. Noël[2]; [1]Tustin, CA/US, [2]Philadelphia, PA/US, [3]Ōtawara/JP
Purpose: To use 3D-printed anthropomorphic abdominal phantoms to compare trends in low contrast detectability (LCD) across various reconstruction algorithms and doses.
Methods or Background: An anthropomorphic abdominal phantom, consisting of two modules, was 3D-printed with PixelPrint, a technique that converts patient CT images and/or synthetic datasets into printer instructions which modulate printed density at sub-resolution scale to mimic realistic tissue densities and textures. The first module consisted of native anatomy, while the second incorporated ten digitally added rods (5 mm diameter, 30 HU contrast) within the same native anatomical background. Scans were acquired using an abdominal CT protocol on a clinical CT scanner (Aquilion ONE INSIGHT, Canon Medical Systems) across four water-equivalent diameters (Dw = 15, 27, 31, and 35 cm) at dose levels from 4-30 mGy. Images were reconstructed with Filtered Back Projection (FBP), Hybrid Iterative Reconstruction (HIR), two Deep Learning Reconstructions (DLR1 and DLR2), and Super Resolution-Deep Learning Reconstruction (SR-DLR). The LCD was determined via a Non-Prewhitening Model Observer with an eye filter. The trend in detectability index (d′) across reconstruction algorithms was compared at various dose levels and phantom sizes.
Results or Findings: At the highest dose (30 mGy) and largest size (Dw 35 cm), the d' were 1.84, 1.56, 1.44, 1.23, and 0.75 for SR-DLR, DLR1, DLR2, HIR, and FBP, respectively. At the lowest dose (4 mGy), the corresponding d' were 0.95, 0.99, 0.85, 0.89, and 0.30. The SR-DLR generally showed better LCD performance than conventional algorithms across dose levels and phantom sizes.
Conclusion: Lifelike 3D-printed abdominal phantoms replicate clinical imaging conditions, demonstrating in this study that SR-DLR improves visualization of subtle lesions—even in larger patients or at reduced doses—thereby supporting greater diagnostic confidence.
Limitations: Future reader studies are required for full clinical translation.

Contribution of Photon-Counting on Slit-Beam Radiography Image Quality: Cross-Center Benchmarking and Validation (6 min)

Virginia Tsapaki; Vienna / Austria

Author Block: I. Fitton[1], S. Alkhazzam[2], M. H. Kharita[2], M. Dimailing[1], M. Khalife[1], C. Van Ngoc Ty[1], V. Tsapaki[3]; [1]Paris/FR, [2]Doha/QA, [3]Vienna/AT
Purpose: Slit-beam radiography is recognized as a low-dose imaging technique particularly suitable for spine, hips, and knees. Additional clinical applications could be expanded with photon-counting technology. The aim of this study was to evaluate the image quality of photon-counting (PCD) compared to pressured Xenon gaseous linear (GLD) detectors, using the ATIA International Atomic Energy Agency (IAEA) methodology.
Methods or Background: Seven EOS imaging systems including two models based on PCD and GLD technologies were studied. The IAEA test-object was propped along each detector. A block of 30 × 30 × 10 cm3 PMMA plates was placed at the output of the X-ray tube as an attenuator. Acquisition parameters were fixed : 70kV, 20mA, scanning speed of 6, no modulation. Image acquisitions were repeated five times on each of the detectors. « For-processing » (FPRO) and « For-presentation » (FPRE) image formats were compared when available. Signal-difference-to-noise ratio (SDNR), Normalized Noise Power Spectrum (NNPS), Modulation Transfer Function (MTF), detectability indexes (d') for small lesions with diameters of 0.3mm and 4mm were automatically quantified using PyATIA software. A Wilcoxon-test was used to compare both technologies.
Results or Findings: Results showed that task-based detectability metrics (SDNR and d′) were substantially higher on photon-counting. The spatial resolution was higher on PCD compared to GLD at high frequencies in FPRE: 11.21 lp/mm[8.55–12.24] vs. 2.64 lp/mm[2.16–3.44] ($p<0.05$).
The noise variance was greatly reduced on PCD and close to zero. The noise level was four times lower on PCD compared to GLD.
Conclusion: The IAEA ATIA methodology proved valid for inter-technology comparison, enabling benchmarking between PCD and GLD detectors. PCD demonstrated statistically superior image quality compared to GLD. This paves the way to a range of clinical applications of slit-beam radiography beyond spinal conditions.

Robust VFA T1 Mapping with Optimal-Control RF Excitation (6 min)

Alexander Rauscher; Vancouver / Canada

Author Block: C. Graf[1], A. Jaffray[1], A. Rund[1], S. Steinerberger[2], A. Rauscher[1]; [1]Vancouver, BC/CA, [2]Seattle, WA/US
Purpose: The T1 relaxation time of the MRI signal can characterize brain tissue microstructure, e.g. to monitor disease progression and treatment response in conditions such as multiple sclerosis, tumours, or brain trauma. Variable flip angle (VFA) T1-mapping is fast but prone to bias from off-resonance, B1-inhomogeneity, imperfect spoiling, and magnetization transfer (MT). Our aim was to design excitation radiofrequency (RF) pulses with optimal control (OC) that are robust to B0/B1-variations and satisfy controlled-saturation MT (CSMT) to reduce MT-related bias, enabling accurate VFA-T1 without B1-mapping.
Methods or Background: Non-selective OC excitation pulses were designed for α=6° and 15° at 3T and 7T. Robustness levels covered B1-scales of 80-120% of nominal and B0-offsets of ±2.4ppm. Pulses were optimized by a semi-smooth quasi-Newton method with exact discrete derivatives; Bloch dynamics were solved via symmetric operator splitting. To enforce CSMT, pulses for both flip angles used identical duration and constant maximum amplitude, yielding matched RF energy. Numerical VFA-T1 simulations compared OC versus block pulses at 3T and 7T, sampling wide B0/B1-ranges. Summary metrics within the target robustness box included min/max/mean T1 and the central 90%-range.
Results or Findings: OC pulses produced tighter T1-distributions than block pulses. At 3T, the 90% T1-range for OC was 748-882ms (≤10% from nominal 800ms), versus 540-1129ms (>40%) for block; at 7T, OC yielded 1255-1384ms (<7% from nominal 1300ms) versus 879-1842ms (~40%) for block. OC-T1 remained largely insensitive to B1 within 80-120% of nominal B1, whereas block-pulse T1 increased quadratically with B1.
Conclusion: OC-designed, CSMT-compliant excitation pulses substantially reduce B0/B1-related VFA-T1 bias at 3T and 7T while removing the need for B1-mapping. The approach is vendor-agnostic, patient-independent, and requires no specialized hardware, supporting practical deployment for robust quantitative T1-mapping.
Limitations: Future work will verify results experimentally.

Towards Non-Invasive Characterization of Thyroid Tissue: Feasibility of Magnetic Resonance Elastography with a Custom Passive Driver (6 min)

Vitaliy Atamaniuk; Rzeszów / Poland

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: V. Atamaniuk, L. Hanczyk, M. Obrzut; Rzeszów/PL
Purpose: Magnetic resonance elastography (MRE) is an advanced non-invasive imaging technique that quantifies the biomechanical properties of soft tissue. While clinical MRE is mainly applied to the liver, stiffness-related biomarkers may be valuable for other organs, including the thyroid, where tissue stiffening occurs in multiple pathological conditions. However, due to the gland's small size and anatomical location, MRE of the thyroid is challenging without dedicated hardware. This study aimed to assess the feasibility of thyroid MRE using a custom-designed passive driver.
Methods or Background: 6 adult volunteers (aged 29–59 years) underwent thyroid MRE. A custom two-branch passive driver was built and positioned on the neck to cover both lobes of the thyroid. Vibrations at 120 Hz were generated by an active driver and transmitted through the passive driver to induce shear waves. Imaging was performed on a 1.5T whole-body MRI scanner using a SE-EPI-based 3D vector MRE sequence. Shear modulus magnitude and its storage and loss components were reconstructed using direct inversion. Wave field quality was assessed with octahedral shear strain SNR (OSS-SNR) and a confidence metric. Regions of interest were manually defined on T2-weighted images by a radiologist.
Results or Findings: The custom driver consistently provided excellent shear wave illumination in the thyroid. Mean ± SD OSS-SNR was 4.09±2.11, with confidence 81.39±3.45%. Displacement amplitudes ranged from 6.45 to 149.16 µm (mean ± SD: 51.24±21.45 µm). Mean ± SD stiffness, storage modulus, and loss modulus were 4.11±0.67 kPa, 3.87±0.70 kPa, and 1.22±0.61 kPa, respectively.
Conclusion: A dedicated passive driver makes thyroid MRE technically feasible, yielding reliable shear wave propagation and stiffness quantification. These findings support further research into the role of MRE for non-invasive thyroid characterization.
Limitations: Small sample size and lack of clinical data.

Stage-Specific Prognostic Value of Tumor Burden in Lymphoma Patients Treated With CAR T-Cell Therapy (6 min)
Michael Winkelmann; Munich / Germany

Author Block: M. Kassube, P. F. Linden, K. Rejeski, G. Sheikh, R. Werner, M. Subklewe, J. Ricke, W. G. Kunz, M. Winkelmann; Munich/DE
Purpose: CAR T-cell therapy (CART) has transformed treatment for relapsed or refractory llymphomas. While Ann Arbor staging remains important for risk stratification, tumor burden (TB) may offer additional prognostic insight. The differential impact of TB in early- (I/II) versus advanced-stage (III/IV) disease remains unclear in the context of CART. We assessed the added prognostic value of Lugano-based sum of product diameters (SPD) in stage I/II compared with stage III/IV patients for progression-free (PFS) and overall survival (OS).
Methods or Background: This study was conducted on a cohort of 103 patients treated with CART. Tumor burden at baseline was quantified using SPD according tu Lugano Criteria. Patients were stratified by Ann Arbor stage and SPD levels. PFS and OS were analyzed using Kaplan-Meier curves and log-rank tests.
Results or Findings: Median age was 67 years; 38% female. Patients with Stage III/IV disease had significantly higher baseline SPD compared to Stage I/II (median SPD: 6,088 mm^2 vs. 1,504 mm^2; $p<0.001$). Survival analysis demonstrated significantly inferior PFS ($p<0.001$) and OS ($p=0.018$) in patients with advanced disease. The subdivision of the early stage patients according to their median SPD of 1,504 mm2 resulted in a significant separation of the two groups. The early stage patients with a low SPD showed a significantly longer OS and a slightly longer PFS than those with a high SPD. Interestingly, stage I/II patients with higher TB showed a similar overall survival curve as the advanced stage patients.
Conclusion: Baseline tumor burden, as measured by SPD, had a prognostic value in early-stage lymphoma patients undergoing CART. In this subgroup, higher SPD was associated with inferior OS and slightly inferior PFS. In contrast, SPD did not show a prognostic impact among patients with advanced-stage disease.
Limitations: Monocentric, retrospective study.

Second Progression-Free Survival (PFS2) as a Surrogate Endpoint for Overall Survival in Patients Treated with CD19-Targeted CAR T-Cell Therapy (6 min)
Philipp Franz Linden; Munich / Germany

Author Block: P. F. Linden, M. Kassube, K. Rejeski, G. Sheikh, R. Werner, M. Subklewe, J. Ricke, W. G. Kunz, M. Winkelmann; München/DE
Purpose: CD19-directed chimeric antigen receptor T-cell therapy (CART) has improved outcomes in relapsed/refractory (r/r) B-cell lymphomas. However, long-term survival impact is difficult to assess using conventional endpoints such as progression-free survival (PFS1). Second progression-free survival (PFS2) has been proposed as a more comprehensive endpoint, but has not been studied in CART. This study evaluates associations among PFS1, PFS2, and overall survival (OS).
Methods or Background: We analyzed patients with r/r lymphomas treated with CART at our center. PFS1 was defined as time to first progression, PFS2 as time to second progression. To avoid overfitting, patients in whom death was the event for both PFS1 and PFS2 were excluded. Associations among PFS1, PFS2, and OS were assessed by linear regression and Spearman correlation. Tumor burden prior to CART was calculated as the sum of product of diameters (SPD). Box plots explored SPD outcome associations. Kaplan–Meier estimates were used for survival endpoints.
Results or Findings: Of 140 patients, 51 were excluded (death as event for PFS1: n=13; PFS2: n=38). Median PFS1, PFS2, and OS were 9, 14, and 18 months. PFS2 differed significantly from PFS1 (p=0.044) and was more comparable to OS (p=0.256). PFS2 correlated more strongly with OS (r=0.91) than PFS1 (r=0.77), suggesting superior reflection of outcomes. Patients with shorter PFS1 had higher baseline tumor burden; this association was more pronounced when stratified by median PFS2. Patients with two progressions had shorter OS than those with one, progression-free patients achieved the longest OS.
Conclusion: PFS2 shows strong association with OS in CD19 CART recipients, supporting its use as an efficacy endpoint to capture long-term benefit. Incorporating PFS2 into trial design and real-world assessments may improve evaluation of therapeutic benefit and guide treatment sequencing in CART.
Limitations: Retrospective, monocentric study

Prognostic relevance of Splenomegaly in CAR T-Cell Therapy for Relapsed Myeloma (6 min)

Hans-Jonas Meyer; Leipzig / Germany

Author Block: H-J. Meyer, V. Sotikova, T. Denecke, M. Merz; Leipzig/DE
Purpose: B-cell maturation antigen (BCMA)-directed chimeric antigen receptor (CAR) T-cell therapy has shown significant promise for patients with relapsed or refractory multiple myeloma (RRMM). Despite its efficacy, treatment is frequently complicated by adverse events such as cytokine release syndrome and hematologic toxicities, including severe thrombocytopenia. Identifying reliable prognostic markers is essential to improve patient risk stratification, optimizing treatment strategies, and managing complications effectively. While various prognostic markers have been explored, spleen size has not been extensively studied in this context.
Methods or Background: This study aims to evaluate spleen size as a prognostic marker in RRMM patients receiving CAR T-cell therapy. Specifically, we examine its association with thrombocytopenia, metabolic tumor volume, soluble BCMA (sBCMA) levels, progression-free survival (PFS), and overall survival (OS). Additionally, we compare spleen size to established prognostic markers, including baseline sBCMA, EASIX, and CAR-HEMATOTOX scores, to determine its predictive value. The association of spleen size, assessed via computed tomography imaging, with clinical outcomes was evaluated.
Results or Findings: Splenomegaly (spleen size >340 cm^3) was found to be significantly associated with severe and prolonged thrombocytopenia, higher metabolic tumor volumes, and elevated sBCMA levels. In our cohort, splenomegaly emerged as an independent prognostic factor for both PFS and OS, showing stronger associations than other markers such as sBCMA, EASIX, and CAR-HEMATOTOX scores.
Conclusion: Spleen size may serve as a promising prognostic marker in CAR T-cell therapy for RRMM patients, providing a simple and readily accessible tool for enhancing risk stratification. This finding could inform monitoring strategies and optimize healthcare resource management for these patients.
Limitations: The present study has to address the limitation of its retrospective design. The measurement of the spleen sizes were performed by one reader with potential small reader bias.

Mapping Organ-Specific Depth of Response in Relapsed/Refractory Non-Hodgkin Lymphoma Treated with CD19 CAR T-Cell Therapy (6 min)

Matthias Kassube; Munich / Germany

Author Block: M. Kassube, P. Achhammer, P. F. Linden, K. Rejeski, G. Sheikh, M. Subklewe, J. Ricke, W. G. Kunz, M. Winkelmann; Munich/DE
Purpose: CD19-directed CAR T-cell therapy improves outcomes in relapsed/refractory (r/r) B-cell non-Hodgkin lymphoma (NHL). However, relapse remains common, particularly with extranodal disease. Organ-specific involvement may affect prognosis, yet spatial response data are limited. Radiologic assessment enables evaluation at the organ level. We aimed to identify organ systems whose involvement is linked to poor response or early relapse after CAR T-cell therapy.
Methods or Background: This retrospective study included 153 patients with r/r B-cell NHL treated with CD19 CAR T-cells. Baseline and follow-up imaging (FDG-PET/CT or contrast-enhanced CT) at day 30 (FU1) and 3 months (FU2) was analyzed. Extranodal lesions were documented by frequency, size, and number per organ system. Depth of response (DoR) was assessed by percentage change in sum of product diameters (SPD) according to Lugano criteria.
Results or Findings: Responses were heterogeneous across organ systems. Nodal disease showed stronger reductions compared with extranodal sites (median DoR –89.4% vs. –90.4%). Significant decreases in lesion size occurred from baseline to FU2 in both nodal ($p<0.001$) and extranodal sites ($p<0.001$). Among the five most frequently involved extranodal organs, muscle and pleura demonstrated significant reductions (muscle: $p=0.020$; pleura: $p=0.008$). Bone and lung showed favorable responses (≈–67% SPD) without reaching statistical significance. In contrast, hepatic lesions responded least, with an average reduction of –29%.
Conclusion: Radiologic assessment reveals organ-specific heterogeneity after CD19 CAR T-cell therapy, with lymphoid tissues exhibiting more profound responses than non-lymphoid sites. Specific extranodal involvement, especially of the liver, may limit therapeutic durability and should be validated in future studies.
Limitations: Limitations include the single-center design.
Funding for this study: This study received no external funding and was conducted with institutional resources only.

Prediction of chemotherapy toxicity after four cycles of R-CHOP treatment for diffuse large B-cell lymphoma: effective imaging biomarkers of body composition (6 min)

Shushan Dong; Shanghai / China

Author Block: L. Zuo[1], S. Dong[2], X. Yu[3], D. Yu[1]; [1]Jinan/CN, [2]Beijing/CN, [3]Shanghai/CN
Purpose: This study aims to identify reliable, non-invasive biomarkers and validate findings using follow-up CT scans after four cycles of chemotherapy.
Methods or Background: Diffuse large B-cell lymphoma (DLBCL) patients with a low baseline skeletal muscle (SM) area are more susceptible to severe toxicity during chemotherapy. However, the predictive role of baseline body composition in determining toxicity risk during the initial frontline treatment remains unexplored. We retrospectively included DLBCL patients who received four cycles of R-CHOP treatment between January 2015 and January 2024, with pre-treatment abdominal CT scans. We measured the volume, area, and density of SM, visceral adipose tissue (VAT), and subcutaneous adipose tissue (SAT) to assess their predictive potential for chemotherapy toxicity. Subgroup analyses examined longitudinal changes in body composition, and a logistic regression model identified effective imaging biomarkers associated with grade 3/4 toxicity.
Results or Findings: Among the 179 DLBCL patients (mean age 56.96±13.49 years), 46.9% experienced grade 3/4 toxicity. Lower baseline SM volume and density significantly increased the risk of toxicity, particularly in overweight or obese patients ($P<0.05$). ROC analysis identified SM volume as the best predictor, with a cutoff of 2093.71 cm^3; patients below this threshold had a 3.34 times higher risk ($P=0.001$). A decrease in SM volume was associated with higher risks of hematological toxicity ($P=0.022$) and neutropenic fever ($P=0.021$).
Conclusion: Lower baseline SM volume and its reductions during treatment are associated with an increased risk of grade 3/4 toxicity, particularly in overweight or obese patients. Body composition measurements serve as effective imaging biomarkers.

PET-CT Evaluation of Bone Marrow Metabolism in Lymphoma and Solid Tumors (6 min)

Rathinamoorthy Praveenkumar; Chengalpattu / India

Author Block: F. Abubacker Sulaiman, R. Praveenkumar; Chennai/IN
Purpose: To evaluate the patterns of bone marrow (BM) metabolic activity on ^18F-FDG PET/CT in patients with lymphoma and solid tumors, and to correlate them with clinical, hematologic, and histopathologic parameters for assessing diagnostic and prognostic significance.
Methods or Background: A prospective study was conducted on 90 patients—45 with histologically confirmed lymphoma and 45 with solid malignancies (breast, lung, and gastrointestinal cancers). All patients underwent baseline ^18F-FDG PET/CT before therapy initiation. Bone marrow metabolic activity was visually graded and quantitatively assessed using mean and maximum standardized uptake values (SUVmean, SUVmax) measured in vertebral and pelvic marrow. Patterns of BM uptake (diffuse, focal, or heterogeneous) were correlated with complete blood counts, inflammatory markers, and marrow biopsy findings when available. Statistical analysis included Pearson's correlation and ROC analysis for predictive accuracy.
Results or Findings: In lymphoma, focal or multifocal marrow uptake correlated strongly with biopsy-confirmed infiltration (sensitivity 91%, specificity 86%), while diffuse uptake was commonly reactive. Higher BM SUVmean correlated with advanced stage and elevated LDH levels ($r = 0.72$, $p < 0.001$). In solid tumors, diffuse marrow hypermetabolism was associated with anemia and elevated CRP rather than metastatic infiltration. ROC analysis identified an optimal SUVmean cutoff of 2.9 for predicting marrow involvement in lymphoma (AUC = 0.93).
Conclusion: 18F-FDG PET/CT provides a non-invasive, reliable assessment of bone marrow metabolism, enabling differentiation between reactive and infiltrative changes in both lymphoma and solid tumors, thereby improving staging accuracy and treatment planning.
Limitations: Single-center design, limited histopathologic confirmation, and potential influence of hematopoietic stimulation or infection on FDG uptake. Multicentric validation is recommended.
Funding for this study: No external funding was received for this study.

Whole-Body MRI Versus 18F-FDG PET/CT for Lesion Detection in Multiple Myeloma and Their Association with Hematologic Findings (6 min)

Hilal Ardalı Çakır; Istanbul / Turkey

Author Block: B. Baysal, H. Ardalı Çakır, M. Gezgin, B. Canitez, I. Erdogan Ozunal, M. Tiglioglu, E. Ozturk, H. S. Uslu; Istanbul/TR
Purpose: This study investigates the diagnostic performance of whole-body magnetic resonance imaging (WB-MRI) with diffusion-weighted imaging (DWI) compared with 18F-FDG PET/CT in detecting lesions in multiple myeloma and examines the relationship of imaging findings with serum parameters and bone marrow involvement.
Methods or Background: This retrospective study included newly diagnosed multiple myeloma patients who underwent both WB-MRI and 18F-FDG PET/CT. Demographic, laboratory, and imaging data were collected. Lesion presence in the cranial, cervical, thoracic, lumbar, pelvic, costal–sternal–scapular–clavicular, and extremity regions was compared between modalities using the McNemar test, and the relationship of imaging findings with immunoglobulin subtypes was evaluated.
Results or Findings: Twenty eight newly diagnosed multiple myeloma patients (mean age, 66.1 ± 10.9 years; 53.6% female) were evaluated. IgG was the most frequent heavy chain subtype (46.4%), followed by IgA (32.1%), while 21.4% had no heavy chain; kappa light chain predominated (57.1%). MRI identified marrow involvement as diffuse (35.7%), focal (32.1%), micronodular (14.3%), or absent (17.9%). Compared with PET/CT, MRI showed higher sensitivity in cervical ($p = 0.001$), pelvic ($p = 0.031$), and extremity ($p = 0.008$) regions, with a nonsignificant trend in the cranium ($p = 0.063$). No significant differences were observed in thoracic, lumbar, or costal–sternal–scapular–clavicular regions. PET/CT revealed more cervical lesions in IgA patients and more lumbar lesions in IgA and heavy chain–negative groups, while MRI detection did not differ by heavy or light chain subtype.
Conclusion: Whole-body MRI with diffusion-weighted imaging demonstrated higher sensitivity than 18F-FDG PET/CT in multiple myeloma, particularly in the cervical spine, pelvis, and long bones. These findings suggest that WB-MRI may serve as a prominent diagnostic tool, while PET/CT provides complementary metabolic insights.
Limitations: The main limitations are the small sample size and retrospective design.
Funding for this study: No funding was received for this study.

Whole-Body Diffusion-Weighted MRI for Assessing Therapeutic Response in Lymphoma Patients: An Alternative to PET/CT (6 min)

Francesca Maccioni; Rome / Italy

Author Block: F. Maccioni, L. Bottino, L. Busato, A. Valenti, M. Rutigliano, C. Catalano; Rome/IT
Purpose: This study aims to assess the performance of whole-body DWI MRI (WB-DWI MRI), for staging and monitoring lymphomas. WB-DWI MRI was prospectively compared to PET/CT. The ultimate goal is to propose WB-DWI MRI as a viable alternative or complementary tool to PET/CT, especially in younger patients.
Methods or Background: In this single-center study, 71 patients with HL or DLBCL prospectively underwent both ^18F-FDG PET/CT and WB-MRI (within 15 days). Inclusion required histological confirmation, age ≥18, and ≤2 chemotherapy cycles. Exclusion criteria included contraindications to MRI, other neoplasms, or delayed imaging. WB-MRI included T1, T2, and DWI sequences (b-values: 50–800 s/mm²). Qualitative analysis included assessment of 10 different lymphnodal stations and 3 extranodal organans (liver, spleen, bone marrow) and quantitative parameters (SUVmax/ SUVmean vs. DWI/ADC). PET/CT and WB-MRI images were independently evaluated for qualitative and quantitative parameters (SUVmax/ SUVmean; ADCmin/ADCmean). Statistical analyses included concordance (Cohen's κ), predictive values (PPV/NPV), and correlation tests. Strong inverse correlations were found between SUV and ADC values.
Results or Findings: PET/CT and WB-MRI showed excellent agreement (Cohen's κ = 0.91; PPV/NPV: 0.96/0.97), including 100% concordance in extranodal sites.
Conclusion: Quantitative analysis demonstrated an inverse correlation between ADC and SUV values, reflecting tumor cellularity. Whole-body DWI-MRI, a radiation-free modality, showed high concordance with PET/CT, supporting its integration as a complementary tool for lymphoma management, particularly in younger or radiation-sensitive patients.
Limitations: Limited number of patients.

Nomograms based on clinical characteristics and dual-layer spectral detector computed tomography imaging parameters: Potential role in predicting the efficacy of first-line lymphoma treatment (6 min)

Shen Gui; Wuhan / China

Author Block: Z. Tan, S. Gui, J. Wang; Wuhan/CN
Purpose: To develop spectral CT-based nomogram for predicting response and prognosis in lymphoma patients after first-line therapy.
Methods or Background: The baseline clinical and spectral CT data of 91 lymphoma patients were retrospectively analyzed. Patients were assessed for therapy response using the Lugano criteria and were categorized into complete response (CR) and non-complete response (non-CR) groups. Spectral CT parameters of each patient's largest lesion, including the arterial phase (AP) and venous phase (VP) were measured. Univariable and multivariable logistic regression were performed to identify independent predictors of response. In addition, the model was visualized using a clinical model, spectral CT model, and nomograms, and its performance was assessed via receiver operating characteristic curves. Overall survival and progression-free survival (PFS) in patients with different parameters were estimated using the Kaplan-Meier method.
Results or Findings: In the multivariate analysis, B symptoms, Ki-67, iodine concentration (IC), normalized IC at AP, and arterial enhancement fraction based on IC (AEF-IC) were identified as independent predictor factors for CR. The nomogram incorporating all five independent predictors outperformed spectral CT and the clinical model with the highest AUC of 0.856 (95% CI: 0.767-0.921). AEF-IC, the clinical model, spectral CT model, and nomogram were associated with PFS, and the nomogram had the strongest association with unfavorable PFS, with a hazard ratio of 4.725 (95% CI: 2.275-9.817, P<0.001).
Conclusion: Spectral CT and the clinical models were useful in predicting efficacy and PFS in lymphoma patients. Combining spectral CT parameters and clinical characteristics in a nomogram improved predictive performance.
Limitations: A retrospective study conducted at a single center with a small sample size that used a spectral CT scanner from a specific manufacturer, the results may lack generalizability.
Funding for this study: This spectral CT-based nomogram integrating clinical characteristics is a non-invasive and easily obtainable tool for accurately predicting first-line treatment response and prognosis, thereby aiding clinicians in performing personalized treatment planning in lymphoma patients.
