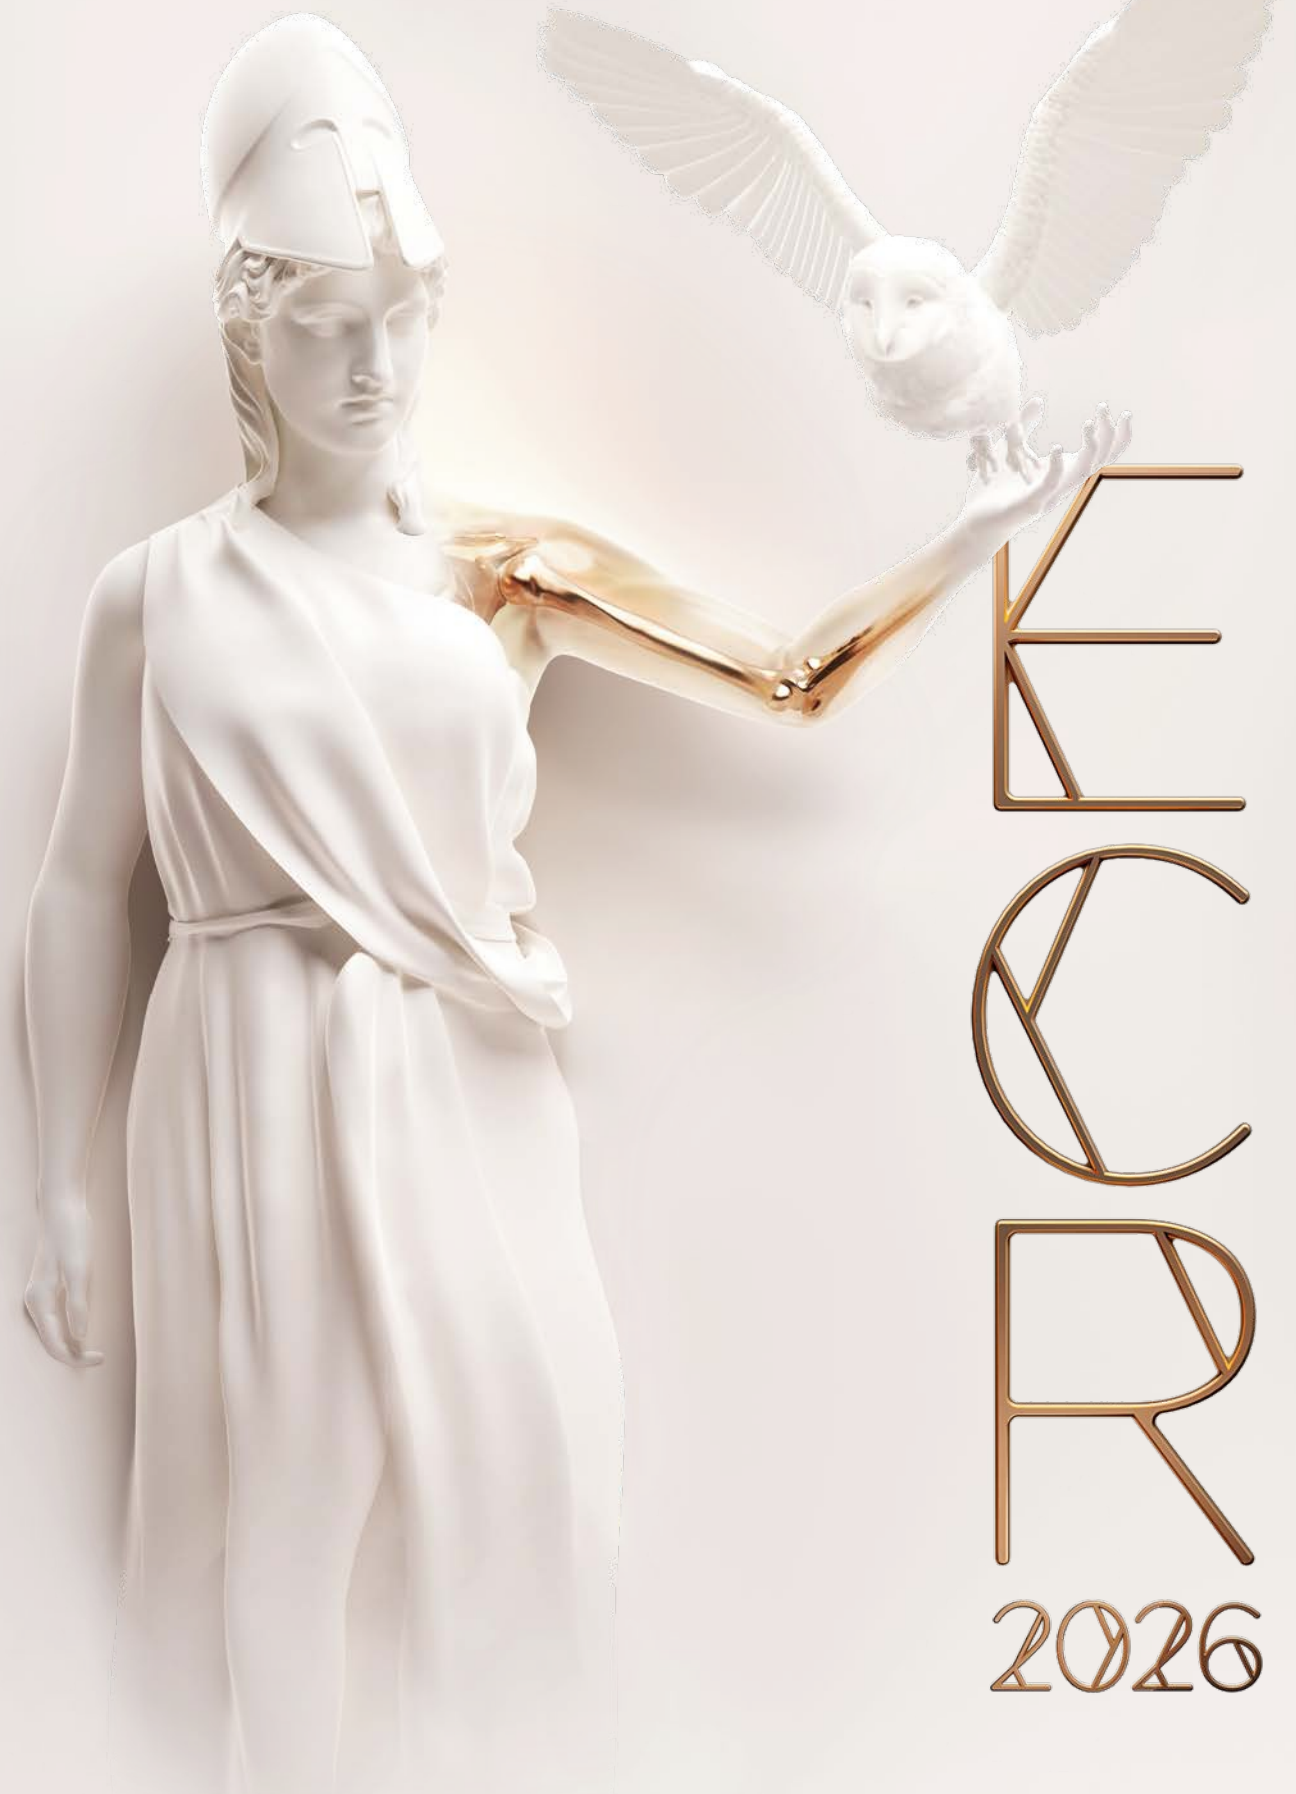
RAYS OF KNOWLEDGE



ECR 2026

EUROPEAN CONGRESS OF RADIOLOGY / VIENNA / MARCH 04 - 08

THE ANNUAL MEETING OF / ESR EUROPEAN SOCIETY OF RADIOLOGY · EFRS EUROPEAN FEDERATION OF RADIOGRAPHER SOCIETIES · ESHI MT MOLECULAR TRANSLATIONAL HYBRID IMAGING / MYESR.ORG

FOREWORD BY THE ESR PRESIDENT MINERVA BECKER

Dear Colleagues and Friends,

It gives me immense joy to unveil the scientific and educational programme for the European Congress of Radiology 2026.

Under the guiding motto, "Rays of Knowledge," ECR 2026 will be a celebration of education and innovation at the heart of radiology. It will shine a light on the power of learning and discovery that continues to advance our field with a strong focus on progressive educational methods, multidisciplinary collaboration, and technological advancements. It is my hope that this meeting will serve as a roadmap for the future of patient-centred, knowledge-driven imaging practice.

In 2026, the In Focus programme returns with the theme 'The Art of AI in Clinical Practice', dedicated to exploring how artificial intelligence is transforming radiology with creativity and precision. Through expert-led sessions, attendees will discover how AI is democratising screening, enhancing communication, and redefining oncologic follow-up. Ethical considerations, regulatory frameworks, and innovative diagnostic approaches will be central themes, offering a comprehensive look at AI's evolving role in clinical practice.

Familiar favourites of our annual meeting such as the AI Theatre and The Cube will also return, along with session formats we know and love, ranging all the way from Image Interpretation Quizzes and Open Forums through to Basic Knowledge and Master Classes.

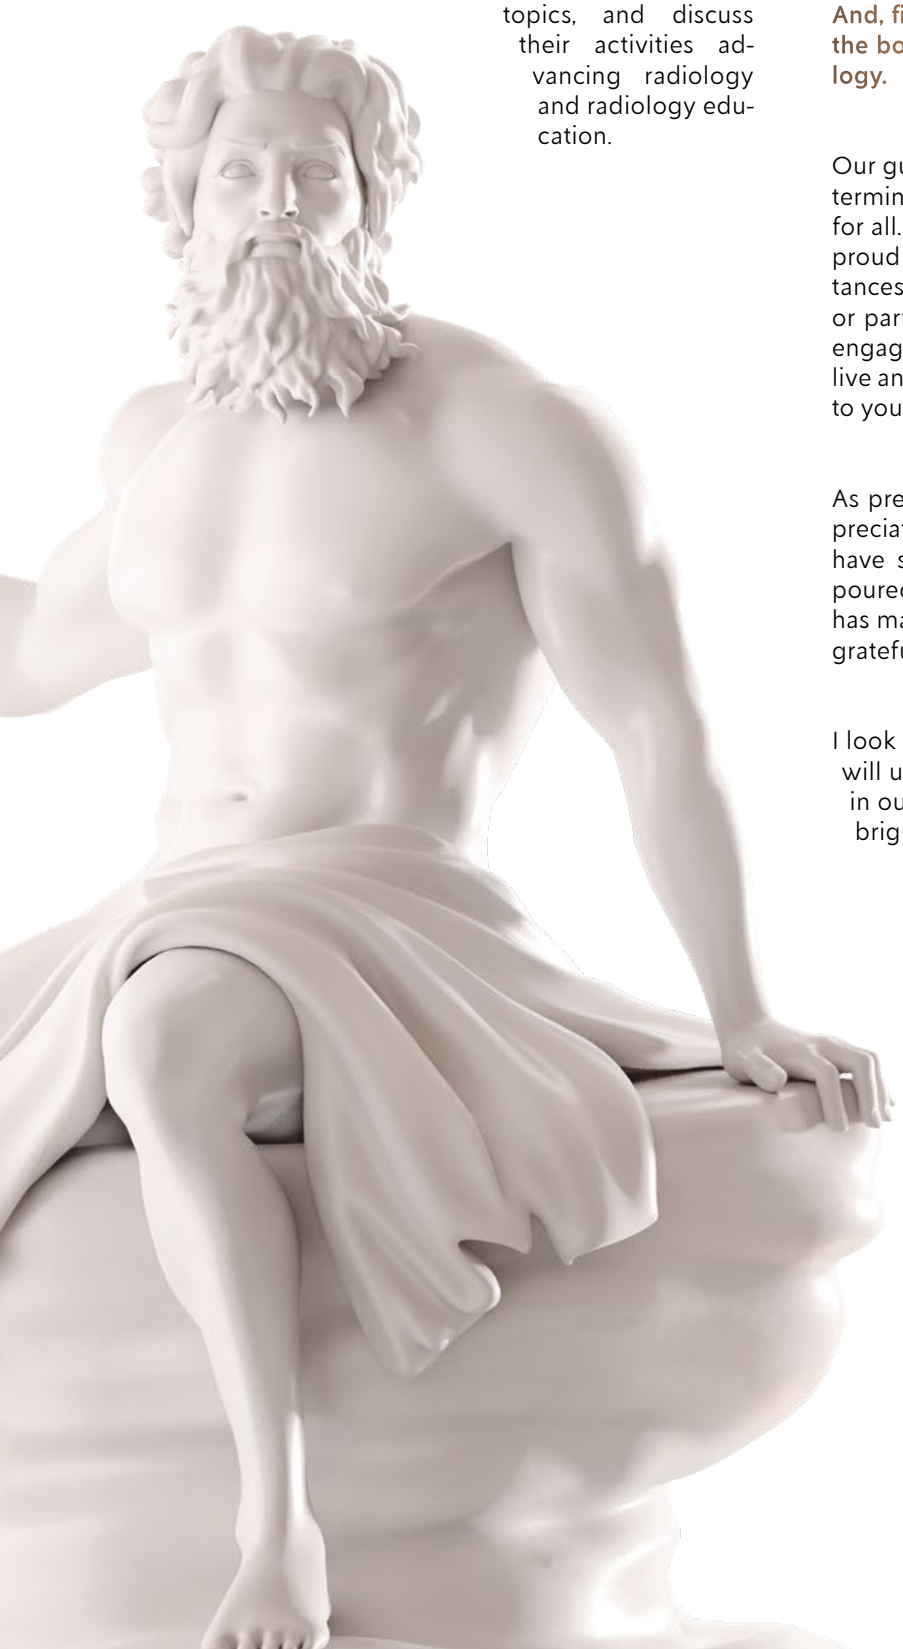
The immersive course "Decoding the Diagnosis: Radiology Meets Pathology" will offer a unique journey that bridges the gap between what we see in imaging and pathologic truth. By pairing striking imaging findings with their precise pathologic counterparts, participants will sharpen diagnostic skills and recognise subtle patterns with greater confidence. Perfect for trainees and seasoned radiologists alike, it will be an inspiring way to see imaging with fresh eyes and elevate everyday practice.

A new format at ECR 2026 will be the 'How We Do It' session series. This collection of open forum sessions will address essential topics in radiology practice in a less conventional way. Shared experience didactics replaces the frontal lecture with presenters approaching the topics by engaging with their daily clinical experiences and inviting the attendees to do the same.

I am also very excited to share the news that there will be not three, but four outstanding speakers for the Plenary Lectures at ECR 2026, taking place over three thrilling sessions and covering the topics of AI, liver disease and stroke.

In four captivating ESR Meets sessions, we'll discover how radiology is approached across our featured countries - France, Japan, Switzerland, and the United States.

ECR has long stood as more than a congress for radiologists alone - it is a hub of diversity within the imaging and healthcare community bringing together expertise and talents from across disciplines. With this in mind, I am pleased to announce that on Saturday, March 7, we will hold a new 'Subspecialties on Stage' series. These sessions aim to showcase the beauty of selected subspecialties, highlight some current topics, and discuss their activities advancing radiology and radiology education.



Another discipline that we have a long-term alliance with is radiography. With ECR also acting as the official congress of the European Federation of Radiographer Societies (EFRS), I extend a heartfelt invitation to our radiographer colleagues and to professionals from all allied fields to join us in an inspiring exchange of ideas and expertise at this meeting.

And, finally, we will have some truly memorable 'Out of the box' lectures blending art, history, music, and radiology.

Our guiding vision, "Rays of Knowledge," reflects our determination to make learning accessible and illuminating for all. In keeping with ECR's spirit of adaptability, we are proud to offer a truly hybrid experience that bridges distances and time zones. Whether you are with us in Vienna or participating online, you will have the opportunity to engage with a rich, interactive programme available both live and on-demand, bringing the essence of ECR directly to you, wherever you are.

As preparations continue, I want to extend my deep appreciation to everyone whose energy and commitment have shaped this congress. Countless individuals have poured their passion into every detail. Their dedication has made ECR 2026 possible, and for that, I am sincerely grateful.

I look forward to welcoming you all to Vienna, where we will unite radiologists, researchers and industry partners in our shared pursuit of excellence and grow under the bright light of "Rays of Knowledge".

With warm regards,

Prof. Minerva Becker,
ECR 2026 PRESIDENT

FOREWORD BY THE EFRS PRESIDENT
PATRIZIA CORNACCHIONE

Dear Colleagues and Friends,

It is with great pleasure that I welcome you to the European Congress of Radiology 2026, held under the inspiring theme "Rays of Knowledge". This theme captures the essence of our profession: radiographers stand at the meeting point of light and learning, transforming invisible signals into understanding and technology into care.

Paraphrasing Leonardo da Vinci, "Impara a vedere. Comprendi che tutto è connesso – Learn to see. Realize that everything is connected", this timeless insight perfectly reflects the spirit of this year's congress. Knowledge in radiology and radiography is not confined to individual expertise: it is a network of shared understanding that connects disciplines, generations and cultures in the service of better healthcare.

The programme for ECR 2026 embraces this vision of connection. It provides a dynamic and inclusive platform where radiographers, radiologists, medical physicists and allied professionals come together to learn with and from each other. Interdisciplinarity is not merely a principle. It is the very foundation of innovation in imaging. Through dialogue and collaboration, we strengthen our collective ability to deliver precise, safe and compassionate care.

This year's sessions will explore the expanding frontiers of radiography: advanced imaging and data analysis, the integration of artificial intelligence, sustainability in medical imaging, patient-centred communication and the evolving leadership of radiographers in current and new clinical and research settings.

Education remains at the heart of our mission. The Rays of Knowledge programme invites participants to engage in interactive learning, critical discussion and practical exploration. Through the Radiographers' Scientific Programme, workshops and networking events, we aim to empower professionals at every stage of their career to connect ideas, evidence and people.

We are particularly proud of the EFRS Meets session, which showcases the achievements of our member societies and highlights innovation from across Europe. The Student and Radiographers' Open Forum will once again offer a space for young professionals to share their enthusiasm, creativity and vision for the future of radiography.

ECR 2026 is more than a congress: it is a living network of minds and hearts. Every encounter, every collaboration, every question asked becomes part of a larger picture of understanding. Together, we embody the wisdom of Leonardo's words: by learning to see, we truly comprehend how everything is connected.

Let us gather in Vienna to learn, to share and to shine together as one community, united by purpose and guided by knowledge.

Warm regards,

Patrizia Cornacchione, PhD
PRESIDENT, EUROPEAN FEDERATION
OF RADIOGRAPHER SOCIETIES

ECR 2026 SESSION DEFINITIONS

ARTIFICIAL INTELLIGENCE THEATRE SESSIONS

The AI Theatre sessions feature the latest breakthroughs in AI in the form of keynote lectures, panel discussions, and sessions discussing systems' interoperability. In a less formal setting, these 60-minute sessions aim to present the latest developments in the field, engage attendees in relevant discussions, and offer networking opportunities.

CLINICAL TRIALS IN RADIOLOGY SESSIONS

In Clinical Trials in Radiology (CTiR) sessions, scientific evidence is presented for imaging tests that are very likely to impact a radiologist's clinical practice in the future. Each CTiR presented during these sessions is accompanied by a commentary from experts in the respective field.

CONNACTION - RADIOLOGY CONNECTING DISCIPLINES

The „connAction - Radiology Connecting Disciplines" event will feature some of radiology's biggest names sharing the stage with experts from other medical disciplines. The sessions will cover a wide range of topics and will share a common thread in examining radiology's place in the healthcare continuum and emphasising the importance of taking a multidisciplinary approach to care. The sessions are characterised by very short presentations and a long case-based discussion, simulating multidisciplinary interaction in a daily clinical practice.

E^3 - ADVANCED COURSES

„The E^3 - Advanced Courses are a series of sessions covering subjects of great relevance. Conducted by specialists in their discipline, the various sessions within each course demonstrate the multiple facets of the covered topics while complementing one another to provide an in-depth exploration of the respective field. The Interactive Teaching sessions are under the same umbrella and allow attendees to learn through cases while interacting with lecturers using the digital voting tool. The E^3 - Advanced Courses cater to the European Training Curriculum (ETC) learning objectives for the Level II (general radiology) and III (specialised radiology)."

E^3 - ECR MASTER CLASSES

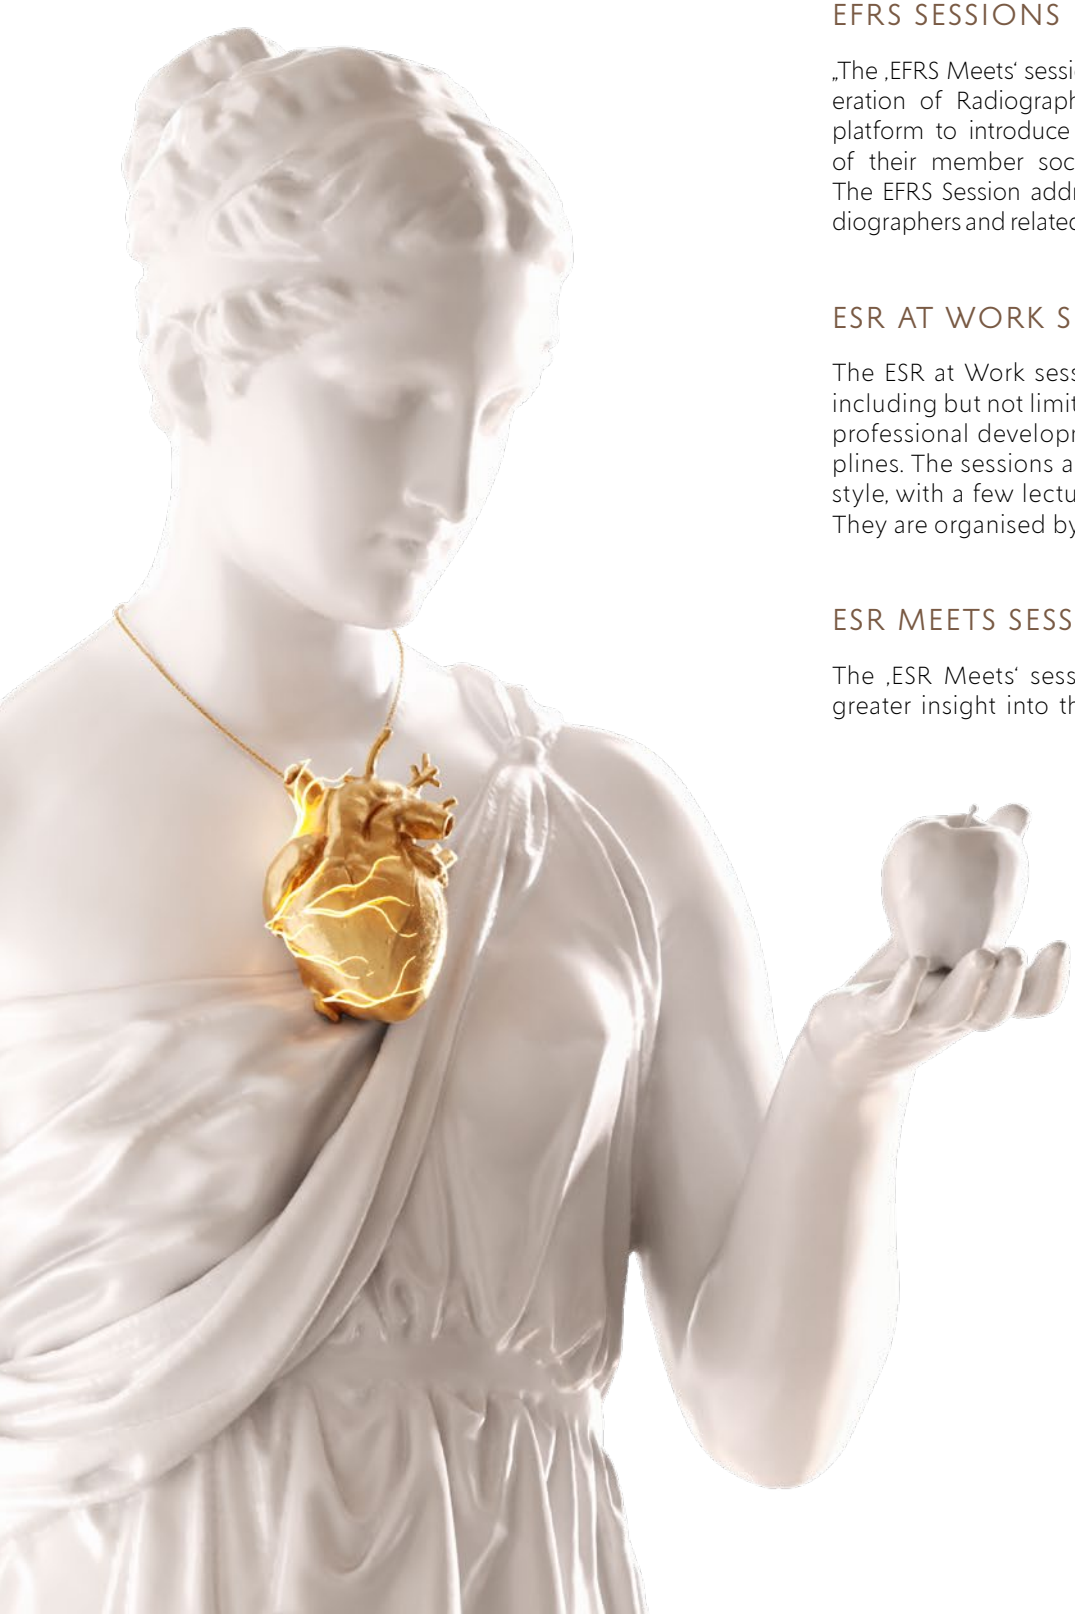
The E^3 - ECR Master Classes focus on continuous professional development and lifelong learning. The classes are designed for subspecialised radiologists, seeking cutting-edge information in their particular fields of interest. They are held by experts in the field and reflect state-of-the-art knowledge, as well as emerging trends. The contents mostly cover Level III European Training Curriculum (ETC) learning objectives.

E^3 - EUROPEAN DIPLOMA PREP SESSIONS

The E^3 - European Diploma Prep sessions prepare attendees for future European Diploma in Radiology (EDiR) examinations. The sessions are organised in close cooperation with the European Board of Radiology (EBR) and offer an opportunity for residents to gain insight into topics relevant to EDiR and their national board examinations. The topics are repeated over two years and cover Levels I and II of the European Training Curriculum (ETC).

E^3 - THE BEAUTY OF BASIC KNOWLEDGE SESSIONS

The E^3 - Beauty of Basic Knowledge sessions offer participants the chance to refresh their knowledge in fundamental topics of imaging, allowing anyone from residents to board-certified radiologists to strengthen their understanding of the essentials of specialised radiology.



E^3 - YOUNG ECR PROGRAMME

The E^3 - Young ECR Programme is specifically tailored to address various essential topics for radiology residents and trainee radiographers. The programme is also suitable for students. Five sections of the programme (Basic Sessions, Case-Based Diagnosis Training Session, Student Sessions and the Radiology Trainees Forum (RTF) Quiz and Highlighted Lectures) ensure that all relevant topics are covered.

EFRS SESSIONS

„The ‚EFRS Meets' session is organised by the European Federation of Radiographer Societies (EFRS) and provides a platform to introduce and highlight the accomplishments of their member societies in the world of radiography. The EFRS Session addresses timely topics interesting to radiographers and related to professional issues in radiography."

ESR AT WORK SESSIONS

The ESR at Work sessions cover a wide range of topics, including but not limited to research, education, audit, and professional development in radiology and related disciplines. The sessions are usually structured in a traditional style, with a few lectures followed by a panel discussion. They are organised by the ESR and ESR-related bodies.

ESR MEETS SESSIONS

The ‚ESR Meets' sessions are an opportunity to gain a greater insight into the innovations and perspectives of other countries and their radiological communities. The ESR is proud to host these sessions, which showcase the ESR's bond with national societies of countries worldwide.

HANDS-ON WORKSHOPS

The ECR Workshops are an excellent opportunity for attendees to practice their skills in a „learning by doing" approach. Through demonstrations, immersive scenarios, and engaging activities, attendees are encouraged to participate actively in acquiring knowledge about relevant topics in the field of radiology. The ECR Workshops cover all levels of the European Training Curriculum (ETC) for radiology, while Workshops organised for radiographers cover topics of interest to trained radiographers.

HOW WE DO IT: FUNDAMENTALS OF RADIOLOGY PRACTICE

The How We Do It session series addresses essential topics in radiology practice in a less conventional way. Shared experience didactics replaces the frontal lecture. The presenters approach the topics by engaging with their daily clinical experiences and inviting the attendees to do the same.

IN FOCUS PROGRAMME

Every congress, the In Focus Programme presents a topical matter to ECR attendees in a multidimensional way. Through expert-led sessions, attendees receive a comprehensive overview of a topic that is transforming clinical practice and radiology as a discipline.

ISRRT SESSIONS

The ISRRT sessions, organised by the International Society of Radiographers and Radiological Technologists (ISRRT), demonstrate the vital role that radiographers play in the medical imaging profession. This is accomplished through the exploration of the practice, research, and unique challenges faced by radiographers.

JOINT SESSIONS

The Joint Sessions are an opportunity to gain a deeper insight into the multidisciplinary collaboration of the ESR with a multitude of other disciplines related to the world of medical imaging. The sessions highlight collaborative efforts in regards to science and professional issues.

(JUNIOR) IMAGE INTERPRETATION QUIZZES

The Image Interpretation Quizzes, two traditional interactive highlights of every ECR, provide both education and entertainment. Distinguished radiologists will share their knowledge and diagnosis strategies with the audience.

MULTIDISCIPLINARY SESSIONS

The Multidisciplinary (MS) sessions promote a multidisciplinary approach to diagnosing and treating diseases. They aim to simulate multidisciplinary collaboration through presentations and interactive case discussions.

NEW HORIZONS SESSIONS

The New Horizons (NH) sessions provide an insight into recent developments within a specific area of practice, be that innovations in technique, evolvements within a speciality, or improvements in disease treatment. Exploring these topics allows presenters to highlight advancements that may become routine in the near future, or that indicate a whole new area of research and clinical application.

OPEN FORUM SESSIONS

The Open Forum (OF) sessions are dedicated to topics that cannot be presented in a traditional frontal teaching style. The sessions are conceptualised in an open space, with short introductory lectures and long discussions. Attendees are invited to share their opinions and experiences during the discussion.

PLENARY LECTURES

Carefully selected experts present topics that have the potential to change the radiology field. The ECR Plenary Lectures (PL) are a condensed presentation of research, innovation and upcoming trends.

PROFESSIONAL CHALLENGES: SHAPING OUR PROFESSIONAL FUTURE SESSION

The Professional Challenges (PC) sessions aim to provide a platform for important issues experienced by those working within the field of radiology. Subjects of current relevance, such as training, education, research, communication, and management, are presented.

REFRESHER COURSES

The Refresher Courses (RC) are comprised of a variety of key radiological topics orchestrated by the scientific subcommittees. The aim of the sessions is not only to refresh the audience's knowledge, but also to review, inform, and offer updates of the various fields through engaging presentations suitable for those new in radiology, as well as experienced doctors. A small portion of the Refresher Courses – called Collaborative Learning - is organised in cooperation between two scientific subcommittees to demonstrate the strength of inter-subspeciality cooperation.

RESEARCH PRESENTATION SESSIONS

The Research Presentation (RP) sessions feature the best of submitted abstracts. These sessions present cutting-edge radiology science from all over the world. The scientific subcommittees have carefully selected abstracts and created sessions that touch on some of the essential topics in radiology research.

SPECIAL FOCUS SESSIONS

The Special Focus (SF) sessions explore developments within the world of clinical radiology, tackling these complex matters through in-depth analysis and debate.

SUBSPECIALTIES ON STAGE

The Subspecialties on Stage sessions are a new format debuting at ECR 2026. These sessions aim to showcase the beauty of selected subspecialties, highlight some current topics, and discuss their activities advancing radiology and radiology education.

STATE OF THE ART SYMPOSIA

The State of the Art (SA) symposia are an opportunity for experts in their field to educate and inform the audience on essential topics such as anatomical regions, specific diseases, or particular techniques. Presentations are backed by experience, evidence and data of the chosen subjects.

THE ART OF ACTIONABLE REPORTING

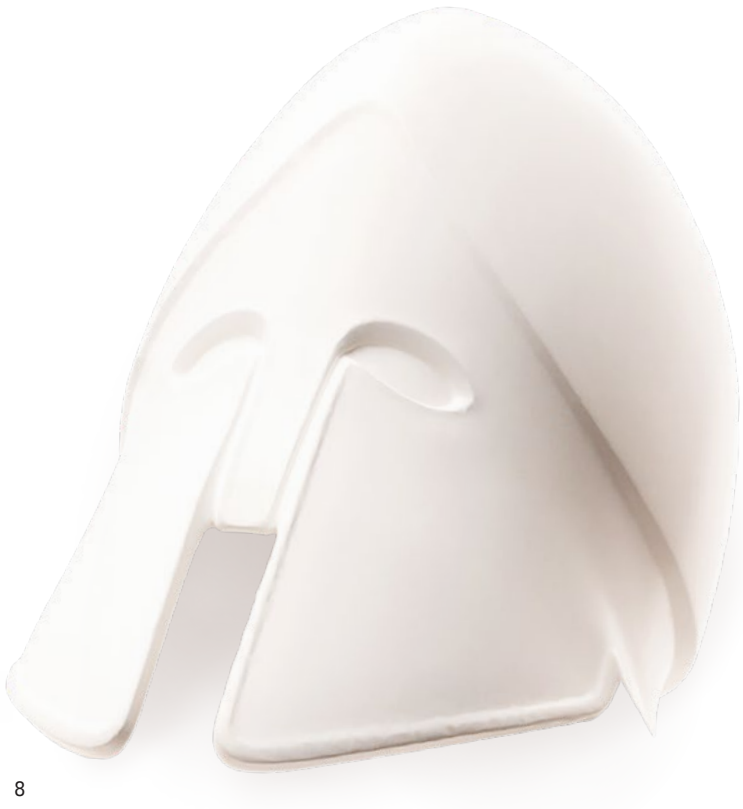
The theoretical and practical Art of Radiology Reporting session series establishes guiding principles in radiology reporting for those seeking to improve or learn new report-writing techniques. The theoretical sessions are accessible on a first-come, first-served basis. The practical sessions have a limited number of attendees and are accessible only upon preregistration. The attendance limitation is due to the session's format, which asserts a small-group, intense learning setting.

THE CUBE: UNCONVENTIONAL. INTERVENTIONAL

The Cube sessions are part of a four-day interventional radiology event that focuses on peripheral, central, oncological, and neurological interventional radiology in an engaging and hands-on environment. The sessions are 30 minutes long, interactive, and organised by a group of experts from the field. They aim to present basic tools of interventional radiology, discuss cases and the explore the newest developments in the field.

TRANSATLANTIC COURSE OF ESR AND RSNA

The Transatlantic Course (TC) combines the resources of the ESR and RSNA (Radiological Society of North America) to present a series of sessions concentrated around a central topic. The sessions usually include case-based interactive discussions and align with Levels II and III of the European Training Curriculum (ETC).



Preliminary programme printed on February 26, 2026
subject to change without previous notice

ST 1 - Morning Welcome with Minerva Becker

Categories: General Radiology, Professional Issues, Education, Multidisciplinary

Date: March 4, 2026 | 07:45 - 08:00 CET

Grab your morning coffee and join our studio moderators as they discuss the most exciting highlights of the upcoming day with Congress President Prof. Minerva Becker. Make a list of what not to miss and hear her insights on some of the biggest trends currently rocking the world of radiology.

Moderator:

Mélisande Rouger; Bilbao / Spain

Interview (15 min)

Minerva Becker; Geneva / Switzerland

BS 1a - Breast imaging

Categories: Imaging Methods, Breast
ETC Level: LEVEL I+II
Date: March 4, 2026 | 08:00 - 09:00 CET
CME Credits: 1

Moderator:
Mihai Lesaru; Bucuresti / Romania

Chairperson's introduction (5 min)
Mihai Lesaru; Bucuresti / Romania

Introduction to breast imaging: understanding mammography, ultrasound, and MRI (15 min)
Ioana Bene; Cluj-Napoca / Romania

1. To explain the role of mammography in diagnosing breast cancer.
2. To explain the role of ultrasound in diagnosing breast cancer.
3. To explain the role of MRI in diagnosing breast cancer.

BI-RADS made simple: how to categorise breast findings (20 min)
Thiemo Van Nijnatten; Maastricht / Netherlands

1. To understand BI-RADS categories and descriptions.
2. To explain the structured reporting & best practices in BI-RADS.
3. To learn practical strategies for writing clear BI-RADS reports.

MRI in breast imaging: when is it needed and what to look for? (20 min)
Elisabetta Giannotti; Cambridge / United Kingdom

1. To explain the indications for breast MRI.
2. To identify key MRI findings.
3. To learn how to write an effective breast MRI report.

EFRS 1 - EFRS and the Radiography Journal: building a research culture across the profession

Categories: Radiographers, Professional Issues, Research, Evidence-Based Imaging, Education
Date: March 4, 2026 | 08:00 - 09:30 CET
CME Credits: 1.5

Moderators:
Nejc Mekis; Ljubljana / Slovenia
Karen Brage; Odense / Denmark

Chairpersons' introduction (2 min)
Nejc Mekis; Ljubljana / Slovenia
Karen Brage; Odense / Denmark

The Radiography Journal: where we are and what lies ahead (14 min)
Jonathan Mcnulty; Dublin / Ireland

1. To highlight the performance of the Radiography Journal.
2. To explore challenges and opportunities regarding the Radiography Journal and our profession.
3. To identify opportunities for enhanced professional engagement.

A reflection on the development of radiography research over the past 20 years (14 min)
Julie Michelle Nightingale; Sheffield / United Kingdom

1. To explore our profession’s research journey over the past 20 years.
2. To reflect on the areas where significant progress has been made.
3. To consider areas where radiographers and the profession must strive to progress in the years ahead.

Moving our research up the pyramid of scientific (14 min)
Karen Knapp; Newton Abbot / United Kingdom

1. To understand the hierarchy of scientific evidence and its relevance to radiography research.
2. To identify strategies for enhancing the methodological rigor and impact of radiographic studies.
3. To explore pathways for translating radiography research into higher levels of evidence.

Radiography research culture: an international study exploring the barriers, facilitators and potential solutions to promote research career pathways (14 min)
Bo Redder Mussmann; Odense / Denmark

1. To introduce the Radiography Journal editorial fellowship project.
2. To explore the barriers and facilitators impacting the development of a cross-profession research culture.
3. To discuss examples of real-world solutions to promote research across our profession.

Building a professional research culture: the work of the EFRS and the journal (14 min)
Nejc Mekis; Ljubljana / Slovenia

1. To highlight the position of the EFRS on advancing our professional evidence-based and strengthening a European professional research culture.
2. To discuss key aspects of the need for the EFRS to collaborate with the Radiography Journal as its official journal.
3. To reflect on areas of strategic activity for the EFRS linked to building a professional research culture in partnership with the journal.

Panel discussion: What is our collective vision for the future? (18 min)

ESR/IRIA - Radiology for screening and prevention

Categories: Imaging Methods, Chest, Breast, President's Choice

ETC Level: LEVEL II+III

Date: March 4, 2026 | 08:00 - 09:30 CET

CME Credits: 1.5

Radiology is rapidly evolving from a tool of early detection to a driver of true prevention. From breast and lung cancer screening to cutting-edge applications like AI-driven risk stratification, low-dose CT, and cardiovascular imaging, radiology is reshaping how we identify disease risk before symptoms appear. This session will highlight how imaging is transforming clinical practice—reducing mortality, guiding public health strategies, and paving the way for personalised prevention.

Moderators:
Sandeep Kavthale; Latur / India
Marie-Pierre Revel; Paris / France

Chairpersons' introduction (5 min)
Sandeep Kavthale; Latur / India
Marie-Pierre Revel; Paris / France

Role of PET-CT in preventative oncology (15 min)
Sikandar Mohd Shaikh; Hyderabad / India

Breast cancer screening with mammography: requisites, guidelines and practice (15 min)
Sophia Zackrisson; Malmö / Sweden

Preventive radiology strategies to address obesity syndrome (15 min)
Rijo Mathew Choorakuttil; Cochin, Kerala / India

Lung cancer screening with low-dose CT: current methods and AI integration (15 min)
Marie-Pierre Revel; Paris / France

Panel discussion: Can radiology shift from detection to true prevention?
All speakers and (25 min)
Murali Krishna Logudoss; Chennai / India
Arangasamy Anbarasu; Coimbatore / India
Caroline Justich; Vienna / Austria

E³ 121 - Contrast media: what young radiologists should know about sustainability, cost and deposition of contrast media

Categories: General Radiology, Emergency Imaging, Contrast Media, Medico-legal
ETC Level: LEVEL I+II
Date: March 4, 2026 | 08:00 - 09:30 CET
CME Credits: 1.5

Sustainability (30 min)

Marc-André Weber; Rostock / Germany

1. To get awareness of the sustainable and responsible use of iodinated contrast media.
2. To learn about various measures that can be taken today to reduce the environmental impact and conserve resources.
3. To learn that contrast media use can be made more efficient by optimising contrast-enhanced CT examinations.

Waste (30 min)

Andrew England; Cork / Ireland

1. To explain the consequences of inappropriate contrast agent disposal.
2. To discuss current methods for the responsible disposal of waste contrast media.
3. To explore future contrast waste disposal and recycling opportunities.

Deposition/Retention (30 min)

Giles Hannibal Roditi; Glasgow / United Kingdom

1. To review the history of knowledge regarding the deposition/retention of contrast agents and/or their components in human tissues.
2. To explain the current understanding of the mechanisms behind these phenomena.
3. To review the evidence as to whether there are any clinically important consequences to these processes.

MS 1 - Acute retrosternal chest pain: from symptom to diagnosis

Categories: General Radiology, Chest, Evidence-Based Imaging, Vascular, Cardiac
ETC Level: LEVEL I+II
Date: March 4, 2026 | 08:00 - 09:30 CET
CME Credits: 1.5

SESSION RECOMMENDED BY EIBIR | EUROPEAN INSTITUTE FOR BIOMEDICAL IMAGING RESEARCH

In this multidisciplinary session, we share evidence-based approaches to diagnose the patient with acute retrosternal chest pain in the emergency room. An emergency radiology physician, cardiologist and radiologists present the pathway steps from initial symptoms to final diagnosis. The role of imaging is discussed, and typical imaging findings are highlighted. The session ends with an interactive case discussion in which the audience is also asked for feedback.

Moderator:
Rozemarijn Vliegenthart; Groningen / Netherlands

Chairperson's introduction (5 min)
Rozemarijn Vliegenthart; Groningen / Netherlands

Clinical triage: the first minutes (15 min)
Gilles Lemesle; Lille / France

CT to exclude cardiac causes? (15 min)
Rodrigo Salgado; Antwerp / Belgium

Do we need an echo or a direct cath? (15 min)
Joanna Jadwiga Wykrzykowska; Groningen / Netherlands

Imaging to diagnose a non-cardiac cause (15 min)
Christian Loewe; Vienna / Austria

Multidisciplinary case discussion (25 min)
Rozemarijn Vliegenthart; Groningen / Netherlands

PC 1a - What radiologists need to know about the European Health Technology Assessment (HTA) Regulation and why it matters

Categories: Professional Issues, Management/Leadership, Evidence-Based Imaging, President's Choice
ETC Level: LEVEL II+III
Date: March 4, 2026 | 08:00 - 09:30 CET
CME Credits: 1.5

Moderator:
Jacob Johannes Visser; Rotterdam / Netherlands

Chairperson's introduction (5 min)
Jacob Johannes Visser; Rotterdam / Netherlands

Demystifying the new EU HTA regulation (18 min)
Béla Dajka; Brussels / Belgium

1. To elaborate on the Health Technology Assessment (HTA) regulation.
2. To present the timeline and scope of implementation across EU countries.
3. To present key changes and how they affect technology evaluation in healthcare.

The radiology perspective: risks, opportunities, and responsibilities (18 min)
Daniel Pinto Dos Santos; Mainz / Germany

1. To talk about the impacts of HTA on the adoption of imaging technologies.
2. To argue the role of evidence generation in radiological innovation.
3. To show what radiologists, manufacturers, and healthcare providers must prepare for.

Getting involved: how radiology can shape HTA outcomes (18 min)
Jacob Johannes Visser; Rotterdam / Netherlands

1. To explain how to build strong clinical data and patient-reported outcomes.
2. To talk about how to collaborate with HTA bodies and policy-makers.

Panel discussion (31 min)

PC 1b - Empowering leaders in radiology: inspiring, innovating, and collaborating

Categories: Professional Issues, Research, Education, Multidisciplinary, Artificial Intelligence, President's Choice
ETC Level: ALL LEVELS
Date: March 4, 2026 | 08:00 - 09:30 CET
CME Credits: 1.5

Moderator:
Regina G.H. Beets-Tan; Amsterdam / Netherlands

Chairperson's introduction (5 min)
Regina G.H. Beets-Tan; Amsterdam / Netherlands

Leadership in multidisciplinary collaboration: enhancing radiology's role in patient-centred care (15 min)
Laurie Loevner; Philadelphia / United States

1. To understand the role of radiologists in patient-centred multidisciplinary care.
2. To learn effective communication and leadership skills for radiologists in tumour boards and clinical settings.
3. To explore how digital tools can enhance multidisciplinary workflows.

Leading through change: adapting to AI, digitalisation, and new clinical demands (15 min)
Najat Cherif Idrissi El Ganouni; Marakech / Morocco

1. To explore the impact of digitalisation and AI on radiology leadership.
2. To learn how to manage organisational changes while ensuring quality and efficiency amidst AI, digitalisation and new clinical demands.
3. To understand strategies for balancing technology adoption with human expertise in radiology.

Motivating young radiologists: leadership for engagement and knowledge growth (15 min)
Carlo Catalano; Rome / Italy

1. To understand the challenges young radiologists face in expanding their knowledge and how to address them (e.g. new ways of teaching).
2. To explore how different leadership styles can positively influence young radiologists' career development and job satisfaction.
3. To highlight the importance of mentoring and professional development programmes to support continuous growth.

Building successful research groups: strategies for impact and sustainability (15 min)
Mathias Prokop; Nijmegen / Netherlands

1. To learn key principles for establishing and sustaining high-impact research groups.
2. To understand how to mentor and retain top talent in academic radiology.
3. To appreciate the role of collaboration and funding strategies in achieving research success.

Panel discussion: Shaping the future of radiology leadership: navigating change, innovation, and growth (25 min)

RPS 101 - Frontiers in colorectal cancer imaging: from diagnosis to precision therapy

Categories: Oncologic Imaging, GI Tract, Research
Date: March 4, 2026 | 08:00 - 09:30 CET
CME Credits: 1.5

Moderator:
Monique Maas; Amsterdam / Netherlands

AI-Optimized Colon MRI Protocols: Prospective Validation of Image Quality and Staging Accuracy Versus Contrast-Enhanced CT (6 min)
Zhen Guan; Beijing / China

Author Block: Z. Guan, Y-S. Sun; Beijing/CN
Purpose: To prospectively validate an AI-optimized colon MRI protocol integrating L_1-regularized compressed sensing (ACS) and deep learning reconstruction (DeepRecon) against contrast-enhanced CT (CECT) for staging accuracy and image quality.
Methods or Background: This prospective single-center study (August 2022-April 2024) included 132 patients with pathologically confirmed colon cancer undergoing both 3.0T MRI (tri-oblique planes) and CECT within 1 week. Overall image quality, sharpness of peritoneum, sharpness of colonic wall, tumor conspicuity, lymph node conspicuity and artifacts were assessed using a modified 4-point Likert scale. Contrast-to-noise ratio (CNR) and edge rise distance (ERD) were obtained and reported as medians and IQRs. Surgical pathology correlation was performed in 33 cases.
Results or Findings: This study included 153 matched examinations from 132 participants (mean age, 58 years ± 11 [SD]). The AI-optimized MRI protocol demonstrated statistically superior performance compared to CECT in both qualitative and quantitative assessments. MRI showed higher median overall image quality scores (4 [IQR 3-4] vs. 3 [3-3]), improved CNR (5.5 [IQR 4.2-7.0] vs. 1.3 [IQR 0.7-2.2]), and reduced ERD (1.6 mm [IQR 1.2-2.8] vs. 3.7 mm [IQR 2.8-5.0]). Qualitative analysis demonstrated superior performance of MRI in peritoneal sharpness (75.8%), colonic wall visualization (100%), tumor conspicuity (92.1% preferred/equal), and lymph node assessment (86.9% preferred/equal). However, CECT provided better artifact control (45.1% preferred). MRI achieved higher T-staging accuracy (78.8% vs. 30.3%) and N-staging specificity (93.3% vs. 13.3%) compared to CECT.
Conclusion: AI-optimized MRI protocol significantly outperformed CECT in image quality and preliminary staging accuracy while eliminating radiation, demonstrating potential as a preoperative assessment tool.
Limitations: It was conducted at a single center.
Funding for this study: Project funded by National Natural Science Foundation of China (U24A20752, 82471958, 82271955), Beijing Natural Science Foundation (L242038), Beijing Hospitals Authority Clinical Medicine Development of Special Funding Support (ZLRK202522), Capital's Funds for Health Improvement and Research (2024-1-1022), Peking University Medicine Sailing Program for Young Scholars' Scientific & Technological Innovation, the Fundamental Research Funds for the Central Universities (BMU2025YFJHPY038).
Has your study been approved by an ethics committee? Yes

The value of preoperative prediction of microsatellite instability in colon cancer based on CT-derived extracellular volume fraction (fECV) (6 min)
Feiyu Wu; Guiyang City, Guizhou Province / China

Author Block: F. Wu, C. Huang; Guiyang City, Guizhou Province/CN
Purpose: To investigate the value of CT-derived extracellular volume fraction (fECV) in predicting microsatellite instability (MSI) status in colon cancer.
Methods or Background: The clinical and imaging data of 168 patients with colon cancer who underwent radical surgery were retrospectively analyzed. The imaging features of the lesions were extracted and fECV was calculated. According to the postoperative results, the patients were divided into MSI group (17 cases) and MSS group (151 cases). The binary logistic regression model was constructed for combined diagnosis, and the ROC curve was used to evaluate the diagnostic efficacy.
Results or Findings: The differences in tumor location, differentiation grade, and lymph node status between the MSI and MSS groups were statistically significant (P<0.05); both fECV and △tumor values in the MSI group were higher than those in the MSS group (P<0.05). The area under the curve (AUC) for predicting MSI status using fECV, tumor location, differentiation grade, and lymph node metastasis were 0.834, 0.661, 0.667, 0.623, and 0.684 respectively. The imaging model (fECV + tumor location), pathological model (lymph node metastasis + differentiation grade), Model 1 (tumor location + pathological model), and Model 2 (fECV + Model 1) showed AUC, sensitivity, and specificity for predicting MSI status as follows: 0.915, 76.47%, 90.07%; 0.770, 94.12%, 51.66%; 0.818, 70.59%, 77.48%; 0.951, 100.00%, 79.47%. DeLong test suggests Model 2 was superior to all single indicators and models (P<0.05), followed by the imaging model which outperformed all single indicator models and pathological combination models (all P<0.05).
Conclusion: fECV have high diagnostic value for MSI and can be used to predict MSI status.
Limitations: This study is a single-center retrospective study lacking external validation; due to MSI-positive cases constraints, detailed subgroup analysis could not be conducted.
Funding for this study: No funding was provided for this study.

Optimizing Quantum Iterative Reconstruction for Abdominal Photon-Counting CT in Preoperative Colorectal Cancer TNM-staging: A Prospective Study (6 min)

Lina Zhu; Zhengzhou / China

Author Block: L. Zhu[1], K. Nie[2], Z. Zhao[1], Z. Zhou[1], J. Gao[1]; [1]Zhengzhou/CN, [2]Shanghai/CN
Purpose: To determine the optimal quantum iterative reconstruction (QIR) level in abdominal photon-counting detector CT (PCD-CT) for preoperative TNM staging of colorectal cancer (CRC), focusing on image quality and diagnostic confidence.
Methods or Background: A total of 98 consecutive patients with biopsy-confirmed colorectal cancer who underwent enhanced abdominal PCD-CT for preoperative staging were enrolled between September 2024 and February 2025. Virtual monoenergetic images (VMI) at 60 keV in the portal venous phase were reconstructed without QIR (QIR-off) and with QIR levels 1–4 (slice thickness: 1 mm). Quantitative metrics (signal-to-noise ratio [SNR], contrast-to-noise ratio [CNR]) of primary tumors, regional lymph nodes, and liver metastases were measured. Two blinded radiologists independently evaluated qualitative metrics of the image quality and diagnostic confidence for CRC T-staging and liver metastases with a 5-point Likert scale.
Results or Findings: From QIR-off to QIR-4, image noise progressively decreased, with corresponding significant improvements in both SNR and CNR for colorectal tumors, regional lymph nodes, and 38 liver metastatic lesions (all P < 0.001). Both readers rated QIR-4 superior to other reconstructions across all qualitative metrics, including conspicuity and edge sharpness of the colorectal tumors and lymph nodes, peritumoral vessel clarity, conspicuity of liver metastatic lesions, and overall image quality (all P < 0.01). Furthermore, QIR-4 improved the diagnostic confidence for CRC T-staging and the small liver lesions with maximum diameter <10mm compared with other reconstructions (all P < 0.05).
Conclusion: High-strength level QIR-4 on abdominal PCD CT provided optimal image quality for preoperative TNM-staging evaluation of colorectal cancer and improved the diagnostic confidence of the radiologists.
Limitations: This was a single-center study with a relatively small sample size.
Funding for this study: The study received no funding.

Meta-Analysis of CT Colonography for Detection of Colorectal Polyps (6 min)

Yousef Ahmed Sliem; Giza / Egypt

Author Block: Y. A. Sliem, M. A. Shaaban; 6th of October City/EG
Purpose: To perform a meta-analysis of the diagnostic accuracy of CT colonography in detecting colorectal polyps ≥6 mm.
Methods or Background: Background: Colorectal cancer (CRC) remains a leading cause of cancer-related morbidity and mortality worldwide. Early detection of adenomatous polyps is critical for prevention. Conventional colonoscopy, although highly accurate, is invasive and associated with low patient compliance. CT colonography (CTC) offers a noninvasive alternative, but reported diagnostic performance varies.

Methods: Systematic search of PubMed, Embase, and Cochrane databases (2005–2025) for studies comparing CTC with conventional colonoscopy as reference. Inclusion criteria: sensitivity and specificity data for polyps ≥6 mm, ≥50 patients. Pooled sensitivity, specificity, and diagnostic odds ratio were calculated using a random-effects model. Heterogeneity was assessed with I^2 and publication bias was evaluated.
Results or Findings: Fifteen studies (n=5,100 patients) met inclusion criteria. Pooled sensitivity and specificity for polyps ≥6 mm were 92% (95% CI: 89–94%) and 88% (95% CI: 85–91%), respectively. The diagnostic odds ratio was 102 (95% CI: 80–128). Subgroup analysis indicated higher sensitivity in studies using 64-slice CT scanners compared to earlier technology. Patient compliance increased by 25% with noninvasive CTC.
Conclusion: CT colonography is a reliable noninvasive method for colorectal polyp detection, with diagnostic accuracy approaching conventional colonoscopy. Adoption may improve screening uptake and early CRC prevention.
Limitations: Motion artifacts
Funding for this study: None

Gut decisions based on the liver: A radiomics approach to boost colorectal cancer screening (6 min)

Anna Hinterberger; Heidelberg / Germany

Author Block: A. Hinterberger[1], J. Bohn[1], J. Betge[2], S. Grosu[3], S. O. Schönberg[2], D. Nörenberg[2], J. N. Kather[4], F. Grawe[1], K. Maier-Hein[1]; [1]Heidelberg/DE, [2]Mannheim/DE, [3]Munich/DE, [4]Dresden/DE
Purpose: Noninvasive colorectal cancer (CRC) screening represents a key opportunity to improve colonoscopy participation rates and reduce CRC mortality. This study explores the potential of the gut-liver-axis for predicting colorectal neoplasia through liver-derived radiomic features extracted from routine CT images.
Methods or Background: In this retrospective study, we analyzed data of 1,997 patients who underwent colonoscopy and abdominal CT. Patients either had no colorectal neoplasia (n=1,189) or colorectal neoplasia (ntotal=808; adenomas n=423, CRC n=385). Radiomic features were extracted from 3D liver segmentations using the Radiomics Processing ToolKit (RPTK), which performed feature extraction, filtering, and classification. The dataset was split into training (n=1,397) and test (n=600) cohorts. Five machine learning models were trained with 5-fold cross-validation on the 20 most informative features and ensembles.
Results or Findings: The radiomics-based XGBoost model achieved best validation performance with a test AUROC of 0.810 [95% CI: 0.767–0.837], clearly outperforming the best clinical-only model (test AUROC: 0.457 [95% CI: 0.411–0.506]). After Youden index-based threshold optimization, the final model reached a test sensitivity of 74.1% and specificity of 72.3% for predicting the presence of colorectal neoplasia. Subclassification between colorectal cancer and adenoma showed lower accuracy (test AUROC: 0.674 [95% CI: 0.606–0.741]).
Conclusion: Our findings establish proof-of-concept that liver-derived radiomics from routine abdominal CT can predict colorectal neoplasia. Beyond offering a pragmatic, widely accessible adjunct to CRC screening, this approach highlights the gut–liver axis as a novel biomarker source and sparks new mechanistic hypotheses for future translational research.
Limitations: This single-center, retrospective study was intended as a proof-of-concept to demonstrate technical feasibility. Validation in larger, prospective, and multicenter cohorts will be essential to confirm generalizability and clinical utility.
Funding for this study: No funding or grant support was received for this study.

Computed tomography based texture analysis and Node-RADS in colon cancer (6 min)

Jakob Leonhardi; Leipzig / Germany

Author Block: J. Leonhardi, A-K. Höhn, M. Mehdorn, T. Denecke, H-J. Meyer; Leipzig/DE
Purpose: Texture analysis provides quantitative imaging markers and might improve tumor tissue characterization. Node-RADS classification is a classification system to improve lymph node description in oncological imaging. The present analysis investigated the diagnostic benefit of both methods to categorize and stage lymph nodes in patients with colon cancer.
Methods or Background: For Node-RADS analysis, 108 patients (n = 49 females, 45.3%, age 70.08 ± 14.34 years) were included. All patients were surgically resected and lymph nodes were histopathological analyzed. Lymph nodes were scored in accordance to the Node-RADS classification by two experienced radiologists. 85 patients were eligible for texture analysis of the lymph nodes (n = 39 females, 45.9%). Interreader variability was assessed with Cohen's kappa analysis, discrimination analysis was performed with Mann-Whitney-U test and diagnostic accuracy was assessed with ROC curve analysis.
Results or Findings: Out of 279 extracted CT texture features, 7 parameters independently showed statistically significant differences between lymph node metastasis to negative lymphnodes. A multivariate model based on n = 7 independent texture parameters reached an AUC of 0.79 (95% CI: 0.69-0.89) with sensitivity of 0.77 and specificity of 0.70. Node-RADS scores showed statistically significant differences between N-/N + stage (N- mean 1.89 ± 1.09 score versus N+ 2.93 ± 1.62 score, p = 0.001). ROC curve analysis showed an AUC of 0.68 for Node-RADS-based lymph node discrimination, with an optimal sensitivity of 0.62 and specificity of 0.71.
Conclusion: Texture analysis can improve the diagnostic accuracy for nodal CT staging in patients with colon cancer. Node-RADS scores showed only limited diagnostic accuracy in colon cancer with high interreader variability. This should question clinical translation.
Limitations: This was a retrospective study design with possible known inherent bias. Further validation studies are needed to confirm present results.
Funding for this study: No Funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective, observational study involving human participants was performed in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki Declaration and its later amendments or comparable ethical standards. This retrospective study was approved by our institutional ethics review board (Ethics Committee of the University of Leipzig EK: 243-14-14072014), and the requirement for informed consent of patients was waived.

Feasibility of 40-keV Virtual Monoenergetic Images for Evaluating Extramural Vascular Invasion in Rectal Cancer: Comparison with Rectal MRI as Reference Standard (6 min)

Masashi Asano; Gifu / Japan

Author Block: M. Asano, Y. Noda, N. Kawai, T. Suto, T. Kaga, S. OMATA, T. Miyoshi, H. Kato, M. Matsuo; Gifu/JP
Purpose: To evaluate the feasibility of 40-keV virtual monoenergetic images (VMIs) derived from dual-energy CT for assessing extramural vascular invasion (EMVI) in patients with rectal cancer.
Methods or Background: Fifty-six patients with rectal cancer underwent both contrast-enhanced dual-energy CT and rectal MRI were retrospectively analyzed. The 40-keV VMIs at the portal venous phase were reconstructed for all patients. Two radiologists evaluated the EMVI scores on 40-keV VMIs. Another radiologist interpreted rectal MRI and created the reference standard. The diagnostic performance for detecting EMVI (EMVI scores of 3 and 4) in 40-keV VMIs was compared with rectal MRI findings as a reference standard using McNemar test.
Results or Findings: The sensitivity and specificity for detecting EMVI in 40-keV VMIs were 85.7% and 88.6%, respectively. When comparing with rectal MRI, the 40-keV VMIs showed no statistical difference in the sensitivity (P =.25) and specificity (P =.13). The κ value was 0.42 in 40-keV VMIs, indicating moderate interobserver agreement.
Conclusion: When compared with rectal MRI, the 40-keV VMIs had no statistical difference in the sensitivity and specificity for diagnosing EMVI in patients with rectal cancer.
Limitations: Small sample size, evaluated only EMVI of rectal cancer, not compared with the pathological results, and only used rapid-kilovoltage-switching DECT.
Funding for this study: This study received no funding.

Ethics committee - additional information: Our institutional review board approved this retrospective study and waived written informed consent due to the retrospective nature of the study.

Reliability of MRI in Detecting Lymph Node Involvement in Rectal Cancer (6 min)

Merve Gezgin; Istanbul / Turkey

Author Block: N. Gündüz, M. Gezgin, B. Akgun, H. Seneldir, B. Atalay, O. Alimoglu, G. Erdem; Istanbul/TR
Purpose: Rectal cancer affects more than 700,000 people annually worldwide and accounts for 3.2% of cancer-related deaths.Regional lymph node(LN) status is a critical determinant in TNM staging, treatment planning, and prognosis.Magnetic resonance imaging(MRI) is the preferred modality for local staging, yet its diagnostic reliability for LN involvement remains debated. This study aimed to evaluate the diagnostic performance and reliability of MRI in assessing LN metastasis in rectal cancer.
Methods or Background: This retrospective study included patients with rectal cancer who underwent preoperative pelvic MRI and subsequent surgical resection between 2020 and 2023. Patients without either imaging or pathology data were excluded. Two abdominal radiologists(1–10 years of experience) independently reviewed MRIs using the 2016 ESGAR criteria.LN morphology(short-axis size, round shape, irregular border, heterogeneity) was assessed. Nodes ≥9 mm, 5–9 mm with ≥2 malignant features, or <5 mm with ≥3 features were classified as malignant; mucinous nodes were also considered malignant. In patients receiving neoadjuvant therapy, nodes >5 mm were classified malignant. MRI findings were compared with histopathology. Interobserver agreement was analyzed with kappa statistics.
Results or Findings: Of 68 patients, 42 were eligible (mean age 57.6 years; 24 male, 18 female).Histopathology confirmed LN metastases in 16 cases, all detected by MRI(sensitivity 100%). Of 26 LN-negative cases, MRI correctly identified 15 but overcalled 11, yielding specificity 57.7%. Overall diagnostic accuracy was 73.8%, with positive predictive value 59.3% and negative predictive value 100%. Interobserver agreement was excellent (κ=0.94).
Conclusion: MRI demonstrated high sensitivity but relatively low specificity in detecting LN involvement in rectal cancer, consistent with prior literature. Awareness of potential false positives is essential, and refinement of morphologic malignancy criteria may improve specificity.
Limitations: Single-center design, retrospective analysis, modest sample size, and inability to stratify histopathological LN subtypes may limit generalizability.
Funding for this study: No funding

Postinduction Response Evaluation in Total Neoadjuvant Therapy of Rectal Cancer: Toward Response-guided Management Strategy (6 min)

Yu Shen; Chendu / China

Author Block: Y. Shen[1], T. Jiang[1], X. Gong[2], W. Meng[1], Z. Wang[1]; [1]Chengdu/CN, [2]Cheng du/CN
Purpose: Total neoadjuvant therapy (TNT) has improved the pathological complete response (pCR) rate for locally advanced rectal cancer (LARC). The relationship between tumor response after the induction chemotherapy (INCT) and pCR has not been decided. We aimed to evaluate the association between the post-induction (PI) tumor response after INCT and the ultimate treatment response in LARCs undergoing TNT.
Methods or Background: From 2018 to 2022, consecutive patients diagnosed with LARC who received TNT before radical surgery and had MRI examinations at both PI and pre-operation (PO) were included. 360 LARC patients were enrolled for initial assessment, with 224 patients included in the final analysis. The primary outcome was the pCR rate. MR-TRG and tumor longitudinal length reduction rate (TLLR) were used to evaluate the tumor response to INCT at PI. The combination of MR-TRG and DWI was used to determine the presence of MRI complete response (mriCR) at PO. A univariate logistic regression model was used to establish associations between PI response and PO response, PI response and pathological response.
Results or Findings: The current study included 224 patients (median [IQR] age, 56 [49-65] years; 136 [60.7%] male). Compared with patients who did not achieve partial response (PR) at PI, patients who achieved PR at PI have higher PO mriCR rate (OR 3.788, 95%CI 1.740-8.202, p<0.001) and higher final pCR rate (OR 4.412, 95%CI 1.881-10.347, p<0.001).
Conclusion: Tumor response to INCT is related to the final pathological response in LARC patients who underwent TNT. Good responders to INCT have higher odds of reaching a mriCR or pCR, supporting mid-term tumor response evaluation after INCT in a response-guided treatment strategy.
Limitations: Survival outcomes were not included in the current study because the data were still unavailable.
Funding for this study: This work was supported by the Postdoctoral Fellowship Program of CPSF (No. GZB20250525), the National Natural Science Foundation of China (82103541, 82203474, 82203394, 82103918), Department of Science and Technology of Sichuan Province (No. 2022YFS0162, 2021YFS0025, 2022YFS0209), Sichuan Province Natural Science Foundation Project (2022NSFSC0840, 2023NSFSC1834), 1·3·5 Project for Disciplines of Excellence-Clinical Research Incubation Project, and West China Hospital, Sichuan University (No. 22HXFH001, 2019HXFH031).

Offering behavioural economics messages or sigmoidoscopy or CT-colonography to increase participation of non-respondents in population-based colorectal cancer screening: a randomized controlled trial (6 min)

Lapo Sali; Florence / Italy

Author Block: G. Gorini[1], L. Sali[1], B. Mallardi[1], C. Campanino[1], E. Betti[1], F. Battisti[1], S. Stoffel[2], P. Mantellini[1]; [1]Florence/IT, [2]Basel/CH
Purpose: To evaluate if offering behavioural economics messages or alternative tests improve participation of non-respondents in immunochemical faecal test (FIT) based colorectal cancer (CRC) screening.
Methods or Background: 20,225 non-respondents to FIT (aged 50-70 years) in a CRC screening program were randomized into six groups and invited by mail: 1) to FIT with standard letter (SL); 2) to FIT with SL plus feedback message (F); 3) to FIT with SL plus social norm message (MN); 4) to FIT with SL and combination of F+MN; 5) to sigmoidoscopy ; 6) to CT colonography. The primary outcome measure was the participation rate within 90 days from invitation. The trial was registered: ISRCTN11841256.
Results or Findings: Overall 1,106 non-respondents to FIT partecipated. Screening participation rates were 5.7% in SL, 7.4% in F , 6.7% in MN, 6.6% in F+MN, 2.0% in sigmoidoscopy, 4.1% in CT colonography groups. F group invitees were more likely to participate as compared to SL control group (aOR=1.32; 95%CI: 1.10-1.57), to sigmoidoscopy group (aOR=0.32; 95%CI: 0.24–0.42) and to CT colonography group (aOR=0.67, 95%CI:0.52–0.86).
Conclusion: Behavioural economics interventions can increase participation in FIT-based CRC screening programs more than offering different screening tests. In non-respondents to FIT CT colonography recorded a two-fold participation to screening as compared to sigmoidscopy.
Limitations: Detection rates of colorectal neoplasia were not evaluated in presente study.

Diagnostic Accuracy of Hounsfield Units in Virtual Non-Contrast (VNC) vs. True Non-Contrast (TNC) for Differentiating Hepatic Cysts and Colorectal Cancer Liver Metastases (6 min)

Mohsen Kabiri; Frankfurt am Main / Germany

Author Block: M. Kabiri, M. Nejati, C. Booz, I. Yel, K. Eichler, T. Vogl; Frankfurt am Main/DE
Purpose: The differentiation of hepatic cysts and colorectal cancer liver metastases (CRLM) is critical for accurate diagnosis and treatment planning. This study evaluates the diagnostic accuracy of Hounsfield Units (HU) in Virtual Non-Contrast (VNC) imaging compared to True Non-Contrast (TNC) imaging for distinguishing these lesions.
Methods or Background: A retrospective analysis was conducted on 120 patients who underwent Dual-Energy Computed Tomography (DECT) scans between January 2020 and December 2022. Patients with confirmed hepatic cysts or CRLM were included. HU values were measured in regions of interest (ROIs) within the lesions. Statistical analyses included paired t-tests and ROC curve analysis to evaluate diagnostic performance.
Results or Findings: The TNC method achieved an AUC of 0.864 (sensitivity: 70.51%, specificity: 82.26%), while the VNC method achieved an AUC of 0.861 (sensitivity: 66.88%, specificity: 84.62%). No significant difference was observed between the two methods ($p = 0.850$). VNC imaging demonstrated slightly higher mean HU values for both cysts and metastases compared to TNC imaging.
Conclusion: VNC imaging offers comparable diagnostic accuracy to TNC imaging for differentiating hepatic cysts and CRLM, with the added benefit of reduced radiation exposure. These findings support the integration of VNC imaging into routine clinical practice.
Limitations: The limitations of this study are minimal and unlikely to impact the validity of the findings.
Funding for this study: The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

Virtual Biopsy vs Whole-Liver Radiomics: A Comparative Study for Non-Invasive Prediction of Chemotherapy-Associated Steatohepatitis in Colorectal Liver Metastases (6 min)

Angela Ammirabile; Milan / Italy

Author Block: A. Ammirabile[1], F. Mastroleo[2], R. De Martino[1], M. Waddle[2], A. Laghi[1], L. Viganò[1]; [1]Milan/IT, [2]Rochester, MN/US
Purpose: Chemotherapy-Associated Steatohepatitis (CASH) increases the risk of postoperative liver failure and 90-day mortality after hepatic resection. Although hepatomegaly is common, non-invasive diagnosis remains challenging: liver biopsy samples a limited parenchymal portion, and imaging cannot reliably distinguish simple steatosis from CASH. A radiomic-based virtual biopsy (VB) approach has shown promising results. This study evaluated CT-based radiomics for preoperative CASH prediction, comparing VB and whole liver parenchyma.
Methods or Background: This retrospective analysis included patients from the public Colorectal-Liver-Metastases dataset (internal) and from Costa et al. (2021) (external). Inclusion criteria were: portal-phase CT (thickness ≤5mm) after preoperative chemotherapy for colorectal liver metastases and pathological CASH assessment. IBSI-compliant radiomic features were extracted with PyRadiomics from total liver parenchyma (Liver-VOI) and VB (manually segmented 2 mL cylinder of non-tumoral parenchyma on 3D Slicer). Liver volume was estimated using three orthogonal diameters. Four XGBoost predictive models were developed (70/30 split, 5-fold cross-validation): clinical; clinical+VB-radiomics (ViB); clinical+VB-radiomics+liver volume (ViBE+); clinical+Liver-VOI radiomics (WholeLiver). ViBE+ underwent external validation. Performance was statistically compared by AUC, with SHAP analysis for clinical interpretability.
Results or Findings: 180 patients were included: 105 in the internal (63 males, mean age 58.9 years, 38% NASH+) and 75 in the external (44 males, mean age 62.4 years, 19% NASH+) cohorts. At internal validation, the clinical model had the lowest performance (AUC=0.713). WholeLiver and ViBE+ achieved the best prediction (0.857 vs. 0.831, p=0.814), while ViB showed AUC=0.724. Liver volume metrics emerged as key predictors in SHAP analysis. VIBE+ achieved AUC=0.745 at external validation.
Conclusion: VB provides a reproducible, non-invasive method for CASH prediction. Combined with liver size metrics, it achieves performance comparable to whole-liver analysis and supports clinically applicable preoperative risk stratification.
Limitations: Retrospective design; Modest sample size; Chemotherapy-only etiology of steatohepatitis.

Evaluation of the influence of human factors towards a new AI-CADe/x system for lung cancer risk stratification in the radiology workflow (6 min)
Andrew Scarsbrook; Leeds / United Kingdom

Author Block: C. Santos[1], M. Santos[1], J. H. R. Cairns[2], A. Johnstone[2], M. Darby[2], C. Arteta[1], A. Scarsbrook[2]; [1]Oxford/UK, [2]Leeds/UK
Purpose: Integration of AI-based computer aided detection (CADe) and computer aided diagnosis (CADx) tools could help improve and standardize CT reporting and increase efficiency. However, clinical benefit may in part depend on user's attitudes towards AI technologies. The effect of human factors on a new AI-CADe/x tool for assisting CT-based lung nodule risk stratification was evaluated.
Methods or Background: A Multiple Reader Multiple Case (MRMC) study assessed the effect of an AI-CADe/x tool on readers estimates of lung cancer likelihood from CT scans. This facilitated pulmonary nodule detection, segmentation, and lung cancer risk prediction. Twelve radiologists evaluated 240 cases (95 cancers), with and without AI-assistance. Technology acceptance was modelled using a 5-point Likert Scale survey assessing Perceived Ease of Use (PEO) and Usefulness (PU), attitudes towards AI and trust. These were correlated with mean effect size (ES), determined via the Dorfman-Berbaum-Metz method (z-test used for difference between ES; 95% confidence intervals reported).
Results or Findings: The AI tool increased user reporting confidence, median survey score (interquartile range) was 4 (4-4.25), being highly rated for PEO (4 (4-5)) and PU (4 (4-5)). Participants expressed greater trust towards CADe (4 (3-4)) than CADx (3 (2-4)) components. ES was affected by levels of trust, automation, aversion and confirmation biases. Participants without tendency for confirmation bias (n=5), i.e. who considered the AI suggestion even when it challenged their initial assessment, showed a significantly higher ES from AI-assistance (p=0.028) than those exhibiting bias, with an ES of 6.25% [-1.95, 8.35] versus 3.02% [2.02, 6.31], respectively.
Conclusion: Attitudes towards AI influence radiologist interaction with AI-based CADe/CADx tools. Positive attitudes and greater trust resulted in improved benefits from AI assistance for lung cancer risk-stratification.
Limitations: Preliminary technology acceptance modelling across twelve radiologists.
Funding for this study: The study was jointly funded by the National Institute for Health and Care Research (NIHR) and the Office for Life Sciences (OLS) under project ID NIHR207547.

Commercially available AI products for CT-based lung cancer screening: capabilities, clinical evidence, and alignment with international screening frameworks (6 min)
Noa Antonissen; Nijmegen / Netherlands

Author Block: N. Antonissen[1], S. S. Schalekamp[1], H. Hahn[2], K. G. Van Leeuwen[3], C. Jacobs[1]; [1]Nijmegen/NL, [2]Bremen/DE, [3]Utrecht/NL
Purpose: To evaluate certified capabilities of CE-marked AI products for lung nodule analysis in CT lung cancer screening, assess their alignment with international screening frameworks, and analyze their supporting peer-reviewed evidence.
Methods or Background: Six core clinical tasks (nodule detection, classification, measurement, growth assessment, malignancy risk estimation, structured management) were defined by analyzing four major screening frameworks: the Lung CT Screening Reporting and Data System (Lung-RADS) version 2022, British Thoracic Society (BTS) guidelines, European Union Position Statement (EUPS) recommendations, and European Society of Thoracic Imaging (ESTI) nodule management recommendations. CE-marked AI products were identified through the Health AI Register. Vendors confirmed certified capabilities using a standardized questionnaire; public documentation supplemented non-responders. Scientific evidence was evaluated using a six-level efficacy framework and assessed for study characteristics.
Results or Findings: In total, 16 products from 16 vendors were included, and 10 vendors completed the questionnaire. Regarding capabilities, 14 products detect and measure solid and subsolid nodules, 12 support growth assessment, and none support endobronchial or cystic lesion evaluation. For risk estimation, 9 products provide malignancy-risk outputs: 5 use the PanCan model and 4 provide proprietary AI-based scores. Six products had no peer-reviewed publications. The remaining 10 products were supported by 60 studies, of which 7% were prospective and 45% vendor-independent, with external testing including multicenter (40%), multinational (7%), and screening cohort (40%) datasets. Overall, evidence was concentrated at lower efficacy levels: 70% assessed standalone diagnostic accuracy, 25% examined effects on diagnostic decision-making, and none reported patient or societal outcomes.
Conclusion: CE-marked AI solutions fulfill core functions for nodule assessment but lack certified capabilities for endobronchial and cystic lesions and are supported by limited prospective, higher-level clinical evidence.
Limitations: Product capability assessment relied on publicly available and vendor-reported data.
Funding for this study: This project is co-funded by the SOLACE project, funded under the EU4Health Programme 2021–2027 under grant agreement no. 101101187.

Diagnostic performance of Harrison.ai CT chest algorithm for detection of lung nodules using the DUKE Lung Cancer Screening Dataset (6 min)

Melissa Ryan; Sydney / Australia

Author Block: M. Ryan[1], M. Steele[1], G. Sanderson[1], J. Tang[2]; [1]Sydney/AU, [2]Victoria/AU
Purpose: To evaluate the performance of an artificial intelligence (AI) algorithm for pulmonary nodule detection on low-dose CT chest scans to determine the clinical utility of AI-based nodule detection as a decision support tool in lung cancer screening.
Methods or Background: Low-dose CT chest scans (n=1,060), available at https://doi.org/10.5281/zenodo.10782890, as part of the DUKE lung cancer screening dataset were evaluated using the Harrison.ai CT chest device. The dataset represents a cohort of screening CT scans from a high-volume contemporary lung cancer screening center with associated Lung-RADS scores, and where applicable, histologic type and stage of future lung cancer.

All images were analysed by the device, which automatically identifies cases with identified nodules, as well as localisation of each nodule instance within an image series. Patient-level and instance-level sensitivity were evaluated. Stratified performance based on gender and malignancy was also performed.
Results or Findings: Preliminary results of 1,037 cases that were successfully processed demonstrated patient-level sensitivity of 91% and instance-level sensitivity of 62%, with an average of 1.12 false positive instances per case. False positive rate may be in part due to AI detection of nodules below the datasets minimum size threshold (4 mm).
Conclusion: The Harrison.ai CT chest device demonstrated excellent diagnostic performance at the case level which supports the potential role for AI in enhancing efficiency and reliability in lung cancer screening programs using low-dose CT.
Limitations: The retrospective design and reliance on a single institutional dataset limit generalisability. The algorithm's performance may vary with differing scanner protocols, populations, and nodule characteristics not fully represented in the DUKE dataset.

AI-Assistance Improving Lung Nodule Risk Assessment in Lung Cancer Screening: Results from RELIVE, A Multi-Reader Multi-Case Study to Evaluate the Performance of an end-to-end AI/ML-based CADe/CADx (6 min)

Charles Michael Voyton; Valbonne / France

Author Block: C. M. Voyton, P-H. SIOT, B. Renoust, B. Huet, V. Bourdes; Valbonne/FR
Purpose: Evaluation of LDCT exams for lung cancer screening (LCS) is time intensive, and nodule risk stratification is challenging and prone to false positives. This multi-reader multi-case (MRMC) study evaluated the improvement in radiological review and nodule risk assessment with the support of an end-to-end AI/ML-based CADe/CADx.
Methods or Background: In this paired split plot (PSP) design MRMC, 480 retrospective LCS patients (160 cancer, 320 non-cancer) and 16 US board-certified radiologists were split into 4 balanced blocks of 120 patients and 4 radiologists respectively; each case within each block was read twice (with and without the assistance of the AI/ML-based CADe/CADx) with at least 28 days of washout in between. Readers were asked to locate, measure and assign a 1-100 risk score per nodule as well as assign a recommended patient management.
Results or Findings: AUROC (AUC) and specificity (sp) with the support of the AI (AUC: 0.843, sp: 0.700) significantly increased ($p < 0.05$) versus without (AUC: 0.828, sp: 0.648) demonstrating LCS report improved diagnostic performance. Less experienced radiologists (2-6 years of experience) showed the largest increase in AUC of 4.77% ($p = 0.0308$). The inter-reader agreement was also significantly improved ($p<0.0001$) for readers using the device with an increase in intraclass correlation coefficient (ICC) from 0.707 to 0.830.
Conclusion: The AI system enhanced radiologists' diagnostic accuracy for pulmonary nodule malignancy risk assessment in a LCS cohort. These findings support its potential role as a key decision-support tool in clinical practice, especially for early career clinicians.
Limitations: Retrospective study on an enriched cohort that does not fully reflect real-world cancer and nodule characteristic prevalences.

A 'Grounded Theory' exploration of stakeholders' opinions of Radiology AI for Prioritised Imaging and Diagnosis of lung cancer (the 'RAPID-LC' study) (6 min)

Clare Rainey; Cork / Ireland

Author Block: C. Rainey[1], A. Gill[2], S. L. Mcfadden[2]; [1]Cork/IE, [2]Belfast/UK
Purpose: Lung cancer is a leading cause of death globally and projected to reach 3·55 million deaths by 2050. Currently many patients in Northen Ireland (NI) are identified at advanced stages leading to a poor survival rate. AI has been proposed to assist clinicians, however the perceptions of the clinician and patient need to be considered . This will ensure that AI is used optimally and designed with the end-user in mind.
Methods or Background: A grounded theory methodology was adopted. 1:1 interviews were conducted with members of the public (patients) and clinicians (two nurses, an oncologist, a medical physicist, a radiographer and an anesthetist) currently working in the lung cancer pathway in NI. Data were transcribed verbatim and Braun and Clarkes thematic analysis used.
Results or Findings: Seven themes and eight subthemes emerged from the data.
Patients trusted the clinicians' scrutiny of the AI system whilst the clinician required robust ongoing validation and education. The public/patient participants are unconcerned about the cost implications of AI.
Both groups were positive about using AI to streamline care/reduce waiting times. They were more cautious in its use for symptomatic presentations.
Whilst results are optimistic, various concerns exist around (i) trust, (ii) communication, (iii) validation (iv) infrastructure. These remain central to discussions around AI adoption in NI and internationally.
Conclusion: Clinicians require robust and transparent validation, while the public are happy to trust the clinician. Neither group feels that autonomous AI is acceptable currently. Both groups feel strongly that AI is needed to support healthcare systems. Education and co-design have been proposed to facilitate adoption.
Limitations: This study was conducted with participants from NI, where the lung cancer pathway may differ slightly from the rest of Europe.
Funding for this study: SBRI Research grant

A preliminary study: Homology-based detection of lung cancer lesion in CT images (6 min)

Kentaro Doi; Osaka / Japan

Author Block: K. Doi, H. Numasaki, Y. Anetai, M. Imai, Y. Natsume-Kitatani; Osaka/JP
Purpose: We proposed the homology-based feature (HF) map to pulmonary quantify fibrotic lesions in CT images (Doi, et al. IJCARS 2025). However, lung cancer lesions reduce this quantitatively performance. This study addressed this issue by detecting lung cancer lesions prior to the quantification of pulmonary fibrosis through the optimizing the HF map calculation.
Methods or Background: We utilized publicly available forty CT images and the corresponding radiotherapy structure datasets from the cancer image archive. These datasets include the coordinate information of lung cancer lesions defined by radiologists, so the coordinate information was utilized as a ground truth. HF maps were obtained from the collected CT images, and predicted lung cancer lesions were generated by the threshold processing for HF maps. This method can be regulated by hyperparameters such as the tile size, tile shift size, range of CT value for analyses, and threshold value of HF map. Here, these hyperparameters were optimized using the DICE coefficient as an objective function, which can indicate similarity between a predicted lung cancer lesion and a ground truth.
Results or Findings: The DICE coefficient has achieved 0.93 by optimized hyperparameters as followings: the tile size, 16 pixels; tile shift size, 2; range of CT value for analyses; -800 to 100; and threshold value of HF map, 85% of the maximum value of HF maps. The range of CT values differs from that of the quantification of fibrosis, which might be caused by differences in those CT values.
Conclusion: We have demonstrated the potential of the HF map to detect lung cancer lesions in CT images.
Limitations: This methodology will be optimized for each lung cancer type related to the CT value. Moreover, more deeply validation of this study using validation datasets is required.
Funding for this study: This work has been supported by JSPS KAKENHI [grant number 24K23909] and the Japan Science and Technology Agency COI-NEXT [grant JPMJPF2018].

In-vivo classification between lung adenocarcinoma and squamous cell lung cancer through late fusion of a clinical model and an MRI radiomic model (6 min)

Frédérique Frouin; Orsay / France

Author Block: J-E. Al Khoury[1], C. Nioche[1], M. Lacroix[2], M. Hamadouche[3], C. Suchel[3], P-Y. Brillet[3], F. Frouin[1]; [1]Orsay/FR, [2]Paris/FR, [3]Bobigny/FR
Purpose: Improving a classification model between lung adenocarcinoma (ADK) from squamous cell lung cancer (SQc) through the integration of clinical and MRI data.
Methods or Background: Clinical and MRI radiomic logistic regression models were developed from a training/validation set of 80 patients with advanced lung cancer (59 ADK and 21 SQc). A late fusion model combining the probabilities of the two models was defined. The three models were tested on 50 patients (30 ADK and 20 SQc). Clinical data were recorded including age, weight, BMI, smoking status, and TNM staging. Following brain MRI to discover possible brain metastases, a contrast-enhanced T1-weighted (CET1w) chest MRI was performed. After preprocessing of CET1w MRI, including intensity normalization and spatial resampling (1 mm3 isotropic voxels), the lung tumor was delineated in 3D. Radiomic features including radial intensity measures were extracted using LIFEx software (version 25.9.4). Model training was based on a forward selection of features that maximises balanced accuracy.
Results or Findings: Only one parameter (age) was selected for the clinical model. Only one RIM feature (mean gradient calculated between the mean intensities of successive layers within the tumor) was selected for the radiomic model. Based on a five-fold cross-validation framework, the balanced accuracy was 0.62 for clinical, 0.61 for radiomic, and 0.68 for late fusion models in the validation phase. When applied to the test set, the balanced accuracies were 0.62 for clinical, 0.62 for radiomic, and 0.67 for late fusion models.
Conclusion: The late fusion of the clinical model and the MRI radiomic model shows improved results for the classification task (ADK compared to SQc) when compared to each individual model. All three models were robust and showed stable performance in the test set.
Limitations: No limitations were identified

Benchmarking lung tumour segmentation models: stratified performance of deep learning models across tumour sizes and cancer stages (6 min)

Alonso Cerrato Nieto; Utrecht / Netherlands

Author Block: A. Cerrato Nieto, E. Scholten, S. S. Schalekamp, M. Prokop, C. Jacobs; Nijmegen/NL
Purpose: Accurate lung tumour segmentation in CT scans is crucial for staging, radiotherapy planning, and treatment monitoring. Published deep learning models for lung tumour segmentation show varying consistency across tumour stages and may fail in complex tumours. This study compared five publicly available models with an in-house model trained to be robust to variation in tumour sizes and cancer stages.
Methods or Background: A dataset of 588 CT scans from lung cancer patients (2006-2020) was retrospectively collected and annotated at Radboud University Medical Center. A deep learning model was trained using the nnU-Net architecture on subsets of Radboud patients (n=505), the NSCLC-Radiomics dataset (n=362) and the Medical Segmentation Decathlon dataset (n=56). Our model was compared with five publicly available models, including the Universal Lesion Segmentation baseline model, the Medical Segmentation Decathlon lung model, DuneAI, TotalSegmentator and nnInteractive. Segmentation accuracy was assessed using volumetric and boundary metrics, including stratified analyses by tumour size (≤30 mm, >30–50 mm, >50–70 mm, >70 mm) on our internal test dataset (n=83).
Results or Findings: Our proposed model performed equal to or superior to the best public models regarding volumetric Dice scores (median ≥0.87), showing an increase ranging from 0.01 to 0.28, depending on the model and the tumour size group. The model demonstrated substantially improved consistency with interquartile ranges ≤ 0.10 for all tumour sizes. It also achieved higher surface Dice together with lower Hausdorff distance, indicating improved tumour border accuracy. Performance remained superior in clinically demanding cases with cavities, local invasion, and large masses.
Conclusion: Our model improves performance and robustness over prior models across tumour sizes, including challenging cases. It represents a promising step towards automated evaluation of lung tumours.
Limitations: Independent validation in larger multicentre datasets is required.
Funding for this study: Public private consortium with funding from NWO, Dutch Ministry of Economic Affairs, and MeVis Medical Solutions, Bremen, Germany.

Ethics committee - additional information: The institutional review board waived the need for informed consent because of the retrospective design and data pseudonymization.

Benchmarking of Artificial Intelligence and Radiologists for Indeterminate Lung Nodule Malignancy Risk Estimation on Screening CT: Results of the LUNA25 Challenge (6 min)

Bogdan Obreja; Nijmegen / Netherlands

Author Block: D. Peeters[1], B. Obreja[1], N. Antonissen[1], Z. Saghir[2], U. Pastorino[3], G. De Bock[4], R. Vliegenthart[4], M. Prokop[1], C. Jacobs[1]; [1]Nijmegen/NL, [2]Hellerup/DK, [3]Milan/IT, [4]Groningen/NL
Purpose: Accurate risk classification of indeterminate (5-15mm) lung nodules can reduce unnecessary follow-up in lung cancer screening. AI may assist in risk classification, however, benchmarking studies are limited. Here, we present the results of the LUNA25 challenge, a public competition that evaluates AI and radiologist performance for malignancy risk estimation of indeterminate nodules at screening CT.
Methods or Background: LUNA25 consists of an AI study and a reader study. For AI development, participants had access to a public dataset of 4069 CT scans from the National Lung Cancer Screening Trial (NLST), with 555 malignant and 5608 benign nodules. AI evaluation was performed on an external test set with 156 malignant and 312 benign indeterminate solid and part-solid nodules from baseline scans of the Danish (DLCST), Dutch-Belgian (NELSON), and Italian (MILD) lung cancer screening trials. For the reader study, radiologists assessed 300 nodules from the test set, assigning each a malignancy risk score (0–100) and management recommendation (low, intermediate, or high-risk). Performance was compared using area under the ROC curve (AUC), sensitivity, and specificity.
Results or Findings: On the subset of 300 nodules, the top-performing AI system showed a statistically superior AUC of 0.78 (95% CI :0.73-0.84, p<0.001) in comparison to the average AUC of 75 readers with an AUC of 0.69 (95% CI :0.64-0.74). At the ≥ indeterminate risk threshold, the AI correctly classified 12% more malignant cases at matched specificity, and 20% fewer false-positives at matched sensitivity.
Conclusion: The top-performing AI system demonstrated statistically significant superior performance compared to the average radiologist in estimating malignancy risk for indeterminate lung nodules detected on screening CT, highlighting its potential use as a decision-support tool.
Limitations: LUNA25 only benchmarks AI's stand-alone performance and does not address workflow integration or radiologist-AI interaction.
Funding for this study: This work was supported by a public-private research projectwith funding from the Dutch Research Council (NWO), the Dutch Ministry of Economic Affairs, and MeVis Medical Solutions (Bremen, Germany), as well as by a public-private project with funding from the Dutch Cancer Society (KWF Kankerbestrijding, project number 9037) and Siemens Healthineers, as well a project with funding from the Dutch Cancer Society (KWF Kankerbestrijding, project number 14113).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Ethical approval for the training set was granted with the NLST trial receiving institutional review board approval at all 33 centers participating in the trial. In addition, informed consent was provided by all participants involved in the trial. Access to this dataset was granted through the National Cancer Institute's Cancer Data Access System (CDAS) under project number NLST-74, NLST-111, NLST-164 and NLST-267.
Ethical approvals for the testing set were obtained from the Ethics Committee of Copenhagen County (DLCST), the institutional review board of Fondazione IRCCS Istituto Nazionale Tumori di Milano (MILD), and the Dutch Minister of Health with support from the Dutch Health Council (NELSON), along with authorization from the Ethical Boards of participating centres.

Can traditional radiomics help in ultra-low dose early lung cancer diagnosis? (6 min)

Anna Mrukwa; Gliwice / Poland

Author Block: A. Mrukwa[1], M. Socha[1], J. Polanska[1], R. Dziadziuszko[2]; [1]Gliwice/PL, [2]Gdańsk/PL
Purpose: Lung cancer is the deadliest cancer in the world due to the usually late diagnosis. If diagnosed early on, during the screening programs, many patients could be saved. Nodules in LDCT scans are miniscule and hard to spot, so it is important to create a system to assist with malignancy assessment while retaining method explainability. Radiomic features were designed for diagnosis in advanced stages, thus may not be suitable for this case.
Methods or Background: Nodules were extracted from Pilot Pomeranian Lung Cancer Screening Program using MiMSeg on lungs without bronchovascular bundles. Only changes meeting radiomics calculation size requirements are considered, disqualifying 49 of them. 363 malignant nodules were used and 1054 benign. Pyradiomics radiomic features and additionally introduced sphericity and spikularity are evaluated with Kruskal-Wallis test and post hoc analysis using Dunn's test.
Results or Findings: Effect size between groups is medium at most, whereas post hoc analysis showed that the most different group is calcification, with the suspicious changes not distinct from other groups. Thus, binary multilayer perceptron trained on the features achieved balanced accuracy of only 54.9% and 53.3% for medium effect features. For multiclass classification, balanced accuracy is 22.8% for all features, 25.7% for selected. This improvement comes from calcification (over half correctly classified) and is tradeoff for others (accuracy for suspicious dropping from 0.189 to 0.057).
Conclusion: Traditional methods do not perform well with LDCT and do not provide a reliable method for early lung cancer diagnosis. Additionally, the smallest nodules are not suited for this analysis type. Thus, introduction of Deep Learning methods seems to give the biggest promise.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study.

Evaluating research quality of lung cancer CT radiomics using RQS 1.0 and METRICS (6 min)

Maurizio Balbi; Turin / Italy

Author Block: M. Balbi[1], V. Giannini[1], N. C. Culasso[2], A. Defeudis[3], A. U. Cavallo[4], A. Stanzione[5], A. Ponsiglione[5], R. Cuocolo[6], A. Veltri[1]; [1]Turin/IT, [2]Orbassano/IT, [3]Candiolo/IT, [4]Rome/IT, [5]Naples/IT, [6]Baronissi/IT
Purpose: To assess the methodological quality of lung cancer CT radiomics studies using the Radiomic Quality Score (RQS) 1.0 and the METhodological RadiomICs Score (METRICS).
Methods or Background: Lung cancer CT radiomics studies published up to December 31, 2024, were scored by 6 human readers of different expertise using RQS 1.0 and METRICS. Median scores were computed, and differences across clinical aim, publication year, and patient number were assessed using the Kruskal-Wallis test. In cases of significant differences, pairwise Mann–Whitney U tests were performed to evaluate group-wise comparisons.
Results or Findings: A total of 834 studies were included. Median METRICS and RQS 1.0 percentage scores were 0.63 (IQR, 0.51–0.72) and 0.36 (IQR, 0.52–0.71), respectively. The main methodological limitations included the lack of external validation or any validation strategy, the unavailability of open data, and the retrospective, single-center study design. Median METRICS scores of studies published in 2024 (0.67) and 2023 (0.69) were significantly higher than those published before 2023 (≤0.65; all $p < 0.04$). Similarly, median RQS 1.0 scores of studies published in 2024 (0.42) were significantly higher than those previously published (≤0.39; all $p < 0.01$). Studies including >100 patients showed significantly higher METRICS and RQS 1.0 scores than those with ≤100 patients (all $p < 0.001$). Differences across clinical aims were observed, with patterns varying between METRICS and RQS 1.0.
Conclusion: Research quality in lung cancer CT radiomics was rated as good by METRICS while RQS 1.0 yielded comparatively lower scores. Both tools highlighted an improvement in quality over time and higher scores in studies involving >100 patients.
Limitations: -Lack of reproducibility analyses.
-Lack of evaluation according to RQS 2.0 (published after data collection and analysis).
Funding for this study: No funding.

Comparative analysis of multiple AI software packages on detection performance of the reference nodule for lung cancer screening application (6 min)

Xiaotong Ouyang; Groningen / Netherlands

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: X. Ouyang[1], K. Togka[2], D. Han[2], I. Schuldink[2], B. Jiang[1], C. Van Der Aalst[1], H. J. De Koning[1], M. Oudkerk[2]; [1]Rotterdam/NL, [2]Groningen/NL
Purpose: Over the past five years, artificial intelligence(AI) for pulmonary nodule detection on Computed Tomography(CT) has rapidly advanced, and multiple commercial AI software packages are now available. However, independent validation—particularly at the reference nodule level—remains limited. This study compares four CE-certified commercial AI software packages for reference nodule detection on low-dose CT, aiming to provide scientific evidence for their application in lung cancer screening(LCS).
Methods or Background: A total of 560 baseline LDCT scans were consecutively selected from three Dutch 4-IN-THE-LUNG-RUN(4ITLR) centers following the trial's protocol. Expert radiologists established consensus reference standards. Four CE-certified(three FDA-cleared) commercial AI packages(A–D) were evaluated using an internal automatic platform. Finally, 554 participants were divided into two cohorts per the NELSON 2.0-European Position Statement by reference standard: positive(77 with the largest nodule ≥100 mm^3) and negative(477 with the largest nodule <100 mm^3 or no nodules). AI detection in the positive cohort was classified as "Correct positive" or "Negative misclassification." Subgroup analyses were performed by nodule volume, pulmonary-lobe location, and attachment. Logistic regression was applied to examine their effect on AI detection.
Results or Findings: Correct positive rates were: Software A: 60/77(77.9%), B: 71/77(92.2%), and C: 59/77(76.6%), D: 66/77(85.7%). Software A showed increasing detection with nodule volume, while D showed negative coefficients. Both C and D each missed 2/6 masses. All packages performed better for right-lung nodules and non-attached nodules, with significant inter-software differences ($p<0.05$). Logistic regression confirmed higher detectability for right-sided and non-attached nodules (log-odds>0).
Conclusion: Despite high reported performance in the literature, commercial AI packages show variable detection in a low-dose CT lung cancer screening dataset. Reference nodule detectability is influenced by pulmonary location, nodule volume, and attachment, highlighting the need for independent, comprehensive validation before and during LCS application.
Limitations: Not applicable

Automated CT Quantification of Interstitial Lung Abnormalities and Prognostic Associations in Lung Cancer Screening (6 min)

Pardeep Vasudev; London / United Kingdom

Author Block: P. Vasudev, M. Azimbagirad, B. Selvarajah, A. Bhamani, S. Aslani, D. Alexander, *. SUMMIT consortium, S. Janes, J. Jacob; London/UK
Purpose: Interstitial lung abnormalities (ILA) are increasingly recognised in lung cancer screening cohorts and may indicate early fibrotic change. Their prognostic importance has been shown, but large-scale reproducible assessment remains challenging. Automated CT-based quantification offers a scalable solution. The aim was to determine whether automated measures are associated with mortality and whether prognostic performance improves with expert radiologist ILA diagnosis.
Methods or Background: This was a retrospective analysis of a multi-centre prospective lung cancer screening cohort. Low-dose chest CT scans from 4,411 participants were included, with ILA status determined by expert radiologist assessment: 3,622 had no ILA and 789 had ILA (17.9% of participants). An automated pipeline segmented the lungs, airways, and vessels, and quantified abnormal parenchymal density by normalising CT intensities and applying mean- and standard deviation-based thresholds to generate density maps. Multivariable Cox proportional hazards regression assessed associations between parenchymal density metrics, expert radiologist ILA diagnosis, and mortality, adjusting for age, sex, smoking history, and forced vital capacity (FVC). Hazard ratios (HR) with 95% confidence intervals (CI) and p-values were reported.
Results or Findings: Abnormal high-density lung volume was independently associated with increased mortality (HR 1.03, 95% CI 1.01–1.04, $p=2.04\times10^{-3}$). Prognostic associations strengthened when expert radiologist ILA diagnosis was incorporated (HR 1.03, 95% CI 1.01–1.04, $p=9.72\times10^{-9}$). Significant covariates included age (HR 1.08, 95% CI 1.06–1.11, $p=8.18\times10^{-15}$), sex (HR 0.60, 95% CI 0.45–0.79, $p=2.21\times10^{-4}$), and FVC (HR 0.97, 95% CI 0.97–0.98, $p=1.42\times10^{-10}$). Smoking history was not statistically significant.
Conclusion: Automated CT quantification of parenchymal density abnormalities was associated with mortality in lung cancer screening participants. Prognostic associations were stronger when expert radiologist ILA diagnosis was combined with automated measures, supporting their use as objective biomarkers for further validation.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Ethical approval for the lung cancer screening study was obtained from a NHS Research Ethics committee (17/LO/2004) and the NHS Health Research Authority's Confidentiality Advisory Group (18/CAG/0054).

Diagnostic Performance of Magnetic-Resonance Imaging Radiomics in Evaluation of Response after Neoadjuvant Chemotherapy in Head and Neck Squamous Cell Carcinoma (6 min)
Saeed Mohammadzadeh; Tehran / Iran

Author Block: S. Mohammadzadeh, I. Kiani, F. Mahdavi Sabet, S. Mohammadzadeh; Tehran/IR
Purpose: Head and neck squamous cell carcinoma (HNSCC) is the seventh most common malignancy worldwide. Over two-thirds of cases present at a locally advanced stage, and neoadjuvant chemotherapy (NACT) can improve survival, reduce distant metastases, and facilitate organ preservation. We aimed to evaluate diagnostic performance of MRI-based radiomics for evaluating response to NACT in HNSCC patients.
Methods or Background: We performed a comprehensive search until July 2025 to include studies evaluating diagnostic performance of MRI radiomics in response assessment. Risk of bias was assessed using METRICS. Using a random-effects bivariate model, diagnostic values of area under the curve (AUC), sensitivity, specificity, positive and negative likelihood ratios, and diagnostic odds ratio were calculated. Meta-regression and subgroup analyses were used to explore the source of heterogeneity when I2 was ≥ 50%.
Results or Findings: Twenty-one studies were included. The overall diagnostic performance of MRI-radiomics in the validation set was good, with a summary AUC of 0.84 (95% CI: 0.81–0.87) in differentiation of complete or partial response (CR/PR) and stable or progressive disease (SD/PD). High heterogeneity was observed, but there was no evidence of publication bias (Deeks' test p = 0.20). Subgroup analysis showed similar performance of the model across different therapeutic regimens, study designs, study qualities, and MRI magnitudes of strength. For classifying only CR as responders and PR+SD+PD as non-responders, MRI-radiomics achieved an AUC of 0.83 (95% CI: 0.79–0.86) with low heterogeneity.
Conclusion: MRI-based radiomics demonstrates high diagnostic performance for evaluating treatment response to NACT in HNSCC. This non-invasive approach shows strong potential for post-treatment assessment and clinical decision-making.
Limitations: The variety in the model-developing method across multiple centers may limit the reproducibility of the radiomics model. Also, most of the included studies were retrospective and lacked external validation.

Image Quality Improvement in Head and Neck Angiography based on Dual-energy CT and Deep Learning (6 min)
He Zhang; Xuzhou / China

Author Block: H. Zhang, Y. Meng; Xuzhou/CN
Purpose: Compare image quality of image reconstructed using DLIR and IR algorithms for head and neck dual-energy CT angiography (DECTA)
Methods or Background: This prospective study comprised patients with head and neck DECTA. Images reconstructed by four algorithms (120-kVp-like with ASIR-V40%,50 keV with ASIR-V40%,50 keV with DLIR-M,50 keV with DLIR-H) were compared. CT attenuation, image noise, SNR, CNR, edge-rise distance (ERD) and edge-rise slope (ERS) were calculated. Subjective image quality scores were evaluated.
Results or Findings: CT attenuation of vessels in 120kVp-like images were lower than 3 sets of 50 keV images with significant difference. In 50 keV images, both sternocleidomastoid muscle and white matter had a minimum noise in DLIR-H, and a maximum in ASIR-V40% group with significant difference. SNR and CNR in 50 keV images of all vessels had the same results: highest in DLIR-H group and lowest in ASIR-V40% group with significant differences. The mean value of ERD showed no significant difference among four groups. While 120kVp-like images had the lowest ERS, which showed statistically significant difference with the other groups. In terms of overall image quality, sharpness, and artifacts, the scores of DLIR-M and DLIR-H at 50 keV were not statistically different, and were higher than ASIR-V40% at 50 keV images, and higher than ASIR-V40% at 120 kVp-like. The scores of DLIR-H at 50 keV were highest in terms of noise and average scores.
Conclusion: DLIR is a potential solution for DECTA reconstruction since it can greatly reduce image noise, improving image quality of head and neck DECTA at 50 keV.
Limitations: First, our population was relatively small. Secondly, our study only compared 40%ASIR-V and DLIR, without including higher levels of ASIR-V for comparison. Finally, patients with BMI out of the normal range were excluded.
Funding for this study: We acknowledge financial support from the Jiangsu Traditional Chinese Medicine Science and Technology Development Plan Project (MS2021100), and the Key Research and Development Program of Xuzhou Science and Technology Bureau (KC20159).

Beyond the T: Volumetric MRI Predicts Lymphatic Spread in HNSCC (6 min)

Davide Giardino; Frankfurt am Main / Germany

Author Block: D. Giardino, A-I. Nica, P. Thoenissen, T. J. Vogl, I. Yel, R. Sader, C. Booz; Frankfurt/DE
Purpose: To investigate the relationship between primary tumor volume, the spatial distribution of cervical lymphnode metastases, and TNM staging in patients with oral and pharyngeal squamous cell carcinoma (HNSCC) using high-resolution MRI.
Methods or Background: This retrospective analysis evaluated 116 predominantly male (62.9%) patients (age 67.7 ± 11.5 years) with histologically confirmed HNSCC who underwent surgical resection with neck dissection or definitive chemoradiation. MRI-based volumetry and center-to-center distance measurements between primary tumor and cervical lymphnode metastases were performed using 3D postprocessing software.
Results or Findings: Tumor-to-lymphnode distances ranged from 11.7 to 117.3 mm (mean: 47.6 ± 19.4 mm). Tumor volume varied from 0.5 to 87.2 cm^3 (median: 13.3 ± 13.2 cm^3), and was higher in male patients. Significant correlation was observed between tumor volume and lymphnode distance and pT-stage ($p<0.0001$). The correlation between tumor volume and the distance to metastatic lymphnodes was stronger (Spearman's $r=0.4541$, $p<0.0001$) than the correlation between the pT-stage (TNM classification) and nodal distance (Spearman's $r=0.2682$, $p=0.0036$).
Conclusion: MRI-based assessment revealed that tumor volume is a stronger predictor of the spatial extent of lymph node metastases than T-stage alone. Larger tumors were associated with greater distances to metastatic lymph nodes. These findings highlight the value of quantitative 3D MRI-based volume and distance analyses in potentially improving surgical and radiotherapeutic planning.
Limitations: Limitations of the study include its retrospective nature.
Funding for this study: No funding was obtained for this study.

Surveillance Imaging in Head & Neck Cancer: Node-RADS Validation in the Treated Neck (6 min)

Akshat hitesh Shah; Kolkata / India

Author Block: A. h. Shah, S. Sen, A. Gehani, A. Chandra, P. Ghosh, S. Mukhopadhyay, A. Chatterjee, J. Khoda, A. Patra; Kolkata/IN
Purpose: Node-RADS was originally designed for staging untreated lymph nodes. Its performance in the post-treatment neck, where fibrosis and necrosis mimic recurrence, is unknown. We confirmed Node-RADS in treated head and neck cancer patients, with subsite-specific analysis across CT and MRI cohorts.
Methods or Background: We retrospectively reviewed 602 patients with head and neck squamous cell carcinoma treated between 2012 and 2024, yielding 1,098 post-treatment nodes. Imaging modality was decided by subsite: oral cavity and larynx underwent CT, while oropharynx and nasopharynx were assessed with MRI (no dual-modality cases). Two head and neck radiologists independently assigned Node-RADS categories (1-5). Reference standards included histopathology, MDT consensus, or ≥12-month imaging follow-up. Diagnostic performance and predictive values were calculated overall and by subsite; inter-observer agreement was assessed (κ).
Results or Findings: Node-RADS categories correlated strongly with recurrence risk ($p<0.001$). At a cutoff of Node-RADS ≥4, sensitivity was 81% and specificity 86%, with overall accuracy 84%. NPV exceeded 92% for Node-RADS 1-2, while Node-RADS 5 achieved PPV 89%. Subsite analysis showed comparable performance across CT-evaluated subsites (oral cavity, larynx) and MRI-evaluated subsites (oropharynx, nasopharynx). Interobserver agreement was substantial ($\kappa = 0.74$), aligning with prior untreated Node-RADS studies (κ ~0.6–0.7). Clinical concordance was high: 71% of Node-RADS 4–5 prompted MDT-directed biopsy or salvage, while most Node-RADS 1–2 remained under surveillance.
Conclusion: This is the first validation of Node-RADS in the treated neck. Structured nodal reporting retains strong predictive value post-therapy, with high reproducibility and clear MDT alignment. Node-RADS offers a practical lexicon for post-treatment surveillance, bridging radiology and clinical decision-making.
Limitations: Single-center retrospective design

Intraoperative and Histopathological Evaluation of Paragangliomas Following Preoperative Embolization: Comparing Outcomes of Particles, Onyx, and Glubran (6 min)

Hannah Steinberg; Mülheim / Germany

Author Block: H. Steinberg[1], N. van Landeghem[1], D. Van Landeghem[1], B. M. Schaarschmidt[1], M. Forsting[1], I. Wanke[2], C. Deuschl[1], Y. Li[1]; [1]Essen/DE, [2]Zürich/DE
Purpose: Head and neck paragangliomas are rare, hypervascular tumors for which preoperative embolization is often required to mitigate intraoperative blood loss.
This study compares intraoperative and histopathological outcomes of paragangliomas following preoperative embolization using particles, Onyx, or Glubran.
Methods or Background: Retrospective analysis of patients undergoing preoperative embolization for paragangliomas at a tertiary care center from 2010 to 2024. Outcomes included post-embolization angiographic devascularization, intraoperative bleeding, histopathological necrosis, inflammatory response, and resection margins.
Results or Findings: Twenty-two patients (15 female; mean age 52.6 years) were included. The mean interval between embolization and surgery was 5.1 days. Liquid embolic agents (Onyx: 54.5%, Glubran: 22.7%) were used in 77.3% of cases, with particles in the rest. Liquid embolics demonstrated superior tumor devascularization (median 90% vs. 50%, $p=0.05$) and necrosis (20% vs. 0%, $p=0.039$) compared to particles. However, no significant differences were observed in intraoperative blood loss (hemoglobin loss 1.4 g/dL for liquid embolics vs. 0.5 g/dL, $p=0.676$), procedure duration (134 vs. 96 minutes, $p=0.085$), or peritumoral inflammation. Complete resection (R0) was achieved in 81.25% of liquid embolic cases versus 100% with particles. Onyx and Glubran showed comparable efficacy.
Conclusion: Liquid embolic agents (Onyx/Glubran) achieved greater tumor devascularization and necrosis than particles, though surgical outcomes (blood loss, complete resection rates) were comparable. Agent selection may depend on procedural goals, balancing angiographic efficacy against surgical feasibility.
Limitations: The limitations of this study are its retrospective and single-center study design.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the ethics committee of the University of Duisburg-Essen.

Discriminating Orbital Lymphoma from Inflammation and Correlating with Histopathology Using Microstructure-Based Time-Dependent Diffusion MRI (6 min)

Hangzhi Liu; Beijing / China

Author Block: H. Liu; Beijing/CN
Purpose: Preoperative discrimination between orbital lymphoma and inflammatory lesions remains a significant challenge using conventional imaging. This study evaluates the potential of time-dependent diffusion MRI (td-dMRI) alongside diffusion-weighted imaging (DWI) to improve differential diagnosis.
Methods or Background: Patients with suspected orbital tumors were prospectively enrolled between October 2023 and November 2024. All participants underwent td-dMRI using oscillating gradient spin-echo (OGSE) and pulsed gradient spin-echo (PGSE) sequences on a 3T scanner. Microstructural parameters—including cell diameter (d), cellularity, extracellular diffusivity (Dex), and intracellular volume fraction (Vin)—were derived. Correlations between ADC, d, cellularity, and histopathological metrics were assessed through quantitative morphometric analysis. Diagnostic performance was evaluated using receiver operating characteristic (ROC) analysis.
Results or Findings: A total of 48 patients were included (20 with orbital lymphoma, 28 with inflammatory lesions). Interobserver agreement was excellent for all imaging parameters (ICCs range: 0.82–0.93). Strong correlations were found between imaging and histology for cell diameter ($r = 0.75$), cellularity ($r = 0.71$), and ADC ($r = -0.74$; all $p < 0.001$). Lymphomas exhibited significantly lower ADC, d, and Dex, and higher Vin and cellularity compared to inflammatory lesions (all $p < 0.01$). Cellularity demonstrated the highest discriminative power (AUC = 0.87), followed by Vin (AUC = 0.82), while ADC showed moderate performance (AUC = 0.74). No significant differences in diagnostic efficacy were observed among the parameters.
Conclusion: The td-dMRI provides highly reproducible and histologically correlated biomarkers, effectively differentiating orbital lymphoma from inflammatory conditions and offering valuable non-invasive characterization for preoperative diagnosis of orbital lesions.
Limitations: The study has limitations of a relatively small sample size and a limited range of orbital tumors and tumor-like lesions, so future studies with larger cohorts are required to validate and refine the application of this technique in orbital pathologies.

The Prognostic Value of Intra- and Peri-tumoral Habitat Analysis in Nasopharyngeal Carcinoma: Combining IVIM and ASL (6 min)

Fan Yang; Beijing / China

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: F. Yang, M. Lin, H. Zhang; Beijing/CN
Purpose: To evaluate the value of intravoxel incoherent motion (IVIM) and arterial spin labeling (ASL)-based habitat analysis of intra- and peri-tumoral regions for predicting overall survival (OS) and progression-free survival (PFS) in NPC.
Methods or Background: 106 patients were prospectively included. Primary tumors were delineated on T2-weighted imaging, and three peritumoral regions (3, 5, and 10 mm) were automatically dilated and manually corrected according to the clinical tumor volume outlining criteria. The pure diffusion coefficient (D) and mean kurtosis (MK) maps of IVIM, and blood flow (BF) map of ASL were used for habitat analysis. Volume fraction and histogram parameters (Mean, Kurtosis and Skewness) were extracted for each subregion. Univariate and multivariate Cox analyses were used to construct intra- and peri-tumoral, Clinic, and combined models, which were assessed by the C-index. Nomogram, calibration curves, and Kaplan-Meier curves were also plotted.
Results or Findings: The intra-tumoral subregion 4 was characterized by high D and low BF and MK value, representing the radiotherapy-resistant region and patients with treatment failure had higher proportion of subregion 4. The Intra-score independently predicted OS (hazard radio [HR]: 1.023, P = 0.002) and PFS (HR: 1.028, P = 0.001). Combined clinical factors with intra- and peri-tumoral habitat features showed the highest performance (C-index: 0.780 [OS] and 0.721 [PFS]) and outperformed the Clinic model (C-index: 0.691 [OS] and 0.666 [PFS], $P \leq 0.03$). The post-hoc subgroup analysis confirmed robustness.
Conclusion: Peri-tumoral regions provide valuable prognostic information. Combining IVIM-ASL-based habitat analysis offers a non-invasive approach to predicting treatment outcomes.
Limitations: Small sample size and lack of histopathological confirmation information were the limitations.

Preoperative Prediction of Cervical Lymph Node Metastasis in Thyroid Cancer Using Dual-Layer Spectral CT Combined with Node-RADS (6 min)

Zhao dong Ai; Changsha, / China

Author Block: Z. d. Ai[1], Z. Huang[2], X. Yu[1]; [1]Changsha/CN, [2]Guangzhou/CN
Purpose: To develop and validate a noninvasive preoperative prediction model integrating dual-layer spectral CT (DLCT) quantitative parameters with the Node Reporting and Data System (Node-RADS) for discriminating metastatic from benign cervical lymph nodes in thyroid cancer.
Methods or Background: This retrospective study included 254 lymph nodes (166 metastatic, 88 benign) from 131 patients who underwent preoperative DLCT and Node-RADS scoring. Nodes were randomly allocated into training (70%) and validation (30%) cohorts. Candidate DLCT parameters were selected using univariable logistic regression ($p < 0.10$) and subsequently incorporated into a multivariable model ($p < 0.05$). The final model comprised four predictors: normalized lymph-node attenuation to paraspinal muscle, normalized iodine concentration to paraspinal muscle, electron density value, and Node-RADS score. Model performance was evaluated using ROC analysis, accuracy, precision, sensitivity, specificity, and F1-score.
Results or Findings: The combined DLCT and Node-RADS model demonstrated strong discriminative performance. In the training cohort, it achieved an AUC of 0.958, accuracy of 88.1%, precision of 86.4%, sensitivity of 82.6%, specificity of 91.7%, and an F1-score of 0.844. Performance remained robust in the validation cohort, with an AUC of 0.939, accuracy of 80.5%, precision of 84.2%, sensitivity of 78.0%, specificity of 83.3%, and an F1-score of 0.810.
Conclusion: Integration of DLCT quantitative metrics with Node-RADS provides a high-performing, noninvasive tool for preoperative prediction of cervical lymph node metastasis in thyroid cancer, which may improve diagnostic confidence and surgical planning.
Limitations: The retrospective design and single-center data source may limit generalizability. Further validation in larger, multicenter cohorts is warranted.

Deep learning-enhanced MRI assessment of the optic nerves: A focus on AiCE denoising (6 min)

Emma O'Shaughnessy; PARIS 10 / France

Author Block: A. Sajust De Bergues De Escalup, A. Lecler, E. O'Shaughnessy; Paris/FR
Purpose: Orbital MRI is essential for assessing optic nerve disorders but is limited by motion artifacts, low signal-to-noise ratio (SNR), and susceptibility effects. Deep learning–based reconstruction improves image quality and shortens acquisition time. Canon's Advanced intelligent Clear-IQ Engine (AiCE) reduces noise while preserving detail. This study evaluated AiCE's impact on image quality and diagnostic confidence in coronal T2- and post-contrast T1-weighted orbital MRI.
Methods or Background: This retrospective single-center study included 72 orbital MRI exams on a 3T MRI. Coronal T2-WI (n=71) and post-contrast T1-WI (n=25) were reconstructed with and without AiCE. Two blinded radiologists separately reviewed series, assessing optic nerve hyperintensity, atrophy, and qualitative features (optic nerve sharpness, brain sharpness, overall quality) on 5-point scales. Motion artifacts were rated separately. SNR and contrast-to-noise ratio (CNR) were measured using. Wilcoxon and McNemar tests with Bonferroni correction were used. Agreement was assessed with Cohen's κ and ICC.
Results or Findings: In coronal T2-WI, mean SNR rose from 25.94 ± 16.94 (non-AiCE) to 49.04 ± 26.01 (AiCE), and CNR from 14.29 ± 15.87 to 25.57 ± 22.48 ($p < 0.001$). In post-contrast T1-WI, SNR and CNR were unchanged ($p = 1$; $p = 0.72$). AiCE significantly improved brain and optic nerve sharpness and overall quality ($p \leq 0.001$). Detection of optic nerve hyperintensity and atrophy was unchanged. Inter-reader κ for diagnostic features ranged 0.795–0.966; intra-reader κ for diagnostic features was 0.87–1; weighted κ for qualitative metrics was 0.209–0.803. ICCs ranged 0.234–0.624.
Conclusion: AiCE improved orbital MRI quality, especially in coronal T2-WI, without compromising diagnostic feature detection. These gains support its use for confident optic nerve assessment in routine practice.
Limitations: Quantitative gains were variable, with higher intra- than inter-reader agreement. Further studies should optimize its use across centers.
Funding for this study: No funding was provided for this study.

ADC-Based Radiomics for Cholesteatoma Diagnosis: Comparison with Conventional Imaging (6 min)

RAMAZAN ORKUN ÖNDER; Giresun / Turkey

Author Block: R. O. ÖNDER[1], T. Bekçi[1], A. Tosun[2]; [1]Giresun/TR, [2]Trabzon/TR
Purpose: To evaluate the diagnostic performance of conventional radiological findings (CT and DWI) and radiomic features derived from ADC maps in the diagnosis of cholesteatoma, and to assess the added value of their artificial intelligence-based combination.
Methods or Background: In this retrospective study, 51 patients with suspected cholesteatoma (January 2020–August 2024) were analyzed. Non-contrast temporal bone CT and DWI were assessed, and radiomic features were extracted from ADC maps. Reproducibility was tested with intraclass correlation coefficients (ICC ≥0.75). Machine learning (ML) models, including a three-layer artificial neural network, were trained using radiology, radiomics, and combined datasets. An independent validation group (n=15) was used to confirm generalizability.
Results or Findings: Of 51 lesions, 23 (45.1%) were histopathologically confirmed as cholesteatoma. Cholesteatomatous lesions had higher CT HU values (p=0.004), more frequent diffusion restriction (p<0.001), and lower ADC values (p<0.001). Radiomic analysis identified 20 significant features. The combined ML model achieved the best performance (accuracy 98.0%, AUC 0.982), which remained robust in the validation cohort (accuracy 93.3%, AUC 0.951).
Conclusion: Artificial intelligence and ADC radiomics provide complementary diagnostic value to conventional radiology in the detection of cholesteatoma. The artificial intelligence-assisted integration of radiomics and radiology achieves superior performance, thereby supporting its potential role in non-invasive diagnosis and the clinical decision-making process.
Limitations: Single-center, retrospective design with a limited sample size; external validation is required.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective study was approved by the Scientific Research Ethics Committee of Giresun Training and Research Hospital on 4 September 2024 (decision no. 17).

Prediction of Ki-67 status in tongue squamous cell carcinoma using histogram features of spectral images derived from dual-layer spectral-detector CT (6 min)

Xiaomin Liu; Guangzhou / China

Author Block: H. K. Zhang[1], F. Chen[1], Y. Liao[2], X. Liu[2]; [1]Haikou/CN, [2]Guangzhou/CN
Purpose: The Ki-67 status is often correlated with the clinical course of cancer. This study aimed to investigate the feasibility of predicting Ki-67 status in TSCC using histogram features of spectral images acquired with dual-layer spectral-detector CT(DLCT).
Methods or Background: A retrospective cohort of 69 patients with TSCC (50 Ki-67-positive and 19 Ki-67-negative, with a threshold of 20%) who underwent surgery with preoperative DLCT scans was collected. Conventional images and spectral images, including Virtual Monoenergetic Images (VMIs) at 40KeV, 70KeV, 100KeV, and 130KeV, iodine density maps, effective atomic number maps, virtual non-contrast (VNC) images, were generated based on venous-phase CT data. Tumor regions of interest (ROIs) were manually delineated on the VMI 40KeV images and then copied and pasted onto other images. A total of 12 histogram parameters were extracted from each image. Feature selection was performed using Spearman correlation analysis (threshold = 0.9) and backward stepwise regression. Logistic regression was used to construct predictive models. Model performance was assessed with receiver operating characteristic (ROC) analysis, and compared with the DeLong's test.
Results or Findings: In the discrimination of Ki-67 status based on individual features, the energy from VNC obtained the highest area under the curve (AUC) of 0.727 (95% CI: 0.578-0.876), followed by the energy from VIMs 70keV with an AUC of 0.719 (0.571-0.867). The model combining valuable features from all spectral images achieved the highest AUC of 0.863(0.765-0.962), which was significantly outperformed than the model corporating valuable features from conventional images with an AUC of 0.663(0.505-0.822), and a P<0.01.
Conclusion: The histogram features of spectral images exhibit promising performance in preoperatively predicting Ki-67 status in patients with TSCC.
Limitations: Retrospective, single-center study with a small sample size
Funding for this study: Not applicable
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The Ethics Committee granted a waiver of informed consent for this retrospective study.

Deep learning-based body composition analysis: Multiple independent prognostic biomarkers from routine CT in head and neck cancer (6 min)

Andreas Michael Bucher; Frankfurt / Germany

Author Block: E. Frodl, L. Golla, L. Gantner, M. Harth, J. Dietz, T. Vogl, P. Thoenissen, A. M. Bucher; Frankfurt/DE
Purpose: To identify independent body composition predictors of overall survival in head and neck squamous cell carcinoma patients using automated deep learning analysis of routine baseline CT at L3 and abdominal cavity levels.
Methods or Background: This retrospective study analysed 181 HNSCC patients (mean age 63.2±12.4 years; 50.8% female) using deep learning-based automated body composition analysis from baseline venous-phase contrast-enhanced CT (91.7%, 5mm slice thickness). The algorithm quantified tissue volumes and densities including intermuscular adipose tissue infiltration (IMAT), subcutaneous adipose tissue (SAT), muscle, and bone. Additionally, muscle-to-bone ratio (MBR) and IMAT/TAT ratio were calculated. Cox regression with multivariate adjustment for age, gender, T-stage, N-stage, and UICC stage identified independent predictors.
Results or Findings: Patients presented with advanced disease (UICC IVA: 31.5%, III: 22.6%, I: 21.6%) with 41.4% nodal involvement. Multiple body composition metrics showed independent prognostic value in multivariate analysis. IMAT/TAT ratios remained significant predictors at both abdominal cavity (volume: HR=1.490, p=0.0008, 95%CI: 1.180-1.882; attenuation: HR=1.465, p=0.0015, 95%CI: 1.158-1.854) and L3 levels (volume: HR=1.458, p=0.0011, 95%CI: 1.163-1.827; attenuation: HR=1.457, p=0.0007, 95%CI: 1.171-1.812). SAT attenuation independently predicted survival at both levels (abdominal: HR=1.469, p=0.0017, 95%CI: 1.156-1.867; L3: HR=1.486, p=0.0005, 95%CI: 1.189-1.857). Uniquely, muscle-bone volume ratio at abdominal cavity showed protective effects (HR=0.741, p=0.0477, 95%CI: 0.550-0.997), unavailable at single-slice L3. All metrics maintained significance alongside UICC stage (HR=2.435, p=0.0015) in multivariate models.
Conclusion: Deep learning-based body composition analysis identifies multiple independent predictors of overall survival in HNSCC. IMAT infiltration and SAT attenuation maintain prognostic value across both anatomical levels. The protective muscle-bone volume ratio, unique to abdominal cavity assessment, supports volumetric analysis. These automatically derived biomarkers enhance risk stratification beyond traditional staging without additional radiation exposure.
Limitations: The limitations of the study are the single-centre retrospective design and pending external validation.
Funding for this study: Funding was provided by the German Federal Ministry of Education and Research through the RACOON project (reference number 01KX2021).
Has your study been approved by an ethics committee? Yes

Time-Saving Potential of Deep Learning-Based Reconstructions in Head and Neck MRI: A Comparative Study (6 min)

Flavia Albisinni; Brescia / Italy

Author Block: F. Albisinni, C. Carbone, M. Ravanelli, D. Farina, G. Corciulo; Brescia/IT
Purpose: This study aimed to evaluate the time-saving potential of deep learning (DL)-based reconstructions in T2-weighted head and neck MRI, while assessing their impact on image quality.
Methods or Background: Fifty-two patients underwent three TSE T2 sequences: (A) standard acquisition without DL (3 signal averages, 2'35"), (B) DL with intermediate strength (2 averages, 1'25"), and (C) DL with maximal strength (1 average, 43"). Images were blindly assessed at two anatomical levels (nasopharynx and oral cavity) by three radiologists of varying experience. Image quality was rated on a 3-point Likert scale across four categories: overall quality, artifacts, edge sharpness, and noise. Readers also attempted to identify the sequence type. Inter-rater agreement and image quality comparisons were analyzed statistically.
Results or Findings: A total of 636 images were evaluated. Acquisition time was reduced by 45% in sequence B and by over 70% in sequence C compared to standard imaging. Despite the substantial time savings, DL-based sequences maintained comparable image quality: overall quality scores for sequences A, B, and C were 2.63, 2.52, and 2.52, respectively ($p = 0.055$). Differences in artifacts and noise were not statistically significant. A minor reduction in edge sharpness was observed between sequences A and B ($p = 0.02$). Inter-rater agreement remained low, and the ability to identify the sequence type was limited (44% accuracy).
Conclusion: Deep learning-based reconstructions enable significant reductions in scan time—up to 70%—in head and neck MRI without compromising diagnostic image quality. These findings highlight DL's potential to support faster, more efficient imaging protocols in clinical practice.
Limitations: This study is limited by low inter-rater agreement, evaluation restricted to T2-weighted images at two anatomical levels, and the absence of diagnostic accuracy analysis.
Funding for this study: This study received no external funding.
Has your study been approved by an ethics committee? Not applicable

The Value of Time-Dependent Diffusion MRI in Nasopharyngeal Carcinoma: Correlation with prognostic factors (6 min)

Haoran Wei; Beijing / China

Author Block: H. Wei, F. Yang, X. Yu, M. Lin, J. Wang, H. Zhang; Beijing/CN
Purpose: To evaluate the correlation between time-dependent diffusion MRI (td-dMRI) parameters and prognostic factors in nasopharyngeal carcinoma (NPC).
Methods or Background: We prospectively enrolled 116 patients (105 NPC, 11 benign hyperplasia). Four td-dMRI-derived microstructural parameters, extracellular diffusivity (Dex), intracellular volume fraction (Vin), Diameter, and Cellularity, along with the apparent diffusion coefficient (ADC) at three oscillation frequencies (ADC0Hz, ADC30Hz, and ADC55Hz), were obtained. TNM stage and prognostic factors including programmed death ligand-1 (PD-L1), epidermal growth factor receptor (EGFR), Ki-67, and Epstein-Barr virus (EBV) related markers were recorded; continuous variables were dichotomized by optimal cut-offs. Correlations, between-group comparisons, and receiver operating characteristic (ROC) analysis summarized diagnostic performance as area under the curve (AUC).
Results or Findings: ADC values correlated with PD-L1, with ADC55Hz achieving an AUC of 0.708. Cellularity and Diameter correlated with EGFR ($r = 0.341$ and -0.329; AUC = 0.740 and 0.730). Dex and ADC55Hz were positively associated with Ki-67 expression ($r = 0.252$ and 0.286). Vin, Cellularity, ADC0Hz, and ADC30Hz were linked to histological subtype, with Vin achieving the highest AUC of 0.706. Diameter ($r = 0.203$ to 0.371) and Cellularity ($r = -0.365$ to -0.284) correlated with TNM stage. ADC30Hz best distinguished NPC (T1–2) from hyperplasia (AUC = 0.847). Negative correlations were observed between several parameters and EBV-based antibodies ($r = -0.269$ to -0.239). Vin, ADC0Hz, and ADC30Hz differed across EBV DNA clearance groups after induction chemoimmunotherapy ($p \leq 0.038$).
Conclusion: td-dMRI parameters reflect tumor microstructure and correlate with prognostic factors in NPC, supporting use in risk stratification and treatment monitoring.
Limitations: The sample size of patients with benign hyperplasia was relatively small, thereby limiting the scope of the analysis.

Sex-Specific Hip and Thigh Muscle Composition in GLP-1RA Users: Automated MRI Phenotyping in the UK Biobank (6 min)

Marjola Thanaj; London / United Kingdom

Author Block: M. Thanaj, B. Whitcher, H. Raza, M. Niglas, C. Bell-Bradford, E. L. Thomas, D. Amiras, J. D. Bell; London/UK
Purpose: Glucagon-like peptide-1 receptor agonists (GLP-1RA) are recommended for treatment of type 2 diabetes (T2D) and obesity, but concerns regarding sarcopenia are reported. We developed automated methods to quantify volume and fat infiltration of 20 hip and thigh muscles, evaluating sex- and GLP-1RA–specific differences.
Methods or Background: UK Biobank participants prescribed with GLP-1RA before the baseline imaging visit (N = 67; mean duration 5.9 ± 2.9 years, range 0.1-12) were matched by sex, age (±1.5 years), BMI (±1.5 kg/m^2), Townsend index (±1.5), T2D, hypertension, cardiovascular disease, muscle disorders, sedentary lifestyle (>10.6 h/day), and cholesterol medication with non-GLP-1RA controls. Sensitivity analyses included dynapenia (handgrip <16 kg women, <27 kg men) and falls (>1). Twenty hip and thigh muscles were segmented from T1w Dixon MRI scans using a deep learning model with MONAI (Medical Open Network for AI) Swin-UNETR architecture. Median fat fraction per muscle group was calculated. Paired t-tests were performed with false discovery rate (FDR) correction.
Results or Findings: In men (N=60), GLP-1RA use showed a higher pectineus fat fraction (mean diff: 0.013, FDR=0.043) and rectus femoris fat fraction (0.018, FDR=0.038), while adductor longus (-42 mL, FDR=0.038), gluteus medius (-67 mL, FDR=0.038), and rectus femoris (-79 mL, FDR=4×10^{-4}) volumes were lower, showing no significant differences in women (N=28). Including dynapenia and falls (44M/20F) eliminated differences in muscle volume and fat fraction.
Conclusion: Our scalable deep learning pipeline shows GLP-1RA–related adductor longus, rectus femoris, and gluteus medius volume reduction and pectineus and rectus femoris fat fraction increase in men, with no differences in women or when including dynapenia and falls. These findings suggest possible sex-specific GLP-1RA effects that require validation in larger cohorts.
Limitations: Small sample size, limited longitudinal data, heterogeneity in GLP-1 exposure, and medication type may restrict interpretation
Funding for this study: No funding was recieved
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Fully anonymised images and participant metadata were obtained through UK Biobank Access Application number 23889. The UK Biobank has approval from the North West Multi-Centre Research Ethics Committee (REC reference: 11/NW/0382), and obtained written informed consent from all participants before the study. All methods were performed in accordance with the relevant guidelines and regulations as presented by the appropriate authorities, including the Declaration of Helsinki.

Decreased Chest CT-Derived Lumbar Skeletal Muscle Mass Associated with Adverse Outcomes in Sepsis Patients: A Multicenter Retrospective (6 min)

Lin Fu; Nanjing / China

Author Block: L. Fu, X-G. Peng; Nanjing/CN
Purpose: While the lumbar skeletal muscle index (SMI) predicts outcomes in sepsis, the significance of its dynamic changes remains unclear. This study evaluated the association between longitudinal changes in CT-derived body composition parameters and clinical outcomes in sepsis.
Methods or Background: We retrospectively included sepsis patients from three tertiary centers. Two non-contrast chest CT scans at the L1 level were analyzed: a baseline scan within 48 hours of diagnosis and a follow-up scan ≥5 days later. Parameters included SMI, skeletal muscle density (SMD), subcutaneous and visceral fat area (SFA, VFA) and density (SFD, VFD). X-tile determined the optimal ΔSMI cutoff for mortality. Patients were classified into high and low skeletal muscle wasting (SMW) groups. Survival was analyzed using Kaplan–Meier and log-rank tests. Cox regression identified mortality-associated factors.
Results or Findings: A total of 561 patients (median age, 69 years; interquartile range, 58–79 years; 378 males) were analyzed. The optimal ΔSMI cutoff for defining high SMW was > 4.04 cm^2/m^2. Patients in the high SMW group had significantly higher 28-day, 3-month, and 1-year mortality Among 561 patients (median age 69; 378 male), the optimal ΔSMI cutoff for high SMW was > 4.04 cm^2/m^2. The high SMW group had significantly higher 28-day (56.5% vs 3.0%), 3-month (82.4% vs 6.8%), and 1-year mortality (88.6% vs 17.4%) (all P<0.001). No other Δparameters correlated with mortality. Multivariate Cox analysis identified ΔSMI, age, Charlson Index, mechanical ventilation, APACHE II, and creatinine as independent predictors. ΔSMI was the strongest predictor (HR: 1.165 per 1 cm^2/m^2 loss; 95% CI: 1.133–1.198; P<0.001).
Conclusion: Longitudinal loss of lumbar muscle mass, quantified by serial CT, independently predicts mortality in sepsis. Monitoring muscle dynamics could enhance risk stratification and guide targeted interventions to improve outcomes.
Limitations: This study requires prospective validation.
Funding for this study: Longitudinal loss of lumbar muscle mass, quantified by serial CT, independently predicts mortality in sepsis. Monitoring muscle dynamics could enhance risk stratification and guide targeted interventions to improve outcomes.

The Body Beneath: CT Body Composition and Its Impact on Transplant Success (6 min)

Giulio Boscaro; Vigonza / Italy

Author Block: G. Boscaro, M. Visoná, S. Silvestrin, D. Trevisani, A. Michielin, E. Faccioli, A. Dell'Amore, R. Stramare, C. Giraudo; Padova/IT
Purpose: To assess the role of CT-based body composition in bilateral lung transplant candidates (BLTc).
Methods or Background: We included BLTc referring to our tertiary center who performed at least one HRCT <18 months before the transplant. The paravertebral muscle and subcutaneous tissue were segmented at the level of the 12th thoracic vertebra to extract density (Hu) and area (cm2); the skeletal muscle index (SMI) was then computed. According to Moon et al, the following SMI thresholds, 7.13cm2/m2 for women and 8.67cm2/m2 for men, were used to define sarcopenia. Using the Spearman correlation coefficient, the relationship between muscle strength, hand-grip test, sarcopenia, muscle density, and area was explored. By the ANOVA for repeated measures any change in body composition over three time points (before the transplant, ≤36 months after the transplant, and ≤48 months after the transplant) was investigated. The logistic regression analysis was used to evaluate if demographics, spirometry metrics, and sarcopenia before the transplant predicted the survival.
Results or Findings: Sixty-two BLTc were included (24 female; average age 53±13 years; 25 died). Twenty-three (37.1%) BLTc were affected by sarcopenia before the transplant. The ANOVA demonstrated a significant decrease of muscle area at first follow-up after BLT (p<0.001). An inverse, significant but moderate correlation emerged between sarcopenia and muscle strength as well as grip test (r=-.310,p=0.014 and r=-.409,p<0.001, respectively) and a positive moderate correlation occurred between muscle area and muscle strength and grip test (r=445,p<0.001 and r=.342,p=0.007). The multivariate logistic regression showed that sarcopenia predicts mortality (p=0.014, 95%CI for sarcopenia 1.523–45.429).
Conclusion: More than a third of BLTc are affected by sarcopenia which may have an impact on the success of the transplant.
Limitations: Single center study.

Simplifying CT-Based Muscle Quality Assessment Using Local Muscle Surrogates: Validation in a Large, Heterogeneous Imaging Cohort (6 min)

Leon David Grünewald; Frankfurt / Germany

Author Block: J. Gotta, L. D. Grünewald, V. Koch, S. Mahmoudi, T. Vogl; Frankfurt am Main/DE
Purpose: Advanced CT-derived body composition metrics are physiologically relevant but computationally demanding. This study aimed to evaluate whether attenuation and volume measurements from individual muscle groups, specifically autochthonous, gluteal, and iliopsoas muscles, can serve as surrogates for established metrics of muscle quality and quantity, including skeletal muscle radiodensity (SMRA), myosteatosis, skeletal muscle area (SMA), and muscle volume.
Methods or Background: In this retrospective analysis of 25,252 abdominal CT scans, attenuation and volume metrics were extracted for the iliopsoas, autochthonous, and gluteal muscles. Generalized additive models (GAMs) were fitted to assess their association with reference myosteatosis metrics, including L3-SMRA, volumetric muscle radiodensity, intramuscular fat proportion, L3-SMA, and volumetric muscle percentage. All predictors were modeled as continuous spline terms, and model performance was evaluated using pseudo R^2 (deviance explained). Laterality was excluded. Relationships were visually assessed for linearity.
Results or Findings: Attenuation of the autochthonous muscles was the strongest surrogate for L3-SMRA ($R^2 = 0.88$), followed by gluteus medius ($R^2 = 0.73$), gluteus maximus ($R^2=0.70$), and iliopsoas ($R^2 = 0.69$). For volumetric abdominal myosteatosis, gluteus maximus HU achieved the highest explained variance ($R^2 =0.59$), followed by autochthonous ($R^2=0.57$), gluteus medius ($R^2=0.54$), and iliopsoas ($R^2=0.43$). Normalized L3-SMA was best predicted by iliopsoas muscle volume ($R^2=0.69$), followed by autochthonous ($R^2 = 0.64$), gluteus medius ($R^2=0.60$), and gluteus maximus ($R^2 = 0.49$). Associations with volumetric muscle percentage were consistently weaker across all compartments ($R^2 \leq 0.35$). All results were statistically significant ($p < 0.001$).
Conclusion: Attenuation metrics of the autochthonous and gluteal muscles are strong linear surrogates for SMRA and myosteatosis, while iliopsoas muscle volume most accurately predicts L3-SMA. These findings suggest that selective muscle-based surrogates can approximate advanced body composition metrics with lower computational cost than full segmentation.
Limitations: Retrospective study

Preoperative Visceral Adipose Accumulation and Skeletal Muscle Density Reduction Predict Adverse Outcomes in Kidney Transplantation: A Prospective Cohort Study (6 min)

Yu Zhang; Chengdu / China

Author Block: Y. Zhang, J. Tang, Z. Li; Chengdu/CN
Purpose: This study aimed to use computed tomography (CT) to assess muscle reduction and adipose deposition and examined the predictive values of those indicators on clinical outcomes after kidney transplantation.
Methods or Background: Abnormal body composition has been widely observed in kidney transplant recipients. However, how muscle reduction and adipose deposition affect the prognosis after kidney transplantation is not fully understood, especially in Chinese population. This prospective study examined a consecutive series of patients who underwent their first kidney transplant at our medical center between June 1, 2020 and June 30, 2023. Within 30 days before surgery, skeletal muscle mass index (SMI), skeletal muscle density (SMD), visceral adipose area index (VAI) and subcutaneous adipose area index (SAI) were evaluated using abdominal computed tomography. Multivariable logistic regression and cox regression were used to explore associations between each index and prognosis in terms of infection, delayed graft function and rejection after kidney transplantation.
Results or Findings: The final analysis included 455 patients (147 women, mean age 34.5 ± 10.18 years), who were followed up for a median of 47.67 (IQR, 34.23 – 51.72) months. In the multivariable Cox regression model, each one standard deviation increase in SMD was associated with a 20% lower risk of urinary tract infections (HR, 0.80; 95% CI, 0.69–0.95; p = 0.008), indicating that patients with lower SMD were at significantly higher risk. Elevated VAI independently predicted lung infections (HR, 1.25, 95 CI%, 1.03-1.52, p = 0.022). Patients with high VAI increased delayed graft function risk 1.44-fold (HR 1.44, 95%CI 1.04-1.98, p = 0.028).
Conclusion: Visceral adipose accumulation and skeletal muscle density reduction before kidney transplantation are independently associated with greater risk of poor prognosis on clinical outcomes after kidney transplantation.
Limitations: This was a single-center study.
Funding for this study: None.

Sarcopenia in patients undergoing vertebroplasty and kyphoplasty: diagnostic definitions and impact on clinical outcomes. Systematic review and meta-analysis (6 min)

Mariachiara Basile; Catania / Italy

Author Block: M. Basile, M. Zanardo, S. Gitto, D. Albano, L. M. Sconfienza; Milano/IT
Purpose: This systematic review and meta-analysis evaluated the impact of sarcopenia on clinical outcomes after percutaneous vertebroplasty (PVP) and kyphoplasty (PKP) in patients with osteoporotic vertebral compression fractures (OVCFs), and examined the heterogeneity in sarcopenia definitions across studies.
Methods or Background: A comprehensive literature search was conducted in PubMed, Embase, and Scopus through June 2025. Eligible studies assessed sarcopenia in OVCF patients treated with PVP or PKP. Extracted data included diagnostic modalities (CT, MRI, DEXA, BIA), anatomical landmarks, muscle indices (skeletal muscle index [SMI], psoas muscle index, psoas-to-lumbar vertebral index, appendicular muscle index), functional parameters (handgrip strength, gait speed), clinical outcomes (refracture, residual low back pain [RBP]), and statistical measures.
Results or Findings: Eighteen studies (3,531 patients; 1,357 sarcopenic) were included. CT was the most frequently employed diagnostic tool (72%), followed by MRI (27%), DEXA (11%), and BIA (0.2%). The most common reference levels were L3 (28%) and T12 (28%). SMI was reported in 7 studies (38%), with cut-off values ranging from 29–30.6 cm^2/m^2 in males and 36–42.6 cm^2/m^2 in females. Six studies (33%) assessed functional parameters, while only three (17%) fully adhered to EWGSOP2 criteria. Pooled analysis demonstrated that sarcopenic patients had a markedly higher risk of refracture (HR 3.61; 95% CI 2.49–5.23; $p<0.05$) and an increased likelihood of RBP (OR 2.78; 95% CI 1.50-5.00).
Conclusion: Sarcopenia significantly worsens outcomes after PVP and PKP in OVCF patients. Adoption of a standardized diagnostic framework—integrating CT-based muscle mass quantification (particularly SMI at T12), muscle strength (handgrip), and physical performance (gait speed)—is recommended to enhance risk stratification. Tailored management strategies for sarcopenic patients may improve postoperative outcomes.
Limitations: Heterogeneity in sarcopenia definitions, the predominance of retrospective study designs, and limited generalizability underscore the need for further prospective, standardized, multicenter studies.

Sarcopenia in patients with colorectal carcinoma undergoing chemotherapy (6 min)

Daniel Vogele; Ulm / Germany

Author Block: D. Vogele, S. Waibel, K. Mueller, T. Ettrich, M. J. Beer; Ulm/DE
Purpose: Sarcopenia is associated with poor oncologic outcomes, increased risk of falls, hospitalization, and reduced quality of life. However, diagnostic approaches remain heterogeneous. This study evaluated a simple radiological method for sarcopenia detection in colorectal cancer patients using routine staging CT scans, and assessed its prognostic relevance. The role of radiomic features combined with machine learning for diagnosing sarcopenia and predicting tumor progression was also analyzed.
Methods or Background: CT scans of 57 rectal and 46 sigmoid carcinoma patients undergoing chemotherapy were retrospectively reviewed. At the third lumbar vertebra, muscle areas of the psoas major, quadratus lumborum, erector spinae, and rectus abdominis were measured. The Psoas Muscle Index (PMI) was calculated as psoas muscle area/$height^2$. Sarcopenia was defined using Bahat et al. cut-offs. Tumor response was assessed by RECIST at diagnosis (T1) and after 9 months (T3). Sex and tumor entity differences were evaluated. Radiomic features of skeletal muscles were extracted, and feature selection performed by lasso regression to train a neural network.
Results or Findings: Psoas muscle assessment yielded high imaging quality in 97.7% of cases; unilateral and bilateral measures were equivalent ($p=0.064$). Low PMI showed a non-significant trend toward predicting progressive disease (PD) in univariate regression (OR=0.79; $p=0.07$), but not in multivariate analysis (OR=1; $p>0.5$). No association was observed between PMI and PD-free survival. Machine learning achieved 0.71±0.08 accuracy (AUC=0.79±0.07) for sarcopenia detection, but only 0.63±0.04 (AUC=0.66±0.06) for PD prediction.
Conclusion: The psoas muscle is a simple, reproducible CT marker for sarcopenia in colorectal cancer. Although PMI was not an independent predictor of PD, a protective trend was observed. Machine learning showed promise for sarcopenia detection but limited value for predicting progression. Larger prospective studies are warranted.
Limitations: Small cohort (n=103), retrospective design, single measurement timepoint
Funding for this study: None

Associations of gestational diabetes mellitus and reduced skeletal muscle quality in premenopausal women assessed using texture analysis of quantitative magnetic resonance imaging (6 min)

Yannick Stohldreier; Munich / Germany

Author Block: Y. Stohldreier[1], M. Dieckmeyer[2], O. Dietrich[1], S. Schläger[1], J. Seißler[1], U. Ferrari[1], N. Hesse[1], A. Gersing[1]; [1]Munich/DE, [2]Bern/CH
Purpose: To evaluate associations between metabolic status and proton density fat fraction (PDFF) and second-order texture features of vertebral bone marrow (VBM) and autochthonous (AM) and psoas muscles on magnetic resonance imaging (MRI) in premenopausal women with and without recent gestational diabetes mellitus (GDM).
Methods or Background: Thirty-six premenopausal women (GDM, n=19; healthy controls (HC), n=17; mean age, 36.3±3.9 years) underwent MRI at 11.0±2.4 months postpartum. Multivariable logistic regression models adjusting for age and BMI were used to assess associations between GDM and metabolic-syndrome parameters (triglycerides, HDL, waist circumference, fasting plasma glucose and blood pressure) and differences in muscle and bone marrow quality, measured using texture analysis of PDFF maps.
Results or Findings: PDFF values of the thoracic (PDFF T9-12) and lumbar (PDFF L1-4) VBM were significantly higher in the GDM group compared to HC (PDFF T9-12 41.6±12.3% vs. 33.9±7.6%, p=0.03; PDFF L1-4 46.7±12.4% vs. 39.5±8.1%, p<0.05), whereas AM and psoas showed no significant PDFF difference (p>0.05). After adjustment for age and BMI, PDFF of VBM was significantly associated with GDM status (PDFF T9-12 p=0.02; PDFF L1-4 p=0.03). In addition, several muscle second-order texture features also remained associated with GDM status (dissimilarity AM (OR 4.30 [95% CI 1.61, 16.78], p=0.01), homogeneity AM (OR 0.26 [95% CI 0.07, 0.63], p=0.01), dissimilarity psoas (OR 3.98 [95% CI 1.57, 14.25], p=0.01) and homogeneity psoas (OR 0.29 [95% CI 0.09, 0.71], p=0.01)), indicating a reduced muscle quality in GDM patients.
Conclusion: Women with recent GDM exhibit more heterogenous paraspinal skeletal muscle tissue after adjusting for age and BMI, suggesting a reduced muscle quality in patients with GDM compared to healthy controls, which indicates that muscle PDFF may be a useful biomarker for muscle health in patients with metabolic impairment.
Limitations: Retrospective monocentric study.

Using vision transformer to classify sarcopenia severity on two-dimensional magnetic resonance images of the foot in patients with diabetic foot disease (6 min)

Manal Ahmad; London / United Kingdom

Author Block: M. Ahmad, D. Amiras, J. Shalhoub, A. Davies, A. G. Rockall; London/UK
Purpose: Vision transformer (ViT) is a recent development in the world of deep learning models (AI) and is an alternative to existing convolutional neural networks. ViTs aim to classify, detect and segment images. Diabetic foot disease (DFD) is a complex disease and is associated with lower limb amputation. Magnetic resonance imaging (MRI) is commonly used in patients with DFD. Our aim was to explore the use of deep learning models to identify predictors on MRI for limb loss in patients with DFD by using sarcoepenia as a potential surrogate marker by stratifying the extent of sarcopenia on MRI images of the foot.
Methods or Background: Two-dimensional images of the foot at the base of the 1st metatarsal were classified as having mild, moderate or severe sarcopenia. A subset of 50 images were also graded by a musculoskeletal radiologist to establish the inter-rater reliability. 824 images were annotated. Following data pre-processing and data augmentation, 1740 images were available for the deep learning models which were split into a 70:20:10 ratio for training:validation:testing. A ViT model was applied to classify the images as mild, moderate or severe.
Results or Findings: The inter-rater reliability was 0.827 [95% CI 0.726-0.928; p-value <0.001]. ViT had an accuracy of 78.7% with an F1 score of 79.9% in classifying sarcopenia severity on two-dimensional MRI pictures. The model had a high precision (81.5%) and recall (78.7%). The confidence threshold could be set to 51% without any deterioration in the model's performance.
Conclusion: ViT is a useful deep learning model in classifying the severity of sarcopenia in patients with diabetic foot disease.
Limitations: Further external validation is required to test the robustness of the model on different datasets.

CT-based Body Adipose Mass Quantification and Correlation with MRI-based Meniscal Tears (6 min)

Hasan Abbasguliyev; Muğla / Turkey

Author Block: H. Abbasguliyev[1], A. Yalçın[2], M. S. ATEŞ ÇETİN[2], F. Alper[2]; [1]Muğla/TR, [2]Erzurum/TR
Purpose: This study aimed to quantify intra-abdominal visceral adipose tissue (VAT) using CT and assess its relationship with BMI. Additionally, we evaluated the association between meniscal damage on knee MRI and both BMI and intra-abdominal fat, while also testing the reproducibility of automated fat quantification.
Methods or Background: From January 2010 to December 2023, patients who underwent abdominal CT and also had knee MRI within one year were retrospectively identified. BMI values were classified into four groups (underweight, normal, overweight, obese). Meniscal signal changes on T2WI were graded in five stages (1, 2a, 2b, 2c, 3). Subcutaneous adipose tissue (SCAT) and VAT volumes were calculated using 3D Slicer software. Correlations between BMI, SCAT, VAT, and meniscal damage were analyzed ($p < 0.05$).
Results or Findings: Forty-one patients were included (21 men, 20 women; mean age 30 ± 9 years; mean BMI 25.9 ± 4.6). Mean SCAT volume was 260.31 ± 145.74 and VAT volume 315.74 ± 226.96. VAT showed a negative correlation with BMI ($r = –0.3$, $p = 0.01$), while SCAT did not ($r = 0.2$, $p = 0.8$). Medial meniscus damage correlated strongly with BMI ($r = 0.7$, $p = 0.01$), but not with SCAT. Lateral meniscus damage showed no significant association with BMI, SCAT, or VAT ($p = 0.6, 0.8, 0.8$, respectively).
Conclusion: This study demonstrates a novel link between VAT, BMI, and medial meniscus damage. Automated VAT quantification shows promise as a reproducible index, warranting larger studies to clarify its potential as a complement to BMI.
Limitations: The retrospective design required exclusion of patients with motion artifacts on knee MRI or abdominal CT, as well as those failing to meet at least one inclusion criterion.

Reliability of ultrasound measurements of upper arm muscle thickness in relaxed and maximally contracted states, and their relationship to strength (6 min)

Michel PAVOŠEV; Ljubljana / Slovenia

Author Block: M. PAVOŠEV[1], D. Wieman[2], J. Menzinga[2], C. Chimbunde[3], F. Ernst[4], L. Sardinha[5], G. D. J. Colombo[6], C. D' Helft[7]; [1]Ljubljana/SI, [2]Groningen/NL, [3]Bloemfontein/ZA, [4]Cormondrèche/CH, [5]Lisbon/PT, [6]Milan/IT, [7]Dublin/IE
Purpose: Ultrasound (US) assessment of muscle thickness might be a safe and accessible method for the evaluation of sarcopenia. US can reliably measure muscle thickness during relaxation, but its functional meaning is limited. Therefore, this study investigates whether US-measured upper arm muscle thickness during contraction, incorporating neuromuscular activation, can also be assessed reliably, and how it is correlated to strength across physical activity levels and arm dominance.
Methods or Background: Twenty-four subjects completed a digital survey capturing demographics, sporting habits and arm dominance. US and maximal isometric strength measurements were taken respectively by the SonoScape Doppler E2 and MicroFET2 dynamometer, in Fowler's position with the arm stabilized in ~135° elbow flexion. Reliability was assessed using the intraclass correlation coefficient (ICC). Correlations were computed for the relaxed and contracted state between muscle thickness and strength for the entire study population, and subgroups based on physical activity level and arm dominance.
Results or Findings: ICC values indicated good to excellent intra-observer (>0.837) and inter-observer (>0.781) reliability in both relaxed and contracted states. Significant correlations ($p<0.001$) between muscle thickness and strength were observed: $rs=0.737$ (relaxed) and $rs =0.748$ (contracted). In the low-to-moderate activity group ($n=15$), correlations were respectively $rs =0.829$ and $rs =0.850$. No significant correlations were found in the high activity group ($n=9$). For arm dominance ($n=21$), significant correlations ($p<0.001$) were found for both dominant and non-dominant arms: $rs =0.748$ and $rs =0.700$ (relaxed), $rs =0.670$ and $rs =0.778$ (contracted).
Conclusion: Upper arm muscle thickness can be reliably measured using US in both relaxed and contracted states, and shows strong correlation with strength.
Limitations: Population size is limited and age is unevenly distributed, consisting mainly of young adults.
Funding for this study: No funding was received for this study.

Muscle Fat Content Outperforms Fat Volume in Predicting History of Back Pain in German Population (6 min)

Paul Platzek; Munich / Germany

Author Block: P. Platzek, R. Graf, J. S. Kirschke, J. H. W. Bodden; Munich/DE
Purpose: Paraspinal intramuscular fat content is associated with chronic low back pain (CLBP). This study explores the relationship between paraspinal muscle fat infiltration, subcutaneous (SAT), and visceral adipose tissue (VAT) with CLBP using MRI data from the NAKO database.
Methods or Background: Fully automated whole-body segmentations were obtained in all NAKO MRI datasets using an in-house developed segmentation framework. Paraspinal muscle (erector spinae medialis (ESM) and lateralis (ESL), psoas major (PS), and quadratus lumborum (QL)) proton density fat fraction (PDFF, ‰) values were extracted and SAT and VAT volumes (cm3) were obtained. PDFF, SAT and VAT were assessed as standard deviation from the cohort mean. Multivariate logistic regression models were used to investigate associations between SAT, VAT, muscle PDFF, and self-reported CLBP (no CLBP; low, medium, or high CLBP), adjusted for age, weight, and height.
Results or Findings: VAT and SAT were measured in 24,634, and PDFF in ≥22,875 participants. Higher intramuscular fat was associated with greater odds for any degree of CLBP, and chances increased with CLBP severity (low CLBP: OR=1.09-1.22; medium CLBP: OR=1.08-1.28; high CLBP: OR=1.14-1.36; $p < .001$). PDFF of ESM, ESL, and QL further distinguished participants with non-CLBP (duration <3 months) (OR ≥1.07, $p \leq .001$). In contrast, VAT and SAT (p=0.34 and 0.72) were not associated with significantly increased odds for CLBP and VAT was negatively associated with CLBP duration <3 months (OR=0.89, p=0.001).
Conclusion: Paraspinal muscle PDFF predicted CLBP presence and severity, while VAT and SAT did not. Results withstood adjustments for age, height, and weight.
Limitations: Due to fat-water swaps, PDFF measurements were not available in a minority of participants. It remains unclear whether CLBP promotes intramuscular fat accumulation or if intramuscular fat itself contributes to pain and instability.

Automated muscle compartment volume assessment: a deep learning approach on whole-body Dixon MRI (6 min)

Charles Jean Marie Louis Edeline; Lausanne / Switzerland

Author Block: C. J. M. L. Edeline, P. Margain, P. Omoumi; Lausanne/CH
Purpose: Assessing muscle volume is crucial for understanding how training, aging, immobilization, and disease affect muscle health. Whole-body Dixon MRI enables robust tissue characterization, but manual segmentation for volume estimation is time-consuming. This study developed and evaluated a deep learning model for automated volume estimation of nine thigh and leg muscle compartments, assessing accuracy versus manual labels and test–retest repeatability.
Methods or Background: Nine compartments were analyzed: posterior, anterior, and medial thigh; sartorius; gluteal muscles; and superficial posterior, deep posterior, anterior tibial, and lateral tibial leg compartments. Whole-body Dixon MRI (1.95×1.95×4.00 mm; ~5 min) from 21 asymptomatic participants (12 males, 9 females; 44.2 ± 16.9 y; BMI 22.3 ± 2.5 kg/m²) from the Lausanne Knee Study were used. Manual segmentations were created on four sequences (fat-sat, water-sat, in-phase, out-of-phase). A 3D U-Net trained on in-phase images with five-fold cross-validation was evaluated for accuracy (MAE, Pearson r) and scan–rescan repeatability; test–retest metrics (ICC and coefficient of variation [CV]) were computed on n = 9 scans.
Results or Findings: High accuracy was observed, with mean absolute errors (MAE) of 4.4–30.4 cm³ (1.1–6.3% of mean volume). Pearson correlations exceeded 0.95 for most compartments ($p < 0.001$). Test–retest repeatability (n = 9 scans) was excellent: ICC = 0.98–0.99 and CV = 0.33–1.75% across the nine compartments.
Conclusion: A 3D U-Net can accurately and repeatably quantify muscle compartment volumes on whole-body Dixon MRI. The combination of high accuracy and excellent reliability supports application in large-scale cohorts and longitudinal or clinical studies, pending external validation.
Limitations: Limitations include data derived from a single center and a single protocol, as well as the use of an asymptomatic cohort. Therefore, the model should be validated in participants with relevant conditions, such as sarcopenia.

Assessment of Sarcopenia and Body Composition Using Low-Dose CT from PET-CT (6 min)

Ashraf Ahmed Basheer Ahmed; Melmaruvathur / India

Author Block: F. Abubacker Sulaiman, A. A. Basheer Ahmed; Chennai/IN
Purpose: To evaluate the feasibility of assessing sarcopenia and body composition using low-dose CT (LDCT) data obtained from routine ^18F-FDG PET/CT scans and to correlate these measurements with clinical parameters and treatment outcomes in oncologic patients.
Methods or Background: A prospective study was conducted on 70 patients who underwent whole-body ^18F-FDG PET/CT for staging or response assessment. Cross-sectional muscle and fat areas were analyzed at the third lumbar vertebral (L3) level using LDCT images reconstructed from PET/CT datasets. Skeletal muscle index (SMI), visceral fat area (VFA), and subcutaneous fat area (SFA) were quantified using semi-automated segmentation software. Sarcopenia was defined using established sex-specific SMI cutoffs. Associations between SMI, BMI, serum albumin, and treatment response were statistically analyzed using Pearson's correlation and regression models.
Results or Findings: Sarcopenia was identified in 32 patients (45.7%), predominantly among older and low-BMI individuals. Mean SMI values showed strong correlation with serum albumin levels ($r = 0.72$, $p < 0.001$) and moderate correlation with treatment response on follow-up PET/CT ($r = 0.64$, $p < 0.01$). Patients with sarcopenia exhibited higher incidence of adverse events and poorer metabolic response. LDCT-based measurements were reproducible, with excellent interobserver agreement (ICC = 0.92). Radiation dose from LDCT did not exceed 2.5 mSv per scan.
Conclusion: Low-dose CT from routine PET/CT provides a reliable, opportunistic tool for assessing sarcopenia and body composition without additional imaging or radiation exposure, adding valuable prognostic information in oncology.
Limitations: Single-center design, limited sample size, and absence of longitudinal survival analysis. Larger multicentric studies are warranted for validation.
Funding for this study: No external funding was received for this study.

White Matter Integrity Drives Bilateral Differences and Dynamic Evolution of the Glymphatic System After Intracerebral Hemorrhage: A Prospective Longitudinal Cohort Study (6 min)
Sihui Wang; Beijing / China

Author Block: S. Wang[1], H. Li[2], Y. Zhang[1], S. Sun[1], Y. Ju[1]; [1]Beijing/CN, [2]Shanghai/CN
Purpose: To investigate the dynamic evolution of glymphatic function after spontaneous intracerebral hemorrhage, including interhemispheric differences, and to determine the driving role of white matter microstructural integrity in these changes.
Methods or Background: This prospective longitudinal cohort study enrolled 78 patients with ICH, each undergoing MRI at 3 days, 14 days, and 30 days post-ictus. Linear mixed-effects models were applied to analyze the longitudinal trajectory of the ALPS index between affected and unaffected hemispheres. Fixed effects included time, hemisphere, and their interaction, while covariates included white matter microstructural parameters (fractional anisotropy FA, mean diffusivity MD). Spearman correlation analyse was used to assess the relationship between the ALPS index and peri-hematomal edema volume.
Results or Findings: (1) Significant interhemispheric difference in ALPS index was observed post-ICH ($P < 0.011$). This difference became non-significant after adjusting for FA and MD ($P = 0.662$), indicating white matter microstructure as the primary underlying factor.
(2) A significant time-by-side interaction was found ($P = 0.027$). Affected hemisphere ALPS index rebounded after a 14-day nadir, unlike the unaffected side's steady increase.This pattern remained significant after covariate adjustment.
(3) The ALPS index in the affected hemisphere negatively correlated with peri-hematomal edema volume at 14 days ($R = -0.327$, $P = 0.035$) and 30 days ($R = -0.461$, $P = 0.018$). This correlation disappeared after adjusting for FA and MD.
Conclusion: Our findings demonstrate that white matter microstructure is a key driver of dynamic glymphatic function evolution after ICH. The ALPS index should be interpreted as a composite biomarker that integrates both the structural basis of white matter and fluid transport function, rather than merely a functional metric.
Limitations: This study focuses on system-level interactions. Future work should longitudinally correlate glymphatic function metrics with detailed neurological scores.
Funding for this study: This study was supported by the National Natural Science Foundation of China (No.82371939).
Has your study been approved by an ethics committee? Yes

Evaluation of the Ocular Glymphatic System and Optic Nerve in Humans Using Magnetic Resonance Imaging (6 min)
Mert Can; Ankara / Turkey

Author Block: M. Can, A. Karaosmanoğlu, R. Göçmen, N. P. Acar Özen, M. A. Tuncer, G. F. Yavaş, I. Koç, A. I. Colpak Işıkay, E. Gümeler; Ankara/TR
Purpose: We aimed to determine whether an ocular glymphatic pathway exists on magnetic resonance imaging (MRI) and how it relates to ocular findings.
Methods or Background: Twelve healthy volunteers (age 24–52) with 23 normal fundoscopic exams were prospectively enrolled. MRI was performed with 3 T MR scanner (GE SignaTM Architect) with 48 channel head coil. Heavily T2-weighted 3D Fluid attenuated inversion recovery (FLAIR) sequence (TR/TE/TI: 9000/520/2250 ms) was used to detect subtle signal intensity (SI) changes. Three subjects were scanned at baseline and at 4, 8, 12, 18, and 24 hours following IV gadobutrol (1.0 mmol/mL) to evaluate contrast clearance from the optic nerve (ON) sheath. Based on these results, the remaining subjects were scanned at 0, 4, and 18 hours (figure 1). Subtracted images were generated (baseline vs. post-injection) using SPM25 after normalization and coregistration. SI volume in the ON sheath was semi-automatically measured. We measured enhanced volume from subtracted image of baseline from 4th hour and residual volume from subtracted image of baseline from 18th hour. We calculated clearance volume and ratio of clearance with this information (figure 2). We performed Spearman's correlation analysis between age, intraocular pressure (IOP), retinal nerve fiber layer (RFNL) thickness and these measurements.
Results or Findings: Correlation analysis revealed a significant negative correlation between IOP and clearance volume (r=-.575, p=0.004) and clearance ratio (r=-.549, p=0.007). No correlation was found with age or RNFL thickness.
Conclusion: Our findings support the presence of a bidirectional ocular glymphatic system in humans, modulated by IOP and the intraocular–intracranial pressure gradient. While existing literature contains limited evidence for a similar pathway in humans, our preliminary findings provide the first obvious demonstration of this correlation in a human cohort.
Limitations: Intracranial pressure, concentration of contrast media not available

Enlarged choroid plexus drives longitudinal hippocampal atrophy (6 min)

Kentaro Yuba; Kyoto / Japan

Author Block: K. Yuba[1], K. Watanabe[1], N. Kuriyama[2], E. Ozaki[1], D. Matsui[1], Y. Marunaka[1], K. Akazawa[1], K. Hayakawa[1], K. Yamada[1]; [1]Kyoto/JP, [2]Shizuoka/JP
Purpose: The glymphatic system is a brain-wide clearance pathway for metabolic waste. Although dysfunction of this system has been implicated in neurodegenerative disorders, its long-term impact on brain structure remains unclear. The choroid plexus (CP) is thought to play a critical role in glymphatic function. Enlargement of CP has been reported in Alzheimer's disease and mild cognitive impairment, suggesting a link with CP dysfunction. We hypothesized that CP dysfunction is associated with subsequent hippocampal atrophy, given the hippocampus is a key structure for memory and spatial cognition. This study aimed to investigate whether baseline CP volume predicts longitudinal hippocampal volume change.
Methods or Background: We analyzed 154 community residents (median age, 67 years; 64% male) from a brain health check-up program who underwent 1.5-T MRI at baseline (2012-2013) and follow-up (2018-2019), after excluding those scoring <27 on the Mini-Mental State Examination (MMSE) to restrict the sample to cognitively normal individuals. Three-dimensional T1-weighted images were processed using the Sequence Adaptive Multimodal SEGmentation tool implemented in FreeSurfer (v7.3.2). Linear regression models were applied to assess the association between baseline CP volume and hippocampal volume loss over six years, adjusting for age, sex, intracranial volume, and MMSE.
Results or Findings: Baseline CP volume was a significant predictor of hippocampal volume loss over the subsequent six years ($\beta = -0.05$, $p < 0.01$) after adjustment for covariates, with CP showing a significant increase and hippocampal a significant decrease during this period.
Conclusion: In cognitively normal older adults, larger CP volume at baseline was linked to subsequent hippocampal atrophy over six years. These findings suggest that impairment in the glymphatic system may contribute to accelerated hippocampal atrophy.
Limitations: CP volume increase may reflect other factors such as inflammation and immunity, warranting further study.
Funding for this study: No funding.

White matter hyperintensity-associated iron overload links glymphatic system dysfunction to cognitive impairment in cerebral small vessel disease (6 min)

Yage Qiu; Shanghai / China

Author Block: Y. Qiu, Y. Hu, Q. Fu, W. Hu, Y. Wang, Q. Xu, Y. Dai, Y. Sun, Y. Zhou; Shanghai/CN
Purpose: Glymphatic dysfunction is implicated in cognitive impairment in cerebral small vessel disease (CSVD). Iron overload within white matter hyperintensity (WMH), indicating metabolic abnormalities, may be a key mechanism underneath. This study aimed to investigate the relationships between WMH iron burden, glymphatic function, and cognition in CSVD.
Methods or Background: A total of 102 patients with CSVD and 29 matched healthy controls (HCs) were enrolled. WMH iron burden was quantified using the sub-voxel approach iterAtive magnetic suscePtibility sources sepARaTion Quantitative Susceptibility Mapping (APART-QSM), and glymphatic function was assessed with the Diffusion Tensor Image Analysis aLong the Perivascular Space (DTI-ALPS) index. Correlation and mediation analyses were performed.
Results or Findings: CSVD patients exhibited higher WMH iron burden, lower DTI-ALPS index, and poorer cognitive performance than HCs. Elevated WMH iron burden was associated with deficits in attention-executive (att-exe), memory, and visual-spatial domains, whereas reduced DTI-ALPS index correlated with impaired att-exe and memory function. More importantly, WMH iron burden fully mediated the link between DTI-ALPS index and both att-exe and memory function in CSVD patients.
Conclusion: These findings non-invasively identify WMH iron overload, a probable representative of microglial activation, as a critical mediator between glymphatic dysfunction and cognitive decline in CSVD, prompting a potential therapeutic target.
Limitations: The limitations of the study are as follows. First, the DTI-ALPS index is an indirect measure of glymphatic flow and does not quantify clearance efficiency directly; future multimodal imaging could provide a more holistic assessment. Second, in some subjects, regions of interest for DTI-ALPS were shifted to avoid WMH, which may introduce bias by excluding areas of potential glymphatic dysfunction. Third, future studies using habitat analysis and longitudinal designs are needed to clarify the spatiotemporal dynamics of iron deposition.

The association of Choroid Plexus volume with Clinical Status of Parkinson's Disease (6 min)

Omer Cetin; Istanbul / Turkey

Author Block: B. Atalay, O. Cetin, M. Gezgin, M. B. Doğan, H. Yıldız, F. B. Ozdilek; Istanbul/TR
Purpose: The choroid plexus, which regulates cerebrospinal fluid dynamics and contributes to the glymphatic clearance system, has been implicated in neurodegenerative processes. This study aimed to investigate the association between the choroid plexus volume (CPV), and clinical status of Parkinson's disease (PD).
Methods or Background: We retrospectively analyzed 57 patients with PD, and 45 controls who underwent brain MRI. CPV was manually segmented using ITK-SNAP on T1-weighted FSPGR images and normalized to intracranial volüme (ICV), which was calculated using volBrain software. Clinical parameters included Mini Mental State Examination (MMSE), Unified Parkinson's Disease Rating Scale (UPDRS), Hoehn and Yahr (HY) scale, disease duration, and levodopa equivalent daily dose (LEDD). Group comparisons were conducted using Mann–Whitney U, and chi-square tests where appropriate. Correlation analyses were performed using Spearman's test.
Results or Findings: Mean CPV was 27.6±4.2 cm3 in patients and 28.5±7.2 cm3 in controls ($p = 0.68$). Within the Parkinson's cohort, CPV and CPV/ICV showed significant negative correlations with MMSE ($r = –0.38$, $p = 0.01$; $r = –0.45$, $p = 0.01$, respectively). Conversely, positive correlations were observed with UPDRS-III ($r = 0.30$, $p = 0.03$; $r = 0.27$, $p = 0.04$, respectively) and HY stage ($r = 0.32$, $p = 0.02$; $r = 0.33$, $p = 0.02$, respectively). CPV was also negatively correlated with LEDD ($r = –0.31$, $p = 0.03$). Furthermore, CPV was significantly higher in patients with dementia (2.18 ± 0.65) compared to those without dementia (1.53 ± 0.70; $p = 0.01$).
Conclusion: CPV correlates with cognitive and motor symptoms severity in PD, highlighting its potential as an imaging biomarker of disease progression.
Limitations: The retrospective design, use of manual segmentation, and absence of longitudinal data limit causal interpretation.

Glymphatic MRI Indices and Cognitive Function in Patients with Tuberculous Meningitis: A Longitudinal Study (6 min)

Yilin Wang; Beijing, China / China

Author Block: Y. Wang, D. Hou; Beijing, China/CN
Purpose: Tuberculous meningitis (TBM) is a severe central nervous system infection frequently associated with cognitive impairment, while the underlying mechanisms remain unclear. Glymphatic dysfunction has been implicated in cognitive decline, but its role in TBM has not been fully elucidated. This study aimed to investigate MRI-derived perivascular network alterations in TBM patients with and without mild cognitive impairment (MCI) and to examine their associations with neuropsychological performance.
Methods or Background: A total of 123 participants were enrolled, including 61 healthy controls (HCs), 30 TBM patients without mild cognitive impairment (TBM-nonMCI), and 32 TBM patients with MCI (TBM-MCI). All subjects underwent 3D T1-weighted and DTI sequences as well as comprehensive neurocognitive assessments. MRI metrics included perivascular spaces (PVS), choroid plexus volume (CPV), and the ALPS index. Group comparisons, partial correlation analyses, and mediation analyses were performed.
Results or Findings: TBM-MCI patients showed significantly reduced ALPS indices compared with HCs ($p<0.01$). Both TBM subgroups demonstrated increased CPV ($p<0.001$), while hippocampal PVSVF was reduced ($p<0.05$). The ALPS index correlated positively with information processing speed and negatively with executive function, while hippocampal PVSVF correlated positively with global cognition, processing speed, and verbal fluency. Conversely, CPV correlated negatively with MMSE, MoCA, and SDMT. Mediation analysis indicated CPV partially mediated the associations between ALPS and cognition. ROC analysis revealed the right ALPS index effectively distinguished TBM-MCI (AUC=0.719), while the left ALPS index predicted cognitive outcome after treatment (AUC=0.857).
Conclusion: Cognitive impairment in TBM is associated with glymphatic dysfunction, particularly involving ALPS and CP alterations. The ALPS index may serve as a promising biomarker for cognitive prognosis and a potential therapeutic target in TBM-related cognitive impairment.
Limitations: The study was single-centred with a limited sample size, and further research is needed to confirm these findings.
Funding for this study: This research was funded by the National Natural Science Foundation of China (No. 82271962) and the Capital's Funds for Health Improvement and Research (No.2024 2-2162).
Has your study been approved by an ethics committee? Yes

Ultra–High–In-Plane–Resolution 2D T2-Weighted Imaging at 5T Compared to 3T: Visualization of Enlarged Perivascular Spaces (6 min)

Jiaming Lu; Nanjing / China

Author Block: J. Lu[1], X. Zhang[1], Y. Wang[2], R. Tang[2], B. Zhang[1]; [1]Nanjing/CN, [2]Shanghai/CN
Purpose: To compare PVS visualization and quantification between 3T and 5T ultra–high in-plane resolution 2D T2-weighted imaging, and to examine associations with glymphatic-related diffusion and volumetric metrics, as well as behavioral measures.
Methods or Background: From September 2025 to May 2025, 36 healthy adults (mean age ± SD, 26.6 ± 3.3 years; 12 men) underwent same-day 3T and 5T brain MRI, including 2D T2-weighted imaging, 3D T1-weighted imaging, and multi-shell diffusion prospectively. PVS were segmented from Enhanced PVS Contrast images, and five morphological metrics (volume, volume fraction [VF], diameter, solidity, length) were extracted for whole brain, basal ganglia, and hemispheric regions. Associations with free water fraction (FWF), ALPS index, choroid plexus volume (CPV), and clinical scales (HAMA, BMI, PSQI) were evaluated. Paired t-tests and interaction models were applied.
Results or Findings: Median qualitative PVS visualization scores were higher at 5T versus 3T (5.0 vs 3.0, P<.001). Quantitatively, 5T imaging yielded increases of 49.5% in PVS volume, 37.2% in VF, 5.6% in diameter, 14.5% in solidity, and 14.5% in length (all P<.001). 5T-derived PVS metrics showed stronger associations with FWF, ALPS index, and CPV (R^2 up to 0.41) than 3T (R^2 < .01), with significant field strength interactions (P = .032). Only 5T detected significant correlations between PVS morphology and behavioral measures, including HAMA, BMI, and PSQI.
Conclusion: 5T MRI substantially improves PVS visualization and quantification compared with 3T, enabling stronger detection of structural–functional coupling and behavioral associations relevant to glymphatic function.
Limitations: This study is limited by its focus on healthy young adults, the limited availability of 5T MRI systems, and its cross-sectional design, which precludes causal inference. These factors may restrict generalizability and immediate clinical translation.

Alterations in Cortical Structural Networks and Imaging–Transcriptomic Mechanisms in Cerebral Small Vessel Disease Patients with Mild Cognitive Impairment (6 min)

Min Xu; Wuxi / China

Author Block: M. Xu, H. Mao, J. Yang, M. Li, Q. Gao, Y. Shi, L. Ma, F. Wang, X. Fang; Wuxi/CN
Purpose: To investigate alterations in cortical individualized structural networks and their molecular basis in patients with cerebral small vessel disease and mild cognitive impairment (CSVD-MCI), using a multi-modal imaging–transcriptomic approach, and to compare the identified molecular signatures with peripheral blood transcriptomic profiles.
Methods or Background: T1-weighted images were processed with FreeSurfer to extract five cortical morphological features and construct individualized structural networks. Regional group differences were assessed, followed by spatial transcriptomic analysis using Allen Human Brain Atlas data and partial least squares (PLS) regression. Significant genes were identified by bootstrap and FDR correction. Functional enrichment and cross-system comparisons were performed with peripheral blood RNA-seq.
Results or Findings: In this prospective study, 245 CSVD patients (152 NCI, 93 MCI) underwent neuropsychological testing and MRI. Compared with the NCI group, MCI patients showed significantly lower whole-brain mean MIND values ($p = 0.002$) and regional reductions across 90 cortical regions, mainly in the frontal, parietal, temporal, insular, and cingulate cortices. Network analyses showed pronounced decreases in default mode and dorsal attention networks ($p < 0.005$). PLS1 explained the strongest spatial covariance ($\rho = 0.397$, $p\_spin < 0.001$), identifying 860 positively and 594 negatively weighted genes. Enrichment analyses indicated positive weights for ion transport and synaptic signaling, and negative weights for protein translation and MAPK regulation. Overlapping pathways were observed with peripheral blood profiles.
Conclusion: CSVD-MCI involves widespread cortical network reorganization with distinct transcriptional signatures, partially mirrored in peripheral blood, supporting their potential as molecular markers of cognitive impairment. These findings highlight a novel cross-system molecular link, offering opportunities for early risk stratification and targeted interventions.
Limitations: Cross-sectional design and reliance on postmortem transcriptomic data may limit causal inference.

Baseline QSM Metrics as Predictors of Cognitive Decline in Cerebral Small Vessel Disease (6 min)

Yuwei Hao; Beijing / China

Author Block: Y. Hao[1], X. Fan[1], E. Li[2], H. You[1], Y. Zhu[1], F. Feng[1]; [1]Beijing/CN, [2]Shanghai/CN
Purpose: Cerebral small vessel disease (CSVD) is associated with microstructural changes in subcortical gray matter that relate to cognitive performance, with potential regional heterogeneity across subregions. This study investigates the predictive value of baseline quantitative susceptibility mapping (QSM) metrics for cognitive function in patients with CSVD
Methods or Background: From September 2022 to June 2025, a prospective cohort of 248 participants [90 with mild CSVD vs 108 with severe CSVD vs 50 healthy control (HC)] were recruited. All participants had cognitive examination including Montreal Cognitive Assessment (MoCA) and Mini-Mental State Examination (MMSE) and MRI including multiecho gradient echo (mGRE) sequence. QSM images were segmented into 32 subcortical gray matter regions, with baseline QSM metrics (mean, median, interquartile range [IQR], and maximum susceptibility) analyzed. Propensity score matching adjusted for baseline confounders. Cognitive function were evaluated using Cox regression models, and risk stratification was performed based on thresholds identified through receiver operating characteristic (ROC) analysis
Results or Findings: After adjusting for potential confounders, the susceptibility values in right posterior caudate ($\beta = 4.675$, $P = 0.003$) and the right posterior hippocampus ($\beta = 1.516$, $P = 0.025$) were positively associated with CSVD severity, and those in the globus pallidus, putamen and caudate nucleus were negatively associated with cognitive function. Baseline QSM metrics, particularly the mean susceptibility (QSMmean) (AUC=0.833) and the median susceptibility (QSMmedian) (AUC=0.750) demonstrated moderate to substantial predictive performance for cognitive decline. Patients with severe CSVD showed a 5.2-fold increased risk of cognitive impairment compared to those with mild CSVD
Conclusion: QSM metrics, serving as a complementary imaging biomarker, demonstrated significant predictive value for cognitive function. Validation in larger, independent cohorts is warranted
Limitations: Susceptibility values are affected by noniron-related molecules, especially myelin, which are consistently found in structures like the thalamus
Funding for this study: This study was supported by the National Natural Science Foundation of China (grants 82371946 and 82401557), the Chinese Academy of Medical Sciences Innovation Fund for Medical Sciences (grant 2021-I2M-1-025), and the National Postdoctoral Researcher Funding Program (No. GZC20240138)

Causal Structural Covariance Network Revealing Atrophy Progression In Cerebral Small Vessel Disease Continuum (6 min)

Ronghua Mu; Guilin / China

Author Block: R. Mu[1], P. Yang[1], W. Zheng[1], X. Qin[1], J. Lv[1], B. Huang[1], X. Liu[2], L. Cheng[1], X. Zhu[1]; [1]Guilin/CN, [2]Guangzhou/CN
Purpose: Structural covariance networks (SCNs) provide an important framework for understanding large-scale brain network damage across the continuum of cerebral small vessel disease (CSVD). However, it remains unclear how progressive cross-regional structural injury drives SCN disruption.
Methods or Background: From May 2020 to November 2021, 500 community participants were enrolled, including patients with vascular dementia, vascular mild cognitive impairment, CSVD with preserved cognition, and cognitively normal elderly controls. A multimodal CSVD cognitive impairment database was established, integrating neuroimaging (3D T1-weighted MRI), neuropsychological assessments, and clinical data. T1-weighted images were automatically preprocessed using a standardized SPM12 pipeline. Morphology-based independent component analysis was applied to extract gray matter SCNs, enabling network-level characterization of CSVD-related structural alterations and whole-brain atrophy patterns. Causal structural covariance networks (CaSCNs) were further constructed with a sliding time-window approach to identify the temporal causal relationships between key driving nodes and progressive atrophy. Finally, functional decoding was used to map structural alterations to behavioral domains and to explore their associations with cognitive impairment.
Results or Findings: Compared with normal aging, SCNs exhibited progressive disruption in CSVD with preserved cognition, vascular mild cognitive impairment, and vascular dementia. Dynamic CaSCN analysis based on composite cognitive scores identified hippocampus and frontal lobes as key causal hubs, with their atrophy significantly predicting subsequent atrophy in other regions. Functional decoding confirmed specific associations between network-level damage originating from these regions and impairments in executive function, attention, and memory.
Conclusion: This study systematically delineated the spatial distribution and interregional associations of brain atrophy across the CSVD continuum. Hippocampus and frontal lobes emerged as central origins of atrophy, whose degeneration predicted widespread secondary atrophy. These findings highlight the causal and temporal dynamics of whole-brain atrophy and provide novel network-level insights into CSVD progression.

Combining plaques and cerebral small vessel diseases imaging characteristics for ischemic stroke prediction in intracranial atherosclerotic disease (6 min)

Jun Zhang; Shanghai / China

Author Block: J. Zhang, J. MIAO; Shanghai/CN
Purpose: The aim of this study was to investigate the predictive value of intracranial plaques and cerebral small vessel diseases (CSVDs) imaging characteristics for ischemic stroke, further elucidated the impact of coexisted large and small intracranial vessel diseases on stroke events.
Methods or Background: Patients who underwent contrast-enhanced higher–resolution vessel wall MRI (HRVW-MRI) with intracranial atherosclerotic disease were recruited from January 2021 to April 2024. Plaque features like intraplaque hemorrhage (IPH), enhancement grade, maximum wall thickness (Max WT), lumen area (LA) were assessed in HRVW-MRI. We used total CSVDs score based on 4 CSVDs imaging markers, including lacunes, white matter hyperintensities (WMLs), cerebral microbleeds (CBMs), and enlarged perivascular spaces (EPVSs), and the overall CSVDs burden score was 0–4. Binary logistic regression analysis and receiver operating characteristic (ROC) curve were used for data analysis.
Results or Findings: Of the total 237 patients (the median age was 63, 154 males), 163 patients occurred stroke. Binary logistic regression revealed that patients with greater Max WT, larger LA, more CBMs and EPVSs, higher enhancement grade, total CSVDs and WMLs score were more likely occurred stroke (all $p < 0.05$). The combination of these variables achieved a higher area under the curve (0.85, 95% CI 0.80-0.96, p□0.000) than that of the plaques (0.77, 95% CI 0.71-0.89, p□0.000) and CSVDs (0.79, 95% CI 0.72-0.87, p□0.000) imaging characteristics alone.
Conclusion: Plaque features combined with CSVDs imaging makers provides incremental value for stroke prediction, which is helpful for the clinical management of high-risk patients.
Limitations: Firstly, the sample size was small. Secondly, the present study was restricted to patients with anterior circulation infarct. Thirdly, this was a retrospective study with bias.

Prognostic Significance of the Hyperdense Sinus Sign on Admission CT in Cerebral Venous Sinus Thrombosis (6 min)

Ruth Eliahou Eliahou; Modiin macabbim reut / Israel

Author Block: R. E. Eliahou[1], J. Molad[2], E. Auriel[1], A. Honig[3]; [1]Petah Tikva/IL, [2]Tel Aviv/IL, [3]Beer Sheva/IL
Purpose: To characterize patients presenting with the hyperdense sinus sign (HDSS) on admission non-contrast CT (NCCT) in cerebral venous sinus thrombosis (CVST) and assess its association with clinical and radiological outcomes.
Methods or Background: We retrospectively analyzed 465 consecutive adult CVST patients from six comprehensive stroke centers (2014–2023). HDSS was defined as venous sinus hyperdensity ≥60 Hounsfield units on NCCT. Demographics, risk factors, venous involvement, parenchymal injury, and oral contraceptive use were recorded. Outcomes at 90 days included functional status (modified Rankin Scale, mRS), seizure occurrence, and recanalization. Multivariable logistic regression was used to identify independent predictors of outcomes.
Results or Findings: HDSS was present in 178 patients (38.3%). Compared with non-HDSS patients, those with HDSS had higher rates of oral contraceptive use (28% vs 18%, p=0.009), seizures at presentation (23% vs 14%, p=0.015), multi-site venous involvement (34% vs 22%, p=0.002), intracerebral hemorrhage (27% vs 13%, p<0.001), and venous infarction (22% vs 11%, p=0.004). At 90 days, HDSS was associated with fewer excellent outcomes (mRS 0–1: 71% vs 82%, p=0.022) and more remote seizures (9% vs 3%, p=0.001), while recanalization rates were similar. Multivariable analysis confirmed HDSS as an independent predictor of lower odds of excellent recovery (OR 0.50, 95% CI 0.26–0.97) and higher risk of remote seizures (OR 2.54, 95% CI 1.01–6.42).
Conclusion: HDSS on admission CT identifies CVST patients with more extensive venous involvement, greater parenchymal injury, and worse clinical outcomes. Recognizing this marker may support risk stratification and guide management.
Limitations: Retrospective design may introduce bias. Symptom onset timing and precise HDSS location in multi-site thrombosis were unavailable. 101 patients lacked HDSS evaluation, although baseline characteristics were similar to included cases.

Arterial spin labeling perfusion in accidental carbon monoxide intoxication: a longitudinal study (6 min)

Torstein Torgan; Eiksmarka / Norway

Author Block: T. Torgan, W. Norhøy, C. M. Page, F. Fridtjof Heyerdahl, A. Bjørnerud, L. Tjelta Westlye, P. W. Sowa; Oslo/NO
Purpose: To investigate longitudinal changes in gray matter (GM) cerebral blood flow (CBF) following accidental carbon monoxide (CO) poisoning, using arterial spin labeling (ASL).
Methods or Background: Survivors of CO intoxication may experience persistent or recurrent neurological symptoms, even when conventional MRI findings are minimal. ASL perfusion imaging may detect subtle changes.
Twenty-six young adults (average 24.6 years old) with varying degrees of CO poisoning were admitted to the hospital and recruited in this longitudinal study. MRI was done at four timepoints (TP), after average of 5.1 days (TP1), 2.1 months (TP2), 7.6 months (TP3), and 18.2 months (TP4). ASL data were processed using ExploreASL and compared with HbCO levels. CBF was assessed globally, in subcortical regions, and across vascular-territorial cortical areas. Linear and mixed effects regression were used to evaluate the association between HbCO levels and CBF at each TP, and across all TPs.
Results or Findings: There was decrease of CBF in TP1 in Putamen, and negative correlation between CBF and HbCO levels at TP2 in all but one evaluated brain regions (CBF falling 0.34 ml/100g/min per 1 % increase HbCO for global grey matter, p=0.031).
The mixed-effects analysis showed association between HbCO levels and CBF across all TPs in most areas, with the strongest effect in Putamen (CBF falling 0.63ml/100g/min per 1 % increase in HbCO, p=0.001), as well as effect of TP4 for CBF reduction in thalamus (p=0.049).
Conclusion: GM ASL perfusion is reduced in CO poisoning after 2.1 months (earliest and most strongly in putamen), indicating usefulness of ASL for evaluating neurotoxicity. There is a dose-dependent association between HbCO levels and reduced perfusion. Perfusion in thalamus appears to be affected also at a later timepoint.
Limitations: Small study, variations in CO exposure, new technique
Funding for this study: Funded by Oslo University Hospital

The multimodal imaging features and temporal evolution of SLE in patients with MELAS: A multicenter cohort study (6 min)

Sirong Piao; Beijing / China

Author Block: Q. Yu, R. Wang, C. Sun, D. Geng, J. Lin, S. Piao, Y. Li; Shanghai/CN
Purpose: Mitochondrial encephalomyopathy with lactic acidosis and stroke-like episodes (MELAS) is a rare maternally inherited disease. As a recurrent paroxysmal clinical event, the heterogeneity underlying the progression of stroke-like episode (SLE) remains unclear.
Methods or Background: In this retrospective, multicenter, observational cohort study, we sought to confirm the clinical, genetics, radiological and temporal evolution characteristics of SLEs. Brain atrophy was assessed using Global Cortical Atrophy (GCA) and quantitative brain volumetric measures(QBVM). Both methods were employed to explore brain atrophy changes over time among these patients.
Results or Findings: Between August 2012 and December 2024, we identified 171 MELAS patients who developed SLEs. Based on the age of first SLE, these patients were divided into two groups, juvenile group and adult group. Hearing loss and diabetes mellitus were significantly more frequent in the adult group ($p<0.05$). Nausea/vomiting was significantly more frequent in the juvenile group ($p=0.017$). SLEs were significantly more prone to involve the frontal lobe in the juvenile group ($p=0.002$). Stroke-like lesion (SLL) areas were significantly larger in the juvenile group ($p=0.005$). Furthermore, a total of 67 patients with available follow-up imaging data were assessed for GCA and QBVM. MELAS patients showed rapidly annual increasing scores according to the GCA (median, IQR; 2.55, [1.48,5.14]), and significant ventricular enlargement based on QBVM (median annual change rate, IQR; 0.05, [-0.01, 0.14]). In the longitudinal assessment of GCA , an exponential-like change was observed. By approximately two years of follow-up, the progression appeared to stabilize, entering a phase where changes were markedly less pronounced.
Conclusion: Our findings highlight the clinical, radiological and temporal evolution characteristics of SLEs between both groups. We demonstrated that MELAS shows a rapid brain atrophy progression within a 2-year interval and follows different natural courses.
Limitations: Not applicable.

Foundation Model Based Lesion Tracking For The Longitudinal Follow-Up of Solid Tumors on CT and MRI (6 min)
Léo Machado; Saint-Mandé / France

Author Block: L. Machado, A. Prat, H. Philippe, T. Danielou, K. Le Floch, M. Ronot, D. Tordjman, P. Manceron, P. Hérent; Paris/FR
Purpose: RECIST 1.1 remains the reference for longitudinal assessment of solid tumors but is slow, labor-intensive, and prone to inter-reader variability. Most AI tools are unimodal, organ-specific, and restricted to single timepoints, limiting clinical use. We present a pan-tumor, CT/MRI lesion-tracking pipeline for semi-automated longitudinal follow-up using foundation models.
Methods or Background: To achieve lesion tracking, we used features from Curia, a multimodal foundation model (Dancette et al., 2025, arXiv). From the baseline lesion, Curia enables the generation of a bounding-box on the follow-up exam, localizing the follow-up lesion. This bounding-box is then processed by the segmentation model Oncopilot-v2 to obtain the follow-up mask. Oncopilot-v2 is a fine-tuning of Raps3D (Danielou et al., 2025, arXiv) on 16,035 lesions (e.g., liver, lung, brain, lymph nodes) in CT and MRI, following the same procedure as Oncopilot (Machado et al., 2025, NPJ Precision Oncology).
Evaluation used a multicenter dataset of 238 patients with 391 baseline target lesions (mean 1.64/patient; CT/MRI ratio 1.15; mean follow-up 290 days). Longest diameter and short axis were computed on baseline and follow-up masks, and RECIST classification derived from the sum of largest diameters (SLD).
Results or Findings: Median DICE was 0.80. CT lesion tracking was superior to MRI (0.82 vs 0.78). Median absolute error on SLD was 3.2 mm (8.5% of SLD). RECIST classification accuracy reached 71% for PR/SD/PD and 79% for PD vs non-PD.
Conclusion: This pipeline enables longitudinal propagation of target-lesion masks on CT and MRI, advancing toward a semi-automatic RECIST workflow with potential productivity gains and reduced variability.
Limitations: Full RECIST requires integration of non-target lesions. Complete-response cases were absent. The lesion tracking accuracy could be improved. Radiologist oversight remains essential to validate and refine segmentation. Prospective studies are needed to confirm clinical utility.

Deep-Learning (DL) image reconstruction and Chemical Shift Correction (CSC) algorithm boosts the performance of Zero Echo Time (ZTE) sequence to detect lytic myeloma lesions (6 min)
Darius Lepot; Bruxelles / Belgium

Author Block: D. Lepot[1], C. Chabot[1], G. Duchêne[1], S. Mandava[2], M. Fung[3], J. Poujol[4], N. Michoux[1], P. Triqueneaux[1], F. Lecouvet[1]; [1]Brussels/BE, [2]Atlanta, GA/US, [3]New York, NY/US, [4]Buc/FR
Purpose: The mineral bone has traditionally been inaccessible to MRI. Pseudo-CT MRI sequences now allow visualization of the bone mineral structure for applications like oncology. However these pseudo-CT sequences still have limitations. We compared the accuracy of three pseudo-CT MRI sequences (native Zero-Echo-Time (ZTE), Deep Learning (DL)-Chemical Shift Correction (CSC) reconstructed ZTE (ZTE-DL), and gradient-echo Black-Bone (BB)) in detecting osteolytic multiple myeloma (MM) lesions, using CT as reference.
Methods or Background: Newly diagnosed MM patients underwent ZTE and BB sequences of the lumbar spine, pelvis, and proximal femurs within a 3T whole-body MRI study (Signa Premier, GE HealthCare) (prospective trial: NCT05381077). ZTE-DL was obtained by reconstructing ZTE raw data using an algorithm combining AIR™ Recon DL (ARDL) and CSC.

All patients also underwent 18FDG-PET/CT including an optimized CT within a week. Ten bone regions and two scores (lesion presence/absence, lesion number) were evaluated by three readers. Repeatability and reproducibility (Gwet's AC1/AC2), differences in lesion number, and accuracy (Acc) were assessed by sequence, region, and reader.
Results or Findings: Ten participants were included. Repeatability was moderate for ZTE (AC1≥0.45), good for ZTE-DL and BB (AC1≥0.60) and very good for CT (AC1≥0.80). Reproducibility was fair for ZTE and BB (AC2≥0.20), good for ZTE-DL (AC2≥0.60) and very good for CT (AC2≥0.80). AccZTE-DL ranged from 80 to 93% with an increase in accuracy ranging from +23% to +32% compared to AccZTE, and equal to +19% compared to AccBB. ZTE-DL detected more lesions than ZTE/BB (+30%/+25%, respectively).
Conclusion: DL and CSC reconstruction improves repeatability, reproducibility, and accuracy of ZTE sequences for detecting MM lesions. ZTE-DL detects more lesions than ZTE/BB.
Limitations: The limitation of the study were a mononcentric/ small cohort and a study only covering the lumbar spine, pelvis, proximal femurs.
Funding for this study: Frederic E. Lecouvet's research works are funded by the Peterbroeck Research Professorship fund and Allard-Janssen Fund for Cancer Research, Belgian nonprofit organizations.
Caroline Chabot is a PhD student supported by the Fondation Saint Luc, a Belgian non-profit organization.

AI-enhanced prostate MRI: unveiling unreported prostate incidental findings through routine screening for prostate cancer (6 min)

Dominika Skwierawska; Erlangen / Germany

Author Block: D. Skwierawska[1], S. Heidarikahkesh[1], D. Bounias[2], R. J. Jóźwiak[3], D. Hadler[1], M. Bachl[1], M. Uder[1], F. B. Laun[1], S. Bickelhaupt[1]; [1]Erlangen/DE, [2]Heidelberg/DE, [3]Warsaw/PL
Purpose: To evaluate the feasibility of automated detection and segmentation of incidental findings in prostate MRI.
Methods or Background: This IRB-approved, retrospective study included n=425 prostate MRI examinations (1.5T and 3.0T), comprising n=306 internal cases from our institution and n=119 external cases from three independent datasets. Manual segmentations were performed for sigmoid diverticulosis (SD), perirectal lymph nodes (PLN), urinary bladder diverticula (UBD), bladder wall thickenings (BWT), inguinal hernias (IH), degenerative changes of the hip (DC), synovial cysts (SC) and hydrocele testis (HT) on T2-weighted images for n=265 internal cases (n=520 ROIs). An nnU-Net model was trained on n=213 of these cases, and the remaining independent n=52 cases were used for the quantitative evaluation of model performance. Further, n =160 additional examinations (n=41 internal, n=119 from three independent external datasets) were evaluated by a radiologist.
Results or Findings: Segmentation performance varied between the incidental findings. Quantitatively, the highest mean Dice scores were achieved for SD (0.80 ± 0.14), HT (0.76 ± 0.20), and DC (0.70 ± 0.07). Radiologist evaluation across four datasets (one internal and three external) demonstrated accuracies of 0.98/0.77/0.93/0.93 for PLN, 0.98/0.87/0.85/0.88 for SD, 0.93/0.90/0.80/0.88 for IH, and 0.93/0.85/0.76/0.80 for DC, with accuracies for most other incidental findings also exceeding 0.85.
Conclusion: Our method can automatically detect and segment incidental findings in prostate MRI across four independent datasets, demonstrating potential to enhance the efficiency and consistency of reporting, supporting further research with larger, more diverse datasets including additional annotations and targets.
Limitations: The dataset was curated to maximise all targeted findings, and despite reflecting real-world prevalence, it remained imbalanced. Rarer and more subjective findings, such as mild bladder wall thickenings or degenerative changes of the hip, were challenging to annotate due to subtle appearances and patient-specific variations.
Funding for this study: Funding from the Bavarian Academic Center for Central, Eastern, and Southeastern Europe (BAYHOST) Scholarship, and from the German Research Foundation (DFG; project 500397400) is gratefully acknowledged.

Direct breast cancer segmentation in k-space from dynamic contrast-enhanced MRI using a novel deep learning model (6 min)

Lukas Thomas Rotkopf; Heidelberg / Germany

Author Block: L. T. Rotkopf[1], M. Rempe[2], C. Strack[2], H-P. Schlemmer[1], J. Kleesiek[2]; [1]Heidelberg/DE, [2]Essen/DE
Purpose: Medical image segmentation models predominantly operate in the image domain and require fully reconstructed images as input. We investigate a novel deep learning model that directly predicts the k-space representation of breast cancer segmentations from DCE-MRI data and compare its performance to a state-of-the-art image-domain framework.
Methods or Background: The DUKE subset cohort of the publicly available MAMA-MIA breast MRI dataset was selected for this study, consisting of 291 examinations in patients with confirmed breast cancer. For our proposed method, axial k-space slices were generated from the subtraction DCE-MRI volumes using Fourier transforms. A custom 2D U-Net was trained via 5-fold cross-validation to predict the complex-valued k-space tumor mask directly from subtraction k-space. This was compared against a standard 3D nnU-Net baseline trained on reconstructed 3D volumes. The pooled slice-level Dice similarity coefficient for the foreground tumor class was used as primary evaluation metric.
Results or Findings: The proposed k-space segmentation model achieved a mean Dice score of 0.69 ± 0.02 across the five cross-validation folds. The 3D nnU-Net baseline in the image domain achieved a mean Dice score of 0.62 ± 0.26. These results show direct k-space prediction can achieve performance comparable to established image-domain methods.
Conclusion: Our results demonstrate the potential of performing tumor segmentation directly in the k-space MRI domain, with performance levels competitive to established image-domain baselines. Operating in k-space is a novel approach that could open new avenues for developing integrated reconstruction and segmentation pipelines, and may offer advantages in accelerated, undersampled MRI acquisitions.
Limitations: This study was conducted retrospectively on a single-center cohort, which may limit the generalizability of the findings.
Funding for this study: This study was supported by the Jöster Foundation.

Evaluating medical AI image segmentation models using augmentation (6 min)

Matthias Neitzel; Frankfurt am Main / Germany

Author Block: M. Neitzel, M. Sayed, B. Wichtlhuber, E. Frodl, J. Dietz, T. Vogl, P. Reschke, A. M. Bucher; Frankfurt/DE
Purpose: Unreliable AI segmentations can compromise clinical decisions, so we developed and validated Seg-Eval, a model-agnostic, ground-truth-free pipeline that estimates segmentation quality from uncertainty maps of ROI masks on clinical CT.
Methods or Background: We conducted a retrospective multi-cohort study (GastricBCA n=161, PDAC Surgical n=362, PDAC Palliative n=309; total 832 CTs). For each scan, 10 random augmentations (rigid, elastic, or combined) were generated and segmented with TotalSegmentator into 117 ROIs. Masks were mapped back to native space, yielding 8,320 inverse-segmentation masks (ISMs), with the native TotalSegmentator masks on original scans serving as reference. We computed ROI-wise DICE (ISMs vs. native masks), ASSD, coefficient of variation of DICE, augmentation loss, uncertainty (1 − modal agreement), and Pearson correlations; a subset of ROIs (n=90) underwent reader scoring and correction to link uncertainty with DICE improvement.
Results or Findings: Across all cohorts, we observed consistent inverse associations between segmentation quality and variability. DICE correlated strongly and negatively with uncertainty (Gastric $r=-0.76$; Surgical $r=-0.59$; Palliative $r=-0.57$; all $p<0.001$), indicating that lower performance was accompanied by higher predictive uncertainty. Similarly, higher augmentation loss was linked to increased uncertainty ($r=0.70, 0.60, 0.42$; all $p<0.001$), while higher DICE scores were consistently associated with lower variability ($r=-0.93, -0.90, -0.91$; all $p<0.001$). Pooling data across cohorts revealed a strong negative correlation between average uncertainty and DICE (Pearson $r=-0.69$, $p<0.001$), underlining robustness across subgroups. Reader analysis confirmed that higher-uncertainty ROIs yielded larger DICE gains after correction ($r=-0.86$, $p<0.001$).
Conclusion: Seg-Eval provides ground-truth-free, model-agnostic QC by flagging uncertain ROIs and passing reliable results, reducing workload and error propagation while supporting standardised, vendor-neutral integration into clinical workflows.
Limitations: The limitation of the study is that only one segmentation engine was tested.
Funding for this study: Funding was provided by the German Federal Ministry of Education and Research through the RACOON project (reference number 01KX2021).

Automated response assessment from free-text radiology reports in metastatic melanoma using privacy-preserving Large Language Models (6 min)

Julius C Holzschuh; Heidelberg / Germany

Author Block: J. C. Holzschuh, F. Wäscher, F. Winneknecht, C. H. Ziener, J. Hassel, H-P. Schlemmer, L. T. Rotkopf; Heidelberg/DE
Purpose: Response evaluation in oncology trials relies on manual annotations and therefore limits trial sizes. Because free-text radiology reports are routinely generated, we hypothesize that large language models (LLMs) can automatically convert them into accurate, structured assessments. However, reliance on cloud-based or closed models raises privacy concerns. We therefore evaluate local, on-premises LLMs to accurately extract RECIST response categories from radiology reports.
Methods or Background: In this retrospective study we included 63 patients from clinical trials evaluating immunotherapy for metastatic melanoma. Two state-of-the-art LLMs (MicrosoftPhi-4-14B and DeepSeekR1-32B) were prompted to predict the RECIST category at the first follow-up imaging from the unstructured baseline and follow-up clinical radiology reports. Ground-truth targets were validated clinical RECIST assessments. Performance was measured using multiclass accuracy and sensitivity and specificity for each response category.
Results or Findings: Overall multiclass accuracies for RECIST 1.1 prediction at the first follow-up were 0.56 and 0.64 for Microsoft Phi-4 and DeepSeek-R1, respectively. Class-wise accuracies were 0.55 vs 0.40 for PR, 0.00 vs 0.33 for CR, 0.30 vs 0.55 for SD, and 0.90 vs 1.00 for PD. For predicting PD, Phi-4 and DeepSeek-R1 achieved sensitivities of 0.90 and 1.00, respectively, and specificities of 0.65 and 0.70. No significant differences between models were found (all $p>0.05$).
Conclusion: On-premises, privacy-preserving LLMs demonstrate promising capabilities in extracting RECIST response categories from free-text radiology reports, especially for differentiating progressive from non-progressive disease. This automated approach potentially reduces the burden of manual evaluation in future clinical trials.
Limitations: Limited include the relatively small sample size, single-institution data, and focus on metastatic melanoma.
Funding for this study: No funding.

Multimodal Volumetric Body Composition Analysis with AI: Agreement Between Whole-Body MRI and PET/CT (6 min)

Julius C Holzschuh; Heidelberg / Germany

Author Block: J. C. Holzschuh[1], L. Rotkopf[1], F. Bauer[2], C. Sachpekidis[1], A. Dimitrakopoulou-Strauss[1], H. Goldschmidt[1], M-S. Raab[1], H-P. Schlemmer[1], M. Wennmann[1]; [1]Heidelberg/DE, [2]Cologne/DE
Purpose: Imaging-derived body composition metrics are increasingly recognized as prognostic biomarkers in oncology. Advances in deep learning now allow automated segmentation of skeletal muscle and adipose tissue, enabling large-scale and potentially routine clinical application. However, the reproducibility of these measures across imaging modalities, particularly between computed tomography (CT) and magnetic resonance imaging (MRI), remains uncertain.
Methods or Background: We analysed same-day whole-body PET/CT and T1-weighted MRI scans from 42 patients from the prospective GMMG-HD7- and GMMG-HD8-/DSMM-XIX-study. A fully automated deep learning pipeline based on the TotalSegmentator Framework was created to segment skeletal muscle, visceral and subcutaneous adipose tissue to derive volume measurements. Volumetric agreement between CT- and MRI-based metrics was assessed using pearson correlation coefficient (r), intraclass correlation coefficients (ICC), and Bland-Altman analyses.
Results or Findings: CT- and MRI-derived body composition measures demonstrated strong correlations ($r > 0.97$) and high reproducibility for volumetric metrics (ICC > 0.95) across the analyzed compartments, although systematic modality-specific volumetric differences were observed. Compared with CT, MRI yielded lower estimates of adipose tissue and skeletal muscle volumes as Bland-Altman analysis demonstrated a mean bias of -353 cm3 (95% LOA: -2576 to 1869) for subcutaneous adipose tissue, -211 cm3 (-774 to 351) for visceral abdominal adipose tissue, and -2653 cm3 (-4854 to -452) for skeletal muscle.
Conclusion: Automated deep learning-based body composition analysis is feasible and reproducible across CT and MRI, although systematic modality-specific biases were identified. While these are small relative to the overall variance, they should be accounted for in research and clinical implementation. These findings contribute towards using multimodal, imaging-derived body composition biomarkers, potentially guiding future personalized cancer care.
Limitations: While the standardized single-scanner T1-weighted MRI protocol ensures consistency, future studies are required to validate generalizability across scanners, sequences, and larger cohorts.

An AI-driven radiogenomics framework decodes the "proliferation-quiescence paradox" in prostate cancer evolution and identifies CDC20 as a stable therapeutic target (6 min)

Xiaojing He; Chongqing / China

Author Block: Q. Xiaofeng, X. He; ChongQing/CN
Purpose: To develop and validate a novel AI-driven radiogenomics framework capable of non-invasively predicting progression to castrate-resistant prostate cancer (CRPC) by decoding tumour evolution under androgen deprivation therapy (ADT), and to identify evolutionarily stable therapeutic targets.
Methods or Background: In this retrospective, ethics-approved study, we first applied unsupervised K-means clustering to 14 quantitative mpMRI features from 121 PCa patients undergoing ADT to discover inherent imaging phenotypes. A supervised prediction model incorporating the discovered phenotype was then developed and validated. Then developed a "genomic proxy score" based on the imaging phenotype's biological characteristics and validated our findings in independent genomic cohorts (TCGA-PRAD, n=501; SU2C mCRPC, n=332). Cross-cohort survival analyses were performed to identify core risk genes.
Results or Findings: Unsupervised analysis of mpMRI data revealed a previously unrecognised "high-risk radiomic habitat," strongly associated with shorter progression-free survival. A supervised model incorporating this habitat status achieved high predictive accuracy for CRPC progression (AUC = 0.847 [95% CI: 0.806-0.910]), with the habitat being the most important predictor. Radiogenomic analysis in external cohorts uncovered a "proliferation-quiescence paradox": while resistant tumours exhibited global suppression of key metabolic and proliferative pathways, a core programme of proliferation-related genes remained the principal driver of mortality. And we identified the CDC20 as the sole risk gene stable across both disease stages.
Conclusion: Our AI-driven framework successfully translated routine clinical mpMRI into a powerful biomarker for CRPC risk. More importantly, this framework enabled the discovery of a paradoxical resistance mechanism mediated by a small, highly proliferative subclone within a largely quiescent tumour, which led to the identification of CDC20 as a critical, evolutionarily stable therapeutic target for overcoming treatment resistance in PCa.
Limitations: Retrospective study; the samples from two hospital districtsthe of single center; sample size is relatively small

Evaluating the AI and Radiologist scoring for PIRADS in Prostate cancer diagnosis (6 min)

Rio Hermawan; Banten / Indonesia

Author Block: R. Hermawan[1], T. Budianto[1], S. J. S. Gardezi[2], D. Kumar[3], A. Gandhamal[3], G. Marcel[1]; [1]Jakarta/ID, [2]Sharjah/AE, [3]Delhi/IN
Purpose: Prostate cancer is one of the most frequently diagnosed cancers in men worldwide, representing about 30% of the male cancer burden. Early diagnosis and treatment is key for long-term and progression-free survival in prostate cancer[1]. Artificial intelligence (AI) techniques leveraging deep learning (DL), are increasingly applied in prostate cancer detection to enhance accuracy and lower costs. This study aims to leverage DL for automatic detection , diagnosis and classification of prostate cancer.
Methods or Background: This retrospective study included 40 patients (mean age: 62 years) diagnosed with prostate cancer at Dharmais Cancer Hospital, Indonesia. PIRADS scores were computed using a deep learning–based assessment application (United Imaging Intelligence®). tumor diameter, volume along with right–left (RL), superior–inferior (SI), and anterior–posterior (AP) diameters, were computed. The AI system automatically classified detected prostate tumors into PIRADS categories based on the obtained scores.
Results or Findings: A strong correlation was found between radiologist- and AI-derived prostate volumes ($r = 0.976$, $p = 2.47 \times 10^{-23}$). Over 40% of cases were classified as PIRADS 5, 22.5% as PIRADS 4, with the remainder in lower categories. Moreover the category wise PIRADS analysis showed highest agreement for PIRADS 5 (62.5%), moderate for PIRADS 3 (42.9%), minimal for PIRADS 4 (11.1%), and no matches for PIRADS 1–2 . Overall the agreement was more reliable in higher categories and minimal in lower categories.
Conclusion: The study underscores the of AI-powered DL application for prostate cancer detection and PIRADS classification. The results exhibit a strong correlation with radiologist-derived prostate volumes and achieved higher agreement in advanced PIRADS categories, highlighting the utility of AI in supporting radiologists.
Limitations: However, more diverse cohort, along with multi-radiologist evaluations, are required to improve reliability across all PIRADS categories and establish broader clinical usage.

Spatial Mapping of Tumor Response and Mesorectal Involvement on Pretreatment Contrast-Enhanced CT in Locally Advanced Rectal Cancer (6 min)

JIali Li; Wuhan / China

Author Block: H. Gan, J. Li, Z. Li, Z. Zhou; Wuhan/CN
Purpose: To explore spatiotemporal features from large-scale multi-center contrast-enhanced computed tomography (CECT) data to construct quantitative spatiotemporal models for tumor response in locally advanced rectal cancer(LARC) patients to neoadjuvant chemoradiotherapy(NCRT).
Methods or Background: This study retrospectively collected CECT and clinical information of 337 pathologically confirmed LARC patients from three centers. Two radiologists performed the annotation of tumors and the mesorectum on dual-phase CECT. The cohort was randomly partitioned into training (70%), validation (20%), and test sets (10%). Radiomic extraction yielded 1,223 features per phase. Pathologic response to CRT was assessed histopathologically and graded using the AJCC tumor regression grade (TRG) system (0–3). Treating TRG as a four-class outcome, we evaluated the performance of the radiomics-based multiclass classifier using a one-vs-rest scheme with macro-averaged ROC AUC. We trained thirteen models to predict tumor, mesorectal involvement. Two input schemes were evaluated: single-phase arterial (A) or venous (V) data and a dual-phase V–A difference design, which leverages multiphasic information for improved detectability. Bayesian optimization was used for hyperparameter tuning.
Results or Findings: Among the total population, TRG0 accounts for 9.7%, TRG1 for 13.3%, TRG2 for 41.5%, and TRG3 for 35.5%. For tumor model, arterial phase achieves the highest AUC, at 0.7844; for mesorectum model, the V-A difference performs best, with an AUC of 0.7527. Across Phases A, V, and V-A difference, the tumor model consistently demonstrates better performance than mesorectum , with respective ΔAUC of 0.057, 0.0384, and 0.0097.
Conclusion: The tumour-mesorectum model can effectively explain the spatiotemporal changes of tumors in LARC after NCRT by integrating features across multiple phases and characteristics of different spatial regions. It provides a quantitative tool for evaluating tumor response and mesorectal involvement, and addressing poor efficacy prediction accuracy.
Limitations: Retrospective study.
Funding for this study: None

Automated Segmentation of Primary Colorectal Cancer on Dual-Layer Spectral CT Iodine Density Images Using 3D nnU-Net: A two-Center Study (6 min)

Ziqi Jia; Guangzhou / China

Author Block: Z. Jia, W. C. Chen, H. Zhang, G. Liu, X. Liu; Guangzhou/CN
Purpose: To evaluate the feasibility of automated segmentation of primary colorectal cancer (CRC) on iodine density images from arterial phase (AP) and venous phase (VP) using the 3D nnU-Net.
Methods or Background: This retrospective study included 499 patients with pathologically confirmed CRC from two independent centers, scanned with two models of dual-layer spectral CT (DLSCT). Iodine density images were manually annotated by experienced radiologists to generate ground truth volumes of interest (VOIs). The 3D nnU-Net was trained and validated using a cascaded approach with low- and high-resolution stages. Performance was evaluated on an independent external test set using segmentation coverage ratio (SCR), Dice similarity coefficient (DSC), recall (REC), and precision (PRE).
Results or Findings: In the external test set, for AP iodine images, the SCR, DSC, REC, and PRE were 0.704, 0.738, 0.704, and 0.825, respectively; for VP images, they were 0.750, 0.768, 0.750, and 0.825. Subgroup analysis by tumor location showed superior segmentation for left-sided colon and rectal cancers (DSC 0.776–0.793), moderate for right-sided colon (DSC 0.705–0.719), and variable for transverse colon (DSC 0.467 in AP vs. 0.750 in VP). Venous phase images generally yielded higher segmentation accuracy than arterial phase.
Conclusion: The 3D nnU-Net enables effective automatic segmentation of primary CRC tumors using DLSCT iodine density images, with better performance in VP, showing potential for clinical application.
Limitations: Not applicable

Investigating longitudinal radiomic features variation on MRI to predict tumour upgrading of prostate cancer during active surveillance (6 min)

Lucilla Violetta Sciacqua; Milan / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: L. V. Sciacqua, B. Dionisi Ferrera, E. Gioscio, C. Marenghi, F. Badenchini, T. Rancati, N. Nicolai, A. Casale, A. Messina; Milan/IT
Purpose: We investigated whether changes in whole-prostate MRI-derived radiomic-features RFs during active-surveillance are associated with histopathological upgrading at repeat biopsy. Specifically, we tested whether increasing time from diagnosis allows aggressive tumor foci to become more detectable on mp-MRI (predictive delta-RFs). We also examined whether these RFs provide signals at diagnostic MRI and whether baseline radiomics adds predictive value to clinical models based on PSA density and number of positive biopsy cores. Frequent ISUP upgrades outside MRI-visible lesions support whole-prostate radiomics.
Methods or Background: We studied 147 consecutive patients (60 with upgrading) from a prospective single-center active-surveillance cohort, monitored with mpMRI (diagnosis, years 1, 2, 4) and targeted biopsies for PIRADS >2 lesions (years 1, 4). Candidate delta-RFs (between diagnosis and last-available mp-MRI) were identified using multiple-ANOVA, and logistic models were built from MANOVA-selected RFs at diagnosis. RFs (T1, T2, ADC maps) were extracted from diagnostic and last-available MRI using a standardized pipeline to calculate absolute baseline RFs and delta-RFs. Associations of delta-RFs with upgrading were tested with multiple-ANOVA, and logistic models were developed using baseline RFs.
Results or Findings: The number of positive cores (OR=1.8, 1 core vs >1) and PSA density (OR=1.6 per 0.05 ng/ml/cc increase) were linked to upgrading (AUC=0.68). The MANOVA model included six delta-RFs: four T2, one T1, one ADC. ADC (morph_vol_dens_aabb) explained most variance. Baseline morph_vol_dens_aabb was associated with decreased upgrading risk (OR=0.90, AUC=0.65). Adding morph_vol_dens_aabb to the clinical-pathological model improved AUC (=0.73).
Conclusion: Prostate radiomics aspects related to the coherence and compactness of ADC maps predict upgrading, indicating prostates with globally organized diffusion are less likely to harbor undetected higher-grade foci.
Limitations: The limitations of the study are the need for independent external datasets to ensure robustness and further analyses of lesion-level RFs.
Funding for this study: No funding was received for this study.

Deep learning radiomics models for the identification of HER2 expression using super-resolution ultrasound images (6 min)

Jiajing Zhuang; Fuzhou / China

Author Block: J. Zhuang, C. Yuefan, Y. Xie, Q. Ye; Fuzhou/CN
Purpose: The human epidermal growth factor receptor 2 (HER2) expression status varies across different histological types and staging stages of bladder cancer, making it crucial for prognosis assessment. This study investigates the potential of deep learning radiomics models using ultrasound images reconstructed through super-resolution for HER2 status identification.
Methods or Background: A total of 113 patients with confirmed bladder urothelial carcinoma were retrospectively analyzed and divided into the train and test sets in a ratio of eitht to two. A super-resolution (SR) reconstruction technique based on a generative adversarial network (GAN) was applied to increase the spatial resolution of ultrasound images by two and four times. Radiomic features were extracted from the regions of interest (ROIs). The deep learning features were extracted based on ResNet101, and the principal component analysis (PCA) was used for dimensionality reduction. Least absolute shrinkage and selection operator (LASSO) regression was conducted to further screen the radiomic features, deep learning features, and clinical features. Finally, the screened features were involved for machine learning (ML) modeling.
Results or Findings: Four models were developed, including logistic regression (LR), support vector machine (SVM), k-nearest neighbor (KNN), and light gradient boosting machine (LightGBM). Overall, the combined models based on ultrasound images with four times resolution improvement showed the best performance. Among them, the SVM achieved the highest AUC of 0.994 and 0.929 in the train and test sets, respectively. The decision curve analysis (DCA) suggested its potential for assisting clinical decision-making.
Conclusion: The super-resolution (SR) sampling helps to improve the performance of ultrasound-based prediction models. A machine learning model combining clinical features, radiomics features, and deep learning features shows potential for HER2 detection in urothelial carcinoma of the bladder.
Limitations: No limitations were identified.

SF 1 - Abdominal imaging in pregnant women

Categories: Emergency Imaging, GI Tract, EuroSafe Imaging/Radiation Protection, Genitourinary, Abdominal Viscera
ETC Level: LEVEL II
Date: March 4, 2026 | 08:00 - 09:30 CET
CME Credits: 1.5

SESSION RECOMMENDED BY ESR EUROSAFE IMAGING

Moderator:
Sabine Schmidt Kobbe; Lausanne / Switzerland

Chairperson's introduction (5 min)
Sabine Schmidt Kobbe; Lausanne / Switzerland

Managing abdominal emergencies (23 min)
Vikas Shah; Leicester / United Kingdom

1. To identify appropriate imaging modalities for evaluating acute abdominal pain in pregnancy and recognise key limitations and pitfalls.
2. To list characteristic imaging findings of acute appendicitis and other causes of abdominal pain in pregnancy, including bowel, ovarian, pancreatic, renal, and uterine pathology.
3. To interpret and differentiate imaging appearances of these conditions, with an emphasis on the diagnostic role of MRI.

Protocol optimisation for safe imaging in pregnancy (23 min)
Charis Bourgioti; Athens / Greece

1. To become familiar with CT safety issues for mother and fetus.
2. To learn about MRI safety issues for the mother and fetus.
3. To discuss indications and contraindications regarding the use of contrast agents in pregnant women.

Liver and pregnancy (23 min)
Jules Gregory; Paris / France

1. To describe the key physiological changes in the liver during pregnancy and explain how these modifications influence imaging interpretation.
2. To identify pregnancy-specific hepatic conditions (intrahepatic cholestasis of pregnancy, pre-eclampsia/eclampsia, HELLP, acute fatty liver of pregnancy) as well as those exacerbated or revealed in pregnancy.
3. To analyse how radiological findings direct therapeutic decisions and anticipate severe complications to optimise maternal–fetal outcomes.

Panel discussion: Abdominal imaging and pregnancy: what to look for and how? (16 min)

TF - No one's favourite: radiology's most avoided territories

Categories: Head and Neck, Genitourinary, Cardiac, Education, President's Choice
ETC Level: LEVEL I+II
Date: March 4, 2026 | 08:00 - 09:30 CET
CME Credits: 1.5

Radiology Trainees Forum

Moderators:
Ioana Andreea Gheonea; Craiova / Romania
Saif Afat; Tübingen / Germany

Chairpersons' introduction (10 min)
Ioana Andreea Gheonea; Craiova / Romania
Saif Afat; Tübingen / Germany

Lost in the labyrinth: making sense of head and neck imaging (20 min)
Nour Maalouf; Tübingen / Germany
Marco Essig; Winnipeg / Canada

1. To learn a systematic approach to evaluating complex head and neck anatomy in cross-sectional imaging.
2. To appreciate the most common diagnostic pitfalls and how to avoid them in daily reporting.
3. To understand when advanced imaging (e.g. DWI, perfusion, dual-energy) truly adds value in clinical scenarios.

Heartbreak in the reading room: demystifying cardiac CT and MRI (20 min)
Shibani Mehra; Delhi / India
Jan Michael Brendel; Cambridge / United States

1. To learn the basic principles and protocols for cardiac CT and MRI relevant to general radiologists.
2. To appreciate the strengths and limitations of cardiac imaging in various clinical settings (e.g. chest pain, myocarditis, cardiomyopathies).
3. To understand how to recognise common pathology and integrate structured cardiac reporting into routine practice.

Pelvis confidential: what they didn't teach you about female imaging (20 min)
Thomas Huber; München / Germany
Shiwa Mansournia; Munich / Germany

1. To learn the key anatomical landmarks and typical imaging appearances of the uterus, ovaries, and adnexal structures.
2. To appreciate the spectrum of normal variants and pathological findings across the menstrual cycle and in different age groups.
3. To understand how to differentiate benign from malignant features and when further workup or multidisciplinary input is needed.

Panel discussion (20 min)

BS 1b - Ongoing radiographer PhDs in 180 seconds

Categories: Radiographers, Professional Issues, Education, President's Choice

Date: March 4, 2026 | 08:15 - 09:15 CET

CME Credits: 1

The aim of this session is to promote networking amongst the radiography community, allowing at the same time, to showcase innovative research from radiographers' PhD candidates, each presenting their work in just 180 seconds. Covering a diverse range of topics from imaging technology to patient safety and AI, this session offers a glimpse into the future of radiographic science aligned with clinical practice.

Moderator:

Louise A. Rainford; Dublin / Ireland

The parallel journey: how to define an AI business case: learnings from the automotive industry (20 min)
Ioannis Panagiotelis; Best / Netherlands

1. To learn how the automotive industry integrates AI into decision-making systems and explain parallels and the concept of autonomous Imaging Workflow.
2. To understand how healthcare can learn from automotive's successes and failures to accelerate safe AI development and deployment while avoiding costly mistakes.
3. To understand how lessons from the automotive sector can inform safe and effective AI adoption in healthcare.

How to deploy AI: locally or nationally? (20 min)
Sotirios Bisdas; London / United Kingdom

1. To learn about the different models of AI deployment in radiology, from local hospital implementations to over regional infrastructures.
2. To appreciate the advantages and challenges of each approach, including scalability, governance, cost, interoperability, and patient trust.
3. To understand which deployment strategy best support value-based radiology.

Q&A: Next steps for AI in radiology given these lessons learned (15 min)

How 1 - How we do it: MRI with or without GBCA. Updates and recommendations from the ESMRMB-GREC

Categories: Neuro, Head and Neck, Evidence-Based Imaging, Contrast Media, Sustainability

ETC Level: LEVEL II+III

Date: March 4, 2026 | 08:30 - 09:30 CET

CME Credits: 1

Gadolinium-based contrast agents (GBCA) are used for contrast-enhanced MRI and may significantly influence image interpretation and clinical decision. Indications for use of GBCAs to enhance the contrast-to-noise ratio in MRI are specific to each subspecialty. The session is organized by the Gadolinium Research and Education Committee of the ESMRMB to present the latest updates on the appropriate use of GBCA in common clinical contexts in neuroradiology and head and neck radiology.

Moderators:

Carlo Cosimo Quattrocchi; Trento / Italy

Aart J. Van Der Molen; Leiden / Netherlands

ST 2 - Rays of Knowledge in Radiography: Education, Research, Clinical Innovation and Leadership

Categories: Radiographers, Research, Management/Leadership, Education

Date: March 4, 2026 | 08:30 - 09:00 CET

In this opening interview, the President of the European Federation of Radiographer Societies (EFRS) will be joined by the Chair of the ECR Radiographers' Scientific Subcommittee and the Chair of the EFRS Research Hub to explore how the ECR 2026 theme, "Rays of Knowledge", comes to life in radiography. Together, they will discuss how education, clinical innovation and research are increasingly interconnected, and how radiographers are assuming evolving leadership roles in imaging departments, academia and multidisciplinary teams.

The conversation will highlight the vision behind the Radiographers' Programme, the strategic aims of the EFRS Research Hub and the opportunities ECR 2026 offers to students, early-career and experienced radiographers alike. By connecting perspectives from practice and research, the interview will set the stage for a congress that truly "learns to see" how everything in radiography is connected in the service of better patient care.

Moderators:

Mélisande Rouger; Bilbao / Spain

Conny Lee; Vienna / Austria

From problem to prototype: developing devices and patents in vascular access (14 min)
Michael Tal; Miami Beach / United States

1. To learn the step-by-step process of translating a clinical problem into a medical device or patented innovation in interventional radiology.
2. To appreciate the practical challenges and opportunities in designing, testing, and protecting novel tools for vascular access.
3. To understand how collaboration between clinicians, engineers, and industry can accelerate innovation and improve patient care.

Saving the access, and keeping it: tools, techniques, and strategy for long-term AVF success (14 min)
Panagiotis M. Kitrou; Patras / Greece

1. To learn effective tools and techniques for rescuing failing or thrombosed arteriovenous fistulas.
2. To appreciate the importance of long-term access planning, surveillance, and tailored decision-making.
3. To understand how interventional radiologists can take a proactive role in improving AVF patency and patient outcomes over time.

ST 3 - Building the Future of Cancer AI: Data, Platform, and Practice

Categories: Breast, Research, Imaging Informatics

Date: March 4, 2026 | 09:30 - 10:00 CET

SESSION RECOMMENDED BY EIBIR | EUROPEAN INSTITUTE FOR BIOMEDICAL IMAGING RESEARCH

The European Institute for Biomedical Imaging Research (EIBIR) coordinates three EU-funded projects that collectively define the strategic European roadmap for AI in cancer imaging: EUCAIM, BreastSCan, and COMPASS-AI. EUCAIM forms the foundational pan-European federated infrastructure—Cancer Image Europe—for unifying imaging data. BreastSCan contributes a massive, diverse dataset of breast images necessary for training robust AI tools for early detection and personalized screening. COMPASS-AI develops evidence-based guidelines and best practices, overcoming real-world barriers to ensure the safe, equitable, and effective implementation of AI in diverse clinical settings across Europe. In this interview, Prof. Francesco Sardanelli from BreastSCan, M.D. Laurens Topf from COMPASS-AI and Katrine Riklund from EUCAIM will discuss together the critical synergies between these three projects, presenting a cohesive, end-to-end European approach to integrating AI into radiology and delivering tangible benefits for cancer patients.

Moderators:

Mélisande Rouger; Bilbao / Spain

How to handle difficult patients in cardiac CT: calcifications, arrhythmias, and high heart rates (15 min)
Monika Radikė; Liverpool / United Kingdom

1. To learn practical techniques for optimising cardiac CT image quality in challenging clinical scenarios.
2. To appreciate the role of advanced CT technology in managing calcifications and high heart rates.
3. To understand the impact of arrhythmias on image interpretation and how to effectively mitigate their effects.

How to handle artefacts in CMR (15 min)
Nicola Galea; Rome / Italy

1. To learn strategies for identifying and minimising common artefacts in cardiovascular magnetic resonance imaging.
2. To appreciate the importance of patient preparation and advanced imaging protocols.
3. To understand the technical methods available for reducing artefact-induced diagnostic errors.

Stent imaging: physiology or spatial resolution: what matters most? (15 min)
Hatem Alkadhi; Zürich / Switzerland

1. To identify the strengths and limitations of myocardial perfusion assessment for evaluating coronary stent patency.
2. To recognise advantages and challenges associated with recently introduced ultra-high-definition scanning modes in photon-counting CT (PCCT) for coronary stent imaging.
3. To establish optimal clinical decision-making criteria for selecting the appropriate imaging modality based on patient characteristics and specific stent types.

Panel discussion: Cardiac imaging in 2026: which challenges remain unsolved? (10 min)

How we assess pyloric stenosis (15 min)
Amandeep Singh; Amritsar / India

1. To learn about the clinical presentation and role of ultrasound in diagnosis.
2. To know key sonographic measurements and diagnostic criteria.
3. To understand how to differentiate pyloric stenosis from other causes of vomiting in infants.

How we de-invaginate: non-surgical intussusception reduction (15 min)
Giulia Perucca; London / United Kingdom

1. To learn about the clinical background and indications for imaging-guided reduction.
2. To know which imaging modalities are used (ultrasound and fluoroscopic enema techniques).
3. To understand procedure steps, success criteria, and potential complications.

How we perform a hip ultrasound for dysplasia (15 min)
Veit Manfred Vassen; Langenthal / Switzerland

1. To identify the different methods, indications and management algorithms for hip dysplasia.
2. To know the key imaging criteria of the different methods for hip dysplasia.
3. To understand common errors in the diagnosis of hip dysplasia.

Open forum discussion (13 min)

MR 2 - Imaging biomarkers in clinical practice

MRI and biomarkers: current status and future prospectives (15 min)
Marion Smits; Rotterdam / Netherlands

1. To learn the potential of MRI biomarkers for clinical application.
2. To appreciate the current limitations of MRI biomarkers.
3. To understand the pathway towards clinical implementation of MRI biomarkers.

How do we establish methods and standards for biomarkers in MRI: challenges and goals in quality assurance (15 min)
Ioannis Tsougos; Larissa / Greece

1. To learn about the current methodologies used in the identification and validation of MRI-based biomarkers and their role in clinical and research settings.
2. To appreciate the key challenges in establishing standardised protocols for biomarker quantification and the impact of variability across sites, platforms, and acquisition parameters.
3. To understand the principles and goals of quality assurance in MRI biomarker development, including reproducibility, harmonisation efforts, and emerging international frameworks.

Using the ESR EIBALL Biomarkers Inventory for clinical MRI (15 min)
Aad Van Der Lugt; Rotterdam / Netherlands

1. To learn about EIBALL and the potential value of quantitative imaging biomarkers.
2. To appreciate the challenges and solutions of MRI in quantitative imaging biomarker assessment.
3. To understand the necessary steps to assess reliably and reproducibly.

Panel discussion: Can we begin using biomarkers in clinical practice? (10 min)

OF 2Y - Residents as teachers: effectively using new interactive teaching technologies (part 1)

Categories: Students, Research, Management/Leadership, Education

ETC Level: ALL LEVELS

Date: March 4, 2026 | 10:00 - 11:00 CET

CME Credits: 1

Teaching is a core skill for radiology residents, especially when sharing knowledge with peers and students. This session highlights how residents can actively contribute to education using modern, interactive methods. From team-based learning to flipped classrooms and shared use of digital tools, we explore how technology can empower residents to become confident, creative educators.

Moderators:

Annemiek Snoeckx; Zandhoven / Belgium

Amelie Lutz; Kreuzlingen / Switzerland

Chairpersons' introduction (5 min)

Annemiek Snoeckx; Zandhoven / Belgium

Amelie Lutz; Kreuzlingen / Switzerland

How we learn: an overview of modern teaching approaches in radiology (10 min)

Josephine Berger; Tübingen / Germany

Apps, videos and coffee: co-learning with digital tools (10 min)

Katharina Mueller-Peltzer; Freiburg Im Breisgau / Germany

Team-based learning: how to implement and use in radiology (10 min)

Sandeep Kavthale; Latur / India

Open forum discussion: Can residents really lead teaching? (25 min)

RC 201 - Preneoplastic lesions in hepato-pancreato-biliary (HPB) system: see and wait?

Categories: Imaging Methods, Oncologic Imaging, Abdominal Viscera, Multidisciplinary
ETC Level: LEVEL II+III
Date: March 4, 2026 | 10:00 - 11:00 CET
CME Credits: 1

Moderator:
Charikleia Triantopoulou; Athens / Greece

Chairperson's introduction (3 min)
Charikleia Triantopoulou; Athens / Greece

Preneoplastic liver lesions: distinguishing the harmless from the dangerous (15 min)
Roberto Cannella; Palermo / Italy

1. To review the imaging features of regenerative and dysplastic nodules in cirrhosis.
2. To identify risk factors and imaging signs of progression to hepatocellular carcinoma.
3. To propose imaging follow-up strategies and thresholds for intervention.

Biliary and gallbladder preneoplastic conditions: ignore, monitor, or operate? (15 min)
Martina Pezzullo; Brussels / Belgium

1. To understand the imaging spectrum of biliary intraepithelial neoplasia (BilIN), intraductal papillary neoplasm of the bile duct (IPNB), and gallbladder polyps.
2. To learn size, morphology, and enhancement features that raise concern.
3. To align radiological findings with surgical and oncologic decision-making.

Pancreatic cystic lesions: how not to overcall or overlook (15 min)
Nikolaos Kartalis; Stockholm / Sweden

1. To differentiate between intraductal papillary mucinous neoplasm (IPMN), mucinous cystic neoplasm (MCN), and other cystic lesions based on imaging criteria.
2. To apply risk stratification systems and guidelines.
3. To outline practical surveillance intervals and indications for resection.

Panel discussion: How to share knowledge and responsibility in multidisciplinary teams (12 min)

RC 207 - Female pelvic oncology: an update

Categories: Imaging Methods, Oncologic Imaging, Research, Genitourinary, Education, President's Choice
ETC Level: LEVEL II
Date: March 4, 2026 | 10:00 - 11:00 CET
CME Credits: 1

Moderator:
Milagros Otero Garcia; Vigo / Spain

Chairperson's introduction (5 min)
Milagros Otero Garcia; Vigo / Spain

Endometrial cancer (15 min)
Alison Clare Harris; Vancouver, BC / Canada

1. To learn about the clinical indications and imaging modalities for endometrial cancer staging.
2. To learn how to acquire and report MRI images according to the new guidelines appropriately.
3. To understand the clinical implications of imaging.

Cervical cancer (15 min)
Lucia Manganaro; Rome / Italy

1. To learn about the clinical indications and imaging modalities for cervical cancer staging.
2. To learn how to acquire and report MRI images according to the new guidelines appropriately.
3. To understand the clinical implications of imaging.

Ovarian cancer (15 min)
Olivera Nikolic; Novi Sad / Serbia

1. To learn about the clinical indications and updated ESUR imaging criteria for ovarian cancer staging.
2. To learn how to appropriately acquire and report MRI images based on the new ESUR guidelines.
3. To understand the clinical implications of imaging.

Panel discussion: How does imaging influence the management of patients? (10 min)

RC 208 - Thyroid imaging: practice updates

Categories: Oncologic Imaging, Head and Neck, Interventional Radiology, Interventional Oncologic Radiology, President's Choice
ETC Level: LEVEL II+III
Date: March 4, 2026 | 10:00 - 11:00 CET
CME Credits: 1

Moderator:
Salman Qureshi; Abu Dhabi / United Arab Emirates

Chairperson's introduction (5 min)
Salman Qureshi; Abu Dhabi / United Arab Emirates

Thyroid cancer: imaging strategies and staging (15 min)
Edith Vassallo; Msida / Malta

1. To understand the role of various imaging modalities (ultrasound, CT, MRI, nuclear medicine) in the diagnosis, staging, and risk stratification of thyroid cancer.
2. To learn the TNM staging system for thyroid cancer and how imaging findings correlate with tumour size, local invasion, lymph node involvement, and distant metastases.
3. To apply imaging-based criteria to guide clinical decision-making and postoperative management, including surveillance and treatment planning.

Thyroid nodules: evidence-based practice (15 min)
Andrew Sinclair McQueen; Newcastle Upon Tyne / United Kingdom

1. To review evidence-based guidelines and classifications for the initial evaluation and risk stratification of thyroid nodules using clinical assessment and ultrasound features.
2. To understand the criteria for selecting nodules for FNA based on ultrasound risk patterns and clinical context to optimise diagnostic accuracy and reduce unnecessary procedures.
3. To discuss management strategies for benign and indeterminate nodules, including surveillance protocols and indications for intervention.

How and when do I perform FNA and core biopsy of thyroid nodules: tricks and tips (15 min)
Timothy Beale; London / United Kingdom

1. To learn the indications and timing for performing fine-needle aspiration (FNA) and core needle biopsy in the workup of thyroid nodules.
2. To understand technical aspects and best practices for ultrasound-guided biopsy procedures to maximise sample adequacy and minimise complications.
3. To develop skills for interpreting biopsy results and integrating cytologic and histologic findings into clinical management pathways.

Panel discussion: Integrating new thyroid imaging guidelines into practice: where to begin? (10 min)

RC 210 - Handling the details of the wrist

Categories: Musculoskeletal, Imaging Methods, Evidence-Based Imaging, Education, President's Choice
ETC Level: LEVEL II
Date: March 4, 2026 | 10:00 - 11:00 CET
CME Credits: 1

Moderator:
Rainer Schmitt; Ingolstadt / Germany

Chairperson's introduction (5 min)
Rainer Schmitt; Ingolstadt / Germany

Ligaments of the wrists (15 min)
Andrea B. Rosskopf; Zurich / Switzerland

1. To name and identify the extrinsic and intrinsic ligaments and address the role of the ligaments in carpal instability.
2. To discuss injury patterns of intrinsic ligaments in the clinical context.
3. To describe the pathological appearance of the extrinsic ligaments.

Scaphoid non-union advanced collapse (SNAC) and scapho-lunate advanced collapse (SLAC) wrist (15 min)
Kitija Nulle; Riga / Latvia

1. To describe the anatomical and biomechanical differences between SLAC and SNAC wrists, including their underlying causes and progression patterns.
2. To accurately recognise key imaging findings and clinical signs associated with each condition to diagnose and differentiate between SLAC and SNAC wrists.
3. To discuss conservative and surgical treatment approaches for SLAC and SNAC and interpret the postoperative findings.

Triangular fibrocartilage complex (TFCC) (15 min)
Nina Hesse; Munich / Germany

1. To define the anatomy of the triangular fibrocartilage complex, anatomical variants, and functional anatomy.
2. To discuss the imaging of TFCC injuries, considering the clinical assessment and the proper imaging interpretation.
3. To list classifications of traumatic and degenerative TFCC injury and address their limitations.

Panel discussion: How detailed do we need to report changes to the wrist? (10 min)

RC 213 - MR safety management in focus: preventing incidents, promoting excellence

Categories: Imaging Methods, Radiographers, Physics in Medical Imaging, EuroSafe Imaging/Radiation Protection, Medico-legal, Multidisciplinary, President's Choice

MRI: are current practices ensuring examinations are safer than ever? (15 min)

Jolanta Karpowicz; Warsaw / Poland

1. To refresh the understanding of the influence of key MRI system electromagnetic components, including static magnetic field magnet, gradient coils, and RF systems, on patients' and occupational safety.
2. To explore real-world MRI safety incidents worldwide to identify common causes and risk factors.
3. To explore recent advancements in MRI technology, safety good practices, and regulatory guidance that have enhanced patients' and occupational safety in clinical MRI environments.

Safety management of (active and passive) patient implants in MRI (15 min)

Touko Kaasalainen; Helsinki / Finland

1. To differentiate between active and passive implants in the MRI environment, and to understand their respective safety implications, including risks related to heating, displacement, malfunction, and image artefacts.
2. To learn the importance of developing institution-specific protocols for managing implant-related MRI workflows.
3. To explore tools and best practices for implant safety management, such as implant registries, manufacturer documentation, electronic screening systems, and interdisciplinary communication protocols.

RF heat management (15 min)

Marta Maieron; Udine / Italy

1. To understand the biophysical mechanisms of RF-induced heating in MRI, including the role of specific absorption rate (SAR) and its interaction with patient anatomy, positioning, and tissue conductivity.
2. To identify key factors influencing RF heating risk, such as field strength, coil configuration, patient size, scan parameters, and the presence of conductive materials or implants.
3. To learn best practices and safety strategies to minimise RF heating effects, including protocol selections, pulse sequence adjustments, coil selection, etc.

Panel discussion: How to improve MR safety in a multidisciplinary environment? What are the roles of each occupational group in MR safety management? (10 min)

RC 214 - Radiography safety: current trends and future directions

Categories: Radiographers, Professional Issues, EuroSafe Imaging/Radiation Protection
Date: March 4, 2026 | 10:00 - 11:00 CET
CME Credits: 1

SESSION RECOMMENDED BY ESR EUROSAFE IMAGING

Moderators:

Procedural safety: communication, risk, and quality in imaging (10 min)
Anke De Bock; Willebroek / Belgium

1. To understand the critical role that radiographers play in promoting procedural safety within radiography.
2. To identify key leadership behaviours and communication strategies that radiographers can use to advocate for safety and quality care.
3. To learn how to apply procedural safety protocols and risk management principles in real-world imaging scenarios to enhance patient and staff outcomes.

Towards safer work environments for radiographers (10 min)
Vladimir Bahun; Doha / Qatar

1. To understand the work environment aspects that can affect radiographers' safety.
2. To make managers aware of the need for better work conditions and safer practices in radiography.
3. To learn strategies for safer practice.

Radiation protection in nuclear medicine: evolving standards (10 min)
Melissa Carmelo Cruz; Póvoa de Santa Iria / Portugal

1. To recognise key advancements in nuclear medicine technology that minimise patient and staff radiation exposure.
2. To understand current best practices in radiopharmaceutical handling that enhance procedural safety and compliance.
3. To identify quick, practical strategies using time, distance, and shielding to immediately improve radiation safety during nuclear medicine procedures.

Safety assurance in magnetic resonance practice (10 min)
Allison Mcgee; Dublin / Ireland

1. To identify key MRI safety risks and relevant safety zones.
2. To understand the role of audits in ensuring MRI safety compliance.
3. To learn how to apply local MRI safety procedures and respond to safety incidents.

Panel discussion: Safety radiography environment (15 min)

RPS 202 - Beyond the basics: the new era of breast ultrasound

Observer Agreement in Sonographic Glandular Tissue Component Classification and Breast Composition Assessment on Ultrasound: A Multi-Institutional Study (6 min)
Takayoshi Uematsu; Shizuoka / Japan

Author Block: T. Uematsu, U. G. T. C. (. R. C. Japan Association of Breast and Thyroid Sonology; Shizuoka/JP
Purpose: The sonographic glandular tissue component (GTC) has emerged as a potential imaging biomarker for stratifying breast cancer risk in women with dense breasts. Anticipating its inclusion in the upcoming BI-RADS 6th edition, this study aimed to assess the reliability and clinical utility of GTC classification and sonographic breast composition through a multi-institutional observer performance study.
Methods or Background: Fifteen readers (9 physicians, 6 sonographers) from 12 institutions independently assessed 100 paired ultrasound images twice, 1 month apart. GTC was qualitatively classified into four categories by fibroglandular tissue proportion (minimal, mild, moderate, marked); minimal/mild were grouped as low GTC and moderate/marked as high GTC. Breast composition was categorized as dense (high GTC), nondense (fat lobules visible), or intermediate, standardized by an FGT-to-FAT (subcutaneous and retromammary fat) ratio cutoff of 1. Inter- and intra-observer agreement was evaluated using κ statistics.
Results or Findings: Inter-observer agreement for GTC classifications was substantial for both the four-category (κ = 0.66 and 0.73 for the first and second readings, respectively) and dichotomized (κ = 0.61 and 0.64) schemes. Agreement for sonographic breast composition was similarly substantial (κ = 0.65 and 0.67). Intra-observer agreement was also substantial for GTC (four-category κ = 0.78; two-category κ = 0.75) and for breast composition (κ = 0.77).
Conclusion: Both inter- and intra-observer agreement were substantial, indicating that qualitative assessment of GTC and sonographic breast composition is reproducible and reliable. These findings support the integration of GTC into routine clinical practice and research as a practical tool for risk stratification in women with dense breasts.
Limitations: First, its retrospective design may have introduced selection bias. Second, evaluations were based on static images, which do not fully capture the dynamic information available in real-time ultrasound.
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This multi-institutional study was approved by the Institutional Review Board of our hospital (Approval No. T2024-11-2024-10-3).

Non-mass lesions on breast ultrasound: decoding predictors of malignancy through clinico-pathological correlation (6 min)
Eeta Jain; Greater noida / India

Author Block: E. Jain, R. BANSAL, Z. Khan, B. Aggarwal; New Delhi/IN
Purpose: Non-mass lesions (NMLs) are frequently encountered in breast imaging but are not formally defined in the 5th edition of the BI-RADS ultrasound lexicon. This study aimed to characterise their ultrasound features, evaluate corresponding findings on mammography and MRI when available, and identify predictors of malignancy through clinical and pathological correlation.
Methods or Background: This prospective single-centre study included 120 women with non-mass lesions (NMLs) detected on ultrasound between December 2024 and August 2025. Ultrasound served as the index test, with features assessed according to the Japan Association of Breast and Thyroid Sonology (JABTS) criteria, classifying NMLs as ductal abnormalities, hypoechoic areas, architectural distortion, microcysts, or echogenic foci without a hypoechoic area. Histopathology of ultrasound-guided biopsies was the reference standard, with malignant lesions further characterised by immunohistochemistry (ER, PR, HER2, Ki-67). Benign and malignant NMLs were compared for demographics, clinical presentation, and imaging features. Logistic regression was used to identify independent predictors, and receiver operating characteristic (ROC) analysis compared the diagnostic accuracy of BI-RADS with the predictive model.
Results or Findings: Of 120 NMLs, 62.5% were malignant and 37.5% benign. Independent predictors of malignancy were posterior shadowing ($p < 0.001$), echogenic foci ($p = 0.008$), and architectural distortion ($p = 0.006$), while hypoechoic areas were highly sensitive but non-specific. Malignancy rates increased progressively across BI-RADS categories, with BI-RADS ≥4B yielding a sensitivity of 75%, specificity of 80%, and accuracy of 77%. The regression-based predictive model demonstrated superior diagnostic performance (AUC 0.87) compared with BI-RADS alone (AUC 0.78).
Conclusion: Posterior shadowing, echogenic foci, and architectural distortion are key predictors of malignancy in NMLs. As these lesions remain undefined in the BI-RADS lexicon, this study underscores the need for standardised descriptors and integrated imaging to improve diagnostic accuracy.
Limitations: Not applicable.
Funding for this study: No funding was provided for this study.
Has your study been approved by an ethics committee? Yes

Preliminary Results Comparing Diagnostic Accuracy of 12G vs 14G CNB in Non-Mass Breast Lesions (6 min)

Zişan Hayriye Yücel; Başakşehir / İstanbul / Turkey

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: Z. h. Temiz, M. A. Nazli; Istanbul/TR
Purpose: Non-mass breast lesions present diagnostic difficulties due to their subtle imaging features and varied pathology. Although 14-gauge (14G) core needle biopsy (CNB) is standard, 12-gauge (12G) devices may offer better tissue yield. This study aims to compare the diagnostic performance of 12G and 14G CNB in non-mass breast lesions, focusing on tissue yield, sample adequacy, radiology–pathology concordance, upgrade rates of high-risk lesions (B3).
Methods or Background: This retrospective study analyzed 106 non-mass breast lesions (12G: 38; 14G: 68) detected by mammography, ultrasound, or MRI. Biopsies were ultrasound and histopathology was categorized as benign, high-risk, or malignant. Evaluated outcomes included radiology–pathology concordance, calcification, upgrade after surgery/re-biopsy, and management. Statistical analysis used Fisher's exact test with ORs and 95% CI; $p<0.05$ was significant.
Results or Findings: Radiology–pathology discordance was lower in the 12G group (10.5%) compared to the 14G group (20.6%) (OR=0.45, p=0.23). Calcification sampling was significantly higher with 12G (39.5%) versus 14G (17.6%) (p=0.02). Upgrade rates were similar: 12G 13.2% vs 14G 10.3% (OR=1.33, p=0.75). Among calcification-positive lesions, discordance was lower in the 12G group (13.3%) than in the 14G group (33.3%) (OR=0.31, p=0.36), and upgrade rates were also lower (20.0% vs 41.7%; OR=0.35, p=0.40).
Conclusion: The 12G core needle biopsy demonstrated a higher success rate in sampling calcifications and showed a trend toward lower radiology–pathology discordance compared to 14G device, although the difference was not statistically significant. While upgrade rates remained similar between the two groups, these preliminary findings indicate that the 12G needle may provide more reliable sampling, particularly in calcification-rich non-mass breast lesions.
Limitations: This study is limited by its retrospective single-center design, small sample size, and incomplete follow-up, which may affect the accuracy of upgrade rates. Additionally, needle selection bias could have influenced group distribution.
Funding for this study: This study received no funding.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Ethics approval was obtained from the IRB of Başakşehir Çam and Sakura City Hospital.

The number of biopsies taken and the pathological accuracy rate of breast diseases (6 min)

Ahmet Kürşat Kursat Soydan; Istanbul / Turkey

Author Block: A. K. K. Soydan, M. Demir; Istanbul/TR
Purpose: To evaluate the cumulative diagnostic adequacy of sequential 14-gauge tru-cut biopsy samples in breast lesions visible on ultrasonography and determine the optimal number of core samples required for diagnostic accuracy.
Methods or Background: Prospective study conducted June-December 2024 including 86 patients with 86 breast lesions (BI-RADS 3, 4, or 5). Three sequential core biopsy samples were obtained from each lesion under US guidance using 14-G automated biopsy needle. Each sample was sent separately for pathological evaluation. Cumulative diagnostic adequacy was assessed for one, two, and three samples.
Results or Findings: Cumulative diagnostic adequacy: 84.9% (73/86) with first core, 94.2% (81/86) with two cores, 98.8% (85/86) with three cores. All malignant lesions (n=15) were diagnosed with first two samples (100%). Diagnostic adequacy increase was significant from first to second sample ($p<0.05$) but not from second to third ($p>0.05$). First core diagnostic rate was higher for solid lesions (87.3%) versus cystic lesions (50.0%) ($p=0.049$).
Conclusion: Three core samples in US-guided tru-cut biopsy provide very high diagnostic adequacy (98.8%). Two high-quality core samples may be sufficient for diagnosing malignant lesions, suggesting biopsy protocols could be optimized to be less invasive without compromising oncologic safety.
Limitations: Single-center study limiting generalizability. Small sample size of malignant lesions (n=15). Single pathologist evaluation precluding inter-observer reliability assessment. Benign lesion reference standard included follow-up rather than surgical excision in all cases.
Funding for this study: No
Not specified
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Study approved by Clinical Research Ethics Committee of Ümraniye Training and Research Hospital. Conducted according to Declaration of Helsinki principles. Written informed consent obtained from all participants.

Comparison of Shear wave elastography (SWE) characteristics according to receptor status in breast malignancies (6 min)

Unnati Chouksey; Durg / India

Author Block: U. Chouksey, P. B. Thakkar, A. Katdare, P. Haria, N. Shetty, S. Kulkarni; Mumbai/IN
Purpose: Evaluation of qualitative and quantitative characteristics of Shear wave elastography (SWE) among malignant breast lesions according to their receptor status.
Methods or Background: This study was a subset analysis of a larger prospective observational study including 468 lesions in 404 patients. Among these, hormonal and molecular receptor statuses were available for 388 malignant cases. These lesions were broadly categorized into three groups, i.e. first group being receptor positive, that is either ER or PR positive, the second group being HER – 2 enriched and the
third group being triple negative. The mean values along with measures of distribution for Emax and Emean was calculated for each category. Qualitative characteristics were also evaluated, like presence of perilesional stiff rim.

These lesions were accordingly differently classified based on the qualitative internal stiffness and perilesional stiffness into four categories: perilesional stiff rim present and qualitatively soft, perilesional stiff rim present and qualitatively hard, perilesional stiff rim absent and qualitatively soft, and perilesional stiff rim absent and qualitatively hard.
Results or Findings: Majority of the lesions with triple negative receptor status showed a perilesional stiff ring and were internally soft. While 90 percent of the lesions in the HER-2 subgroup demonstrated a perilesional stiff ring (including both hard and soft lesions). No such trend was observed in the receptor-positive subgroup.
Conclusion: 1. A significant difference was found among the values of Emean among the three classifications of molecular and hormonal subtypes but not among Emax values.
2. There was significant association of the perilesional ring present, qualitative soft subset with both TNBC and HER-2 enriched subset. There was no significant association of any of the four categories with the Receptor positive subgroup.
Limitations: Evaluation of qualitative parameters suffered from observer bias.
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This was a subset analysis of a prospective observational study, approved by the institutional ethics committee.

New Ultrasound Techniques for Breast Lesion Characterization: Prospective Comparison of BI-RADS, Histology, CAD "Live BreastAssist", Strain Elastography, Shear Wave, and MV Flow (6 min)

Maurizio Renda; Rome / Italy

Author Block: M. Renda, C. Catalano, G. Bonito, C. Solito, F. Raponi, V. Dolcetti, G. Maglia, G. Lo Conte, V. Cantisani; Rome/IT
Purpose: The purpose of our study was to compare the diagnostic performance of the new ultrasound techniques in the differentiation between benign and malignant breast lesions, in accordance to the BI-RADS classification, evaluating the agreement between the software “Live Breast Assist”, human investigator, and the diagnostic accuracy of Elastography performed with Strain Ratio (SR), 2D-Shear Wave (STE) Point Shear Wave (STQ), and advanced Doppler technique MV-Flow. Inter-operator variability will also be analyzed.
Methods or Background: 92 patients have been enrolled, with a total of 110 focal breast lesions evaluated by an experienced breast imaging radiologist who assigned BI-RADS categories.
All patients were analyzed using Strain Elastography (SE), Shear Wave Elastography (STE),using B-mode ultrasound, color Doppler, MV-FLOW, semi-automatic “Live Breast Assist” software analysis.
All patients underwent biopsy, with histopathology serving as the gold standard.
Results or Findings: A total of 110 breast lesions were analyzed (14% benign, 7.6% B3, 78.4% malignant), with fibroadenomas and fibrocystic mastopathy being the most common benign findings, and infiltrating ductal carcinoma the predominant malignancy. The Live Breast Assist software demonstrated excellent agreement with the operator in assessing size, margins, orientation, and echostructure. Concordance with histological BI-RADS classification was high, while operator–histology agreement was good.
Elastography identified a Strain Ratio cut-off of 1.89, with strain elastography outperforming 2D SWE and pSWE.
The MV FLOW software, which provides advantages over conventional color Doppler, has demonstrated that higher measured values in breast lesions are correlated with the histopathological grade of lesion severity
Conclusion: New advanced ultrasound techniques show promising results for differentiating breast lesions, potentially reducing the need for biopsies, and serving as a support tool in discriminating a suspicious lesion.
Limitations: The limitations of this study include the small sample size, which, however, can be readily increased.
Funding for this study: No
Has your study been approved by an ethics committee? Not applicable

A Novel Deep Learning Radiomics Nomogram Integrating B-mode Ultrasound and Contrast-enhanced Ultrasound for Preoperative Prediction of Lymphovascular Invasion in Invasive Breast Cancer (6 min)

Zhi Li Wang; Beijing / China

Author Block: Z. L. Wang; Beijing/CN
Purpose: To develop a deep learning radiomics nomogram (DLRN) that integrated B-mode ultrasound (BMUS) and contrast-enhanced ultrasound (CEUS) images for preoperative lymphovascular invasion (LVI) prediction in invasive breast cancer (IBC).
Methods or Background: 981 patients with IBC from three hospitals were retrospectively enrolled. Of 834 patients recruited from Hospital I, 688 were designated as the training cohort and 146 as the internal test cohort, whereas 147 patients from Hospitals II and III were assigned to constitute the external test cohort. Deep learning and handcrafted radiomics features of BMUS and CEUS images were extracted from breast cancer to construct a deep learning radiomics (DLR) signature. The DLRN was developed by integrating the DLR signature and independent clinicopathological parameters. The performance of the DLRN was evaluated with respect to discrimination, calibration, and clinical benefit.
Results or Findings: The DLRN exhibited good performance in predicting LVI, with areas under the receiver operating characteristic curves (AUCs) of 0.885 (95% confidence interval [CI], 0.858-0.912), 0.914 (95% CI, 0.868-0.960) and 0.914 (95% CI, 0.867-0.960) in the training, internal test, and external test cohorts, respectively. The DLRN exhibited good stability and clinical practicability, as demonstrated by the calibration curve and decision curve analysis. In addition, the DLRN outperformed the traditional clinical model and the DLR signature for LVI prediction in the internal and external test cohorts (all $P < 0.05$).
Conclusion: The DLRN exhibited good performance in predicting LVI, representing a non-invasive approach to preoperatively determining LVI status in IBC.
Limitations: This study only included patients with unifocal IBC due to the difficulty in identifying the lesion causing ALN metastasis in multifocal and multicentric lesions. The DLRN was developed based on static breast CEUS images rather than CEUS videos due to the retrospective study.
Funding for this study: This study has received funding by National Key Research and Development Program of China (2023YFC2414203), and National Natural Science Foundation of China (No. 82371972).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was authorized by the institutional review board of the Hospital and adhered to the Declaration of Helsinki (S2024-801-01).

Energy sustainability of breast ultrasound: Comparison between automated and handheld ultrasound systems (6 min)

Jeong Taek Lee; Ansan / Korea, Republic of

Author Block: J. T. Lee[1], B. K. Seo[1], J. Y. Lee[1], M. S. Bae[1], Y. Moon[1], K. R. Cho[2], O. Woo[2], S. E. Song[2], S-Y. Kim[2]; [1]Ansan/KR, [2]Seoul/KR
Purpose: Breast cancer is the most common female malignancy worldwide, and ultrasound (US) is widely used for diagnosis and screening. While its clinical utility is well established, the environmental impact has rarely been assessed. This study compared the energy consumption of automated breast ultrasound (ABUS) and handheld ultrasound (HHUS) systems and explored strategies for optimized ultrasound management.
Methods or Background: In this prospective study, one ABUS and two HHUS systems (HHUS-1 and HHUS-2) from different vendors were evaluated using a power meter (1-Hz sampling). A total of 240 patients without prior breast surgery underwent B-mode US (80 ABUS, 80 HHUS-1, 80 HHUS-2). For HHUS, four breast radiologists (16–26 years of experience) each performed 20 examinations per system. We measured average power (kW) during active, idle, and off modes, scan time (min), energy use (kWh), and carbon emissions ($kgCO_2e$). Group comparisons were performed using the Mann-Whitney U test.
Results or Findings: Compared with HHUS-1, ABUS required 28%, 35%, and 100% less average power in active, idle, and off modes, respectively, and 24% shorter scan time, resulting in a 46% reduction in energy consumption and carbon emissions (all $p < 0.05$). Compared with HHUS-2, ABUS showed similar active-mode power but 26% and 100% reductions in idle and off modes and 18% shorter scan time. These changes yielded a 7% overall reduction in energy and emissions; the decreases in idle, off, and scan time were statistically significant ($p < 0.05$). Reducing idle-mode duration further lowered energy consumption by 12–16%.
Conclusion: ABUS demonstrated lower power demand, energy consumption, and carbon emissions compared with HHUS. Optimizing ultrasound workflows, particularly minimizing idle time, may improve environmental sustainability while maintaining clinical utility.
Limitations: Not applicable

Assessment of the stability of intracranial aneurysms using a deep learning model based on computed tomography angiography (6 min)
Lu Zeng; Chongqing / China

Author Block: L. Zeng; Chongqing/CN
Purpose: The aim of this study was to construct a deep learning model (DLM) to identify unstable aneurysms on computed tomography angiography (CTA) images.
Methods or Background: The clinical data of 1041 patients with 1227 aneurysms were retrospectively analyzed from August 2011 to May 2021. Patients with aneurysms were divided into unstable (ruptured, evolving and symptomatic aneurysms) and stable (fortuitous, nonevolving and asymptomatic aneurysms) groups and randomly divided into training (833 patients with 991 aneurysms) and internal validation (208 patients with 236 aneurysms) sets. One hundred and ninety-seven patients with 229 aneurysms from another hospital were included in the external validation set. Six models based on a convolutional neural network (CNN) or logistic regression were constructed on the basis of clinical, morphological and deep learning (DL) features. The area under the curve (AUC), accuracy, sensitivity and specifcity were calculated to evaluate the discriminating ability of the models.
Results or Findings: The AUCs of Models A (clinical), B (morphological) and C (DL features from the CTA image) in the external validation set were 0.5706, 0.9665 and 0.8453, respectively. The AUCs of Model D (clinical and DL features), Model E (clinical and morphological features) and Model F (clinical, morphological and DL features) in the external validation set were 0.8395, 0.9597 and 0.9696, respectively.
Conclusion: The CNN-based DLM, which integrates clinical, morphological and DL features, outperforms other models in predicting IA stability. The DLM has the potential to assess IA stability and support clinical decision-making.
Limitations: The maximum slices of aneurysm images were used to construct 2D models, and some important factors that may affect aneurysm stability may have been missed, possibly leading to bias. More advanced DL algorithms are needed.
Funding for this study: This study was supported by the Science and Technology Commission of Chongqing City, China (CSTB2023NSCQ-MSX0668), the Joint Project of Science and Health of Chongqing City, China (2023MSXM022) and the Science and Technology Research Program of Chongqing Municipal Education Commission (KJQN202200407).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The local ethics committee (Banan Hospital, 2021015; Xinqiao Hospital, 202248201) approved this retrospective study and agreed to the informed consent waiver of patients.

Glioblastoma Response Prediction and Tumor and Organ-at-Risk Segmentation with Radiomics and Deep Learning (6 min)
Alejandro Mora Rubio; Valencia / Spain

Author Block: A. Mora Rubio[1], C. Bravo Vergara[1], M. Beser-Robles[1], G. Ribas[1], P. Garcia Verdu[1], I. Popp[2], A. L. Grosu[2], L. Marti-Bonmati[1], M. Carles Fariña[1]; [1]Valencia/ES, [2]Freiburg/DE
Purpose: The current standard treatment for Glioblastoma Multiforme (GBM) involves radiation therapy (RT) and requires manual tumour segmentation, which is labour-intensive and susceptible to inter-observer variability. Additionally, given the high recurrence rate of GBM patients, accurate response prediction methods can help to improve patient prognosis stratification and optimize treatment plans. The aim of this study is to develop and evaluate automatic segmentation methods based on deep learning and assess the ability of mathematical models employing clinical and radiomics features (RF) to improve the accuracy of response prediction.
Methods or Background: The study included 253 patients with primary/recurrent GBM, prospectively (185) and a retrospectively recruited in 13 institutions. The open-source cohort BraTS2021 of primary glioma patients was also used. The nnU-Net open-source framework was used to develop models for Enhancing Tumour, Peritumoral Edema, RT Planning Target Volume and six Organs-at-Risk, based on segmentation performed by neuroradiologist and radiation oncologist. For response prediction in recurrent GBM of the prospective cohort, the Cox Proportional Hazard and Logistic Regression models for overall survival, time to progression, and early recurrence prediction, were applied.
Results or Findings: The segmentation models achieved good to excellent performance, with average DSC scores in the test set of 0.79 (0.69-0.98). Clinical and MR-RF showed significant discrimination between patients with early and late progression on validation and test sets ($p < 0.05$ in Kaplan-Meier curves). Wavelet transform RF and clinical features like age, methylation status, and tumour localisation were notably significant predictors.
Conclusion: The good performance of the automatic segmentation models supports their use in clinical workflows to simplify procedures, reduce time investment, and increase robustness. Radiomics analysis suggested that the MR-RF model has potential for predicting time to progression.
Limitations: Ongoing work is about the FET-PET complementary information.
Funding for this study: This work was supported by the MATTO-GBM Project under the European TRANSCAN-3 ERA-NET 2022 Program, funded by ISCIII (AC23_1/00012), FAECC (TRANSCAN2022-784-104), and the European Union through the Next Generation EU Funds. The funders had no role in study design, data collection and analysis, decision to publish, or preparation of the manuscript.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: All patients gave written informed consent according to institutional and federal guidelines. All study protocols were approved by the corresponding ethics committee.

Diagnostic accuracy of a commercial AI tool for intracranial large- and medium-vessel occlusion detection in a multicenter emergency-CTA cohort (6 min)

Henrik Andersson; Lund / Sweden

Author Block: H. Andersson, B. Hansen, J. Wassélius; Lund/SE
Purpose: To evaluate the diagnostic accuracy of an AI tool (AIDOC VO), the first commercial AI tool designed to detect both large (LVO) and medium vessel occlusions (MeVO) on head-and-neck CT angiography (CTA), in a region-wide multicenter emergency setting.
Methods or Background: Prospective diagnostic-accuracy study of consecutive emergency CTAs from 3 031 adults (mean age 67 years; 51 % women), acquired 1 March - 8 July 2024 across a ten hospitals healthcare region. AI analysed each scan; the routine radiology report served as comparator. Examinations flagged positive or doubtful by either test underwent rereading by interventional neuroradiologists to establish the reference standard. Sensitivity, specificity, predictive value, and accuracy were calculated for the primary VO analysis, with prespecified sub-analyses for LVO and MeVO. Paired differences were tested with McNemar's test.
Results or Findings: Of 3 031 CTAs, 2 804 (92.5 %) yielded valid AI output, among which VO was identified in 224 (8 %) examinations. VO sensitivity/specificity were 81.7%/99.6% for AI versus 81.2%/99.3% for the clinical radiology report ($p = 0.91$/$p = 0.12$). LVO sensitivity was 92.8% versus 87.0% (p=0.42); MeVO 76.1% versus 79.2% (p=0.55). Paired overall accuracy showed no significant differences (VO p=0.38; LVO p=0.06; MeVO p=0.76). AI identified VO in 42 examinations missed by radiologists (18.8% enhanced detection; 15 per 1,000) and generated 11 false alerts (3.9 per 1,000).
Conclusion: Stand-alone AI matched radiologist performance, with a similar number of enhanced detections and few false alerts, supporting complementary use in emergency stroke workflows.
Limitations: About 7.5% of CTAs failed quality control, only positive/doubtful cases were reread so some false negatives may have been missed, AI heat-map localization was not verified, and effects of AI assistance on readers were not assessed.
Funding for this study: Funding was provided by the Crafoord Foundation, VINNOVA, and SUS Stiftelser & Fonder; sponsors had no role in the study.

Ethics committee - additional information: The Swedish Ethical Review Authority approved the study (#2023-00387-01) and waived informed consent.

Development of predictive models to identify the intracranial aneurysm responsible for subarachnoid hemorrhage in patients with multiple saccular aneurysms (6 min)

Guangxian Wang; Chongqing / China

Author Block: G. Wang; Chongqing/CN
Purpose: To develop and test machine learning (ML) models using CTA to identify the intracranial aneurysm (IA) responsible for subarachnoid hemorrhage (SAH) accurately in patients with multiple saccular IAs and to determine whether these models outperform traditional predictive markers.
Methods or Background: 207 SAH patients with 460 IAs from four hospitals were included and randomly divided into training (80%) and internal validation (20%) sets. Additionally, an external validation set comprising 65 patients with 147 IAs from other four hospitals was used. The predictive models were developed using ML methods that integrated the morphological features of IAs (e.g., size and shape) to identify the responsible IA. These models were then compared with traditional predictive markers that relies on hemorrhage patterns and the maximum IA size.
Results or Findings: The areas under the curves (AUCs) for the hemorrhage patterns and the maximum IA size were 0.496–0.505, 0.502–0.523, and 0.488–0.498 in the training, internal validation, and external validation sets, respectively. Among the 13 ML models, the best-performing models were the Gaussian process, logistic regression, and quadratic discriminant analysis models, with AUCs of 0.912, 0.894, and 0.890, respectively, for the training set; 0.869, 0.872, and 0.853, respectively, for the internal validation set; and 0.898, 0.892, and 0.897, respectively, for the external validation set. DeLong tests revealed no significant differences among these models, but all the models outperformed traditional predictive markers ($P<0.001$).
Conclusion: ML models that integrate multiple morphological features can predict the IA responsible for SAH accurately in patients with multiple IAs. These models outperform traditional predictive markers in identifying the responsible IA, thereby facilitating prompt and effective treatment.
Limitations: The results may not be applicable for predicting the rupture risk of unruptured IAs or for patients with a single IA.
Funding for this study: This study was supported by the Science and Technology Commission of Chongqing City, China (CSTB2023NSCQ-MSX0668) and the Science and Technology Research Program of Chongqing Municipal Education Commission (KJQN202200407).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This multicenter study received approval from the ethics committees of our hospitals. Since this was a retrospective study, informed consent from patients was not needed.

Explainable machine learning model based on pretreatment MRI radiomic features for differentiating brain metastasis from glioblastoma (6 min)

Xiaoping Yi; Chongqing / China

Author Block: X. Yi[1], B. T. Chen[2]; [1]Chongqing/CN, [2]Duarte, CA/US
Purpose: Machine learning prediction models of brain metastasis (BM) and glioblastoma (GBM) are mostly not explainable, which hinders their clinical application. This study aimed to develop an explainable machine learning model utilizing brain magnetic resonance imaging (MRI) radiomics and clinical data.
Methods or Background: This retrospective study consisted of 596 patients from two independent institutions. Clinical demographic information and MRI data were collected. A three-stage feature selection process (Lasso + Boruta + multicollinearity removal) was employed to identify the most significant predictors from the clinical and radiomic datasets. An explainable Extra Tree model was constructed, and the SHAP (SHapley Additive exPlanations) method was utilized to enhance model explanation.
Results or Findings: Twelve features derived from clinical and radiomic data were selected to build the explainable machine learning Extra Tree model. The model achieved area under the curve (AUC) values of 0.9804, 0.9733, and 0.9542 in the training, internal validation, and independent external validation cohorts, respectively. The Extra Tree model exhibited superior classification performance compared to ten other promising models in both internal and external validation cohorts. The explainable Extra Tree model, integrating clinical data, T1 radiomic features and T2 radiomic features, outperformed single-feature models (e.g., clinical-only, T1-only, or T2-only model) as well as pairwise combined models (e.g., clinical+T1, clinical+T2, or T1+T2 model). The Extra Tree model enhanced explanation through four key steps: local explanation, global explanation, feature effect analysis, and sensitivity analysis.
Conclusion: The explainable machine learning Extra Tree model effectively and accurately distinguished BM from GBM, which should help to potentially implement it in clinical use and assist in clinical decision-making.
Limitations: The retrospective nature of this study may lead to inevitable case selection bias and our study was limited with potential overfitting issues.

Diffusion-based deep learning model for automated detection of focal cortical dysplasia using multi-modality PET-MRI (6 min)

Maha Alshammari; London / United Kingdom

Author Block: M. Alshammari[1], M. Yakubu[1], E. Guedj[2], N. Girard[2], J. Cardoso[1], A. Hammers[1]; [1]London/UK, [2]Marseille/FR
Purpose: Co-registration of FDG PET and MRI has been shown to improve detectability of epileptogenic lesions in focal cortical dysplasia (FCD). In previous work, we generated pseudo-normal PET using a diffusion model, which achieved high sensitivity but resulted in an average of 22 false positives per case. Here, we integrate multi-modality data (co-registered PET and MRI) for the generation of pseudo-normal PET.
Methods or Background: A weakly-supervised 2D-UNet-based diffusion model with dual input channels (co-registered PET and MRI) was trained on 280 slices from 35 healthy controls, with synthetic FCD lesions in 140 slices (50%). The model was trained using 5-fold cross-validation, yielding 5 independent models. Each test case was processed through all 5 cross-validated models at 2 different noise levels with 5 samples each, generating 50 pseudo-normal reconstructions. Deviations between original and pseudo-normal images were quantified as voxel-wise robust Z-scores, enhanced using Probabilistic Threshold-Free Cluster Enhancement (pTFCE), and thresholded at FWER-corrected value. Performance was evaluated on 10 independent synthetically lesioned test cases.
Results or Findings: The multi-modality model achieved 80% sensitivity (8/10 lesions detected) with 2.0±2.72 false-positive detections per case. This represents an 11-fold improvement in specificity compared to our previous PET-only approach while maintaining comparable detection sensitivity.
Conclusion: The multi-modality diffusion model successfully detects FCD lesions with dramatically improved specificity. The reduction from 22 to 2 false positives per case demonstrates significant clinical potential for automated epileptogenic zone localisation in presurgical epilepsy evaluation.
Limitations: Validation was performed on synthetically lesioned cases only. Further evaluation with clinical FCD cases and larger diverse datasets is required to establish robust real-world performance.
Funding for this study: Funding for this study: The School of Biomedical Engineering and Imaging Sciences is supported by the Wellcome EPSRC Centre for Medical Engineering at King's College London (WT 203148/Z/16/Z) and the Department of Health via the National Institute for Health Research (NIHR) comprehensive Biomedical Research Centre award to Guy's & St Thomas' NHS Foundation Trust in partnership with King's College London and King's College Hospital NHS Foundation Trust. MA is supported by the Saudi Arabia Cultural Bureau in London under the Saudi scholarship program.

Unmasking Bias in BrainAGE: The Role of Scanner Manufacturer, Field Strength and Sequence Parameters (6 min)

Vivien Lorena Ivan; Düsseldorf / Germany

Author Block: V. L. Ivan[1], M. Vach[1], J. Caspers[1], D. Weiß[1], D. M. Hedderich[2], C. Rubbert[1]; [1]Düsseldorf/DE, [2]Munich/DE
Purpose: Brain Age Gap Estimation (BrainAGE) has emerged as a promising biomarker of brain health and disease. Yet, systematic bias may arise not only from study design but also from technical factors such as scanner manufacturer, field strength, or sequence parameters. This study aimed to quantify their influence on BrainAGE in healthy subjects.
Methods or Background: We included 2,414 cognitively normal participants from four population-based studies (ADNI, HCPA, OASIS3, PPMI). BrainAGE was computed using a standardized pipeline (CAT12/SPM12 preprocessing, PCA, Gaussian process regression) and a model trained on 2,953 independent controls. Differences in BrainAGE were assessed across cohorts, scanner manufacturers, field strengths (1.5T vs 3T), and T1-sequence acceleration using Welch's t-tests or ANOVA with Tukey post-hoc tests. Mean absolute error (MAE) was also calculated.
Results or Findings: Mean BrainAGE differed significantly between cohorts (ADNI: –5.9±5.5 years, HCPA: –4.1±6.2, OASIS3: –4.8±5.4, PPMI: –3.0±5.8; $p<0.0001$). Field strength had a strong impact: 1.5T scans yielded smaller BrainAGE (–2.2±4.8 years, MAE ~4.2) compared to 3T scans (–5.1±5.6, MAE ~6.7; $p<0.05$ across cohorts). Scanner manufacturer also mattered: in ADNI, Philips scanners produced a significantly smaller BrainAGE (–4.9±5.1, MAE 6.0) compared to GE (–6.3±6.2, MAE 7.3; $p=0.008$), while in PPMI Siemens differed from GE ($p=0.008$). By contrast, accelerated vs. unaccelerated 3T T1 acquisitions showed no significant effect ($p=0.47$).
Conclusion: Scanner manufacturer and field strength systematically bias BrainAGE in healthy cohorts, while sequence acceleration does not. These findings highlight that BrainAGE is not scanner-independent and emphasize caution when comparing results across studies or pooling multi-cohort data.
Limitations: The retrospective use of heterogeneous cohort data with only limited scanner parameter detail may confound effects of acquisition protocols with cohort-specific factors
Funding for this study: None

Brain metabolic imaging with 18F-PET-CT and machine-learning clustering analysis reveal divergent metabolic phenotypes in patients with amyotrophic lateral sclerosis (6 min)

Xiaoping Yi; Chongqing / China

Author Block: X. Yi[1], B. T. Chen[2]; [1]Chongqing/CN, [2]Duarte, CA/US
Purpose: This study aimed to identify distinct ALS phenotypes by integrating brain 18F-fluorodeoxyglucose positron emission tomography-computed tomography (18F-FDG PET-CT) metabolic imaging with consensus clustering data.
Methods or Background: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disorder characterized by significant clinicopathologic heterogeneity. This study prospectively enrolled 127 patients with ALS and 128 healthy controls. All participants underwent a brain 18F-FDG-PET-CT metabolic imaging, psychological questionnaires, and functional screening. K-means consensus clustering was applied to define neuroimaging-based phenotypes. Survival analyses were also performed. Whole exome sequencing (WES) was utilized to detect ALS-related genetic mutations, followed by GO/KEGG pathway enrichment and imaging-transcriptome analysis based on the brain metabolic activity on the 18F-FDG-PET-CT imaging.
Results or Findings: Consensus clustering identified two metabolic phenotypes, i.e., the metabolic attenuation phenotype and the metabolic non-attenuation phenotype according to their glucose metabolic activity pattern. The metabolic attenuation phenotype was associated with worse survival ($p = 0.022$), poorer physical function ($p = 0.005$), more severe depression ($p = 0.026$) and greater anxiety level ($p = 0.05$). WES testing and neuroimaging-transcriptome analysis identified specific gene mutations and molecular pathways with each phenotype.
Conclusion: We identified two distinct ALS phenotypes with varying clinicopathologic features, indicating that the unsupervised machine learning applied to PET imaging may effectively classify metabolic subtypes of ALS. These findings contributed novel insights into the heterogeneous pathophysiology of ALS, which should inform personalized therapeutic strategies for patients with ALS.
Limitations: The sample size was relatively small, and this was a cross-sectional study without follow-up neuroimaging data to assess brain fuctional changes over time and their correlations with clinical outcome.
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was approved by the Ethics Committee and Institutional Review Board of Xiangya Hospital, and written informed consent was obtained from all study participants.

Synergistic A.I.: Unique Approach of Dual Algorithm Integration Transforms Trauma Imaging Workflow (6 min)

Carolien Margot Toxopeus; Amsterdam / Netherlands

Author Block: C. M. Toxopeus, D. Duyndam, M. Gorzeman, A. Driessen; Amsterdam/NL
Purpose: Increasing CT scan demand, particularly brain and cervical spine trauma imaging, places significant pressure on emergency departments (ED). OLVG Hospital began evaluating algorithms from AIDOC for these scans in 2021. Previous studies in our hospital demonstrated that AIDOC implementation significantly reduced trauma patient throughput times for CT brain in context of trauma. Since these scans are often combined with CT cervical spine, we investigated the potential for further ED throughput time reduction through a cervical spine fracture algorithm. Algorithm accuracy was thoroughly tested before release to emergency physicians.
Methods or Background: We analyzed 2,564 cases (June 2022 - June 2023) to assess algorithm accuracy. Training modules were developed for emergency physicians. Given lower sensitivity for cervical fractures in severe arthrosis, algorithm use was restricted to patients <65 years, excluding high-energy trauma or neurological deficits. Emergency physicians could consult radiologists for excluded categories. During pilot testing (December 2023 - April 2024), emergency physicians used the cervical algorithm during shifts.
Results or Findings: The accuracy study yielded a positive predictive value >50% and negative predictive value >99.45% and deemed safe within the context of our Level II trauma center. Emergency physician evaluation of cervical spine algorithm use was consistently positive, leading to definitive integration into our collaborative ED workflow.
Conclusion: This study demonstrates that combined application of AIDOC algorithms for CT brain and cervical spine in a Level II trauma center, together with emergency physician training: 1) is safe, 2) results in significant workload reduction for radiologists during shifts, 3) increases efficiency of patient flow in the ED, and 4) has a positive effect on collaboration between radiologists and clinicians.
Limitations: This study was conducted at a Level II trauma center, which may limit generalizability to other trauma centers.
Funding for this study: Innovation Fund of OLVG Hospital.

Structured Reporting and Contrast-Enhanced Ultrasound in Testicular Tumor Assessment: A Retrospective Study to Enhance Diagnostic Clarity and Clinical Decision-Making (6 min)
Moritz Ludwig Schnitzer; Munich / Germany

Author Block: M. L. Schnitzer, F. Herr, J. Rübenthaler; Munich/DE
Purpose: Structured reporting (SR) offers standardized radiological documentation, enhancing clarity and reproducibility. However, its role in contrast-enhanced ultrasound (CEUS) for testicular tumors remains underexplored. This study evaluates SR's impact on diagnostic accuracy, clinical decision-making, and workflow efficiency compared to free-text reporting (FTR).
Methods or Background: In this retrospective, single-center study, 65 male patients with suspected testicular tumors underwent CEUS at LMU University Hospital. Reports were initially documented as FTRs by an experienced radiologist and later converted into SRs using Smart Reporting software. Four board-certified urologists independently assessed both formats using a structured questionnaire. Completeness, readability, trust, and impact on clinical decision-making were evaluated. Statistical analysis included McNemar's test and the Wilcoxon signed-rank test, with $\alpha = 0.05$.
Results or Findings: SRs significantly improved readability (97.3% vs. 10.0%, $p < 0.001$) and information extraction (98.8% vs. 91.9%, $p < 0.001$). However, completeness (56.9% vs. 60.8%, $p = 0.427$) and clinical decision support (85.7% vs. 84.9%, $p = 0.152$) were comparable. Trust in SRs was lower than in FTRs (4.92 vs. 5.22, $p < 0.001$), likely due to missing diagnostic parameters and retrospective SR generation.
Conclusion: SR enhances standardization and workflow efficiency but does not yet outperform FTRs in completeness or clinical decision-making. Interdisciplinary collaboration in template development and the integration of classification systems could improve SR's diagnostic value. Future prospective, multicenter studies should assess real-time SR implementation and its potential impact on diagnostic accuracy and patient management.
Limitations: This study's limitations include its retrospective, single-center design and small sample size, which may limit generalizability. The SRs were generated retrospectively from FTRs, potentially affecting trust and completeness. Additionally, missing diagnostic parameters and lack of real-time SR implementation could have influenced clinical decision-making outcomes.
Funding for this study: No funding.

Pharmaco-penile Doppler ultrasound in erectile dysfunction: experience from a Malagasy tertiary centre (6 min)
Ratsimbasoa Ny Ako; Antananarivo / Madagascar

Author Block: R. Franquine, R. Ny Ako, G. E. P. ANDRIANAH, L. H. N. O. N. Rajaonarison, R. Hasina Dina, A. Ahmad; Antananarivo/MG
Purpose: To describe the indications, findings, and diagnostic contribution of pharmaco-penile Doppler ultrasound in patients with erectile dysfunction in a Malagasy university hospital.
Methods or Background: This descriptive cross-sectional study was carried out at the imaging centre of Joseph Ravoahangy Andrianavalona University Hospital from 04.2022 to 12.2024. All patients who underwent pharmaco-penile Doppler ultrasound were included. Data collected from reports included demographics, clinical history, indications, drugs used (alprostadil), and haemodynamic parameters over time.
Results or Findings: Forty patients were included (mean age 50.3 years; range 22–78). Hypertension and diabetes were common comorbidities. The main indication was erectile dysfunction, with differentiation of vascular versus psychogenic causes. A vascular origin was found in 67.5% of cases, with arterial insufficiency in 42.5% (mean peak systolic velocity 14.3 ± 4.7 cm/s), venous leak in 20% (mean end-diastolic velocity 11.3 ± 0.7 cm/s), and mixed pattern in 5%. Psychogenic dysfunction was suspected in 32.5%. Pathological findings varied with age, with vascular causes predominating after 50 years. The technique was well tolerated and provided key data for therapeutic orientation.
Conclusion: Pharmaco-penile Doppler ultrasound is a minimally invasive and highly informative tool for the evaluation of erectile dysfunction. In our Malagasy cohort, vascular aetiologies were predominant, particularly arterial insufficiency and venous leak. This first structured local series highlights the central role of penile Doppler in differentiating vascular from psychogenic dysfunction and guiding multidisciplinary management. It also demonstrates that advanced functional ultrasound is feasible in resource-limited settings, with findings of international clinical relevance.
Limitations: The limitations of the study are its small sample size, retrospective design, and single-centre setting.
Funding for this study: No funding was received for this study.

Broken or Bruised? The Role of MRI in suspected Penile fracture (6 min)

Johannes Bjergfelt; Kbh s / Denmark

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: J. Bjergfelt, P. Peter Krysfeldt Hansen, R. Mirón Mombiela; Herlev/DK
Purpose: Penile fracture is a rare but acute urological condition that is most often diagnosed clinically. In cases with classic findings such as swelling, discoloration, an audible “snap,” and sudden loss of erection, urgent surgery is recommended without further imaging. However, in cases with an unclear clinical presentation, diagnostic uncertainty may arise, and MRI can be considered a valuable diagnostic tool. The purpose of the study was to investigate the role of MRI in patients with suspected penile fractures.
Methods or Background: We conducted a retrospective case series of 16 patients referred for MRI with suspected penile fracture between March 2024 and July 2025. Data were collected from the electronic medical record and PACS. Clinical history, physical findings, MRI results, treatment decisions, complications, surgical outcomes, and time intervals were analyzed.
Results or Findings: MRI confirmed penile fracture in 7 of 16 patients. Only 4 underwent surgery. The remaining 3 were managed conservatively: 2 due to proximal fractures and 1 due to a complex history with previous trauma. The remaining 9 patients got an alternative diagnosis and avoided unnecessary surgery. No major short-term complications were observed. All MRI’s were performed within 12 hours.
Conclusion: MRI is a cost-effective tool in the diagnostic work-up of patients with clinically uncertain penile fractures. The modality may contribute to a more precise treatment decision, particularly in cases with proximal lesions where surgery may carry a higher risk of complications. In this series, MRI did not delay treatment and avoided unnecessary surgery.
Limitations: This study was limited by its retrospective single-center design, the small number of patients, and the absence of a control group of patients who went straight to surgery.
Funding for this study: None

Radiomics-based detection of Germ Cell Neoplasia In Situ using volumetric ADC and FA histogram features: a retrospective study (6 min)

Maria Veatriki Christodoulou; Ioannina / Greece

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: M. V. Christodoulou, O. Pappa, L. G. Astrakas, E. Lampri, A. Paliouras, E. Douvli, N. Sofikitis, M. I. Argyropoulou, A. C. Tsili; Ioannina/GR
Purpose: Germ Cell Neoplasia In Situ (GCNIS) is the precursor of most testicular germ cell tumors (TGCTs). The aim of this study was to evaluate whether first-order radiomics features derived from volumetric diffusion tensor imaging (DTI) metrics—specifically apparent diffusion coefficient (ADC) and fractional anisotropy (FA) histogram parameters—can detect GCNIS.
Methods or Background: This study included 15 men with TGCTs and 10 controls who underwent scrotal MRI, including DTI. Volumetric ADC and FA histogram metrics were calculated for the following tissues: group 1, TGCT; group 2: testicular parenchyma adjacent to tumor, histologically positive for GCNIS; and group 3, normal testis. Non-parametric statistics assessed group differences in ADC and FA histogram parameters. Pearson's correlation analysis was followed by ordinal regression analysis to identify key predictive metrics.
Results or Findings: Widespread distributional differences ($p < 0.05$) were observed for many ADC and FA variables, with both TGCTs and GCNIS showing significant divergence from normal testes. Among the ADC statistics, the 10th percentile and skewness ($p = 0.042$), range ($p = 0.023$), interquartile range ($p = 0.021$), total energy ($p = 0.033$), entropy and kurtosis ($p = 0.027$) proved the most significant predictors for tissue classification. FA_energy ($p = 0.039$) was the most significant fingerprint of carcinogenesis among the FA metrics. These parameters correctly characterized 88.8% of TGCTs, 87.5% of GCNIS tissues and 100% of normal testes.
Conclusion: Radiomics features derived from volumetric ADC and FA histogram analysis may serve as valuable non-invasive biomarkers for the early detection of GCNIS and provide insights into testicular tumorigenesis.
Limitations: Single-center, retrospective design with a small sample size; manual, consensus-based segmentation; lack of independent validation cohort; analysis restricted to first-order radiomics features; and, lack of histological confirmation in controls.
Funding for this study: No funding was received for this study.

Ultrasound evaluation of inguino-scrotal pathologies: experience from a Malagasy university hospital (6 min)

Ratsimbasoa Ny Ako; Antananarivo / Madagascar

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: C. Randrianandrasana, R. Ny Ako, L. H. N. O. N. Rajaonarison, G. E. P. ANDRIANAH, R. Hasina Dina, A. Ahmad; Antananarivo/MG
Purpose: To describe the spectrum of inguino-scrotal pathologies on ultrasound, with emphasis on urgent entities such as complicated hernia and necrotic testicular torsion, and to determine their prevalence in a hospital-based Malagasy cohort.
Methods or Background: This descriptive cross-sectional study was carried out at the radiology department of CHUJRA Antananarivo from 18.04.2025 to 07.07.2025. All patients undergoing inguino-scrotal ultrasound were included. Demographic data, indications, and sonographic findings were analysed, focusing on prevalence, age distribution, and complications of hernia and torsion.
Results or Findings: Inguino-scrotal ultrasound represented 4.7% of examinations during the study period. The most affected age group was 0–5 years (27.2%). The predominant pathology was inguinal hernia (19.4% of cases). Complications were frequent: 35% of hernias were complicated, and 40% of testicular torsions showed necrosis. Other findings included hydrocoele, varicocele, epididymo-orchitis, and rare tumours. Ultrasound was decisive in differentiating benign from urgent conditions and in guiding immediate management.
Conclusion: Ultrasound is the modality of choice for inguino-scrotal diseases due to its accessibility, non-invasiveness, and high diagnostic value. In our Malagasy cohort, inguinal hernia and testicular torsion were the leading causes, with a significant proportion of complications, reflecting delayed consultation and limited resources. This study underlines the pivotal role of ultrasound in early diagnosis and triage of inguino-scrotal emergencies. As one of the first structured series from Madagascar, it highlights the feasibility of generating clinically impactful imaging data in resource-limited settings, making it of international relevance.
Limitations: The limitations of the study are its monocentric design and short study period.
Funding for this study: No funding was received for this study.

Milos A. Lucic; Sremska Kamenica / Serbia

The prognostic value of baseline CT-perfusion parameters in ischemic stroke patients treated with endovascular thrombectomy in MRPREDICTS prediction model (6 min)
Ching Khan; Rotterdam / Netherlands

Author Block: C. Khan, B. Roozenbeek, P. J. van Doormaal, A. Van Der Lugt, D. Bos, CONTRAST consortium; Rotterdam/NL
Purpose: Endovascular thrombectomy (EVT) has reduced disability in ischemic stroke patients, but significant outcome variability persists despite recanalisation. It is unknown whether CT-perfusion can improve functional outcome prediction. This study investigates the prognostic value of baseline CT-perfusion parameters for functional independence in acute ischemic stroke patients treated with thrombectomy in MR PREDICTS.
Methods or Background: Ischemic patients treated with EVT from MR CLEAN NOIV, MR CLEAN MED, and MR CLEAN LATE, and with available baseline CT-perfusion were included. Post-processing was performed using Siemens syngo.via.VB80C to retrieve penumbra (cerebral blood flow<27ml/100g/min) and ischemic core volumes (cerebral blood volume (CBV)<1.2ml/100ml), hypoperfusion intensity ratio (brain tissue volume Tmax>10s / brain tissue volume Tmax>6s) and CBV-index (average CBV in Tmax>6s within ischemic hemisphere / average CBV in Tmax≤4s tissues). Primary outcome was functional independence defined as modified Rankin Scale (mRS) 0-2 versus 3-6 at 90 days. Secondary outcome was functional outcome using ordinal mRS (0-6). The prediction model MR PREDICTS was used as benchmark and CT-perfusion parameters were added and compared to the benchmark using likelihood ratio tests. Bootstrapping was used for internal validation. Discrimination was reported using (ordinal) c-statistic.
Results or Findings: A total of 354 patients were included. Ischemic core significantly improved the benchmark model ($p<0.05$) and increased the c-statistic for functional independence (0.81, 95% CI 0.77–0.86 versus 0.80, 95% CI 0.76–0.84) and ordinal functional outcome (0.73, 95% CI 0.70–0.76 versus 0.72, 95% CI 0.69–0.75). CBV-index yielded similar results to ischemic core.
Conclusion: Baseline CT-perfusion may slightly improve the MR PREDICTS model for functional independence and outcome in ischemic stroke patients treated with EVT. Future studies should investigate whether CT-perfusion can improve treatment effect prediction for clinical decision making.
Limitations: This study lacks external validation and CT-perfusion post-processing is vendor specific.
Funding for this study: The MR CLEAN NOIV, MR CLEAN MED, and MR CLEAN LATE trials were supported by the Collaboration for New Treatments of Acute Stroke (CONTRAST) consortium, which is supported by the Netherlands Cardiovascular Research Initiative, an initiative of the Dutch Heart Foundation (CVON2015-01: CONTRAST); the Brain Foundation Netherlands (HA2015.01.06); the Ministry of Economic Affairs by means of the PPP Allowance made available by Top Sector Life Sciences and Health to stimulate public–private partnerships (LSHM17016); and unrestricted funding by Stryker, Medtronic, and Cerenovus. CLEOPATRA study led by Amsterdam UMC, the Netherlands, has contributed to the collection of CTP data and is sponsored by Zorgevaluatie Leading the Change.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The MR CLEAN NOIV, MR CLEAN MED, and MR CLEAN LATE were approved by the Medical and Ethical Review Committee in the Netherlands as part of the original trial protocols. All patient records and images were anonymised before analysis, and written informed consent was obtained from all patients or their legal representatives.

Predictive Value of Dual-Energy CT Parameters for Hemorrhagic Transformation After Endovascular Therapy in Acute Ischemic Stroke (6 min)
Ya hui Y ou; Wuhan / China

Author Block: Y. h. Y ou, Y. Xiong, W. Zhu; Wuhan/CN
Purpose: This study aims to evaluate the predictive value of dual-energy CT (DECT) parameters compared to CT perfusion (CTP) for hemorrhagic transformation (HT) after endovascular therapy (EVT) in acute ischemic stroke (AIS) patients, and to analyze their correlations with clinical parameters.
Methods or Background: We included 112 AIS patients who underwent scanning on Revolution CT Power and received EVT. Based on post-treatment HT occurrence, patients were divided into HT (n=25; age 42-89; male=14) and non-HT groups (n=87; age 31-87; male=54). DECT parameters [effective atomic number (Effective-Z), iodine concentration (Iodine Water)], CTP parameters [cerebral blood flow<30% volume (CBF<30%), time to maximum>6s volume (Tmax>6s)], and clinical data were collected. Univariate and multivariate binary logistic regression were used to identify independent predictors and construct prediction models. Predictive performance was evaluated using receiver operating characteristic (ROC) curve analysis.
Results or Findings: Significant intergroup differences (P<0.05) were observed in Effective-Z, Iodine Water, CBF<30% volume, Tmax>6s volume, age, diabetes history, stroke history, prior endovascular intervention/surgery, modified Rankin Scale (mRS) score, and Activities of Daily Living (ADL) score. Multivariate analysis identified Effective-Z, age, diabetes history, and mRS score as independent predictors of HT. ROC analysis showed comparable predictive efficacy between DECT parameters (Effective-Z, AUC=0.67; Iodine Water, AUC=0.66) and CTP parameters (CBF<30% volume, AUC=0.71; Tmax>6s volume, AUC=0.65). The combined model integrating DECT parameters with clinical independent predictors demonstrated optimal predictive performance (AUC=0.80). DECT parameters significantly correlated with both CTP parameters and neurological function scores in Spearman analysis.
Conclusion: DECT parameters demonstrate predictive capability for HT post-EVT in AIS patients comparable to CTP. The combined model incorporating DECT parameters and clinical factors provides the highest predictive value, serving as an effective tool for hemorrhage risk assessment.
Limitations: Not applicable.
Funding for this study: No funding was provided for this study.

A comparative study of cerebral arteries' morphological and haemodynamic features between post-stroke patients and age-matched non-stroke adults as assessed by advanced ultrasonography techniques (6 min)

Simon Takadiyi Gunda; Kowloon / Hong Kong SAR China

Author Block: S. T. Gunda, J. H-Y. Yip, V. T-K. Ng, Z. Chen, X. Han, J. Qu, X. Chen, M. Y-C. Pang, M. Ying; Kowloon/HK
Purpose: Stroke poses a serious public health burden due to high morbidity and mortality worldwide. Ultrasonography has advanced over recent years, and emerging techniques such as three-dimensional(3D) and arterial stiffness analysis may provide new insights on stroke risk biomarkers, critical for preventative and therapeutic management. This study compared cerebral arteries' morphological and haemodynamic features between post-stroke patients and non-stroke (controls) as assessed by novel ultrasonography techniques.
Methods or Background: A cross-sectional study involving post-stroke patients and age-matched (controls) aged 50 yrs and above was conducted. Novel ultrasonography applications, including auto CIMT, 3D, and arterial stiffness analysis assessed extracranial cerebral arteries' morphology and hemodynamic features across the two groups, whereas transcranial color-coded Doppler ultrasound assessed intracranial hemodynamics.
Results or Findings: A total of 124 participants (post-stroke, n=57 and controls, n=67) were enrolled. The carotid beta-stiffness index (CAS β), elastic modulus (CAS kPa), and pulse wave velocity (CAS PWV) were significantly higher in post-stroke patients compared to controls (15.8±26.7 vs. 9.3±7.7, 208.9±333 kPa vs. 123.7±112 kPa, and 7.8±3.9 m/s vs. 6.5±2.2 m/s, all (p<0.05)), respectively. Conversely, carotid compliance and distensibility coefficient were higher in non-stroke (all p<0.05). However, no between group difference in 3D lumen volume stenosis was observed suggesting stenosis-related hemodynamic failure was unlikely the primary stroke mechanism in this population. Furthermore, post-stroke patients showed reduced cerebral blood flow (all DCCA parameters, ICA EDV, and MCA MFV, all p<0.05).
Conclusion: Our study observed significant differences in cerebral arteries' morphological and haemodynamic features, with post-stroke patients exhibiting higher arterial stiffness and reduced cerebral blood flow compared to non-stroke individuals. Reference values for 3D ultrasound-based and arterial stiffness features are provided.
Limitations: No limitations identified.

Application of Extended Angio-CT from the Diaphragm in the Stroke Code: Diagnostic Value and Clinical Impact (6 min)

Sara De Gracia Nájera; Zaragoza / Spain

Author Block: S. De Gracia Nájera, E. Saureu Rufach, C. Miró Ballesté, T. Barrera Yudego, J. A. Rojas Cristancho, G. Mauri Capdevilla, F. Purroy García, R. Mitjana Penella; Lleida/ES
Purpose: Given the low detection rate of cardioembolic sources with transthoracic echocardiography (1%) and the limited availability of transesophageal echocardiography, alternative non-invasive approaches are required for the etiological diagnosis of ischemic stroke, such as extended CT angiography (CTA) without cardiac synchronization performed during the hyperacute phase of stroke.The main objective of this study is to evaluate whether extended CTA provides diagnostic-quality images and enables detection of cardiovascular pathology as a possible stroke etiology. Secondary objectives include evaluating incidental pulmonary or mediastinal findings with potential therapeutic implications for patient management.
Methods or Background: A descriptive, prospective study was conducted including a cohort of 249 patients assessed within the stroke code protocol from January 2024 to September 2025, using extended CTA from the diaphragms upward without cardiac synchronization.
Results or Findings: Out of 249 studies, 223 (89.6%) were considered of moderate or good image quality. A total of 149 patients were diagnosed with ischemic stroke (59.8%). Among this group, 58 were women (38.9%) and 91 were men (61.1%), with an average age of 71 years. In 15 patients (10%), cardiovascular pathology was identified as a potential stroke etiology: 2 with intracardiac thrombus (1.3%), 3 with aortic dissection (2%), 3 with ulcerated plaques in the ascending aorta (2%), and 7 with irregular atherosclerosis in the aortic arch (4.7%). Additionally, concomitant pathologies were observed in 17 patients (11.4%), including pulmonary thromboembolism, neoplastic disease, and infections.
Conclusion: The inclusion of extended CTA in the stroke code protocol may contribute to identifying cardiovascular pathology potentially involved in the etiology of stroke, as well as detecting concomitant conditions that may impact therapeutic management.
Limitations: Not applicable.
Funding for this study: No

Beyond ASPECTS: multimodal CT with perfusion and collateral scoring improves prediction of stroke outcome (6 min)

Tarik Binasa Plojović; Belgrade / Serbia

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: T. B. Plojović, D. Janjic, D. Vasin, F. Crnovršanin, N. Spasojević, S. M. Lekic; Belgrade/RS
Purpose: To evaluate the prognostic value of CT perfusion (CTP) parameters in predicting functional outcome after acute ischemic stroke, to compare their performance with the Alberta Stroke Program Early CT Score (ASPECTS) on non-contrast CT (NCCT), and to assess whether collateral scoring on CT angiography (CTA) provides additional predictive value.
Methods or Background: This retrospective study included 122 consecutive patients with acute ischemic stroke admitted to the Emergency Center between January 2023 and December 2024. All patients underwent NCCT, CTA, and CTP as part of the acute stroke protocol. ASPECTS was calculated on NCCT. CTP maps were analyzed for standard thresholds of core (CBF <30%) and penumbra (Tmax >6s). Collateral status was graded on CTA using a semi-quantitative collateral score. Functional outcome was assessed at 90 days using the modified Rankin Scale (mRS), dichotomized into favorable (mRS 0–2) and unfavorable outcome (mRS 3–6).
Results or Findings: NCCT ASPECTS correlated significantly with outcome ($p<0.05$) but showed limited discriminatory ability (AUC 0.68). CTP-derived parameters, particularly core volume (CBF <30%) and penumbra volume (Tmax >6s), demonstrated stronger correlation with unfavorable outcome ($p<0.001$) and higher predictive accuracy (AUC 0.82). The addition of CTA collateral score further improved the prognostic model (combined AUC 0.89), outperforming both ASPECTS and CTP alone.
Conclusion: CT perfusion provides superior prognostic value compared with NCCT ASPECTS in predicting functional outcome after acute ischemic stroke. Incorporating CTA collateral assessment further enhances predictive accuracy, underscoring the importance of a multimodal CT approach.
Limitations: Limitations of the study include its retrospective, single-center design, potential software-related variability in perfusion analysis, and the lack of long-term outcome data beyond 90 days
Funding for this study: No funding for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was conducted in accordance with the Declaration of Helsinki and approved by the Institutional Ethics Committee.

Code stroke in patients on anticoagulants: Added value of embolic source detection by hyperacute cardiac CT (6 min)

Pablo Gilabert Núñez; Barcelona / Spain

Author Block: P. Gilabert Núñez, H. Cuellar Calabria, M. De Dios, T. Alejandro, A. Roque, A. Calderwood, C. Meza, F. Rizzo, J. Pagola; Barcelona/ES
Purpose: To determine the rate of positive CT results for stroke (CTs+) in patients with a history of atrial fibrillation under a regimen of direct-acting oral anticoagulants (DOAC-AF).
To detect patients with thrombus in the heart or ascending aorta (T+) on a hyperacute cardiac CT in a venous phase.
To find out whether thrombus and left atrial size (LAs) has added value in this clinical presentation.
Methods or Background: DOAC-AF patients admitted to the emergency department with a suspicion of stroke underwent multimodal code stroke CT followed by venous-phase cardiac CT (n=75, 55% men, 81±9 years).
T+ and LAs were correlated with NIHSS (National Institutes of Health Stroke Scale) at admission and discharge and with CTs+, defined as arterial occlusion or ischemia.
Results or Findings: Rates of CTs+ and T+ were 56% and 13%, respectively. Ninety per cent of T+ were CTs+, in contrast to 51% of T- (p=0.02), with sensitivity, specificity, positive and negative predictive values of 21%, 97%, 90% and 49%, respectively. Patients with a severely dilated LAs≥33.2 cm^2 had rates of S+ and E+ of 90% and 52%, respectively (p=0.002 for comparison with LAs<33.2 cm^2). T+ patients presented with higher NIHSS at baseline (16.5 versus 6;p=0.02). None was discharged with NIHSS-0, compared to 39% of T- (p=0.02).
Conclusion: A modified code stroke CT protocol including a venous-phase cardiac CT allowed for the detection of cardiac thrombi in 13% of patients with a history of medically treated atrial fibrillation. This group showed more severely dilated left atria, presented with higher NIHSS scores at admission and suffered more sequelae than patients without source lesions.
Limitations: The limitatios of this study is that most patients did not undergo transesophageal ultrasound owing to poor clinical condition.
Funding for this study: Funding was provided by European Regional Development Fund 24-00333.

Endovascular Thrombectomy for Subterminus Internal Carotid Artery (ICA-I) Occlusions – analysis of 3730 patients (6 min)

Emma Hall; Lund / Sweden

Author Block: E. Hall, B. Hansen, T. Ullberg, J. Wasselius; Lund/SE
Purpose: Subterminus intracranial internal carotid artery (ICA-I) occlusion is an underrecognized stroke subtype which may delay access to endovascular thrombectomy (EVT). This study aimed to:
1) characterise clinical presentation; and
2) assess radiological reporting accuracy in EVT-treated patients with ICA-I occlusions
Methods or Background: EVT-treated patients with ICA-I, ICA terminus (ICA-T), and middle cerebral artery M1 occlusions were identified from a nationwide registry (2016–2022). Outcomes included NIHSS, ASPECT, recanalization success, and 90-day mRS. In a single-center cohort (2016–2025), stroke severity and perfusion deficits were analyzed in relation to anterior and posterior circulation variants, and accuracy of baseline radiology reports was compared with ICA-T and M1 occlusion controls.
Results or Findings: Of 3730 EVT patients, 356 (9.5%) had ICA-I, 657 (17.6%) ICA-T, and 2717 (72.8%) M1 occlusions.
Median preoperative NIHSS was 17 (variance 34) for ICA-I, 19 (variance 25) for ICA-T, and 16 (variance 37) for M1 (p<0.001 between groups). While recanalization rates and 24-hour NIHSS were similar, patients with M1 occlusions had better 90-day outcomes than those with ICA-I or ICA-T occlusions.
Low and high ASPECT were more common for ICA-I occlusions while the intermediate ASPECT values were more common in ICA-T and M1 occlusions (p<0.001).
In ICA-I cases, anterior circulation variants had a greater impact on stroke severity, compared to posterior circulation variants.
Only 29% of ICA-I occlusions were correctly identified in initial radiology reports, compared with 56% for ICA-T and 100% for M1 occlusions.
Conclusion: ICA-I occlusions present with high variability and are often underrecognized on baseline imaging. Greater awareness among radiologists and clinicians is needed to improve diagnostic accuracy and treatment pathways.
Limitations: There is a potential risk of underreporting of ICA-I occlusions due to mild or atypical symptoms.
In Riksstroke, functional outcome is self-reported.
Funding for this study: This study was funded by grants from Teggerstiftelsen to EH, and regional ALF grants to EH, TU and JW, the Crafoord Foundation to JW, VINNOVA to JW, and by SUS Stiftelser & Fonder to JW and BMH. None of the funding bodies had any involvement in the planning of methodology, data retrieval or analysis in the study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The Swedish Ethical Review Authority approved the study and waived individual informed consent (#2024-03485-01).

Neuroimaging Predictors of Futile Recanalization in Anterior Circulation Stroke: A Systematic Review and Meta-Analysis (6 min)

Iman Kiani; Tehran / Iran

Author Block: I. Kiani[1], S. Mohammadzadeh[1], S. Mozaffari[1], H. Mahmoudzadeh[1], D. A. Lakhani[2], J. Kakadiya[3], R. Xu[3], A. Dmytriw[4], V. Yedavalli[3]; [1]Tehran/IR, [2]Morgantown, AL/US, [3]Baltimore, MD/US, [4]Boston, MA/US

Purpose: Despite the widespread success of mechanical thrombectomy (MT) in treating large vessel occlusion acute ischemic stroke, a notable proportion of patients fail to achieve meaningful clinical recovery even after successful recanalization, a phenomenon termed futile recanalization. This study aimed to systematically review and meta-analyze neuroimaging predictors of futile recanalization following MT.

Methods or Background: We conducted a comprehensive systematic review and meta-analysis in accordance with PRISMA guidelines. Eligible studies included adult patients with anterior circulation stroke with large-vessel occlusion who underwent MT, with futile recanalization defined as poor functional outcome despite successful recanalization. Neuroimaging predictors were categorized by imaging modality and pathophysiological domain. Quantitative meta-analyses were performed where data permitted. Quality assessment was conducted using the PROBAST tool.

Results or Findings: A total of 51 studies were included, most of which defined good outcome as a modified Rankin Scale (mRS) score of 0–2 at 90 days. Pooled analysis revealed a significant inverse association between ASPECTS and futile recanalization (OR=0.81; 95% CI: 0.76–0.87), while core volume showed no significant correlation (OR=1.01; 95% CI: 1.00–1.02). Among perfusion and collateral markers, elevated HIR (≥0.3), prolonged peak venous outflow time, low CBV, poor collaterals, and reduced venous outflow were consistently associated with increased odds of FR (ORs up to 8.6). White matter injury, leukoaraiosis, and brain atrophy were strong predictors of FR (ORs up to 10.25).

Conclusion: Neuroimaging findings are helpful for understanding the mechanisms underlying futile recanalization. The integration of quantitative imaging biomarkers into triage protocols has the potential to refine treatment selection and enhance the prediction of outcomes in patients undergoing thrombectomy.

Limitations: Some studies relied on non-standardized or locally defined imaging thresholds, potentially introducing measurement bias. Second, several studies included had retrospective designs and were conducted in single centers.

Funding for this study: Research reported in this publication was supported by the National Institute of General Medical Sciences of the National Institutes of Health under Award Number 5U54GM104942-08. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Association between Ultrasonographic Morphological Features of CP-RADS Category 2 Carotid Plaques and the Risk of Ischemic Stroke Events (6 min)
Yuxin Yang; Shanghai / China

Author Block: J. Yiwen, J. Wang, M. Chen, Y. Yang; Shanghai/CN
Purpose: Objective: To investigate the independent predictive value of plaque characteristics based on conventional ultrasound and contrast-enhanced ultrasound (CEUS)—specifically a composite model integrating intraplaque punctate calcification and contrast enhancement—for new-onset cerebral infarction in patients with CP-RADS category 2 carotid plaques, and to develop and validate a nomogram prediction model incorporating clinical and imaging features.
Methods or Background: Methods: This retrospective study included 744 patients with CP-RADS category 2 carotid plaques who underwent carotid ultrasound and CEUS. Following follow-up, 404 patients were randomized 7:3 into training (n=283) and validation (n=121) sets. Independent predictors of new-onset cerebral infarction were identified through univariate and multivariate logistic regression, and used to develop a nomogram. Model performance was assessed by ROC analysis, AUC, sensitivity, and specificity.
Results or Findings: The plaque characteristics (the composite model of intraplaque punctate calcification and contrast enhancemen) is an independent predictor of new-onset cerebral infarction in CP-RADS Category 2 carotid plaques. Our nomogram demonstrates accurate and stable prediction, offering a reliable tool for early risk stratification and individualized intervention.
Conclusion: Conclusion: Plaque characteristics (the composite model of intraplaque punctate calcification and contrast enhancement) serve as an independent predictor of new-onset cerebral infarction in patients with CP-RADS Category 2 carotid plaques. The nomogram model developed in this study exhibits good predictive accuracy and stability, providing an intuitive and reliable quantitative tool for early identification of high-risk populations and implementation of individualized interventions.
Limitations: This single-center retrospective study has inherent limitations. The single-institution sample limits generalizability, and the retrospective design may introduce systematic bias. To minimize bias, we exclusively enrolled patients with recent cerebral infarction (within 6 months) to clearly define cerebrovascular events. Future multi-center studies with extended follow-up are needed to validate the model's predictive performance and clinical utility.
Funding for this study: No

From Gut to Vessel Wall: TMAO and Carotid Ultrasound in Pediatric Obesity (6 min)
Dana I Stoian; Timisoara / Romania

Author Block: D. I. Stoian, S. MIHUTA, A. BENA, C. Paul; Timisoara/RO
Purpose: PURPOSE. To investigate the relationship between serum trimethylamine N-oxide (TMAO), a gut-derived metabolite, and carotid intima–media thickness (CIMT) as an ultrasound marker of subclinical atherosclerosis in children with obesity.
Methods or Background: METHODS. We enrolled 70 children aged 4–18 years: 50 obese (BMI >95th percentile, waist circumference >90th percentile) and 20 normal-weight controls. Clinical evaluation included BMI, waist-to-height ratio, Tanner stage, and signs of insulin resistance. Serum TMAO was measured by liquid chromatography–mass spectrometry, alongside fasting glucose, insulin, lipid profile, transaminases, creatinine, uric acid, and vitamin D. CIMT was assessed bilaterally with high-resolution ultrasound. Arterial stiffness parameters (pulse wave velocity [PWV], augmentation index, and central and peripheral blood pressures) were recorded for comparison.
Results or Findings: RESULTS. Obese children had significantly higher TMAO levels (median 289.5 vs 218.7 µg/L, p=0.02) and CIMT (0.56 ± 0.07 vs 0.49 ± 0.05 mm, p<0.001) compared to controls. Serum TMAO correlated positively with CIMT (ρ=0.41, p<0.001), PWV (ρ=0.36, p=0.004), and systolic blood pressure (ρ=0.33, p=0.007). In multivariable regression, TMAO remained an independent predictor of CIMT (β=0.37, p<0.001), even after adjusting for BMI, waist measures, age, and puberty stage. Children with insulin resistance had higher CIMT and PWV than their non-insulin-resistant peers, but TMAO levels did not differ significantly between subgroups. Logistic regression showed that higher TMAO was associated with increased odds of acanthosis nigricans (p=0.03).
Conclusion: CONCLUSION. Serum TMAO is elevated in pediatric obesity and independently predicts carotid intima–media thickness, reinforcing the role of ultrasound as the key imaging modality to detect early vascular injury in this population.
Limitations: Limitations: cross-sectional design; limited control sample; absence of dietary/microbiome profiling

Enhancing Stroke Risk Stratification: Ultrasound-Based CP-RADS Integrated with CEUS Neovascularization Features for Carotid Plaque Evaluation (6 min)

Chuanjian Chen; Shanghai / China

Author Block: C. Chen, H. Yunqian, J. Xu, M. Chen; Shanghai/CN
Purpose: This study aimed to evaluate the efficacy of ultrasound-based Carotid Plaque Reporting and Data System (CP-RADS) in stroke risk stratification and to explore the incremental value of contrast-enhanced ultrasound derived intraplaque neovascularization features in refining this classification system.
Methods or Background: A analysis was conducted on cohort of 148 patients with carotid plaques who underwent routine ultrasound and CEUS between May and December 2019. CP-RADS grades (1–4) were independently assigned by radiologists based on ultrasound features. Interobserver and intraobserver reliability were assessed. Patients were followed up for 24 months to record ipsilateral ischemic stroke. Cox regression analyzed associations between CEUS characteristics, plaque grades, and stroke.
Results or Findings: 33 (21.86%) experienced ipsilateral ischemic stroke. The interobserver and intraobserver reliability for CP-RADS grading was well (ICC>0.8). The stroke group exhibited significantly older (P=0.036) and higher prevalence of prior stroke history (P=0.044). Surface microbubble perfusion was more frequent in stroke patients (66.66% vs 41.73%, P<0.05), while no significant difference was observed in neovascularization density. CP-RADS grades showed no intergroup differences, with 60.6% of strokes occurring in CP-RADS 3/4 patients. Surface microbubble perfusion independently predicted stroke risk in CP-RADS 3/4 patients (adjusted HR=4.938, 95CI:1.258-19.381, P=0.022).
Conclusion: Incorporating CEUS-derived microbubble perfusion features enhances accuracy for high-risk plaques (CP-RADS 3/4). This approach provides a cost-effective, simple, and widely applicable tool for optimizing clinical stroke prevention strategies.
Limitations: Several limitations are noted. First, limited sample size (n=151) and relatively short median follow-up (24 months), ongoing cohort studies with expanded patient data are underway. Second, inherent ultrasound limitations in characterizing plaque components (e.g., lipid core, calcification) and observer dependency in imaging feature interpretation may contribute to Carotid Plaque RADS misclassification.

Viscoelastic Characteristics of Carotid Artery Walls in Plaque-Free Populations and Their Role in Cardiovascular Risk Stratification (6 min)

Chuanjian Chen; Shanghai / China

Author Block: C. Chen, J. Xu, H. Yunqian, M. Chen; Shanghai/CN
Purpose: To evaluate the viscoelastic characteristics of carotid artery walls in plaque-free populations under different cardiovascular risk levels by carotid wall viscoelasticity imaging, analyze the correlation between carotid viscoelastic parameters and the degree of cardiovascular risk. Assessing the ability of these parameters to identify high-risk individuals, providing a basis for early detection of high-risk populations for cardiovascular diseases.
Methods or Background: A total of 518 patients undergoing carotid viscoelasticity imaging between April 2023 and June 2024 were consecutively enrolled. Clinical data were collected, and participants were stratified into low-risk (<6%), intermediate-risk (6–20%), and high-risk (>20%) groups based on the Framingham Risk Score. The correlation between carotid wall viscoelastic parameters and cardiovascular risk levels was analyzed, and ROC curves were used to evaluate the discriminative ability of different viscoelastic parameters for identifying high-risk populations.
Results or Findings: The low-risk, intermediate-risk, and high-risk groups comprised 229, 222, and 67 participants, respectively. Correlation analysis revealed linear positive associations between all carotid viscoelastic parameters and increasing cardiovascular risk levels. Among all parameters, C-Emin and C-Vmean demonstrated the highest specificity (0.746) and sensitivity (0.801), respectively, for identifying high-risk individuals.
Conclusion: This study indicates that carotid viscoelastic parameters are positively correlated with elevated cardiovascular risk levels. Elastic parameters and viscous parameters play distinct roles in distinguishing high-risk populations, with C-Vmean providing superior sensitivity. These findings suggest that viscous parameters effectively differentiate cardiovascular risk strata, offering critical insights for early identification of plaque-free individuals at high cardiovascular risk.
Limitations: Current equipment does not support electrocardiogram-integrated viscoelastic imaging, preventing the acquisition of systolic and diastolic viscoelastic parameters.So participants were instructed to maintain breath-holding and stable positioning during examinations, performed exclusively by senior radiologists with extensive viscoelastic imaging expertise. Patients unable to maintain stability were excluded

Value of Carotid-Plaque Viscoelastic Ultrasound for Predicting Ischemic Cerebrovascular Risk in Patients with Mild (<50 %) Carotid Stenosis (6 min)

Qiao Chen; Shanghai / China

Author Block: H. Jin, H. Yunqian, Q. Chen, Y. Yang, M. Chen; Shanghai/CN
Purpose: To determine whether ultrasound-derived viscoelastic properties of carotid plaques can identify individuals with mild (<50 %) carotid stenosis who are at heightened risk of an ischemic cerebrovascular event.
Methods or Background: Consecutive patients with mild carotid stenosis examined between April 2023 and June 2024 were enrolled. Ninety-seven had sustained an ischemic cerebrovascular event within the preceding 6 months; 592 had remained event-free. Gray-scale and viscoelastic ultrasound were used to quantify plaque elasticity and viscosity. Logistic regression was employed to assess the association between viscoelastic parameters and incident events while adjusting for clinical covariates. ROC analysis evaluated the predictive performance of these parameters.
Results or Findings: Plaques in the event group exhibited significantly lower mean elastic modulus (P-Emean) and mean viscous modulus (P-Vmean) than those in the asymptomatic group. Both P-Emean and P-Vmean emerged as independent predictors of events. Combined viscoelastic models yielded excellent discrimination, with the elastic-component model achieving an AUC of 0.871.
Conclusion: In patients with mild carotid stenosis, plaque biomechanics are closely linked to cerebrovascular events. Ultrasound assessment of plaque viscoelasticity can improve risk stratification and lays the groundwork for precision management of this population.
Limitations: Histological validation of the viscoelastic parameters was not performed.
Funding for this study: This research was supported by Shanghai Tongren Hospital, with project numbers TRYJ2022LC09, tx2023xk18, and TK2017r04

Analysis of ultrasound characteristics of plaques in patients with mild carotid stenosis and embolic stroke of unknown cause (ESUS) (6 min)

Maraba Kader; Shanghai / China

Author Block: M. Kader, L. Zhang, H. Yunqian, M. Chen, Y. Yang, Q. Chen; Shanghai/CN
Purpose: This study aimed to investigate the ultrasonic characteristics of plaques in patients with mild carotid stenosis (stenosis <50%) complicated with embolic stroke of unknown cause (ESUS), in order to provide new ideas and basis for the etiological diagnosis and individualized treatment of ESUS.
Methods or Background: This retrospective study analyzed carotid plaque characteristics in 106 stroke patients admitted from May to December 2019 and divided into three groups: Embolic Stroke of Undetermined Source (ESUS, n=23), Extracranial Large Artery Atherosclerosis (LAA, n=28), and a non-stroke control group (n=55), using ultrasound and contrast-enhanced ultrasound. The echo intensity, surface morphology and perfusion pattern of carotid plaques and other related ultrasound parameters were compared between different groups. The binary logistic regression model, ROC curve and multivariate analysis were used to evaluate the diagnostic efficacy of ultrasound parameters and clinical factors.
Results or Findings: Both LAA and ESUS groups exhibited significantly higher frequencies of microbubble perfusion and "inside-to-outside" perfusion patterns compared to controls. Key plaque features including hypoechoic areas, irregular morphology, and incomplete fibrous cap showed significant intergroup differences ($P < 0.05$). The combination of plaque thickness <3.4 mm and absence of "inside-to-outside" perfusion pattern achieved an AUC of 0.802 for ESUS diagnosis with 80.4% accuracy.
Conclusion: These findings suggest that integrated assessment of plaque thickness and CEUS perfusion patterns enhances stroke subtype differentiation and prognostic risk assessment, providing valuable guidance for individualized diagnosis and treatment strategies.
Limitations: The single-center design with small sample size (n=106) affects generalizability, ultrasound assessments carry inherent subjectivity, comprehensive evaluation of embolic sources requires additional imaging modalities, and insufficient follow-up duration prevents long-term outcome assessment.

Diagnostic Performance of Microvascular Ultrasound for Endoleak Detection after EVAR: Comparison with CEUS and CTA (6 min)

Marcin Czeczelewski; Lublin / Poland

Author Block: M. Czeczelewski, A. Drelich-Zbroja, M. A. Kuczyńska; Lublin/PL
Purpose: Patients following endovascular aneurysm repair (EVAR) require long-term imaging surveillance to detect late complications such as endoleaks. CTA remains the gold standard for follow-up but exposes patients to ionizing radiation and iodinated contrast agents. Microvascular ultrasound (MVUS) is a novel, contrast-free technique capable of visualizing slow microvascular flow. This study aimed to compare the diagnostic accuracy of MVUS with CEUS and CTA in detecting endoleaks after EVAR.
Methods or Background: A prospective cross-sectional study was conducted in 73 consecutive patients (60 males, 13 females) who underwent EVAR. Within one week post-procedure, each participant underwent ultrasound assessment including both MVUS and CEUS. CEUS was performed after intravenous administration of 1.6 mL of SonoVue (Bracco, Italy). Within one month, all patients underwent triple-phase CTA, which served as the reference standard. Endoleaks were classified according to the Mayo Clinic classification.
Results or Findings: Among the 73 patients, the stent graft types included Zenith Flex (19; 26%), Zenith t-Branch (27; 37%), Gore Excluder (17; 23%), and Medtronic Endurant II (10; 14%). Ultrasound prior to discharge revealed 42 endoleaks, including 33 detected by both MVUS and CEUS, and 9 detected only by MVUS. One month later, CTA confirmed 28 of the 33 endoleaks initially detected by CEUS and MVUS, while 3 had resolved and 3 patients were lost to follow-up. Of the 9 endoleaks detected only by MVUS, one was confirmed by CTA. These MVUS-only endoleaks were characterized by fine, linear flow signals perpendicular to the transducer.
Conclusion: MVUS demonstrates high sensitivity for detecting endoleaks following EVAR.
Limitations: This single-center study had a limited sample size and short follow-up duration. CTA was performed up to one month after ultrasound, which limits its reliability as a reference standard.

Morphological and functional vascular imaging markers of diabetic atherosclerosis (6 min)

Dusan Jordan Petrovic; Belgrade / Serbia

Author Block: D. J. Petrovic; Belgrade/RS
Purpose: The objective of the survey was to establish the correlation between carotid intima-media thickness (CIMT) and type 2 diabetes mellitus (T2DM), as well as to assess the hemodynamic parameters and their relationship to T2DM.
Methods or Background: 186 participants between the ages of 42 and 84 with proven T2DM (112 men and 74 women; mean age ± SD, 63.13 ± 6.96) were retrospectively examined (prospective design or retrospective analysis of a prospective data set) by the carotid ultrasound Doppler examination measuring carotid morpho-functional features. Subjects were followed for 26 months from the inclusion in the study (regular control examinations and phone contact). Data were recorded on new cases of mortality (CV mortality) and adverse CV events (myocardial infarction - MI, cardiac insufficiency, surgical revascularization - coronary or stroke, etc.).
Results or Findings: In this study, the value of CIMT varies between 0.56 and 1.41mm (mean CIMT=1.05 ± 0.12mm) while functional results were (RI=0.81 ± 7; PI =1.16±0.185; PSV=132.5 ± 16.65; EDV=28.33 ± 9.04; carotid artery diameter = 6.5 ± 0.92mm). After 26 months of time frame follow-up, 24 vascular events were noted (MI, TIA, stroke, and coronary angioplasty).
Conclusion: The evaluation of morphological (CIMT) and functional (RI, PSV, EDV) parameters is a reliable indicator and barometer for assessing the degree of diabetic vascular remodeling during atherosclerosis progression.
Limitations: Relatively limited sample size, retrospective nature.
Funding for this study: No fundings

The Role of Radiology in Promoting Environmental Sustainability: A Policy Perspective (6 min)
Johnbosco Lydia; Chennai / India

Author Block: J. Lydia, F. Abubacker Sulaiman, R. Praveenkumar, M. Nivitha, D. Dharshini, A. Raashid Ibrahim; Chennai/IN
Purpose: Evaluate the environmental impact of radiology services.

Identify policy gaps in promoting sustainable practices in radiology.

Assess awareness and actions related to sustainability among radiology professionals.

Demonstrate practical departmental initiatives toward sustainable radiology practices.
Methods or Background: Literature review of global and regional studies on sustainable radiology practices.

Analysis of existing healthcare policies related to sustainability.

Survey of radiology professionals to assess awareness of sustainable development and adoption of environmentally friendly practices.

Documentation and evaluation of actions implemented in our radiology department, including energy-efficient protocols, waste reduction, and recycling initiatives aimed at future sustainability.
Results or Findings: Survey results revealed moderate awareness among radiology professionals, with varying adoption of sustainable practices. Departmental initiatives led to measurable reductions in energy use and waste. Existing policies are broad and lack modality-specific guidance for radiology.
Conclusion: Radiology can play a key role in healthcare sustainability through awareness, practical initiatives, and policy integration. Structured support at the policy level is essential to standardize and incentivize environmentally responsible practices.

Safe and Sustainable Contrast Media Use: Balancing Patient and Environmental Impact (6 min)
Araceli Cue Castro; Mexico City / Mexico

Author Block: A. Cue Castro, A. Camacho Palomino; Mexico City/MX
Purpose: To evaluate current evidence on the biological and environmental effects of iodinated and gadolinium-based contrast media (CM) and to propose justification and dose-optimization strategies that ensure diagnostic quality while minimizing risks to patients and the environment.
Methods or Background: A comprehensive literature review (PubMed, ESUR, ACR, WHO, 2015–2025) analyzed data on nephrotoxicity, gadolinium deposition, hypersensitivity, and environmental persistence of CM. International guidelines were reviewed to identify best practices in patient risk assessment, indication justification, and imaging protocol optimization.
Results or Findings: Evidence confirms that repeated CM exposure may induce renal and systemic effects in susceptible patients and that gadolinium and iodine residues persist in wastewater, impacting aquatic ecosystems. Personalized dosing (weight- and renal function–based), use of macrocyclic gadolinium chelates and low- or iso-osmolar iodinated agents, and optimized CT/MRI protocols reduce administered doses without compromising diagnostic value. Standardized justification checklists decrease unnecessary contrast use by up to 30–40%.
Conclusion: Rational and justified use of contrast media is essential to balance diagnostic benefit with patient and environmental safety. Radiology departments should integrate contrast monitoring systems, dose optimization protocols, and education programs promoting responsible, evidence-based use of iodinated and gadolinium agents. Professional education should be prioritized to ensure responsible imaging practice.
Limitations: Data heterogeneity and variability in study design limit direct comparison across contrast agents and imaging modalities. Environmental data remain regionally restricted and require broader, multicenter monitoring.

Reducing Idle CT Scanner Energy Consumption Between Examinations: Operational Feasibility and Impact of a Rapid-Reactivation Power Save Mode (6 min)

Paul Hehenkamp; Basel / Switzerland

Author Block: P. Hehenkamp[1], M. Obmann[1], S. Kamber[1], D. Kraft[2], M. Loser[2], E. M. Merkle[1], T. Heye[1], J. Vosshenrich[1]; [1]Basel/CH, [2]Forchheim/DE
Purpose: To assess the efficiency and operational feasibility of a novel CT power save mode designed to reduce inter-examination energy consumption without affecting clinical workflows.
Methods or Background: CT scanners consume substantial energy during idle periods. While powering down systems has been shown to provide substantial energy, cost, and carbon emission benefits, this is infeasible for short inter-examination intervals. To address this current limitation, one CT scanner (SOMATOM X.ceed; Siemens Healthineers) was equipped with a newly developed power save mode. The scanner's power draw was prospectively measured over a 28-week period (Nov 2024–Jun 2025). Data was segmented into active, idle and power save states. Energy and emission savings were calculated, and usability and impact on workflow were assessed via a survey of CT technologists.
Results or Findings: Across 124 workdays, the power save mode reduced power draw by 26.8% compared with idle (1.6 ± 0.1 kW vs. 2.1 ± 0.1 kW), yielding a 15.6% reduction in nonproductive and 7.2% reduction in total operational energy use. Nonproductive time accounted for 66.1% of scanner on-hours with the power save mode being active during 58.1% of this time. 19 CT technologists responded to the structured survey. Awareness of the mode's functionality was high (84%), and 79% of the technologists had manually activated the power save mode at least once. All technologists reported the activation process as "very easy." Importantly, all technologists (100%) denied any technical issues or workflow disruptions.
Conclusion: A novel rapid-reactivation CT power save mode substantially reduces nonproductive energy consumption during inter-examination idle periods without disrupting clinical workflows, representing a practical step toward a more sustainable operation of CT.
Limitations: Only one specific CT scanner model was investigated. Relative and absolute savings may vary by vendor, model, and practice setting.

Energy Consumption Analysis of Six MRI Generations: Implications for Sustainable Imaging (6 min)

Nour Maalouf; Tübingen / Germany

Author Block: N. Maalouf, F. K. E. Mankertz, J. Berger, F. Raab, J. Herrmann, K. Nikolaou, T. Küstner, S. Afat; Tübingen/DE
Purpose: The purpose of this study is to compare the energy consumption of six Siemens MRI systems and assess the implications for sustainability and cost efficiency.
Methods or Background: Aera, AvantoFit, and Sola (1.5 T) and PrismaFit, Vida, and VidaFit (3 T) scanners were evaluated under routine clinical conditions (6.2024–3.2025). Scan data were sent to the manufacturer for centralized analysis of energy consumption (kWh), power output (kW), and time-normalized power (kW/min). Deviations from the fleet mean were calculated across sequence types, with scan duration used to adjust for time-dependent variability. Scanner model and field strength (1.5 T vs 3 T) were analyzed as determinants of energy efficiency. Performance differences were visualized with deviation plots and radar charts. Statistical analysis used confidence intervals.
Results or Findings: Energy use differed markedly across scanners. VidaFit showed the highest deviations (+66% normalized power, +57% energy) and greatest consumption, while AvantoFit and Vida consumed least (−24% to −31% below mean). Radar analysis confirmed VidaFit as the main outlier, with other models clustering near the fleet average.
Conclusion: Energy use differs across Siemens MRI generations despite similar clinical operation, reflecting hardware and gradient design. Selecting lower-consumption scanners for routine exams can cut costs and reduce carbon footprint. Integrating energy-efficiency metrics into MRI procurement supports sustainable radiology without affecting diagnostic quality.
Limitations: A single-center study may limit generalizability, although the trends remained consistent over several months of monitoring.
Funding for this study: No funding was received.

Greening with AI-MRI: Smart, Short, and Sustainable (6 min)

Francesco Mariotti; Ancona / Italy

Author Block: F. Mariotti, A. Borgheresi, A. Agostini, L. Reversi, M. Valenti, A. Giovagnoni; Ancona/IT
Purpose: Magnetic Resonance Imaging (MRI) has high energy demands, raising sustainability concerns in abdominal applications. With growing demand for liver MRI, there is a need to balance diagnostic value with environmental impact. Abbreviated protocols (AMRI) and AI-based acceleration are promising strategies to reduce scan time and electricity use. This study quantifies potential energy and CO_2 savings in upper abdominal MRI while assessing trade-offs between energy neutrality and patient throughput.
Methods or Background: Five literature-based scenarios were modeled: (A) standard multiphasic protocol with contrast (20–30 min, ~20 kWh/exam); (B) abbreviated non-contrast (7–9 min); (C) abbreviated contrast-enhanced (10–12 min); (D) standard with AI-based acceleration (30% scan time reduction); and (E) abbreviated with AI acceleration. Assumptions included an active phase representing 40–60% of total energy, baseline active consumption of 8–12 kWh, and Italian electricity carbon intensity of 0.233 kg CO_2e/kWh (2024). Per-exam savings, annual throughput, and energy neutrality thresholds—the maximum exams within a 114,000 kWh/year budget—were then calculated.
Results or Findings: Compared with the standard protocol, abbreviated non-contrast saved 41–51% of active energy (0.96–1.70 kg CO_2e), abbreviated contrast 70–72% (1.35–2.24), AI ~30% (0.56–0.84), and abbreviated with AI 59–87% (1.23–2.40).
With a 114,000 kWh/year budget, standard protocols allowed ~5,700 exams, abbreviated non-contrast ~7,972, abbreviated contrast ~9,268, AI ~6,705, and abbreviated with AI ~9,819.
Depending on the protocol, between 25% and 72% more liver MRI exams could be performed annually without exceeding the energy budget.
Conclusion: Abbreviated and AI-accelerated liver MRI protocols reduce active energy use by up to 87% and allow thousands of additional exams annually within the same energy budget. Despite trade-offs between diagnostic completeness and efficiency, these strategies support greener radiology, improved productivity, and progress toward sustainable healthcare
Limitations: Theoretical study based on literature-derived data

Carbon Footprint Comparison: CT vs MRI vs Ultrasound (6 min)

Farook Abubacker Sulaiman; Chennai / India

Author Block: F. Abubacker Sulaiman; Chennai/IN
Purpose: To quantitatively compare the carbon footprint and energy consumption of computed tomography (CT), magnetic resonance imaging (MRI), and ultrasound examinations, and to identify potential strategies for sustainable imaging practice.
Methods or Background: A prospective observational study was conducted over six months in a tertiary care imaging center. A total of 300 diagnostic procedures were analyzed—100 each of CT, MRI, and ultrasound. Energy consumption was measured using integrated power meters on imaging systems and converted to carbon dioxide equivalents (CO_2e) based on local emission factors. Ancillary energy use (HVAC, lighting, computing) was proportionally attributed per examination. Patient throughput and scan duration were factored to calculate per-scan carbon footprint. Data were statistically analyzed using ANOVA and correlation with machine age and utilization.
Results or Findings: Average carbon footprint per examination was CT: 9.2 kg CO_2e, MRI: 17.1 kg CO_2e, and Ultrasound: 0.8 kg CO_2e. MRI demonstrated the highest footprint due to long acquisition times and continuous cooling system requirements, whereas ultrasound showed minimal emissions. Optimization of scan protocols and standby power management reduced CT and MRI footprints by approximately 22% and 18%, respectively. Equipment utilization efficiency showed strong inverse correlation with per-scan carbon footprint ($r = -0.78$, $p < 0.001$).
Conclusion: Among cross-sectional imaging modalities, ultrasound remains the most sustainable, while MRI contributes the highest carbon emissions. Implementing energy-efficient hardware, optimized scheduling, and eco-mode settings can significantly mitigate environmental impact in radiology departments.
Limitations: Single-center design, exclusion of contrast media production impact, and regional energy variability may limit generalizability.
Funding for this study: No external funding was received for this study.

Human-Centric AI Adoption in Swiss Radiology: A Comprehensive Radiologist Sentiment Assessment Methodology for Sustainable Technology Integration (6 min)

Sergey Morozov; Brussels / Belgium

Author Block: S. Morozov, N. Heracleous, B. Rizk, C. Thouly, B. Dufour, O. Novarina; Sion/CH
Purpose: To develop and validate a systematic methodology for evaluating radiologist AI adoption patterns, innovation readiness, and user experience across a multi-site radiology network, providing actionable insights for sustainable AI integration in clinical practice.
Methods or Background: Building on four years of AI implementation since 2021 with 10 AI solutions processing 100,000 exams annually, a comprehensive mixed-methods survey was conducted among 58 radiologists across 20 sites of 3R Swiss Imaging Network in June 2025, achieving 91.4% response rate. The methodology combined quantitative metrics including Net Promoter Score (NPS) analysis for 12 AI solutions, sentiment scoring (1-5 scale), and usage frequency assessment. A composite Innovation Index was calculated incorporating AI adoption rate, usage intensity, technology relevance, and innovation sentiment. Qualitative thematic analysis categorized improvement suggestions. Statistical analysis included Shapiro-Wilk normality testing and Spearman correlations to identify predictors of AI acceptance.
Results or Findings: The group achieved a General Innovation Index of 73/100, positioning it in the "Early Adopter" phase among European radiology networks. AI adoption rate reached 91.4/100 with 53/58 radiologists using AI tools. Usage intensity scored 70.3/100 with 66% reporting frequent AI use. NPS varied dramatically across solutions (range: -55.3 to +86.7). Top performers included X-ray Bone Age estimation (NPS +86.7), Trauma and Orthopedic diagnostics (NPS +65.2). Critical improvement themes emerged: speed/latency (48% of concerns), advanced workflow integration (19%), and reliability issues (11%). Strong correlations were found between trust, quality perception, and clinical confidence (r=0.66-0.68).
Conclusion: This human-centric assessment framework successfully identified innovation profiles, user segments, and systematic barriers to AI adoption. The methodology enables evidence-based change management, targeted interventions, and sustainable innovation strategies in radiology practices.
Limitations: Longitudinal validation needed to confirm predictive value of innovation metrics.
Funding for this study: Institution funded.

Patient Acceptance of Sustainable Practices at a Holistic Women Imaging Clinic in Egypt: WAFI-GREEN Pilot (6 min)

Hanan Soliman Gewefel; Cairo / Egypt

Author Block: H. S. Gewefel[1], M. Amin[2], S. Khodair[2], M. Zaher[1], A. Mahmoud[2]; [1]6th of October City/EG, [2]Cairo/EG
Purpose: To assess feasibility and patient acceptance of pragmatic sustainability measures (“green radiology”) in the Women And Fetal Imaging (WAFI) private imaging center in Giza, Egypt.
Methods or Background: Single-center cross-sectional survey of adult women attending mammography and or breast ultrasound at WAFI, the women age was 52.9 ± 13. An online, self-administered questionnaire containing 19 questions was completed by 82 women, capturing their acceptance across a range of domains; (1) energy-conscious scheduling (night/morning slots), (2) digital intake and electronic reports, (3) Heating, Ventilation, and Air Conditioning (HVAC) optimization with preserved comfort, (4) travel consolidation (combining services in one visit), and (5) reassurance about lower-dose X-ray protocols. Survey items were rated on a five-point Likert scale (1 = strongly disagree, 5 = strongly agree). Responses of “agree” or “strongly agree” were classified as indicating acceptance. Data were analyzed using descriptive statistics and reported as proportions (n/N).
Results or Findings: Eighty-two respondents completed the survey, revealing strong acceptance of green radiology practices across multiple domains. Key findings included high interest in clustered/morning appointments (80%) and a willingness to combine services in one visit (82.9%). Most participants preferred digital intake and reports (79%), with 65.7% finding them easy to use, though a small minority (14.6%) still wanted a situational paper option. Patient comfort and reassurance were also highly rated, with 89% satisfied with HVAC optimization and 86.6% confident in the safety of lower-dose X-ray protocols. Overall care satisfaction was exceptionally high at 97.6%.
Conclusion: Conclusion
Women in a real-world breast imaging unit were highly receptive to sustainability measures. This pilot showed that targeted educational strategies improve women's knowledge and engagement with sustainable radiology practices.
Limitations: This study was performed at a single centre and included a relatively small number of participants.
Funding for this study: Acknowledgements:
This work was granted funding by The European Institute for Biomedical Imaging Research (EIBIR) and The European Society of Radiology (ESR).

Radiology for Global Impact: A Guide to Nonprofit Organizations and Opportunities for Engagement (6 min)

Alex Kuehne; New Haven / United States

Author Block: A. Kuehne, D. Chen; New Haven, CT/US
Purpose: Our objective is to provide an overview of the diverse nonprofit and charitable efforts within radiology, categorize the major organizational models, highlight global and European initiatives, and demonstrate practical pathways for radiologists to engage meaningfully in service and advocacy at varying levels of commitment.
Methods or Background: While global medical charities such as Doctors Without Borders and the Red Cross are well known, radiology-specific nonprofit work is comparatively recent, accelerating over the past two decades with advances in digital imaging. Despite radiology’s central role in modern medicine, the World Health Organization estimates that up to two-thirds of the global population lacks access to basic imaging technologies, with access to advanced modalities even more limited. This disparity underscores the need for radiology-focused charitable efforts.
Results or Findings: Radiology nonprofit organizations can be broadly grouped into four categories:

Standalone charitable organizations: RAD-AID, Radiologists Without Borders, Project C.U.R.E., UNITS USA, as well as European groups such as the European Society of Radiology’s (ESR) “Invest in the Youth” and outreach initiatives, and the European School of Radiology (ESOR), which provide training and support in resource-limited settings.
Societal charitable arms: RSNA Research & Education Foundation, ARRS, ASER, ESR Foundation.
Charitable arms of for-profit organizations: VRAD’s First Read Initiative, funding equipment and PACS infrastructure for underserved hospitals.
Educational initiatives: Road2IR, which supports interventional radiology training in Africa, with growing partnerships from European and North American institutions.
Conclusion: Philanthropic opportunities in radiology are expanding rapidly, with significant potential to address global imaging inequities. By engaging in nonprofit efforts, whether through clinical service, education, fundraising, or advocacy, radiologists can leverage their specialized expertise to deliver disproportionate impact in global health, fostering sustainable change across diverse healthcare systems.

Polytrauma workflow: how I do it - from door-to-CT to first report in under 20 minutes (13 min)
Sebastian Leschka; St. Gallen / Switzerland

1. To implement standardised patient positioning and optimised contrast protocols that significantly reduce "door-to-image" time without compromising diagnostic quality.
2. To apply a systematic, prioritised search pattern to rapidly identify and grade life-threatening injuries.
3. To utilise structured reporting templates for the immediate communication of critical findings.

Stop the bleeding: how I do it - quick and safe embolisation techniques for lower GI bleeding (13 min)
Christoph Johannes Zech; Basel / Switzerland

1. To learn about the vascular anatomy of the mesenteric artery and how to best prepare for the procedure.
2. To be aware of catheters and wires to probe also distant mesenteric artery branches.
3. To learn about the different embolic agents and how they can be used to treat GI bleeding.

Breath-hold is not an option: how I do it - ultra-low-dose chest CT in screaming toddlers (13 min)
Seema Toso; Geneva / Switzerland

1. To explain when CT is justified in paediatric chest emergencies and how to minimise radiation exposure.
2. To review free-breathing and motion-robust CT protocols for non-cooperative children.
3. To learn how to report time-critical findings for rapid emergency decision-making.

The skier’s knee: how I do it - assessing multi-ligamentous injuries and posterolateral corner instabilities (13 min)
Anna Hirschmann; Basel / Switzerland

1. To describe the normal anatomy and MRI appearances of the knee ligaments and the posterolateral corner structures.
2. To explain typical imaging findings of multiligamentous injuries and posterolateral corner injuries.
3. To learn how to report complex knee injuries in daily practice.

1. To understand the essential components of what makes an actionable report.
2. To recall the evidence that underpins actionable reporting.
3. To explain why these principles are best expressed as rules.

Controversies in actionable report (30 min)
Paul Mccoubrie; Bristol / United Kingdom

1. To learn the major controversial topics in actionable reporting via an interactive presentation.
2. To appreciate how nuances in reports can have major clinical impact.
3. To list the top five pitfalls in producing actionable reports.

EFRS 3 - The use of AI in research

Categories: Radiographers, Research, Education, Artificial Intelligence

Date: March 4, 2026 | 11:30 - 12:30 CET

CME Credits: 1

This session examines the transformative role of Artificial Intelligence in radiography research and practice. Presentations will cover the application of AI in image data management and analysis, its impact on research communication and academic practice, and the editors' perspective on AI in research. Together, these talks will highlight opportunities, challenges, and ethical considerations, offering participants a comprehensive view of how AI is reshaping the research landscape.

Moderators:

Elona Dybeli; Tirana / Albania

Helle Precht; Middelfart / Denmark

Chairperson's introduction (5 min)

Elona Dybeli; Tirana / Albania

AI in image data management and analysis (12 min)

Christian Schneckenleitner; Vienna / Austria

1. Distinguish between valid and invalid uses of AI in data analysis (e.g. pattern recognition, image analysis, text mining).
2. Recognise and evaluate risks of bias and error introduced when AI models are used to generate or interpret data.
3. Reflect on and apply principles of transparency and reproducibility when integrating AI into research analysis.

AI in research communication and academic practice (12 min)

Karen Brage; Odense / Denmark

1. Use AI responsibly as a support tool in writing and presentation without compromising academic standards.
2. Differentiate between acceptable linguistic/structural support and unacceptable AI-generated text production.
3. Reflect on and apply appropriate practices for disclosing AI use in academic publications.

AI in research - the Editors perspective (12 min)

Jonathan Mcnulty; Dublin / Ireland

1. To be aware of the permitted use of AI in scientific research publications
2. To become familiar with the Radiography journal approach to AI use by researchers
3. To consider how AI will influence future research dissemination

Panel Discussion (19 min)

EIBIR 1 - EIBIR Stage bonus session 1

Categories: Hybrid Imaging, Imaging Methods, Oncologic Imaging, Professional Issues, Multidisciplinary, Artificial Intelligence
Date: March 4, 2026 | 11:30 - 12:30 CET
CME Credits: 1

Moderator:
Rozemarijn Vliegenthart; Groningen / Netherlands

Leveraging Real-World Data for Equitable Implementation of Lung Cancer Screening: Insights from the SOLACE Consortium (8 min)
Emily Nischwitz; Heidelberg / Germany

Author Block: E. Nischwitz[1], A. Kerpel-Fronius[2], J. Chorostowska-Wynimko[3], M-P. Revel[4], I. Horvath[2], M. K. Vasakova[5], T. Gerriet Blum[6], H. Prosch[7], H-U. Kauczor[1]; [1]Heidelberg/DE, [2]Budapest/HU, [3]Warsaw/PL, [4]Paris/FR, [5]Prague/CZ, [6]Berlin/DE, [7]Vienna/AT
Purpose: With strong evidence from clinical trials demonstrating that lung cancer screening (LCS) improves patient outcomes, it is now critical to reinforce these findings by evaluating LCS participant data from newly implemented pilots and programs. A central objective of the Strengthening the Screening of Lung Cancer in Europe (SOLACE) initiative is the systematic collection of real-world data (RWD) across its 19 data-providing sites.
Methods or Background: The SOLACE consortium unites 37 partners from 15 EU Member States across a variety of medical specialties. This multidisciplinary team focuses on supporting the implementation of equitable LCS. The three SOLACE pilots focused on the engagement of previously underrepresented groups in LCS, including women, hard-to-reach individuals, and individuals with co-morbidities linked to lung cancer risk.
Results or Findings: With multidisciplinary input, a core common data model was developed to capture key LCS findings and harmonize the heterogeneous results across the 19 data-providing sites. Both individualized and aggregated data were centrally collected within the SOLACE Database. These data span the entire screening pathway, including demographic and recruitment information, smoking history, screening results, radiation dose, and follow-up and treatment information, when applicable.
The SOLACE Database will contain 25,000 total participant records, including 18,000 individualized records. Previously underrepresented groups in LCS will account for over 90% of the individualized dataset.
Conclusion: The SOLACE Database will enable the systematic evaluation of the benefits and risks of LCS, efficacy of recruitment methods, as well as facilitate the in-depth analysis of sub-populations. This rich resource of RWD will provide critical evidence to guide the equitable implementation of LCS across Europe.
Limitations: Data sharing is limited to the SOLACE consortium; however, the consortium is committed to ensuring the wide dissemination of the findings and insights derived from this dataset.
Funding for this study: This project is co-funded under the EU4Health Programme 2021–2027 under grant agreement no. 101101187.

The Path to Sustainability in Diagnostic Imaging: Assessment by Levels of the CBR Socioenvironmental Seal (8 min)
Mauricio Zapparoli; Curitiba / Brazil

Author Block: M. Zapparoli, C. Barbosa de Souza, R. Guimarães, L. A. Brolini Delle Urban, A. Tachibana; São Paulo/BR
Purpose: The implementation of socio-environmental practices in diagnostic imaging services is still a challenge in Brazil. Certification through the CBR Socio-Environmental Seal allows for the assessment and encouragement of advances in sustainability, considering three certification levels: Bronze, Silver and Gold. This study evaluates nine diagnostic imaging institutions to identify the level of certification they would achieve if they were assessed by the seal, highlighting challenges and opportunities for improvement
Methods or Background: A survey was conducted based on the 73 criteria of the CBR Socio-Environmental Seal, distributed across six pillars: environmental management, human rights, suppliers, infrastructure, labor practices and society. The institutions classified their practices as compliant, partially compliant or non-compliant.
Results or Findings: Of the nine services assessed, seven would achieve Bronze level, one institution would achieve Silver level and one would not achieve certification. The main obstacle to advancing towards certification is low compliance with environmental and social criteria. The average compliance with Bronze level criteria was 78%, while at Silver level it was 35% and at Gold level, 12%.
Conclusion: Most imaging services are still in the early stages of socio-environmental maturity. The CBR Socio-Environmental Seal represents a structured path to boost sustainability in radiology, encouraging continuous improvements and strengthening sustainable practices.
Limitations: There is no limitation.
Funding for this study: There is no financing.
Has your study been approved by an ethics committee? Not applicable
Ethics committee - additional information:

Socio-environmental Certification in Diagnostic Imaging: Methodology and Impacts (8 min)

Mauricio Zapparoli; Curitiba / Brazil

Author Block: M. Zapparoli, L. A. Brolini Delle Urban, C. Barbosa de Souza, R. Guimarães, A. Tachibana, H. Carrete Jr, A. M. C. DE SOUZA; Curitiba/BR
Purpose: The CBR Socio-Environmental Seal was created to certify imaging services that adopt sustainable practices, considering three maturity levels: Bronze, Silver and Gold. The certification process encourages continuous improvement and strengthens socio-environmental governance in the sector. This paper presents the methodology of the CBR Socio-Environmental Seal, detailing the criteria evaluated and their application in radiology.
Methods or Background: The certification is based on 73 criteria distributed across six pillars, structured into three levels: 27 criteria for Bronze, 24 for Silver and 22 for Gold. The assessment is carried out through self-assessment, document audit and evidence analysis.
Results or Findings: The most demanding pillars at the Gold level are environmental management (7 criteria) and human rights (5 criteria). At the Silver level, there is greater demand in infrastructure (6 criteria) and suppliers (4 criteria). The Bronze level mainly requires labor practices and operational safety.
Conclusion: The CBR Socio-Environmental Seal structure allows for a comprehensive assessment of the socioenvironmental practices of diagnostic imaging services. Adopting this certification can raise quality and sustainability standards in the sector.
Limitations: There is no limitation.
Funding for this study: There is no financing.
Has your study been approved by an ethics committee? Not applicable
Ethics committee - additional information:

Implementation of Two National Mammography Quality Certification Programs in Brazil (8 min)

Mauricio Zapparoli; Curitiba / Brazil

Author Block: M. Zapparoli[1], J. E. Peixoto[2], M. B. Schaefer[3], L. A. Brolini Delle Urban[3], A. Tachibana[3], L. F. Chala[3], C. Barbosa de Souza[3]; [1]Curitiba/BR, [2]Rio de Janeiro/BR, [3]São Paulo/BR
Purpose: To ensure the quality of diagnostic mammography and minimize radiation doses for women, the Brazilian College of Radiology and Diagnostic Imaging (CBR) created, in 1992, a voluntary Quality Certification Program. In 2012, the Ministry of Health introduced a federal regulation establishing the National Mammographic Quality Program, mandatory for all 5,176 units in the country, under the responsibility of the National Cancer Institute (INCA/MS) and the National Health Surveillance Agency (ANVISA). This study provides an overview of the implementation and results of two national mammography quality certification programs in Brazil between 2017 and 2021.
Methods or Background: These programs assess radiation dose and phantom image quality in x-ray mammography units through a postal system. Each unit that passes this initial assessment must submit five complete patient examinations. The quality of images and reports is reviewed by radiologists and medical physicists.
Results or Findings: During the study period, 1,007 mammography units from 953 facilities applied for certification, representing 19.5% of all units, located in 205 cities across 20 of the 27 Brazilian states. A total of 934 (92.8%) passed the radiation dose and phantom image quality assessment. Of these, 556 (59.5%) also passed the clinical image and report review, achieving certification. The main issues related to mammography quality were linked to radiologist performance in positioning and interpretation.
Conclusion: The implementation of the two national certification programs in Brazil was carried out by a small workforce and at reasonable cost, using postal resources to accommodate the many units and the vast distances within the country. However, overall program effectiveness (certified/applied units) was 55.2%. The main reason was that 39.5% of units did not submit the required examinations for review. Ongoing efforts are needed to improve effectiveness.
Limitations: There is no limitation.
Funding for this study: There is no financing.
Has your study been approved by an ethics committee? Not applicable
Ethics committee - additional information:

Low Adherence to Accreditation in Imaging Services in Brazil and Its Impact on Diagnostic Quality (8 min)

Mauricio Zapparoli; Curitiba / Brazil

Author Block: M. Zapparoli, A. Tachibana, C. Khawali, R. Guimarães, C. Barbosa de Souza; São Paulo/BR
Purpose: Accreditation of diagnostic imaging services is an essential tool to guarantee exam quality and safety, directly impacting diagnostic accuracy and treatment effectiveness. In Brazil, programs such as PADI, CBR, ONA, QMENTUM and ACSA promote excellence, but adherence remains low with regional disparities. This study analyzes accredited imaging services compared to institutions in the National Registry of Health Establishments (CNES), identifying regional gaps and reinforcing the importance of accreditation for accurate diagnosis and adequate treatment.
Methods or Background: Data were collected from accreditation programs (CBR – PADI and Stamp; ONA – Levels 1, 2 and 3; QMENTUM – International and Diamond; ACSA – Excellent, Advanced and Optimal). The total number of imaging services was extracted from CNES (accessed February 24, 2025). The analysis compared accredited services by state, calculating an accreditation index: accredited services divided by CNES institutions classified as 121–Imaging Diagnostic Service, categorized as private, public and non-profit.
Results or Findings: Of the 6,871 registered services, only 605 are accredited (8.8%). There is wide variation among states: Minas Gerais has the highest index (0.35), followed by Goiás (0.17) and the Federal District (0.14). Maranhão, Pará, Paraíba, Rio Grande do Norte and Roraima have none. São Paulo has the largest absolute number of accredited services (199), but a moderate index (0.13), showing the need for stronger incentives even in states with greater infrastructure.
Conclusion: Low adherence reflects structural and financial challenges. Accreditation is essential to ensure quality and patient safety, directly impacting treatment outcomes. Incentive strategies and public policies can foster equity, ensuring access to accurate, reliable diagnoses nationwide.
Limitations: There are no limitations.
Funding for this study: There was no funding for this work.

Maturity evaluation of European hospital Data Warehouses in the context of the EUCAIM project (8 min)

Carina Soler-Pons; Valencia / Spain

Author Block: P. Serrano[1], C. Soler-Pons[1], S. Flor[1], J. Soto[2], V. Sóñora[3], F. J. Medina Álvarez[4], A. Orduña Galán[4], L. Marti-Bonmati[4]; [1]Valencia, Spain/ES, [2]Madrid/ES, [3]La Coruña/ES, [4]Valencia/ES
Purpose: To assess the maturity of European hospital Data Warehouses (DWHs) within the EUCAIM consortium, focusing on their ability to generate high-quality datasets for secondary use, aligned with the federation's requirements for Real World Data Holders.
Methods or Background: A descriptive cross-sectional study was conducted using a structured self-assessment questionnaire distributed to participating hospitals. Respondents included data scientists, IT specialists, and data protection officers. The questionnaire explored technical characteristics, data domains, standards and vocabularies, accessibility, governance, privacy and legal frameworks, and hardware capacity. Responses were scored on a 0–3 scale to create comparable maturity profiles. Aggregated scores were analyzed visually and statistically, and hospitals were grouped using k-means clustering and expert review.
Results or Findings: The survey revealed a diverse DWH maturity landscape. Most hospitals reported having a DWH with varied capabilities, including ETL processes, backup policies and imaging data integration. Use of common data models and standardized vocabularies was widespread but uneven. Governance and de-identification procedures were present in several institutions, while others lacked formal documentation. Three clusters emerged: entry-level, intermediate and/or transitioning, and advanced hospitals.
Conclusion: DWH maturity varies across European hospitals due to institutional and national challenges. EUCAIM can guide improvement by providing feedback, fostering collaboration, and connecting less mature institutions with advanced ones, enhancing their ability to generate on-demand datasets for research and supporting observational studies in the European Health Data Space.
Limitations: Results are based on 24 hospitals; analyses will evolve as more join. Hospitals face financial, technical, and legal challenges, including limited funding, lack of skilled staff, resistance to change, complex data integration, and regulatory uncertainty around data protection and anonymization. Investment in education, governance, and pilot projects show promising progress, highlighting the need for coordinated strategies.
Funding for this study: Funding was provided by EUCAIM, a project co-funded by the European Union under Grant Agreement 101100633.

Ethics committee - additional information:

From ChAImeleon to EUCAIM: advancing robust anonymization in medical imaging (8 min)

Rocío Catalán Flores; Valencia / Spain

Author Block: R. Catalán Flores[1], C. Soler-Pons[1], J. Munuera Mora[1], R. Martínez Martínez[1], V. Kalokyri[2], K. Nikiforaki[2], I. Karatzanis[2], S. Sfakianakis[2], L. Marti-Bonmati[1]; [1]Valencia/ES, [2]Heraklion/GR
Purpose: Secondary use of clinical data requires robust anonymization to protect privacy. In medical imaging, re-identification risk is critical due to data sensitivity. This work shows the evolution from ChAImeleon to EUCAIM, highlighting advances in anonymization and risk assessment.
Methods or Background: Several efforts were undertaken in the ChAImeleon project, including the development of a custom de-identification profile and the organization of a Re-identification Challenge. In this challenge, 68 participants attempted to re-identify pseudonymized DICOM studies from multiple European sites, modalities, and regions. The studies had been de-identified using methods developed in ChAImeleon and ProCancer-I. No participant was able to trace back patient identities, confirming the robustness of these approaches. These findings highlight both the effectiveness of the applied protocols and the need for standardized methods to further strengthen future anonymization practices.
Results or Findings: Building on the outcomes of ChAImeleon, the EUCAIM project extends anonymization efforts to a federated, multicenter context. Key deliverables include guidelines and a risk analysis framework, the EUCAIM Anonymizer—an automated tool for the project-specific de-identification—and the Wizard Tool, which supports its validation. Integrated within the EUCAIM architecture, these resources ensure consistent data protection and harmonized practices across participating sites.
Conclusion: Reliable anonymization has been demonstrated for large imaging cohorts, enabling secure secondary use of clinical data. Lessons from ChAImeleon have been consolidated in EUCAIM through practical tools. These efforts strengthen trust in the secondary use of anonymized clinical imaging data and support responsible data sharing for research.
Limitations: Despite these advances, risk models remain dependent on the continuous evolution of re-identification techniques. Ongoing validation is necessary across heterogeneous datasets and institutions, and the usability and adoption of the proposed tools may still vary according to local infrastructures.
Funding for this study: ChAImeleon and EUCAIM are two relevant European projects funded by Horizon 2020.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Both European projects and the Re-identification Challenge, which is part of the ChAImeleon project, have been approved by the Ethics Committee of the institutions involved.

ESR DAET 3 - Getting up to speed: emerging technologies in cross-sectional imaging

Categories: General Radiology, Imaging Methods, Physics in Medical Imaging, Artificial Intelligence

ETC Level: LEVEL I+II

Date: March 4, 2026 | 11:30 - 12:30 CET

CME Credits: 1

Review and illustration of the latest advancements in cross-sectional imaging. The session targets non-expert radiologists (or residents) who want to familiarise themselves with the latest technological innovations that are relevant for clinical practice.

Moderator:

Andreas M. Hötker; Zurich / Switzerland

Chairperson's introduction (3 min)

Andreas M. Hötker; Zurich / Switzerland

Photon-counting CT (19 min)

Victor Mergen; Zürich / Switzerland

Deep learning in MR image reconstruction (19 min)

Martin John Graves; Cambridge / United Kingdom

Long-axial field-of-view PET/CT and new tracers (19 min)

Clemens Mingels; Sacramento / United States

ESR eHealth 3 - Improving the patient experience with IT

Categories: Professional Issues, Management/Leadership, Imaging Informatics, Medico-legal, Artificial Intelligence

ETC Level: LEVEL III

Date: March 4, 2026 | 11:30 - 12:30 CET

CME Credits: 1

The session aims to discuss how modern IT tools can improve patient experience in the radiology department, from scheduling, distribution of examination-related information before the appointment and consent. Additionally, it will discuss the impact of artificial intelligence on telemedicine applications and the usage of large-language models to generate summaries or more patient-friendly versions of radiological reports.

Moderator:
Michelle Claire Williams; Edinburgh / United Kingdom

Chairperson's introduction (5 min)
Michelle Claire Williams; Edinburgh / United Kingdom

The patient's perspective: improving digital literacy (15 min)
Erik Briers; Hasselt / Belgium

Exam preparation with GenAI (15 min)
Mansoor Fatehi; Tehran / Iran

The role of AI literacy: evolving the patient-physician relationship (15 min)
Francesca Maccioni; Rome / Italy

Panel discussion: Are we taking enough care of our patients? (10 min)

ETAP - Holistic resident education: learn from ETAP-approved centres

Categories: Education
ETC Level: LEVEL I+II
Date: March 4, 2026 | 11:30 - 12:30 CET
CME Credits: 1

Moderator:
Jeannette Kraft; Leeds / United Kingdom

Chairperson's introduction (2 min)
Jeannette Kraft; Leeds / United Kingdom

How did we implement change after ETAP? (10 min)
Jussi Hirvonen; Turku / Finland

1. To briefly describe the process of obtaining certification.
2. To share experiences from the certification process at their centre.
3. To understand how the assessment has changed the way teaching and supervision for residents are provided.

How do we prepare our residents for EDiR? (10 min)
Pablo Rodríguez Carnero; Madrid / Spain

1. To briefly describe the EDiR examination structure.
2. To appreciate available educational resources for preparation and how they are used in their centre.
3. To understand how EDiR benefited residents in their training centre.

How did we develop and implement our resident teaching curriculum? (10 min)
Chantal Van Ongeval; Leuven / Belgium

1. To briefly describe how the centre developed a structured teaching curriculum.
2. To learn how to include novel teaching methods such as AI.
3. To understand how to balance practical and theoretical learning.

How do we provide supervision and mentorship? (10 min)
Eva Lundström Nordlander; Skellefteå / Sweden

1. To learn about good clinical supervision in diagnostic and interventional radiology.
2. To appreciate the value of continuous feedback for residents.
3. To understand how mentorship and supervision enhance training in their centre.

How do we prepare residents for on-call/night shift? (10 min)
Jens Bremerich; Basel / Switzerland

1. To learn how the centre teaches emergency radiology to its residents.
2. To appreciate how to assess competencies for independent practice.
3. To understand how to supervise best residents working overnight.

Panel discussion (8 min)

E³ 22A - The painful shoulder

Categories: Musculoskeletal, General Radiology, Imaging Methods, Radiographers, President's Choice
ETC Level: LEVEL II
Date: March 4, 2026 | 11:30 - 12:30 CET
CME Credits: 1

Moderator:
Josef Kramer; Linz / Austria

Chairperson's introduction (5 min)
Josef Kramer; Linz / Austria

MRI reporting: a systematic approach (25 min)
Marco Zanetti; Baden / Switzerland

1. To understand the approach used in reporting and classifying MR imaging findings of the painful shoulder.
2. To review the normal anatomy of the rotator cuff, the long head of the biceps tendon, including the pulley system, as well as the cartilage and labrum.
3. To demonstrate differential diagnoses for degenerative and post-traumatic abnormalities of the rotator cuff.

Imaging of sports injuries (25 min)
Andrew J Grainger; Cambridge / United Kingdom

1. To recognise the key imaging findings associated with post-traumatic shoulder instability.
2. To understand the mechanisms of injury that lead to superior labral injury in overhead athletes.
3. To identify the findings that are seen on imaging as a result of repetitive low-grade sporting trauma.

Panel discussion (5 min)

OF 3R - Impact of culture and diversity in radiography

Categories: Radiographers, Professional Issues
Date: March 4, 2026 | 11:30 - 12:30 CET
CME Credits: 1

Moderator:
Patrizia Cornacchione; Rome / Italy

Chairperson's introduction (5 min)
Moreno Zanardo; Milan / Italy

Radiographers' competencies and perspectives about culture diversity and its impact on practice (12 min)
Jane Marie Harvey-Lloyd; Suffolk / United Kingdom

1. To recognise the importance of cultural competence in delivering person-centred radiographic care.
2. To explore radiographers' perspectives on diversity and how these influence communication and clinical interactions.
3. To identify strategies to enhance cultural awareness and sensitivity within radiography teams.

Patient culture and diversity: how to manage it (12 min)
Evelyn Steinthaler; Vienna / Austria

1. To understand how cultural beliefs and values influence patient expectations and healthcare experiences.
2. To develop communication strategies to effectively navigate cultural differences in clinical settings.
3. To promote inclusive practices by recognising the importance of self-awareness and communication in managing cultural diversity in clinical settings.

Effect of workplace culture on patient care (12 min)
Andrea Bellizzi; Mosta / Malta

1. To understand how workplace culture influences radiographers' attitudes, behaviours, and interactions with patients.
2. To identify the link between positive, inclusive, supportive work environments and the quality of patient care delivered.
3. To explore strategies to foster a positive workplace culture that promotes safety, empathy, and patient-centred care.

Open forum discussion (19 min)

OF 3Y - Modern toolbox for publishing

Categories: Professional Issues, Students, Research, Education, Artificial Intelligence, President's Choice
ETC Level: ALL LEVELS
Date: March 4, 2026 | 11:30 - 12:30 CET
CME Credits: 1

Moderator:
Daniel Pinto Dos Santos; Mainz / Germany

Chairperson's introduction (5 min)
Daniel Pinto Dos Santos; Mainz / Germany

Use of AI tools in research (10 min)
Andrea Ponsiglione; Naples / Italy

1. To highlight some of the novel AI tools that can be used for organising one's research.
2. To illustrate how they can be used when preparing an academic paper.

Using large language models for editing your paper (10 min)
Gennaro D'Anna; Legnano / Italy

1. To discuss the benefits of using large language models such as ChatGPT for assistance in writing and editing academic papers.

Using social media for promotion and dissemination of your work (15 min)
Brendan S Kelly; United Kingdom / United Kingdom
Roberto Cannella; Palermo / Italy

1. To highlight the ways in which one can use social media to promote and share their work.
2. To warn of the potential dangers of public data sharing.

Open forum discussion: What are the biggest benefits and concerns of using AI and social media in your academic work? (20 min)

RC 301 - Spectral CT in abdominal imaging: clinical applications

Categories: Imaging Methods, Emergency Imaging, Oncologic Imaging, Abdominal Viscera
ETC Level: LEVEL II
Date: March 4, 2026 | 11:30 - 12:30 CET
CME Credits: 1

Moderator:
Federica Vernuccio; Palermo / Italy

Chairperson's introduction (3 min)
Federica Vernuccio; Palermo / Italy

Spectral CT principles: what every radiologist should know (15 min)
Andre Euler; Baden / Switzerland

1. To understand the technical principles of multi-energy CT.
2. To review the different spectral imaging technologies currently available.
3. To summarise the different spectral imaging reconstructions and their potential use in clinical practice.

Added value in oncologic imaging: liver, pancreas, and beyond (15 min)
Bari Dane; New York, NY / United States

1. To demonstrate how spectral CT improves lesion detection and characterisation.
2. To highlight specific use cases in liver and pancreatic cancer.
3. To learn how iodine quantification and virtual non-contrast can enhance clinical decision-making.

Emergency abdomen: does spectral CT really change the game? (15 min)
Paul Calame; Besançon / France

1. To assess the benefits of spectral CT in bowel ischemia, bleeding, and trauma.
2. To discuss dose reduction and workflow optimisation in acute settings.
3. To review case examples where spectral CT influenced diagnosis or management.

Panel discussion: Should spectral CT become the standard of care? (12 min)

RC 302 - Challenging cases: how we do it

Categories: Imaging Methods, Breast, President's Choice
ETC Level: LEVEL II

CME Credits: 1

Moderator:
Fleur Kilburn-Toppin; Cambridge / United Kingdom

Chairperson's introduction (5 min)
Fleur Kilburn-Toppin; Cambridge / United Kingdom

Second-look ultrasound after abnormal contrast imaging: when and how? (15 min)
Elisabetta Giannotti; Cambridge / United Kingdom

1. To recognise when second-look ultrasound is justified after abnormal findings on contrast-enhanced imaging.
2. To identify common challenges and pitfalls in correlating enhancing lesions with ultrasound targets.
3. To apply practical strategies to improve lesion detection and guide intervention.

Pre-surgical localisation of the breast and axilla: wire and non-wire techniques in practice (15 min)
Tamar Sella; Jerusalem / United Kingdom

1. To compare wire and non-wire localisation options for complex breast and axillary cases.
2. To recognise key technical challenges in difficult localisation scenarios.
3. To tailor localisation strategies to surgical planning and lesion characteristics.

Breast lesions of uncertain malignant potential (B3 lesions): current strategies in assessment and management (15 min)
Simone Schiaffino; Lugano / Switzerland

1. To describe the most frequent subtypes of B3 lesions encountered in clinical practice.
2. To recognise the challenges in selecting between active surveillance, vacuum-assisted excision, and surgery.
3. To consider the potential role of contrast-enhanced techniques in decision-making for B3 lesions.

Panel discussion: When the guidelines end: navigating grey zones in breast imaging (10 min)

RC 307 - Imaging of male and female chronic pelvic pain

Categories: Imaging Methods, Research, Genitourinary, Education
ETC Level: LEVEL II+III
Date: March 4, 2026 | 11:30 - 12:30 CET

Chairperson's introduction (2 min)
Charlie Alexander Hamm; Berlin / Germany

Pelvic congestion syndrome and varicocele (12 min)
Alessandro Posa; Roma / Italy

1. To understand indications for imaging in patients with suspected pelvic congestion syndrome and varicocele.
2. To choose the appropriate imaging modalities based on the clinical scenario.
3. To learn about interventional therapeutic options for vascular pelvic pain.

Chronic pelvic inflammatory disorders (PID) (12 min)
Lorenzo Cereser; Udine / Italy

1. To learn about the most frequent causes of chronic PID.
2. To understand imaging findings of chronic PID.
3. To learn how imaging can guide diagnosis and management.

Imaging of pelvic adhesions and post-surgical complications: diagnostic challenges (12 min)
Paula Pelechano Gomez; Valencia / Spain

1. To identify imaging features of pelvic adhesions and post-surgical complications.
2. To recognise imaging features of urinary leaks and complications from pelvic floor slings.
3. To learn how imaging strategies can address therapeutic challenges in post-operative pelvic assessment.

Dynamic ultrasound in chronic pelvic pain: evaluating pelvic floor static disorders (12 min)
Aleksandra Stankiewicz; Stoke-On-Trent / United Kingdom

1. To understand the role of dynamic ultrasound in assessing pelvic floor disorders.
2. To recognise key ultrasound findings in static pelvic floor abnormalities.
3. To learn to select appropriate ultrasound techniques for evaluating chronic pelvic pain.

Panel discussion: Challenges and consensus in chronic pelvic pain (10 min)

RC 312 - Bone marrow findings

Categories: Musculoskeletal, Paediatric

Moderator:
Ilze Apine; Riga / Latvia

Chairperson's introduction (5 min)
Ilze Apine; Riga / Latvia

Frequent and less frequent findings in healthy children (15 min)
Simone Antonia Johanna Ter Horst; Utrecht / Netherlands

1. To describe the normal pattern of bone marrow conversion in the maturing skeleton.
2. To list the most common sites of residual red bone marrow.
3. To name at least three sites of physiological/self-limiting bone marrow changes in healthy children.

Optimal protocol: how to increase specificity and when to use extra sequences? (15 min)
Lil-Sofie Ording Müller; Oslo / Norway

1. To learn about the basic imaging protocol for bone-marrow imaging with a focus on whole-body MRI.
2. To describe the most relevant additional MRI sequences in equivocal bone marrow findings.
3. To discuss when and how to apply extra sequences in bone marrow imaging.

When to biopsy, when to follow, when to ignore (15 min)
Laura Tanturri De Horatio; Roma / Italy

1. To illustrate the bone marrow findings, which have no alarm features.
2. To list the red flags that require prompt biopsy.
3. To show examples of pathologies where MRI may play a decision-making role.

Panel discussion: How to improve differential diagnosis between variants and pathology? (10 min)

RC 317 - When clots hit: spectrum of disease and imaging techniques

Ischaemic stroke: latest updates on imaging (12 min)
Stefan Roosendaal; Amsterdam / Netherlands

1. To review current imaging protocols for acute ischaemic stroke.
2. To interpret key imaging signs that influence eligibility for reperfusion therapies such as intravenous thrombolysis and mechanical thrombectomy.
3. To understand recent advancements and guideline updates in stroke imaging, including extended time windows and the use of advanced perfusion techniques for patient selection.

Pulmonary embolism and deep vein thrombosis: update on protocols and workflow (12 min)
Ilkay Sedakat Idilman; Ankara / Turkey

1. To review current imaging protocols for diagnosing pulmonary embolism and deep vein thrombosis.
2. To understand workflow optimisations and decision-making algorithms for rapid triage and imaging of patients with suspected thromboembolic disease.
3. To recognise recent advances in diagnosing pulmonary embolism and deep vein thrombosis.

Often underdiagnosed or even ignored diseases of the abdomen and clots in the abdominal veins: how to diagnose and optimise different imaging modalities (12 min)
Ali Devrim Karaosmanoğlu; Ankara / Turkey

1. To identify imaging findings of abdominal venous thrombosis and distinguish bland thrombus from tumoral thrombus across different vascular segments.
2. To learn how to select and optimise the appropriate imaging modality (CT, MRI, or US) based on clinical presentation and specific patient cases.
3. To learn to recognise and evaluate the spectrum of clinical and radiological complications associated with abdominal venous thrombosis.

Cerebral venous and sinus thrombosis: a challenge when on call (12 min)
Tormund Njølstad; Bergen / Norway

1. To recognise the clinical signs and symptoms of cerebral venous sinus thrombosis (CVST) and understand the differential diagnosis when evaluating a patient on call.
2. To understand the role of imaging, particularly MRI and MR venography (MRV), in diagnosing CVST, and differentiate it from other causes of intracranial pathologies.
3. To evaluate the management strategies for CVST, including the indications for anticoagulation, thrombolysis, the role of endovascular intervention, and when to involve a multidisciplinary team.

Panel discussion: Crucial clots that cannot be missed (10 min)

RPS 303 - Coronary CT angiography, plaque burden and risk stratification: coronary plaque composition, adipose tissue and functional insights

Iva Žuža; Rijeka/ Kostrena / Croatia

Volumetry of coronary plaque components on CT coronary angiography: Predictor of MACE? (6 min)
Eline Ekkelenkamp; Zwolle / Netherlands

Author Block: E. Ekkelenkamp[1], S. Dasselaar[2], J. Van Dijk[1], B. Vendel[1], J. Van Dalen[1], R. Vliegenthart[3]; [1]Zwolle/NL, [2]Enschede/NL, [3]Groningen/NL
Purpose: Computed tomography coronary angiography (CTCA) is a valuable tool to detect coronary plaques. Plaque composition may improve risk stratification. Our aim was to establish the value of coronary plaque composition quantification in addition to standard risk factors and CAD-RADS classification to predict occurrence of MACE.
Methods or Background: We identified 1700 patients who underwent CTCA between 2019 and 2021 for whom 2y follow-up was available. The 63 patients who experienced a MACE including all-cause death within 2 years were 1:1 propensity-score-matched to 63 patients without MACE based on CAD-RADS and standard risk factors.
In all 126 matched patients we measured plaque volumes using HU-based thresholds for non-calcified (≤ 30HU), fibrotic (31-350HU) and calcified plaques (>350HU) with commercial software (Advantage Workstation 3.2, GE Healthcare). Volume measurements were categorized into tertiles of low, middle or high plaque volume, for each plaque type. We compared plaque-volume tertiles in terms of MACE-occurrence using a Cox proportional hazards model, with lowest tertile as reference category.
Results or Findings: For the non-MACE and MACE groups, the median volumes of total (508 vs. 527mm3, p=0.36), non-calcified (51 vs. 58mm3, p=0.14), fibrotic (418 vs. 438mm3, p=0.32) and calcified plaque (44 vs. 38mm3, p=0.25) did not differ. Hazard ratios of total and non-calcified plaque tertiles for MACE ranged from 1.11 (p=0.77) to 1.66 (p=0.25), respectively. HR of the middle tertile for fibrotic plaque was 2.93 (p=0.04), and for the highest tertile HR 1.37 (p=0.73). Middle and high calcified plaque tertiles had HRs of 0.59 (p=0.12) and 0.60 (p=0.16), respectively.
Conclusion: We did not find evidence for benefit of CTCA-based volume measurements of coronary plaque components to identify patients at risk of MACE.
Limitations: Relatively small sample due to matched design based on MACE patient cohort.

Association of Socioeconomic Status with Coronary Artery Plaque and MACE: Insights from the DISCHARGE Trial (6 min)
Ann-Christine Stahl; Berlin / Germany

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: A-C. Stahl[1], K. Schulze[1], R. Bockelmann[1], F. Biavati[1], P. Maurovich-Horvat[2], K. F. Kofoed[3], J. Dodd[4], M. Dewey[1]; [1]Berlin/DE, [2]Budapest/HU, [3]Copenhagen/DK, [4]Dublin/IL
Purpose: To assess the association between socioeconomic status (SES), measured by income, and coronary artery plaque on computed tomography (CT) as well as major adverse cardiovascular events (MACE), defined as cardiovascular death, nonfatal myocardial infarction, or nonfatal stroke in both randomisation groups of the Diagnostic Imaging Strategies for Patients With Stable Chest Pain and Intermediate Risk of Coronary Artery Disease (DISCHARGE) trial.
Methods or Background: This is a post-hoc analysis of the multicentre European DISCHARGE trial. Patients ≥30 years with stable chest pain referred for invasive coronary angiography (ICA) were randomised to ICA or CT. SES was determined by monthly net income, adjusted for country-specific price levels and normalised to the national median in the year of randomisation. Patients were categorised into low (≤1) and high (>1) SES groups. Cox survival analysis was used to assess associations between SES and MACE while a general linear model was used for associations with plaque volumes.
Results or Findings: Of 3561 patients, SES data were available for 2624 (1380 low SES). CT-based quantitative plaque analysis was performed in 1232 patients. After adjustment for age, sex, and cardiovascular risk factors, there was no significant difference in MACE between the low and high SES group (hazard ratio: 1.08, p=0.76). Coronary plaque volume was numerically higher in the low SES group, but differences were not statistically significant for total plaque volume (TPV, p=0.48), non-calcified plaque volume (p=0.66), or calcified plaque volume (p=0.36). SES remained not independently associated with TPV after adjustment (p=0.78).
Conclusion: SES was not associated with MACE or plaque volume suggesting that clinical risk factors outweigh socioeconomic influences in stable chest pain patients.
Limitations: SES was based on self-reported income, which may introduce misclassification. Therefore, residual confounding cannot be excluded.

Epicardial Adipose Tissue CT Attenuation in Kawasaki Disease and Association with Coronary Artery Aneurysms (6 min)

Usama Anser; Chengdu / Pakistan

Author Block: U. Anser, S. Azhe, L. Wen; Chengdu/CN
Purpose: To quantify epicardial adipose tissue (EAT) CT attenuation in children with Kawasaki disease (KD) and evaluate its associations with demographic and clinical factors, and the risk of adverse cardiovascular outcomes, aiming to establish EAT as a potential imaging biomarker of coronary risk.
Methods or Background: This retrospective study included 100 KD patients (mean age 8.2 ± 3.9 years) and 35 controls (mean age 8.4 ± 2.8 years) who underwent non-contrast cardiac CT between 2018 and 2024. EAT density was segmented manually (–190 to –30 HU) from the pulmonary bifurcation to the diaphragm. CT scans were performed in both acute and chronic stages of KD, reflecting the heterogeneous timing of imaging in clinical practice. Group comparisons were performed with the Mann–Whitney U test, correlations with Spearman's rho, and predictors of EAT density with linear regression. Statistical significance was set at $p<0.05$.
Results or Findings: EAT CT attenuation was significantly lower in KD patients (–83.9 ± 2.7 HU) compared with controls (–86.3 ± 2.8 HU)($p<0.001$). Within KD, lower EAT CT attenuation was associated with thrombosis ($p=0.04$) and calcification ($p=0.03$). A moderate positive correlation was observed between EAT CT attenuation and coronary Z-score ($\rho=0.53$, $p<0.001$). In regression analysis, both Z-score ($\beta=0.27$, 95% CI: 0.17–0.38, $p<0.001$) and age ($\beta=0.15$, 95% CI: 0.01–0.30, $p=0.035$) independently predicted higher EAT CT attenuation, whereas sex and BMI were not significant. The multivariable model explained 29% of the variance in EAT density ($R^2=0.293$).
Conclusion: These findings suggest that EAT CT attenuation may serve as a potential imaging marker for coronary risk in KD, although larger studies are needed for validation.
Limitations: None

Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was approved by the Institutional Ethics Committee of West China Second University Hospital, Sichuan University. Given the retrospective design and anonymized use of clinical and imaging data, the requirement for informed consent was waived. All procedures were conducted in accordance with the Declaration of Helsinki (2013 revision).

CT angiography analysis of the characteristics of epicardium and pericoronary adipose tissue before coronary artery plaque formation in patients with type 2 diabetes (6 min)

Xiaomin Liu; Guangzhou / China

Author Block: X. Chen[1], X. Liu[2], Z. Li[1], X. Wan[1], T. Xu[1], Y. Liao[2], Y. Xu[2]; [1]Dongguan/CN, [2]Guangzhou/CN
Purpose: To investigate pre-plaque epicardial adipose tissue (EAT), pericoronary fat attenuation index (FAI), and CT-derived fractional flow reserve (CT-FFR) on coronary computed tomography angiography (CCTA) as biomarkers for early cardiovascular risk in type 2 diabetes mellitus (T2DM) patients.
Methods or Background: We retrospectively collected 268 patients(from two hospitals, January 2022 – December 2024) with suspected coronary heart disease, normal coronary arteries on CCTA, newly diagnosed prediabetes(Pre-DM, n=132) or T2DM (n = 136) without prior treatment, and 142 healthy controls with normal CCTA and glucose profiles. Differences in EAT, FAI, and CT-FFR among the three groups were compared. Continuous variables were analyzed via Kruskal-Wallis H test with Bonferroni pairwise comparisons, and categorical variables via chi-square test.
Results or Findings: Kruskal-Wallis H test revealed significant intergroup differences in multiple parameters (EATV, EATV/BMI, FAI-Max□FAI-Mean, FAI-LAD, FAI-LCX; all p<0.05). Post-hoc analyses showed that most parameters significantly differed between the healthy and T2DM groups (EATV, EATV/BMI, FAI-Max□FAI-Mean, FAI-LAD, FAI-LCX; all p<0.05), while only FAI-Max significantly differed between healthy and Pre-DM groups (P=0.025). EATV was the sole parameter differing between Pre-DM and T2DM groups (P=0.03). CT-FFR, including all individual branches and the mean value, did not differ significantly among groups (all P>0.05).
Conclusion: In patients with early T2DM patients (including Pre-DM) but no plaques or functional myocardial ischemia (CT-FFR > 0.8), EATV and FAI (especially FAI-Max) were significantly higher than in healthy individuals. FAI-Max changed significantly at the Pre-DM stage, and EATV further increased with T2DM progression. CCTA-based Imaging features (such as EATV and FAI-Max) are expected to become non-invasive imaging biomarkers for assessing early cardiovascular risk in T2DM patients, providing important information for early clinical intervention.
Limitations: Single-center study with a smal l cohort

Deep learning reconstruction combined with posterior dual-flow variable-speed injection method for coronary CT angiography under different body mass indices: A prospective study (6 min)

Xue Zhao; Guiyang / China

Author Block: X. Zhao; Guiyang/CN
Purpose: To evaluate the image quality of coronary arteries with different body mass index (BMI) patients using a deep-learning reconstruction and to assess the feasibility of a contrast-agent dual-flow variable-rate injection protocol in coronary CT angiograph.
Methods or Background: In this prospective study, patients undergoing coronary CT angiography were randomly assigned to agroup A and group B. Each group was further stratified by BMI into three subgroups (<24.0 kg/m², 24.0–27.9 kg/m², ≥28.0 kg/m²), with 30 patients per subgroup. Group A received 40 mL of contrast at 5 mL/s followed by 10 mL of a 3:7 contrast/saline mixture at 3 mL/s (total contrast 43 mL). Group B received 50 mL of contrast at 5 mL/s. Both groups ended with a 30 mL saline flush; all images were reconstructed with a deep-learning algorithm. Image quality was scored subjectively and objectively (noise, CT attenuation, SNR, CNR). Radiation dose and immediate safety were also recorded.
Results or Findings: Group A used contrast dose 43 mL, while group B with 50 mL, representing a significant iodine reduction that remained adequate even in high-BMI patients. Subjective scores were consistently higher in group A across all BMI strata (p<0.05). Objective analysis showed higher SNR and CNR and lower noise in subgroups A1, A2, and A3 compared with B1, B2, and B3 (p<0.05), whereas CT attenuation values did not differ significantly. Effective radiation dose was lower in all A subgroups (p<0.05). Patient tolerance and safety profiles favored group A, with reduced injection burden.
Conclusion: Combining deep-learning reconstruction with post-dual-flow variable-rate injection protocol delivers high image quality while lowering both contrast volume and radiation dose across the full BMI spectrum, facilitating wider adoption of coronary CT angiography.
Limitations: First, small sample size.
Second, lack of pathological indicators.
Funding for this study: None

Association between allergic inflammatory diseases and computerized tomography-derived coronary inflammation and atherosclerotic disease extent and phenotype: the ALLERGIC-CAD study (6 min)

Chiara Martini; Parma / Italy

Author Block: C. Martini, F. L. Gurgoglione, E. Ridolo, A. A. Palumbo, G. Cicala, F. Nicoletta, C. Baldari, M. De Filippo, G. Niccoli; Parma/IT
Purpose: To evaluate whether patients with suspected chronic coronary syndromes (CCS) and allergic inflammatory diseases show differences in coronary CT angiography (CCTA)-derived atherosclerotic markers — including plaque extent, vulnerable phenotype, and pericoronary fat attenuation index (pFAI) — compared to non-allergic patients.
Methods or Background: Allergic inflammatory diseases are linked to higher risks of myocardial infarction and major adverse cardiovascular events. CCTA detects vulnerable plaques and inflammation markers, such as pFAI, enhancing risk stratification. This study analyzed patients with suspected CCS undergoing clinically indicated CCTA at Parma University Hospital, stratified by allergic history. Plaque burden, vulnerable phenotype (≥2 high-risk features: positive remodeling, low-attenuation plaque, napkin-ring sign, spotty calcification), and pFAI were assessed at patient and lesion levels.
Results or Findings: A total of 289 patients (58 allergic, 20.1%) and 953 lesions were analyzed. CAD prevalence, extent, and severity were similar between groups. Allergic patients showed higher pFAI values (RCA: -65.72 vs -69.36, p=.012; LAD: -64.64 vs -68.81, p=.022; LCX: -61.36 vs -63.05, p=.024) and more vulnerable plaques (53 vs 186, p<.001), including more LAPs (51 vs 127, p<.001), spotty calcifications (31 vs 116, p=.015), and napkin-ring signs (27 vs 67, p<.001). Diabetes (OR 1.143, p<.001), allergy (OR 1.122, p=.003), and pFAI-RCA (OR 1.004, p=.014) predicted vulnerable plaque phenotype.
Conclusion: In suspected CCS, CAD prevalence and severity were similar regardless of allergy, but allergic patients showed greater pericoronary inflammation and more vulnerable plaques.
Limitations: - Single-center design
- Partial inclusion of allergic diseases
- Incomplete allergy characterization
- Lack of systemic inflammatory markers
- Exclusion of acute/prior CVD patients
- No clinical follow-up
Funding for this study: Nothing to declare
Has your study been approved by an ethics committee? Yes

Hemodynamic force derived from cardiac MRI outperforms strain imaging in identifying heart failure with preserved ejection fraction among patients with acute myocarditis (6 min)

Yangzhen Hou; Changsha / China

Author Block: Y. Hou, H. Zhou, L. Weihua; Changsha/CN
Purpose: To investigate the diagnostic potential of left ventricular (LV) hemodynamic force (HDF) parameters to differentiate between acute myocarditis patients with heart failure with preserved ejection fraction (HFpEF) and those without heart failure (non-HF), while systematically comparing their performance against conventional LV strain parameters.
Methods or Background: We retrospectively analysis included 226 consecutive patients with acute myocarditis stratified by heart failure status: non-heart failure (non-HF) group and HF group (with preserved ejection fraction defined as LVEF≥50%). HDF parameters were calculated (I) as the root mean square of the apex-base directions during systole [HDF(Sys)] and diastole [HDF(Dia)]; (II) as the force ratios of the lateral-septal/apex-base directions during systole [R-Sys)], and diastole [R-(Dia)]. Additionally, LV global longitudinal strain (GLS), global circumferential strain (GCS) and global radial strain (GRS) were measured using a CMR feature tracking technique.
Results or Findings: Among 226 myocarditis patients, 53 had HF [HFpEF: 20 (8.8%); HFmrEF/HFrEF: 33 (14.6%)]. Compared to the non-HF group, HFpEF patients exhibited: I. Reduced LVEF (53.55±4.80 vs. 57.78±4.68, P=0.011); II. Impaired left ventricular strain parameters (LVGLS: −20.23±4.02 vs. −22.73±3.77, P=0.020); III. Increased R-Sys (19.49±7.17 vs. 12.90±3.89, P<0.001). R-Sys (AUC 0.836, cutoff 14.40%) distinguished HFpEF with 85.0% sensitivity and 76.3% specificity, outperforming LVEF (AUC 0.758, cutoff 51.98%) and GLS (AUC 0.675, cutoff 21.48%). R-Sys's discriminative power was significantly better than GLS (AUC 0.836 vs 0.675, p=0.043).
Conclusion: The LV hemodynamic force parameter (R-Sys) showed greater diagnostic accuracy than myocardial strain parameter (GLS) for detecting HFpEF in acute myocarditis patients.
Limitations: This study is a retrospective study with potential selection bias.
Funding for this study: This study was supported by the National Natural Science Foundation of China (82071984, 82071894, and 91959117)the Science and Technology Innovation Program of Hunan Province (2020RC4007), and The Scientific Research Program of FuRong Laboratory 2024PT5110.

Coronary sinus: added value to estimate mitral regurgitation severity (6 min)

Thomas Melis; Mestre Venezia / Italy

Author Block: G. Cabrelle, A. Lupi, G. Ruperti, F. Mastro, M. Scordari, T. Melis, C. Zanon, G. Gerosa, A. Pepe; Padua/IT
Purpose: To evaluate whether coronary sinus (CS) size measured by CMR can discriminate between moderate and severe mitral regurgitation (MR).
Methods or Background: Retrospective, single-centre study from Padua University Hospital including patients referred for CMR from July 2024 to June 2025, affected by moderate-severe MR. Exclusion criteria: significant non-mitral valvular disease, history of cardiac surgery, major congenital heart disease, persistent left superior vena cava and ICDs. Cine SSFP sequences (width 6 mm, gap 0) sagittal to mitral anulus were analysed. CS maximum/minimum sagittal caliper and area were measured within 1 cm from CS ostium, together with indexed atrial and ventricular volumes, ejection fraction, mitral regurgitant volume and fraction, global longitudinal and circumferential strain.
Results or Findings: Thirty-four patients (66 ± 11 years, 17F). Moderate MR: 21 patients; severe MR: 13 patients. Ten patients underwent surgery. CS area showed a significant positive association with right indexed atrial volume ($\beta = 3.15$, $p = 0.004$). In multiple regression analysis, CS area was the strongest independent predictor of MR severity ($\beta = 0.95$, $p < 0.0001$), with adjusted $R^2 = 0.75$ for the model ($p = 0.0002$). A CS maximum caliper threshold of 14 mm and area of 0.97 cm^2 provided the best discriminatory performance.
Conclusion: CS maximum caliper and area emerge as predictors of MR severity and may serve as complementary parameters to improve diagnostic accuracy and pre-surgical stratification by CMR in patients with MR.
Limitations: Single center study
Sparse population

Keynote Lecture (10 min)
Justus Erasmus Roos; Lucerne / Switzerland

Assessing Low-Dose CT Image Quality in ESTI's Lung Cancer Screening Protocol: Insights into Patient Size Influence (6 min)
David Christian Rotzinger; Lausanne / Switzerland

Author Block: D. C. Rotzinger, C. Pozzessere, G. Fahrni, T. Saliba, C. Chevallier, Y. Siddiki, V. Vitzthum, C. Von Garnier, L. Gallego Manzano; Lausanne/CH
Purpose: To qualitatively and quantitatively evaluate the European Society of Thoracic Imaging (ESTI) lung cancer screening (LCS) low-dose CT protocol's image quality of the at three weight-based CTDIvol levels, and to assess the effect of participant size on image quality.
Methods or Background: ASiR-V80 lung-kernel reconstructions of 173 LCS participants (69 females, mean age 62.9 years) were retrospectively analyzed, and size metrics (weight, thoracic perimeter) obtained. Three readers independently rated diagnostic quality, noise and sharpness on a 5-point Likert scale. Mean, median, standard deviation, categorical percentage, and inter-reader agreement were calculated. Dose-normalized contrast-to-noise ratio (CNR/CTDIvol) was evaluated as a function of size by linear regression.
Results or Findings: Mean weight and thoracic perimeter were 78kg (43-180) and 107cm (81-142.6). Median CTDIvol was 0.40mGy (0.40–0.51, n=5), 0.85mGy (0.60–2.95, n=96), and 1.69mGy (0.86–3.06, n=72). Reader scores (mean/median/SD) were 4.02/4/0.73 for quality, 3.95/4/0.73 for noise, and 4.06/4/0.72 for sharpness. Quality was rated good/excellent in 77.8% of cases, moderate in 20.4%, and poor/non-diagnostic in 1.7%. Noise and sharpness were rated minimal/excellent in 67.6% and 78% of cases, respectively. Inter-reader agreement was 59.0% for quality, 47.4% for noise, and 58.4% for sharpness. CNR/CTDIvol decreased with increasing weight and perimeter ($p \leq 0.001$), with perimeter explaining more variance in heavier patients (R^2 0.432 vs 0.168 in >80kg; 0.250 vs 0.291 in 50–80kg). At the conservative 25th-percentile, log-CTDI models suggested dose tiers of ~0.4mGy at <63kg/<30cm, 0.9mGy at 87kg/34cm, and 1.6mGy at 98kg/36.3cm.
Conclusion: The ESTI LCS protocol provides high-quality images with potential for further dose reduction. Thoracic perimeter appears more robust than weight in balancing image quality and dose, particularly in heavier patients.
Limitations: Retrospective, single-center design; small <50kg subgroup sample size; single reconstruction algorithm
Funding for this study: No external funding

Training and Education in Lung Cancer Screening: Preliminary Results from a European Survey (6 min)
Rebecca Mura; Vienna / Austria

Author Block: R. Mura[1], A. Kerpel-Fronius[2], T. G. Blum[3], J. Chorostowska-Wynimko[4], P. Zolda[1], H. Prosch[1]; [1]Vienna/AT, [2]Budapest/HU, [3]Berlin/DE, [4]Warsaw/PL
Purpose: To explore the current status of lung cancer screening (LCS) training practices, identify existing gaps, and further define key competencies to be included in LCS educational curricula.
Methods or Background: As part of the European SOLACE project, a structured cross-sectional survey, consisting of 11 closed- and open-ended items, was designed and administered to a panel of European LCS experts. Participants were contacted via email and invited to individual Zoom interviews (May-August 2025), each lasting approximately 30 minutes. Descriptive statistics were used for data analysis.
Results or Findings: Seventeen LCS experts were interviewed (response rate 85%, 17/20) from 11 European countries, including 10 radiologists, 4 pulmonologists, 2 thoracic surgeons, and 1 project manager. Reported training activities ranged from established programs (4/11 countries, mandatory in 2/4), to learning initiatives (4/11) and/or planned programs (4/11). Radiologists (100%), pulmonologists (71%), and thoracic surgeons (67%) were identified as the main target groups for training. On a 6-point Likert scale (0= not important, 5= extremely important), experts indicated limited awareness of training needs as the most relevant gap (mean score 3.1±2.2). Key educational areas to be strengthened included management of incidental findings (4.2±0.6), collaborative (4.1±1.2) and communicative skills (3.8±1.5). Among essential competencies for professionals involved in LCS, the top-rated were familiarity with guideline-based nodule management (4.7±0.5), proficiency in managing of incidental findings (4.5±0.6), and basic knowledge of AI-tools (4.5±0.8).
Conclusion: The findings reveal a highly heterogeneous LCS training landscape across Europe, further challenged by limited awareness of training needs, and highlight the importance of developing shared European curricula. Priorities include technical competencies as well as collaborative and communication skills.
Limitations: Not applicable.

Artificial Intelligence–Supported Early Detection of Lung Cancer from Chest X-Ray in Routine Clinical Practice: Real-World, Multicenter Study Across Czech Hospitals (6 min)

Daniel Kvak; Praha / Czechia

Author Block: K. Kvaková[1], D. Kvak[2], J. Dandár[2], M. Stastny[2], J. Olejko[3], J. Kultan[3], J. Gerold[4], A. Kotoucova[5], C. Vojtek[6], P. Struna[7], E. Dvorackova[8], J. F. Smetana[8]; [1]Brno/CZ, [2]Prague/CZ, [3]Olomouc/CZ, [4]Sumperk/CZ, [5]Benešov/CZ, [6]Nový Jičín/CZ, [7]Slaný/CZ, [8]Kladno/CZ
Purpose: Although AI systems for chest X-ray (CXR) interpretation may enable earlier detection of thoracic malignancy, large-scale real-world evidence remains limited. We present results of a joint Carebot–Bristol Myers Squibb program integrating AI decision-support into routine workflows to evaluate feasibility, flagged-case yield, and downstream actions for suspected malignancy (primary lung cancer or pulmonary metastases).
Methods or Background: All CXRs across nine Czech hospitals (regional and tertiary; two pneumo-oncology centers) from Jan 1–Jun 30, 2025 were automatically analyzed with commercial-stage AI software (Carebot AI CXR; Carebot s.r.o., Czechia). The AI flagged abnormalities; a joint panel of hospital and interim Carebot radiologists classified exams as suspicious for thoracic malignancy. Suspicious cases entered fast-track diagnostics. Primary outcomes: (i) proportion flagged as suspicious, (ii) patients referred for diagnostic work-up, and (iii) confirmed malignancies.
Results or Findings: Among 96 459 CXRs, the algorithm identified abnormalities in 16 030 exams (16.6%). Multidisciplinary review classified 837 CXRs (0.87%) as suspicious. Follow-up status was available in 561/837 (67.0%): 211 (25.2% of all suspicious; 37.6% of those with status) were referred for immediate diagnostic work-up, 350 (41.8% of all; 62.4% of recorded) were cleared without further work-up, and 276 (33.0%) remain under evaluation. Among the 211 investigated, 54 previously undiagnosed thoracic cancers were detected, 70 confirmed known malignancies or pulmonary metastases, 38 await confirmation of nodule origin (biopsy or PET/CT), 20 entered long-term radiologic surveillance, and 29 were recalled owing to missing clinical data.
Conclusion: In this single-country, real-world, multicenter analysis of routine CXR exams during H1-2025, the Carebot–BMS AI triage workflow enabled early identification of thoracic malignancies within routine care while triaging <1% of exams for expedited review. Ongoing follow-up will further characterize the scalability of this AI-supported workflow.
Limitations: This observational study lacks a contemporaneous control.
Funding for this study: Carebot s.r.o. and Bristol Myers Squibb supported software integration and coordination; no public grant funding was received.

The potential role of Digital Tomosynthesis in improving the efficiency of Lung Cancer Screening at reduced radiation doses, costs and radiologists burden (6 min)

Nogah Shabshin; Afula / Israel

Author Block: N. Shabshin[1], Y. Kimmel[2], M. Armoni[3], Y. Schiffenbauer[2], A. Grubstein[3], L. Roshkovan[1], A. Iannessi[4], A. F. Nitu[5], E. Atar[3]; [1]Philadelphia, Afula/IL, [2]Petah Tikva/IL, [3]Petach Tikva/IL, [4]Nice/FR, [5]Bucharest/RO
Purpose: Lung Cancer Screening (LCS) programs are expanding worldwide. However, barriers including high costs, radiologist shortages, and radiation concerns remain. Within LCS populations, 84% present Lung-RADS 1,2, requiring 12-month follow-up, while scores 0,3,4 require closer monitoring. Chest Digital Tomosynthesis (DTS) offers lower radiation, faster reading, and reduced costs compared to CT. Prior studies found DTS may have a potential role in LCS. This study aims to evaluate whether cold-cathode DTS is comparable to CT when classifying patients to 2 groups: A:12-month follow-up (Lung-RADS 1,2) vs. B closer follow-up/workup (Lung-RADS 0,3,4).
Methods or Background: A cohort of 38 patients with a diagnostic chest CT underwent a supine DTS (Nanox.ARC). Three radiologists reviewed the DTS and CTs blindly and independently maintaining a one-month gap between modalities. Patients were classified into groups A and B. The classification was compared between DTS and CT.
Analyses included negative and positive predictive value (NPV, PPV), inter/intra-reader agreement, and concordance between DTS and CT.
Results or Findings: On both CT and DTS, 25 patients were categorized as group B and 13 as group A. None of the patients migrated from one group to the other when compared to CT and therefore DTS and CT showed no difference in follow-up recommendations. NPVs ranged 72.7–90.0% and PPVs 87.5–92.0%. Inter-reader agreement for DTS was comparable to CT (91.4%, 82.9%, 88.6% vs. 88.6%, 82.9%, 88.6%). Inter- and intra-reader agreement were strong, with kappa values >0.65.
Conclusion: Preliminary results suggest DTS can classify patients to those who can continue with 12-months follow-up (Lung-RADS 1–2) and others that require closer follow-up/workup. DTS can potentially reduce the use of CT and thus reduce radiation, costs, and reading time in LCS..
Limitations: small population of clinical patients, not LCS patients
Funding for this study: Study was funded by Nano-x Imaging

Italung2-CCM lung cancer screening pilot: quantitative LDCT-analysis of emphysema and coronary visual score in a baseline cohort of 663 patients as potential risk-based prognostic stratification (6 min)

Ilaria Cecchi; Firenze / Italy

Author Block: L. Gozzi, I. Cecchi, D. Cozzi, E. Cavigli, G. Picozzi, G. Gorini, A. Bindi, C. Moroni, V. Miele; Firenze/IT
Purpose: To investigate the association between emphysema, assessed both visually and quantitatively, socio-demographic, smoking, clinical variables, and radiological signs of lung cancer (LC) and coronary artery calcifications (CAC), in a population of 663 patients enrolled in the Tuscan Italung2-CCM lung cancer screening (LCS) programme.
Methods or Background: We included 663 patients aged 55–75 years, with ≥30 pack-years smoking history. Baseline low-dose CT (LDCT) was evaluated both visually for emphysema/CAC and quantitatively using Pulmo 3D Syngo.Via software (LV, MLD, LAV, P15).
Results or Findings: Among the participants, 96.1% had negative/downgraded LDCT findings, while 26 people (4%) were classified as Lung-RADS 4B/4X; 16 of them were confirmed lung cancers. Emphysema was visually detected in 43% of participants and was significantly more frequent in men (OR=1.60), heavy smokers ≥ 40 pack-years (OR=1.96), and LC patients (OR=8.76). Quantitative emphysema values correlated with male sex, age and former smoker status. CAC was present in 67% of scans, more common in men, older participants, and smokers, but showed no independent association with LC and emphysema. Visual scoring detected more emphysema cases (288) compared to software-based quantification (171), likely due to the masking effect of smoking-induced bronchiolitis on density-based measurements.
Conclusion: This study confirms emphysema as an independent predictor of LC, while CAC reflects shared cardiovascular risks without independent LC association. Visual evaluation outperforms quantitative assessment in detecting emphysema, especially in current smokers, highlighting the need to integrate standardised evaluation of emphysema, CAC, and smoking history in LCS lung programmes.
Limitations: The limitations of the study are inter-scanner variability across centres, potentially affecting CT measures. Moreover, focusing our analysis purely on subjects enrolled in the ITALUNG2-CCM cohort limits the generalisability of its findings. Future studies should harmonize protocols and expand recruitment for broader external validity.
Funding for this study: No funding was received for this study.

Deep learning to predict mortality risk from lung cancer screening CT in heavy smokers (6 min)

Johannes Jahn; Freiburg Im Breisgau / Germany

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: J. Jahn, R. T. Schirrmeister, F. Bamberg, J. Weiß; Freiburg im Breisgau/DE
Purpose: Altered body composition (BC), such as reduced muscle mass or excess adipose tissue, is an independent predictor of cardiovascular and cancer-related mortality. It remains unclear whether deep learning can estimate mortality risk directly from chest CT slices. Here, we developed a deep learning model (CTchest-risk) to estimate mortality risk from lung screening chest CTs in heavy smokers.
Methods or Background: Data from the CT arm of the National Lung Screening Trial (NLST) were used. CTchest-risk was developed in two steps: (1) segmentation of skeletal muscle (SM), subcutaneous adipose tissue (SAT), and intramuscular adipose tissue (IMAT); (2) training of a second model using segmentation masks combined with five axial slices centered at the thoracic vertebra T5 to predict mortality. The training dataset included 14,208 participants (39,304 individual scans). Independent testing was performed on 8,971 individuals not used for development. Primary endpoint was 6-year mortality. CTchest-risk was categorized into three groups (<15%; 15–85% [reference]; >85%). Survival was assessed with Kaplan–Meier analysis and Cox regression adjusted for age, sex, race, BMI, smoking status, diabetes, hypertension, and history of stroke or heart disease. Model performance was evaluated with Harrell's C-index and nested likelihood-ratio tests (LRT).
Results or Findings: In the test cohort (mean age 61.3±5 years; 41.0% female), 462 deaths (5.1%) occurred over a median follow-up of 6.5 years. Kaplan–Meier estimates showed a graded association between CTchest-risk groups (log-rank p<0.0001). High-risk individuals (>85%) had 38% higher adjusted mortality compared with the reference group (aHR 1.38, 95% CI 1.11–1.71, p=0.004). In nested model comparison, adding CTchest-risk to clinical factors improved prognostic performance (C-index 0.725 vs. 0.731; LRT p<0.001).
Conclusion: CTchest-risk identifies high-risk individuals from lung screening chest CT and predicts mortality beyond traditional risk factors in heavy smokers.
Limitations: No external validation set.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: All NLST-participants provided written informed consent for the original trial and secondary use of the data was approved by the local IRB.

Development of an AI model for differentiating focal pneumonia-type lung cancer from focal pulmonary inflammatory lesions using deep learning radiomics (6 min)

Huijie Huang; China / China

Author Block: H. Huang; China/CN
Purpose: The differentiation between focal pneumonia-type lung cancer (F-PTLC) and focal pulmonary inflammatory lesions (F-PIL) presents significant diagnostic challenges due to their overlapping imaging features, often leading to delayed or misdirected clinical interventions. This research develops an artificial intelligence (AI) model that integrates clinic-radiological data, radiomics features, and deep learning features to distinguish between F-PTLC and F-PIL.
Methods or Background: We retrospectively analyzed 299 patients across two centers, splitting them into training (n = 213) and validation (n = 86) datasets. Final radiomics features and deep learning (DL) features were extracted and optimised separately using PyRadiomics and four pre-trained convolutional neural networks (CNNs), thereby providing the foundations for the radiomics (Rad) model and the DL model. Researchers have developed an AI-based diagnostic model by combining radiomic signatures, deep learning algorithms and clinical-radiological data. The model's effectiveness was rigorously assessed through a comprehensive five-fold cross-validation process.
Results or Findings: Univariate and multivariate logistic regression analyses revealed that gender, CEA levels, and CT mean are significant predictive factors. The performance of this AI model surpasses that of all individual models in both the training and testing datasets, with AUC values of 0.917 and 0.845, respectively. Grad-CAM pinpointed critical image areas impacting judgments, whereas SHAP assigned precise weight values to individual predictors, thereby boosting model clarity. The results of the Hosmer-Lemeshow (HL) test indicate a satisfactory fit of the model, while Decision Curve Analysis (DCA) further confirms the significant advantage of the combined model in clinical practice.
Conclusion: This study's multimodal AI system dramatically improved diagnostic accuracy in differentiating F-PTLC from F-PIL cases by combining clinic-radiological data, radiomic analysis, and deep learning algorithms. The integrated approach offers clinicians a robust framework for delivering personalized, precision-based medical care.
Limitations: Not applicable

Development and validation of deep learning model for pulmonary nodule detection (6 min)

Raif Can Yarol; Izmir / Turkey

Author Block: R. C. Yarol[1], S. Gezer[1], E. Unel[2], D. Unay[1], O. Dicle[1]; [1]Izmir/TR, [2]İzmir/TR
Purpose: This study aimed to develop a deep learning based decision support system to assist radiologists in the detection, follow-up, and diagnostic evaluation of nodules on thorax CT images.
Methods or Background: Patients who underwent thorax CT and had at least one pulmonary nodule between January 2022 and December 2023 at one institution were retrospectively screened. A dataset consisting of 2,152 nodules from 205 patients was compiled. In addition to nodule annotations, the location (intrapulmonary, subpleural, perivascular) and density (solid, semisolid, ground-glass) of each nodule were recorded for analysis. The dataset was divided into training and testing subsets.
A 2D U-Net-based model was employed for lung and lobar segmentation.
Vessel structures were labeled using a thresholding method. A 3D U-Net model was utilized for nodule detection and segmentation. The model's performance on the test set was evaluated using sensitivity, specificity, and F1-score. Causes of false positives and false negatives were retrospectively analyzed.
Results or Findings: The developed model achieved a sensitivity of 0.979, specificity of 0.774, and F1-score of 0.864. The models sensitivity for nodules larger than 6 mm was 92.6%, precision was 74.3%, and F1-score was 0.824. For nodules smaller than 6 mm, the sensitivity was 98.8%, precision was 77.9%, and F1-score was 0.871.
The most common cause of false positives (48.8%) was found to be subpleural fibrotic strands. In the analysis of false negatives, there was a statistically significant association between nodule density and false-negative predictions by the model ($p<0.001$). No statistically significant relationship was found between nodule location and false-negative results.
Conclusion: Our deep learning model demonstrated high accuracy in pulmonary nodule detection, highlighting its potential to support radiologists, though further multicenter validation is warranted.
Limitations: Retrospective nature

Ultrasonographic features of ACR TIRADS 3 and 4 thyroid nodules predicting malignant potential (6 min)
Joris Bosschee; Eindhoven / Netherlands

Author Block: J. Bosschee; Eindhoven/NL
Purpose: To identify ultrasonographic features in ACR TIRADS 3 and 4 thyroid nodules to predict malignant potential.
Methods or Background: Thyroid carcinoma incidence in the Netherlands has increased from 372 new cases in 2000 to 904 in 2023, primarily due to population aging and improved imaging techniques. Fortunately the overall prognosis is relatively favorable with a 30 year survival rate of 95%. The inevitable accompanying increase of thyroid ultrasound and ultrasound guided fine needle aspirations (FNA) may result in overdiagnosis and unnecessary patient burden. The revised Dutch thyroid cancer guidelines aim to reduce this overdiagnosis with clinical and radiological recommendations. However, recommendations regarding ACR TIRADS 3 and 4 nodules remain ambiguous, with clinical management relying on expert consensus.

Thyroid ultrasound and FNA results of patients presented to the Catharina hospital in Eindhoven (Netherlands) from 2019-2022 were retrospectively analyzed. All pathological specimens were assigned a Besthesda score and a pathological diagnosis. Predictive ultrasonographic features regarding malignant potential were investigated.
Results or Findings: A total of 341 FNA were analyzed of which 101 (30%) were TIRADS 3 nodules and 124 (36%) were TIRADS 4 nodules. Pathology results were available for 96 TIRADS 3 and 116 TIRADS 4 nodules. A total of 29 (30%) TIRADS 3 noduli scored a Bethesda score 3 or higher and five (5%) turned out to be malignant. 55 (47%) TIRADS 4 noduli scored a Bethesda 3 or higher and 17 (15%) were malignant.
Conclusion: This study will further investigate the predictive ultrasonographic features of TIRADS 3 and 4 nodules that turn out to be thyroid carcinoma. Our goal is to aid radiologists in deciding on ultrasound follow-up and/ or FNA in order to prevent overdiagnosis and consequently unnecessary patient burden and health care costs.
Limitations: Retrospective study.
Funding for this study: No funding was received for this study.

Stiffness Matters: Elastography Enhances Detection of Thyroid Cancer Across Histologic Subtypes (6 min)
Dana I Stoian; Timisoara / Romania

Author Block: D. I. Stoian, M. Latia, A. BENA; Timisoara/RO
Purpose: PURPOSE
To evaluate whether elastography improves diagnostic performance beyond TIRADS in papillary (PTC), follicular (FTC), and medullary (MTC) thyroid cancers, particularly where ultrasound-based stratification underperforms.
Methods or Background: METHODS
We retrospectively analyzed 452 thyroid cancers over 10 years. Subgroups included 29 PTC with 65 benign controls, 32 FTC with 65 Bethesda IV controls, and 20 MTC without controls. All nodules underwent B-mode ultrasound, TIRADS categorization, and strain (SE) and/or shear wave elastography (SWE). Stiffness was integrated as an additional risk factor and compared with TIRADS alone.
Results or Findings: RESULTS
In PTC, 31 nodules were intermediate- and 16 high-risk by TIRADS. Elastography upgraded 8 nodules using SWE and 14 using SE. Diagnostic accuracy improved, with AUC increasing from 0.764 (B-mode) to 0.886 (TIRADS+SWE) and 0.861 (TIRADS+SE). In FTC, only 13/32 nodules (40.6%) were identified as high-risk by TIRADS, versus 27/32 (84.4%) when stiffness was added. In MTC, TIRADS flagged ~60% as high-risk; on SE, 75% scored ES 3–4 (mean ES 3.2), and SWE with a 30.5 kPa cut-off correctly identified 87.5% of malignancies.
DISCUSSION
Elastography significantly enhances TIRADS across histologies. Across subtypes, most nodules were stiff, contradicting the traditional view that FTC and MTC are “soft” cancers. While B-mode alone often misses FTC and MTC, stiffness integration markedly improves cancer detection and supports surgical decision-making.
Conclusion: CONCLUSION
Stiffness is not a stand-alone criterion but consistently augments TIRADS. Elastography should be incorporated into routine assessment of intermediate and high-risk thyroid nodules.
Limitations: LIMITATIONS
Retrospective design, sample sizes, monocentric study.
Funding for this study: No funding

Predictive Value of Arterial Enhancement Fraction Derived from Dual-Layer Spectral Computed Tomography for Thyroid Microcarcinoma (6 min)

Xiaomin Liu; Guangzhou / China

Author Block: J. Yu[1], Y. Chen[1], Z. Song[1], X. Zhang[2], D. Zhang[1], X. Liu[3]; [1]Chongqing/CN, [2]Chengdu/CN, [3]Guangzhou/CN
Purpose: To evaluate the predictive value of dual-layer spectral computed tomography (DSCT)-derived arterial enhancement fraction (AEF) in diagnosing thyroid microcarcinomas.
Methods or Background: A total of 321 pathologically confirmed thyroid micronodules (131 benign, 190 malignant) underwent preoperative DSCT. Quantitative parameters, including normalized iodine concentration (NIC), normalized effective atomic number (NZeff), and the slope of the spectral Hounsfield unit curve (λHU(40–100)), were assessed. Both single-energy CT-derived AEF (AEFS) and DSCT-derived AEF (AEFD) were calculated. Conventional features like microcalcifications were also analyzed. Correlation between AEFD and AEFS was determined using Spearman’s correlation coefficient. Diagnostic performance was evaluated by calculating the area under the curve (AUC) using receiver operating characteristic (ROC) analysis.
Results or Findings: Malignant nodules showed significantly lower AEFD and AEFS than benign nodules ($p < 0.001$). Arterial phase spectral parameters differed significantly between groups ($p < 0.001$), unlike venous phase parameters. Multivariate analysis identified λHU(40–100) as an independent predictor of malignancy (OR: 0.600, $p = 0.002$). AEFD and AEFS were strongly correlated ($r = 0.710$, $p < 0.001$). AEFD demonstrated superior diagnostic performance (AUC: 0.794; sensitivity: 70.5%; specificity: 81.7%; accuracy: 75.1%) compared to AEFS, APλHU(40–100), and calcification. Clinically, using AEFD reduced the unnecessary biopsy rate to 18.3%, preventing 107 procedures.
Conclusion: AEFD correlates strongly with AEFS and shows favorable diagnostic efficacy for thyroid micronodules, significantly reducing unnecessary biopsies and optimizing patient management.
Limitations: Study limitations include its retrospective, single-center design and the need to validate AEFD for other histological subtypes. Future work should automate ROI placement and integrate molecular biomarkers.
Funding for this study: The study was funded by the Post-Doctoral Science Foundation of Chongqing, China (No. CSTB2022NSCQ-BHX0737), the Medical Research Program of the Combination of Chongqing National Health Commission and Chongqing Science and Technology Bureau, China (No. 2024MSXM094), and the Medical Research Youth Program, a joint initiative of the Chongqing National Health Commission and the Chongqing Science and Technology Bureau, China (No. 2024QNXM047).

Ultrasound Detection and Mapping of Suspicious Cervical Lymph Nodes in Patients with PTC: How We Do It?! (6 min)

Tea Charkhalashvili; Kutaisi / Georgia

Author Block: T. Charkhalashvili; Kutaisi/GE
Purpose: According to Global Cancer Observatory (GLOBOCAN 2024), thyroid cancer is among 10 most frequent cancers worldwide. It's most common subtype - PTC spreads to the regional lymph nodes in 20-50% of cases. Accurate preoperative ultrasound (US) evaluation is crucial, as the detection and precise localisation of metastatic nodes directly influence the extent of surgical dissection and better patient outcome. Purpose of this abstract is to highlighting diagnostic criteria, scanning technique and practical tips for mapping LNs and easy communication with surgeons.
Methods or Background: Patients, previously diagnosed with PTC by Thyroid FNA, are scanned with high frequency ultrasound transducer (12-15MHz) prior to surgery in supine position, extending head cranially, with pillow under shoulders, for maximal identity whit surgical position. All the cervical levels are scanned step-by-step on right and left sides. Nodes are assessed for suspicious features: rounded morphology, absence of fatty hilum, microcalcifications, cystic changes and atypical vascularity. LNs are labeled on the neck with marker, as well as on the schematic template for patient history.
Results or Findings: Systematic scanning prevented missed nodes, while structured reporting improved preoperative planning. In our series of standardised Ultrasound mapping of cervical lymph nodes we have high detection rates(80-92%) of regional metastatic LN, and better communications with colleagues.
Conclusion: A standardised systematic ultrasound protocol for cervical lymph node assessment in PTC increases detection rate, accurate cevical level mapping and effective communication with surgeons. Adoption of such protocols improves preoperative planning and contributes to optimised patient outcomes.
Limitations: Small or deeply located nodes may be difficult to visualise, especially in obese patients or those with short necks. Reactive or inflammatory LNs may mimic metastases, lowering specificity, also, early metastases or micrometastases are not be detectable by US.

Thyroid Metastases from Non-Thyroid Malignancies: Systematic Review and Radiological Features (6 min)

Christian Peter; Leipzig / Germany

Author Block: C. Peter, T. Denecke, H-J. Meyer; Leipzig/DE
Purpose: To systematically review clinical and radiological characteristics of thyroid metastases from non-thyroid primary tumors.
Methods or Background: Metastases to the thyroid gland from non-thyroid malignancies are rare but clinically relevant. Reported frequencies vary. Prior reviews mainly addressed clinical and histopathological aspects, while analyses of radiological features remain limited.
We conducted a systematic PubMed search (2010–2025) according to PRISMA guidelines. Eligible studies included case reports, case series and observational studies on histologically confirmed thyroid metastases from non-thyroid primaries with radiological data (ultrasound, CT, or MRI). Studies on primary thyroid malignancies or non-human data were excluded. Extracted data included demographics, primary tumor, interval between primary diagnosis and thyroid metastasis, clinical presentation, and imaging findings
Results or Findings: A total of 215 studies, including 1,006 patients, with mean age of 61.7 years were identified. The most common primary tumors metastasizing to the thyroid are lung cancer, breast cancer and renal cell cancer. Most metastasis are identified metachronous after the initial tumor diagnosis. Most cases present as a painless neck mass and as a unilateral manifestation. On ultrasound, most lesions were hypoechogenic with a blurred border. On CT, metastases were predominantly hypodense. On MRI, lesions were typically intermediate on T2-weighted images and iso- to hyperintense on T1-weighted images. A misdiagnosis is common in up to 31% of cases.
Conclusion: Metastases to the thyroid gland are rare but should be considered in the differential diagnosis of thyroid lesions, especially in patients with a history of malignancy. This systematic review provides an overview of clinical and radiological features, which may aid in diagnosis and differentiation from primary thyroid tumors.
Limitations: Heterogeneity of included studies, small case numbers of case reports with potential publication bias, incomplete radiological data, restricting generalizability to broader clinical practice
Funding for this study: None

Diagnostic Accuracy of ACR-TIRADS Versus S-Detect in Thyroid Nodule Characterization: Comparison with FNAC as the Gold Standard (6 min)

Patrizia Pacini; Frascati / Italy

Author Block: P. Pacini, M. Renda, C. Catalano, V. Dolcetti, C. Solito, F. Raponi, G. Bonito, G. Maglia, V. Cantisani; Rome/IT
Purpose: To compare the diagnostic performance of ACR-TIRADS, assessed by an experienced radiologist, with that of the S-Detect system in the evaluation of thyroid nodules, and to validate both methods against the cytological gold standard, fine-needle aspiration cytology (FNAC).
Methods or Background: This prospective study included 120 patients (35–75 years) with thyroid nodules or lesions detected clinically or on routine neck ultrasound at Umberto I Hospital, Rome. Thyroid nodules are a common finding, with a prevalence exceeding 50% in women and in individuals >60 years. While FNAC remains the diagnostic gold standard, it carries significant financial costs for healthcare systems and psychological stress for patients. Recent efforts have focused on improving ultrasound-based diagnostic accuracy to reduce unnecessary FNAC procedures.
Results or Findings: ACR-TIRADS demonstrated a sensitivity of >97% and specificity of 92%. S-Detect achieved a sensitivity of 94% and specificity of 90%. When compared with FNAC, ACR-TIRADS showed a sensitivity of 94% and S-Detect 91%, confirming strong diagnostic performance for both tools.
Conclusion: ACR-TIRADS demonstrated excellent agreement with FNAC and remains a reliable tool in thyroid nodule characterization. S-Detect also showed high diagnostic accuracy, supporting its role as a complementary, cost-effective aid in clinical practice.
Limitations: A sample size that needs to be expanded

Quantitative CEUS Assessment of Thyroid Nodules (6 min)

Andreea Borlea; Timisoara / Romania

Author Block: A. Borlea, S. Bunceanu, D. I. Stoian; Timisoara/RO
Purpose: To evaluate the diagnostic performance of quantitative contrast-enhanced ultrasound (CEUS) parameters in differentiating benign from malignant thyroid nodules.
Methods or Background: Thirty thyroid nodules with histopathologic confirmation (15 benign, 15 malignant: 12 papillary, 2 follicular, 1 medullary) underwent CEUS. Quantitative time–intensity curve (TIC) analysis included: Arrival Time (AT), Rise Time (RT), Time to Peak (TTP), Fall Time or Wash-out Time (FT), Mean Transit Time (mTT), Peak Intensity (PKI), Area Under Curve (AUC), Wash-in AUC (WiAUC), Wash-out AUC (WoAUC), Ascending Slope (AS), Descending Slope (DS), Slope Ratio (SR), and mean TIC.
Results or Findings: Malignant nodules showed significantly shorter AT (12.3 ± 3.5 vs. 16.7 ± 4.2 s, p=0.01), faster RT (7.1 ± 2.2 vs. 9.8 ± 2.6 s, p=0.02), and earlier TTP (19.4 ± 4.6 vs. 26.5 ± 5.3 s, p<0.01). FT was prolonged (31.2 ± 8.4 vs. 22.5 ± 6.7 s, p=0.02), yielding longer mTT (38.3 ± 9.2 vs. 32.3 ± 7.1 s, p=0.04). PKI was higher in malignant nodules (28.6 ± 5.7 vs. 21.4 ± 4.9 a.u., p=0.01). Perfusion integrals were increased: AUC 1520 vs. 980 a.u.*s (p=0.01), WiAUC 650 vs. 410 (p=0.02), WoAUC 870 vs. 570 (p=0.03). Slopes were steeper in malignancy: AS 2.3 vs. 1.6 a.u./s (p=0.03), DS 2.1 vs. 1.3 (p=0.04), with higher SR (0.91 vs. 0.78). ROC analysis showed AUC 0.86 for TTP and 0.88 for PKI; combining PKI+TTP achieved 0.92 sensitivity and 0.88 specificity.
Conclusion: Malignant thyroid nodules present rapid wash-in, higher peak enhancement, and delayed wash-out. Quantitative CEUS parameters, particularly TTP and PKI, significantly improve diagnostic accuracy and may complement TIRADS and elastography in risk stratification.
Limitations: Small, single-center cohort; larger studies needed for threshold validation.

Analysis of Contrast Enhancement Patterns and Diagnostic Performance of 4D CT in the Detection of Abnormal Parahtyroid Glands in Patient with Primary Hyperparathyroidism (6 min)

Feyza Zengin; Istanbul / Turkey

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: F. Zengin, A. Özel, M. M. Geres; Istanbul/TR
Purpose: This study aimed to evaluate the diagnostic performance of 4D-CT in patients with PHPT, focusing on preoperative localization of abnormal parathyroid glands, comparing enhancement patterns with those described in the literature, and determining overall diagnostic efficacy.
Methods or Background: This retrospective study included 215 parathyroid lesions from 194 PHPT patients who underwent 4D-CT and surgery. An experienced radiologist, blinded to surgical and pathological findings, assessed the scans for lesion detection, size, polar vessel presence, and enhancement characteristics. HU values of lesions and normal thyroid tissue were measured in pre-contrast, arterial, and venous phases.
Results or Findings: 4D-CT localized 90.7% of lesions. Sensitivity, PPV, and accuracy were higher in single-gland cases (94%, 97.5%, 92%) than multiglandular ones (82.3%, 87.5%, 73.7%). Most lesions showed Bahl Type B enhancement (74.4%), but all mislocalizations occurred in this group, suggesting limited specificity. Parathyroid lesions had lower pre-contrast HU than thyroid tissue; however, the <58 HU threshold was only supportive (AUC ≈ 0.72). Arterial enhancement rose by 321.9%, and venous washout reached 42.0%. Absolute (61.3%) and relative (46.5%) washout ratios were strong differentiators. Larger lesions (>11 mm) were associated with polar vessels ($p < 0.001$). Lesion size correlated with arterial HU, washout, PTH, and calcium. Ectopic lesions (4.2%) had fewer polar vessels ($p = 0.010$). The study proposes a novel pattern-based approach incorporating arterial HU ratio and washout rates, suggesting their combination may improve preoperative localization.
Conclusion: 4D-CT is highly effective for preoperative localization in PHPT. Dynamic contrast parameters, particularly arterial enhancement and washout, improve accuracy beyond classical classifications and may further benefit from radiomics integration.
Limitations: The single-center design and the limited number of rare enhancement patterns, non-localized lesions, and multiglandular cases underscore the need for further multicenter studies to validate these findings.
Funding for this study: This research received no specific grant from any funding agency.

Comparison of 4D-CT imaging findings and biochemical parameters in parathyroid adenomas: The role of polar vessel presence (6 min)

BÜŞRA GÖZDE ÜRKMEZ; Ankara / Turkey

Author Block: B. G. ÜRKMEZ, A. Gürsoy Çoruh, M. Kul, S. N. Yılmazer, M. K. Gökcan, Ç. Uzun; Ankara/TR
Purpose: To investigate the association between radiological findings of parathyroid adenomas (PA) on 4 dimensional computed tomography (4D-CT) and biochemical parameters, as well as the impact of polar vessel presence on these relationship.
Methods or Background: This retrospective study included patients who underwent 4D-CT imaging for parathyroid adenoma between 2015 and 2025, with the diagnosis confirmed histopathologically. PV presence was evaluated in consensus by two observers. Densities of PA were measured in pre-contrast, arterial, and venous phases using the largest region of interest excluding cystic/calcified areas. Volume was calculated as 0.523 × long axis × short axis × craniocaudal length. Enhancement indices ('wash-in', 'wash-out', and 'retained') were calculated. Serum parathyroid hormone (PTH), calcium (Ca), and creatinine levels were recorded. Correlations between imaging and biochemical findings were analyzed; Differences according to PV presence were assessed using the t-test/Mann–Whitney U test.
Results or Findings: A total of 84 patients (mean age: 56.42 ± 15.04 years) were included, comprising 45 PV-positive (PV+) and 39 PV-negative (PV−). PV+ patients had higher PTH ($p=0.044$), higher arterial phase density ($p=0.020$), and significantly greater wash-in and wash-out values ($p=0.010$ and $p=0.033$, respectively). PA volume correlated positively with PTH ($r=0.300$, $p=0.006$) and Ca ($r=0.432$, $p=0.014$). Pre-contrast density correlated negatively with PTH ($r=-0.248$, $p=0.023$). No other significant correlations between densities and biochemical parameters were observed.
Conclusion: The presence of a polar vessel is associated with higher arterial enhancement, greater wash-in/wash-out, and elevated PTH levels, supporting its diagnostic role in 4D-CT evaluation of PA. Larger adenoma volume correlates with higher biochemical activity, suggesting a contribution to hypercalcemia through increased PTH secretion. PV assessment should be considered an important imaging finding in the diagnostic work-up.
Limitations: Retrospective design, moderate sample size, and lack of fine-needle aspiration PTH measurements.
Funding for this study: No funding was provided for this study.

Real-Time Digital Documentation in Interventional Radiology: Modular Tools for Efficiency and Quality (6 min)
Michael Schönfeld; Köln / Germany

Author Block: M. Schönfeld, E. Ulrich, J. Kottlors, T. Schömig, K. R. Laukamp; Köln/DE
Purpose: Structured documentation of interventional radiology procedures is critical for quality assurance, billing, and research. In routine practice documentation is often retrospective, time-consuming, and error-prone. We developed a modular digital solution that enables structured, real-time documentation directly during the procedure.
Methods or Background: The tools cover the full spectrum of interventional radiology, including neurovascular (mechanical thrombectomy, carotid stenting, vasospasm treatment, aneurysm, subdural hematoma embolization), oncological/embolization (fibroid, prostate, tumor embolization, TACE, SIRT, BBA, bleeding), percutaneous (biopsy, drainage, cryoablation, microwave ablation), and vascular access procedures (PICC, port, TIPS).
All modules run on sterile-clickable touchscreens in the angiography suite, capturing timestamps, techniques, materials, and findings in real time. From these inputs the system automatically generates: (1) a standardized editable report, (2) procedure codes, (3) structured quality assurance data, and (4) prepared registry entries. Data from the first 95 consecutive procedures documented with the system were analyzed and compared with 100 procedures performed before implementation.
Results or Findings: In the first 95 procedures, the mean time for report creation decreased from 12.2 ± 6.1 minutes before implementation to 1.3 ± 0.5 minutes, with reports now available immediately after the procedure instead of with an average delay of more than 48 hours.
The time required for procedure coding was reduced from 11.4 ± 3.2 minutes, including frequent corrections, to 1.2 ± 0.4 minutes.
The duration of quality assurance documentation decreased from 8.5 ± 2.8 minutes to 2.1 ± 1.3 minutes.
Registry entries also became significantly faster, dropping from 8.2 ± 3.6 minutes to 2.0 ± 1.2 minutes, while completeness increased from less than 20% to more than 90%.
Conclusion: Real-time digital documentation across the spectrum of interventional radiology is feasible and leads to substantial gains in efficiency, accuracy, and quality assurance.

Unveiling the immunomodulatory effects of transarterial chemoembolisation: insights into local T-cell infiltration in hepatocellular carcinoma (6 min)
Luisa Heidemann; Berlin / Germany

Author Block: L. Heidemann, R. Schmidt, E. Y. Yilmaz, Y. He, J. Böhme, K. Harb, D. Müller, B. Gebauer, L. J. Savic; Berlin/DE
Purpose: To investigate local immunomodulatory effects of conventional transarterial chemoembolisation (cTACE) in hepatocellular carcinoma (HCC).
Methods or Background: This single-centre prospective study included HCC patients undergoing interstitial brachytherapy in afterloading technique (iBT) only or cTACE with consecutive iBT (10.2020-08.2023). IRB approval and informed consent were obtained. Biopsies were acquired from untreated HCC before iBT (iBT group) or 24 hours post-cTACE and before iBT (cTACE/iBT group). Based on histopathology and peri-interventional CT images, biopsies were graded as intra- and peritumoural. Immunohistochemistry staining was performed for CD3+, CD4+, CD8+, PD-1+ T cells, and Ki67. On digitized samples, T cell populations were quantified as a percentage of all counted cells using QuPath software. Cell counts were correlated with response according to RECIST version 1.1 assessed on MRI eight weeks post-treatment. Statistics included Shapiro-Wilk and Mann-Whitney U tests.
Results or Findings: This study cohort comprised 82 patients (66 male), with a mean age of 69.6 ± 9.9 years. CD3+ and CD4+ T-cell infiltration was higher in the cTACE/iBT group (n=39) compared to the iBT group (n=43; p=0.043 and p=0.03, respectively). CD3+ (p=0.02), CD4+ (p=0.01), and CD8+ T cell counts (p=0.01) were higher in the peritumoural compartment than intratumourally. In the cTACE/iBT group, responders (n=11) showed higher median CD3+ (p=0.49), CD4+ (p=0.19), and CD8+ T-cell counts (p=0.07) compared to non-responders (n=25).
Conclusion: This study demonstrates early effects of cTACE on T-cell infiltration into the tumour microenvironment, contributing to a greater understanding of peripheral lymphocyte depletion and migration following cTACE.
Limitations: Firstly, longitudinal effects post-cTACE are not captured. Secondly, findings of a single biopsy may not be representative of the entire tumour. Lastly, outcome was measured after iBT or cTACE/iBT, while biopsies were obtained before iBT from untreated tumours or post-cTACE.

An immune-active peptide-based shear-thinning soraphinib-loading hydrogel embolic agent in VX2 kidney tumor (6 min)

Shenbo Zhang; Beijing / China

Author Block: S. Zhang, Z. Wang, Z. Jin; Beijing/CN
Purpose: This study developed an innovative immune-active peptide-based shear-thinning hydrogel loaded with sorafenib (AbSNP-CIR) as a multifunctional transcatheter arterial embolization (TAE) agent for treating VX2 kidney tumors, evaluating its therapeutic efficacy, immunomodulatory effects, and biocompatibility.
Methods or Background: We formulated a CIR host defense peptide hydrogel incorporating albumin-bound sorafenib nanoparticles (AbSNP). The material's shear-thinning properties, injectability, and embolic characteristics were validated in vitro. Twenty-four New Zealand white rabbits with VX2 kidney tumors were randomized into four TAE groups: AbSNP-CIR, CIR (drug-free), Lipiodol®, and control (angiography only). Tumor progression was monitored via contrast-enhanced CT at days 0, 7, and 14. Comprehensive blood analyses assessed systemic toxicity. Histopathological examination of major organs and tumors was performed at endpoint. Single-cell RNA sequencing analyzed immune microenvironment alterations between CIR and Lipiodol® groups. Survival benefits were evaluated using Kaplan-Meier analysis with Log-rank tests.
Results or Findings: Both CIR and AbSNP-CIR hydrogels demonstrated excellent injectability and effective vessel occlusion, inducing significant tumor necrosis. The AbSNP-CIR group exhibited superior tumor growth suppression. scRNA-seq revealed CIR-based hydrogels reversed immunosuppression by significantly downregulating LGALS3 and upregulating CD83 compared to Lipiodol®. Survival analysis demonstrated AbSNP-CIR significantly prolonged median survival (40.5 days) versus control (23 days, p=0.028), CIR (26.5 days, p=0.035), and Lipiodol® (27.5 days, p=0.049). Blood parameters showed no significant systemic toxicity.
Conclusion: The AbSNP-CIR hydrogel represents an advanced embolic strategy that integrates mechanical occlusion, localized sorafenib delivery, and active immunomodulation, significantly enhancing antitumor efficacy and survival in kidney tumor models.
Limitations: Small sample size and single animal model require validation in larger studies.
Funding for this study: This study has received funding from the National Natural Science Foundation of China (Nos. 22232006, Biomolecular Condensates: Phase Separation Modulation and Functionalization)
Has your study been approved by an ethics committee? Yes

Personalized Dosimetry Enhances Hepatocellular Carcinoma Response in Yttrium-90 Resin Microsphere Radioembolization (6 min)

Francesca Calabrese; Milan / Italy

Author Block: F. Calabrese[1], T. T. Makoto[2], E. Di Gaeta[1], A. Casadei-Gardini Andrea[1], C. Canevari[1], L. Strigari[2], F. Ratti[1], C. Mosconi[2], F. De Cobelli[1]; [1]Milan/IT, [2]Bologna/IT
Purpose: The aim of the study is to determine a tumor mean absorbed dose (Dmean) able to predict the therapeutic response to Yttrium-90 (Y-90) resin-microsphere transarterial radioembolization (TARE) in hepatocellular carcinoma (HCC), and evaluate its efficacy and safety profile.
Methods or Background: A retrospective analysis was conducted on HCC patients treated with TARE at two institutions between January 2020 and May 2024. Clinical, radiological and procedural data were collected. Outcomes included objective response rate (ORR) for target lesions (complete or partial), complete response (CR), overall response, time-to-local progression (TLP) and time-to-progression (TTP), assessed on contrast-enhanced CT. Receiver operating characteristic (ROC) analysis identified the optimal Dmean for achieving ORR and CR. ORR comparisons used Fisher's exact test, survival was analyzed using Kaplan-Meier curves, and Cox regression was used for univariable and multivariable analysis.
Results or Findings: Seventy-six lesions from 64 patients (mean age 71.3 ± 9.6; 54 male) were analyzed, with an average tumor size of 54.8 ± 31.5 mm. CR at 3 months was obtained in 41 lesions. Mean TLP and overall survival (OS) were 26.7 ± 2.5 and 36.2 ± 2.9 months, respectively.
The calculated Dmean to obtain ORR was 296.74 Gy (specificity 100, PPV 100%). Patients receiving doses < 296.74 Gy experienced shorter TLP ($p = 0.001$) and a higher progression risk (HR 6.9; $p = 0.009$). No increase in complications was observed at Dmean >296.74 Gy. A Dmean > 435.11 Gy was associated to CR. OS was negatively influenced by BCLC stage C (HR 6.0; $p = 0.003$) and portal vein invasion (HR 3.5; $p = 0.04$).
Conclusion: A tumor Dmean of 296.74 Gy stands out as a powerful predictor of treatment success, delivering strong therapeutic results without compromising patient safety.

Preliminary Exploration of a New Classification of DVT in the Lower Extremities Based on Venography and Physiological Anatomy (6 min)

Yang Geng; Bin Zhou / China

Author Block: Y. Geng, J. Zhu, Y. Xu; Bin Zhou/CN
Purpose: Current classification systems for lower extremity deep vein thrombosis (DVT) lack precision in anatomical stratification, potentially compromising the specificity of therapeutic interventions. This study aims to establish a novel classification system based on venographic characteristics and pathoanatomical correlations to enhance clinical decision-making and research standardization.
Methods or Background: We conducted a retrospective analysis of 2,137 consecutive diagnostic digital subtraction venography (DSV) studies performed at our institution between January 2015 and December 2023 in patients with confirmed lower extremity DVT. Thrombus distribution patterns were systematically categorized through an initial independent review by two vascular specialists, followed by consensus discussion involving a third specialist for discordant cases. The classification framework was developed through iterative correlation of venographic findings (thrombus location, extent, morphology, collateral patterns) with established anatomical landmarks and hemodynamic principles.
Results or Findings: Analysis of the venographic data led to the proposal of a novel taxonomy stratifying lower extremity DVT into six distinct categories: Type I - Musculovenous thrombosis (soleal/gastrocnemius veins); Type II - Tibial and Peroneal Vein Thrombosis; Type III - Popliteal segment thrombosis ;Type IV - Femoral venous thrombosis; Type V - Ilio-caval thrombosis; Type VI - Free-floating thrombus. This system incorporates both anatomical localization and key pathophysiological features.
Conclusion: This anatomically precise classification system has the potential to enhance stratification for targeted therapeutic interventions, support standardized reporting in clinical trials, enable more accurate documentation of thrombotic progression patterns, and guide the implementation of standardized imaging reporting protocols. Its clinical utility requires prospective validation.
Limitations: This venography-based DVT classification needs prospective validation. While reliable for major veins, ultrasound struggles with muscular calf thrombi and complex subtypes. This retrospective single-center system lacks prognostic evidence, requiring further reliability and outcome studies.

Dual-Energy CT Assessment of TIPS Patency: Diagnostic Accuracy, Confidence, and Quantitative Iodine Analysis (6 min)

Moritz Oberparleiter; Basel / Switzerland

Author Block: M. Oberparleiter, J. Vosshenrich, H-C. Breit, A. C. Seifert, P. J. Kaiser, P. Hehenkamp, D. Boll, C. J. Zech, M. Obmann; Basel/CH
Purpose: To compare diagnostic performance, confidence, and reading time between conventional and dual-energy CT (DECT) protocols in evaluating TIPS patency and assess the value of DECT-derived quantitative iodine measurements.
Methods or Background: This retrospective single-centre study included 57 patients with TIPS who underwent portal-venous DECT between 11/2014 and 07/2024. For each case, a conventional CT dataset and a DECT dataset (additional iodine maps and virtual non-contrast images [VNC]) were created. Two abdominal radiologists and three residents assessed TIPS patency and rated diagnostic confidence (5-point Likert scale). Sensitivity and specificity were compared using McNemar's test; confidence and reading time with the Wilcoxon signed-rank test.

Iodine concentrations were measured in the inferior vena cava, portal vein, and TIPS using three circular ROIs each. Diagnostic performance of absolute iodine values and iodine ratios (TIPS/portal vein, TIPS/inferior vena cava) was assessed with ROC analysis. Thresholds were defined via Youden index.
Results or Findings: TIPS occlusion was present in 14 patients. Sensitivity was similar for conventional CT and DECT (93% vs. 97%, p=.219), while specificity increased from 93% to 98% with DECT (p<.01). Diagnostic confidence improved (median 4 [IQR 3–4] vs. 4 [IQR 4–5], p<.01), and reading time decreased (109 s vs. 98 s, p<.001).

Mean iodine concentrations (mg/ml) were: IVC 3.99, portal vein 4.65, open TIPS 4.49, occluded TIPS 0.67. ROC-AUCs were 0.998 (absolute iodine), 1.000 (TIPS/portal vein), and 0.995 (TIPS/IVC). Optimal thresholds were 1.40 mg/ml, 0.262, and 0.263, yielding sensitivities/specificities of 95%/100%, 100%/100%, and 98%/100%, respectively.
Conclusion: Adding iodine maps and VNC images to DECT improves diagnostic specificity, confidence, and efficiency in assessing TIPS patency. Quantitative iodine measurements allow for accurate, objective evaluation and may be useful in inconclusive cases.
Limitations: This was a single-centre retrospective study with a limited sample size.
Funding for this study: This study did not receive any external funding.

Construction of a Postoperative Infection Risk Prediction Model for Microwave Ablation of Hepatic Malignant Tumors and Rational Application Strategy for Prophylactic Antibiotics (6 min)

ZEXIN FU; Guangdong / China

Author Block: Z. FU, Y. LIU, E. Xu; Guangdong/CN
Purpose: This study aimed to identify independent risk factors for post-MWA infections and develop a risk stratification system to guide prophylactic antibiotic use.
Methods or Background: In this retrospective study of 359 patients who underwent MWA for liver malignancies (2019-2025), we collected comprehensive perioperative data including baseline characteristics, preoperative indicators, imaging features, procedural parameters, and infection-related outcomes. Risk factors were identified through univariate and multivariate analyses, and a risk stratification system was established (low-risk: <5%; intermediate-risk: 5%-15%; high-risk: >15%).
Results or Findings: Post-procedural infections occurred in 46 patients (12.8%). Multivariate analysis identified three independent risk factors: history of biliary tract procedures (OR=5.79, 95% CI: 1.53-21.97), presence of five or more tumors (OR=3.69, 95% CI: 1.17-11.63), and larger tumor size (OR=1.03 per mm, 95% CI: 1.00-1.05). The risk stratification model demonstrated good discrimination (AUC=0.82), with infection rates showing significant gradient distribution across risk groups (1.4% vs. 7.8% vs. 34.8%, P<0.001).
Conclusion: Three independent risk factors for post-MWA infections were identified. The risk prediction model may guide rational prophylactic antibiotic use in clinical practice.
Limitations: The single-center design and sample size may limit generalizability, requiring external validation.

A study on the correlation between progressive sarcopenia and progressive myoadiposis and the postoperative efficacy of bronchial artery chemoembolization (6 min)

Jianfei Tu; Lishui / China

Author Block: J. Wu, J. Tu, W. Li; Lishui/CN
Purpose: This study aims to investigate the correlation between progressive muscle loss (progressive sarcopenia), progressive myoadiposis, and the efficacy of bronchial artery chemoembolization (BACE) in lung cancer patients
Methods or Background: A total of 97 lung cancer patients who received BACE treatment at Lishui Central Hospital from December 2016 to August 2021 were selected. The skeletal muscle index (SMI) and skeletal muscle density (SMD) were measured at the level of the fourth thoracic vertebra using CT images. Progressive sarcopenia was defined as a reduction in SMI of ≥ 5%, and progressive myoadiposis was defined as a reduction in SMD of ≥ 5%. The Kaplan-Meier method and COX regression analysis were used to evaluate differences and risk factors for overall survival (OS) and progression-free survival (PFS).
Results or Findings: The median PFS was 7.1 months in the non-progressive sarcopenia group and 3.4 months in the progressive sarcopenia group, with a significant difference between them ($\chi^2 = 4.209$, $P = 0.040$). The median OS was 10.7 months in the non-progressive myoadiposis group and 20.2 months in the progressive myoadiposis group, also showing a significant difference ($\chi^2 = 5.583$, $P = 0.018$). COX regression analysis identified progressive sarcopenia as an independent risk factor for PFS and progressive myoadiposis as an independent risk factor for OS.
Conclusion: rogressive sarcopenia and progressive myoadiposis are independent risk factors for PFS and OS, respectively, in lung cancer patients undergoing BACE.
Limitations: This study has limitations, including a limited sample size and a single-center retrospective design that may introduce selection bias. These findings warrant further validation in larger, prospective studies.
Funding for this study: There is no funding for this study

Occupational Radiation Dose in Interventional Radiology: A Role Stratified Dual Dosimetry Audit at a Comprehensive Cancer Center (6 min)

Naema Ali Almaymani; Muscat / Oman

Author Block: N. A. Almaymani, A. Al Balushi, S. C. Kheruka, N. Al-Makhmari, H. Al Saidi, S. Al Rashdi, T. Al Raii, R. Al Sukaiti, B. Abdi; Muscat/OM
Purpose: To quantify annual occupational dose among interventional radiology (IR) staff—interventionalists, nurses, and radiologic technologists—using dual dosimetry and identifying role-specific optimisation targets for routine practice.
Methods or Background: Prospective one-year audit at a comprehensive cancer center, including 2 interventionalists, 4 nurses, and 3 technologists. Under apron chest TLDs measured Hp (10) (effective dose); ring TLDs measured Hp (0.07) (hand dose); eye TLDs measured Hp (3) (interventionalists and nurses). Real-time PDMs worn over the apron recorded outside the apron Hp (10). Fluoroscopy time, DAP, and Ka,r were recorded for each procedure.
Results or Findings: Under apron chest TLD Hp (10) was effectively < 0.01 mSv across IR staff in 2024. Extremity and eye lens doses remained measurable: hand (interventionalists) 3.51 ± 0.45 mSv (range 3.07–3.21) and eye lens 3.37 ± 0.69 mSv (2.69–4.06), hand (nurses) 3.9± 0.45 mSv (range 3.07–3.90) and eye lens 2.40 ± 0.28 mSv (2.12–2.78). Role stratified outside apron Hp (10) from PDMs was 0.13± 0.06 mSv (interventionalists), 0.47± 0.06 mSv (nurses), and 0.29 ± 0.06 mSv (technologists), yielding the exposure ordering nurses > technologists > interventionalists.
Conclusion: All doses were within regulatory limits; however, pairing under apron TLDs with outside apron PDMs shows that hand and eye lens exposures—not effective dose—are the optimisation drivers, and that nurses experience the highest outside apron exposure in our IR suite. These role-specific signals support targeted actions: strict, documented use of ceiling/table shields and lead eyewear, reinforcement of staff positioning, and dual badge monitoring (collar + under apron) to ensure accurate assessment and continuous quality improvement.
Limitations: A small amount of data was involved in the study
Funding for this study: All doses were within regulatory limits; however, pairing under apron TLDs with outside apron PDMs shows that hand and eye lens exposures—not effective dose—are the optimisation drivers, and that nurses experience the highest outside apron exposure in our IR suite. Imaging and evaluation of cervicothoracic lymphatic drainage pathways in single ventricle patients with Fontan circulation using the mDixon steady state MR angiography (6 min)
Patrick Langguth; Kiel / Germany

Author Block: P. Langguth, M. Huhndorf, H. Seoudy, O. Jansen, A. Uebing, I. Voges; Kiel/DE
Purpose: Patients with Fontan circulation after single ventricle palliation are at increased risk of pathological alterations in the cervicothoracic lymphatic drainage system, including chylothorax and plastic bronchitis. Visualization and classification of these lymphatic pathways may provide prognostic information and help guide clinical management. This study aimed to demonstrate that a 3D mDixon steady-state MR-angiography sequence, commonly used for cardiovascular assessment, can simultaneously visualize lymphatic structures with high diagnostic quality.
Methods or Background: We retrospectively analyzed MR examinations of 88 pediatric and young adult Fontan patients. The 3D mDixon steady-state MR-angiography was assessed for image quality and diagnostic yield regarding cervicothoracic lymphatic pathways. Ventricular volumes, ejection fraction, and mass were quantified from cine imaging. Lymphatic pathways were classified according to an established four-tier system (Types 1–4).
Results or Findings: Image quality of the lymphatic pathways was rated “very good” or “good” in over 90% of cases. Six patients presented with lymphatic complications; five (83.3%) showed higher-grade pathways (Type 3 or 4). Among 88 patients, the distribution was: 31.8% Type 1, 18.2% Type 2, 39.8% Type 3, and 9.1% Type 4. No significant associations were observed between lymphatic type and single ventricle morphology, age at Fontan completion, protein levels, NT-proBNP, or central venous pressure. Likewise, no correlation was found between lymphatic type and ventricular parameters (volumes, ejection fraction, mass).
Conclusion: 3D mDixon steady-state MR-angiography enables high-quality, simultaneous visualization of cardiovascular and cervicothoracic lymphatic anatomy in Fontan patients without additional imaging sequences. Patients with lymphatic complications tended to present with higher lymphatic types, suggesting a role for this technique in risk stratification and follow-up.
Limitations: This was a retrospective study. T2-weighted lymphangiography, the current reference standard for lymphatic imaging, was not systematically performed for comparison. Abdominal lymphatic abnormalities were not evaluated.
Funding for this study: No fundings

Late Gadolinium Enhancement in Kawasaki Disease: its Distribution, Association with Coronary Artery Lesions and Myocardial Strain (6 min)
Shiganmo Azhe; Chengdu / China

Author Block: S. Azhe, Z. Zhou, Y-K. Guo, L-y. Wen; Chengdu/CN
Purpose: To investigate the distribution patterns of late gadolinium enhancement (LGE) in the chronic phase of Kawasaki disease (KD) and its relationship with coronary artery lesions and myocardial strain.
Methods or Background: In this retrospective, single-center study, 185 KD patients who underwent cardiac magnetic resonance (CMR) during the chronic phase were enrolled. They were divided into an LGE-positive group (n=25) and an LGE-negative group (n=160). CMR image analysis was performed using commercial software.
Results or Findings: Left ventricular (LV) LGE was present in 25 (13.5%) patients, involving 15.07 ± 0.12% of the LV mass. The LGE distribution was as follows: longitudinally, the basal (68%) and mid-ventricular (68%) segments were most frequently affected; circumferentially, the lateral (68%) and anterior (44%) walls were predominant; radially, subendocardial (24%), transmural (32%), and subepicardial (32%) patterns were observed. Coronary artery stenosis (OR: 5.48) and a history of thrombosis (OR: 3.87) were identified as independent risk factors for LGE (all $P < 0.05$). The LGE location matched the perfusion territory of stenotic or thrombotic coronary arteries in 19 patients, while 6 LGE-positive patients had no coronary artery lesions. Myocardial strain (global and segmental) was significantly impaired in the LGE+ group across all directions (longitudinal, radial, circumferential) compared to the LGE- group (all $p < 0.05$).
Conclusion: In KD patients, LGE is primarily located in the basal and mid lateral walls of the left ventricle. Coronary artery stenosis and thrombosis history are independent risk factors for LGE. The presence of LGE is associated with subclinical left ventricular dysfunction.
Limitations: This was a single-center, single-vendor, observational study; there was potential for selection bias, and the patient population may not fully represent the global population with KD.
Funding for this study: This study is supported by the National Natural Science Foundation of China (82102020, 82471970) and the Special Project for the Central Government to Guide the Development of Local Science and Technology in Sichuan Province(2023ZYD0100).

Differentiating genetic and viral pediatric dilated cardiomyopathy: a pilot study (6 min)

Tuba Banaz; Istanbul / Turkey

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: T. Banaz, F. Köse, M. F. Kazanbaş, B. Tütüncüoğlu, M. Kadıoğlu, S. Ozkök; Istanbul/TR
Purpose: Dilated cardiomyopathy (DCM) is a major cause of heart failure and transplantation in children. While genetic testing can aid diagnosis, it is often costly, slow, and inconclusive. Viral myocarditis is a common cause of pediatric DCM, but distinguishing it from genetic forms is difficult due to overlapping clinical and imaging features. This study aims to investigate whether magnetic resonance imaging (MRI) signal characteristics of lymphoid organs can non-invasively distinguish between viral and genetic DCM.
Methods or Background: This retrospective study included 131 pediatric DCM patients (<18 years) treated between January 2022 and December 2024. Thirty-one patients with confirmed genetic (n=13) or viral (n=18) etiology were analyzed. Exclusion criteria were congenital heart disease, autoimmune disease, malignancy, or missing data. Diagnoses were based on molecular/genetic testing or pathogen detection.
Myocarditis diagnoses were based on clinical, laboratory, ECG, echocardiographic, cardiac MRI findings. No biopsies were performed. Patients underwent cardiac MRI with T1&T2 mapping. Quantitative values were extracted from the myocardium, spleen, and thymus. Median and interquartile ranges were calculated, intergroup comparisons were performed using independent t-tests.
Results or Findings: No significant differences were observed in conventional cardiac MRI parameters, including biventricular volume indices, ejection fractions, native T1&T2 mapping, or myocardial contrast enhancement percentage ($p>0.05$). Native T1 values were significantly higher in the genetic group in the thymus ($p = 0.033$) and in the spleen ($p = 0.049$). Splenic T2 mapping values were higher in the genetic group ($p = 0.048$).
Conclusion: Conventional MRI may not clearly differentiate genetic and viral DCM. Genetic DCM is linked to prolonged inflammation, with elevated T1 values in thymus and spleen indicating fibrosis or ongoing inflammation, and T2 values in spleen indicating subclinical edema.
Limitations: Retrospective design, small sample size, age/immune/technical variability in lymphoid MRI signals

The value of Time in diagnostic of Generalised Arterial Calcifications of Infants (GACI) and other idiopathic atrerial calcifications in infants (6 min)

Helena Witowicz; Warsaw / Poland

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: H. Witowicz, W. Grajkowska, E. Jurkiewicz; Warsaw/PL
Purpose: The purpose of our study was to assess very rare genetic disease - Generalised Arterial Calcifications of Infants (GACI) and to find possible differences in management with other rare condition - idiopatic artery calcifications from our Institure.
Methods or Background: We retrospectively assessed four new patients by genetic background, clinical symptoms, diagnostic process and treatment responce. Every patient had CT.

For the purpose of our study paper review was performed. From 1899 were published aproximatelly 256 cases of GACI.
Results or Findings: In the first case the patient was admitted to the hospital at the right time- in the first day after birth, which gave doctors enough time to make correct diagnosis(CT reveled typical arterial calcifications, ENPP1 mutation) and the right treatment (bisphosphonates)was started with almost total regression of the calcifications in 3 months.

In the second case the circumstances of addmission was different-the infant was redirected to our Institute too late,three weeks after birth. In this case CT revealed advanced large and middle-size artierial calcifications. No gene analisis were performed. No bisphosphonate treatment was inclueded. Patient died of sudden cardiac arrest.The right diagnosis (GACI) was made postmortem. This case shoud be an important lesson how fast calcifications could develop without treatment and how crucial is early diagnosis with the the right treatment.

In the third and fourth cases of idiopathic artery calcifications no genetic alterations(typical for GACI) were revealed. Calcifications receded by itself without bisphosphonates treatment.
Conclusion: Our study higlights the importance of early diagnostic of GACI and early start of the treatment with bisphosphonates. Time is crucial in this type of diseases. Every day/week of waiting could worsening the disease significantly with plenty of possible complications. That why time is the most valuable resource.

Synergistic and Interpretable AI for Predicting Paediatric RMPP: A Multi-modal Fusion of Clinical and CT Data (6 min)

Lin Deng; Yulin City, Shaanxi Province / China

Author Block: L. Deng, Z. Jia; Yulin/CN
Purpose: Delayed diagnosis of paediatric refractory Mycoplasma pneumoniae pneumonia (RMPP) leads to severe sequelae, as current single-modality predictors lack accuracy. We aimed to develop and validate a synergistic, multi-modal AI framework, integrating heterogeneous clinical data with Swin Transformer-based CT analysis, for high-fidelity and clinically trustworthy early risk stratification
Methods or Background: This retrospective study of 466 children with MPP fused four data pillars: clinical/laboratory data, quantified radiologist knowledge, automated objective CT biomarkers, and deep sub-visual features from a Swin Transformer. An XGBoost model integrated these features, with SHAP analysis ensuring decision transparency. The framework was validated on an independent test set.
Results or Findings: On an independent test set, the fusion model showed excellent discrimination (AUC: 0.92; 95% CI: 0.88-0.96) with high sensitivity (0.85) and specificity (0.88), enabling robust identification of high-risk patients. Ablation studies confirmed the multi-modal approach significantly outperformed single-modality baselines. SHAP analysis revealed a synergy between known clinical factors (e.g., LDH, CRP) and novel, influential sub-visual CT patterns from the Swin Transformer, confirming the data fusion's synergistic gain.
Conclusion: This study’s core contribution is quantitatively confirming a significant synergistic effect among four heterogeneous data dimensions via ablation study, establishing the necessity of multi-modal fusion for RMPP prediction. The proposed explainability framework transforms opaque model decision-making into a transparent, auditable evidence pathway, providing a reliable basis for clinical decisions. This work offers an empirical foundation for a safer, more precise human-machine collaborative model, aiming to improve outcomes through timely intervention.
Limitations: Not applicable

MRI in Fetal and Neonatal Circulation (6 min)

K Saravanan; Chennai / India

Author Block: D. Velan, F. Abubacker Sulaiman, R. Praveenkumar, J. Lydia, M. Nivitha, K. Saravanan; Chennai/IN
Purpose: To explore the feasibility and diagnostic potential of 4D Flow MRI in evaluating dynamic hemodynamics of fetal and neonatal circulation, including intracardiac flow patterns, shunt physiology, and cerebroplacental perfusion.

The study aims to establish normative flow parameters and identify early markers of circulatory compromise in high-risk pregnancies.
Methods or Background: Conventional Doppler ultrasound provides limited two-dimensional assessment of blood flow velocity and direction, lacking volumetric and temporal resolution. 4D Flow MRI, with its time-resolved three-dimensional velocity encoding, enables comprehensive quantification of flow vectors, wall shear stress, and vorticity throughout the cardiac cycle. In this prospective study, 40 fetuses (28–38 weeks) and 20 neonates underwent 4D Flow MRI using a prototype highly accelerated phase-contrast sequence with retrospective gating.

Post-processing included vessel segmentation, streamline visualization, and quantitative analysis of flow through the foramen ovale, ductus arteriosus, and umbilical vessels.
Results or Findings: 4D Flow MRI successfully delineated intracardiac and extracardiac flow pathways in 95% of cases. Quantitative analysis revealed consistent flow patterns correlating with gestational age. In growth-restricted fetuses, altered shunt flow ratios and reduced cerebral perfusion indices were observed.

Neonatal 4D Flow data demonstrated transitional circulatory changes post-delivery, validating physiologic closure of fetal shunts
Conclusion: 4D Flow MRI provides unparalleled insights into fetal and neonatal hemodynamics, overcoming limitations of Doppler ultrasound. It holds transformative potential for early detection of circulatory dysfunction, particularly in placental insufficiency and congenital heart disease.
Limitations: Motion artifacts, fetal heart rate variability, and prolonged acquisition times currently restrict routine clinical application. Absence of real-time gating and small sample size limit statistical generalizability. Further optimization of faster, motion-robust sequences and standardized fetal cardiac gating are required for broader clinical translation.

Fetal Congenital Cystic Lung Diseases: MRI Characteristics and Prognostic Study (6 min)

Yang Jia; Sichuan / China

Author Block: Y. Jia; Sichuan/CN
Purpose: To evaluate the characteristics of fetal congenital cystic lung diseases using MRI and to investigate lung development and prognosis.
Methods or Background: A retrospective analysis was conducted on 230 normal fetuses and 150 fetuses with congenital cystic lung diseases . The normal group underwent measurements of total lung volume and bilateral lung-to-liver signal intensity ratio (LLSIR). The case group was evaluated for lesion signal, volume, cystic volume ratio, bilateral LLSIR, fetal lung volume, and observed/expected fetal lung volume. Postnatal outcomes were obtained via medical record review and telephone follow-up. Cases were classified into a good prognosis group and a poor prognosis group.
Results or Findings: In the normal group, both total lung volume and bilateral LLSIR increased progressively with gestational age. Multivariate logistic regression analysis revealed that the following factors were associated with poor prognosis: lesion volume/affected lung volume (OR = 1.07), absolute difference in bilateral LLSIR (OR = 1.08), and affected lung volume/expected unilateral lung volume (OR = 1.03). ROC curve analysis demonstrated that the combination of lesion volume/affected lung volume and bilateral LLSIR difference showing the highest predictive value. During follow-up, increases in CVR and bilateral LLSIR differences were associated with worse outcomes, while reduction in mass effect indicated better prognosis.
Conclusion: In healthy fetuses, lung volume, bilateral LLSIR, and their differences increase with gestational age. MRI allows precise evaluation of fetal diseases, and its derived indicators hold significant value for predicting poor prognosis. The combination of lesion volume/affected lung volume and bilateral LLSIR difference demonstrates superior predictive performance.
Limitations: Future validation and optimization of these prediction models will require prospective, multicenter studies with larger sample sizes to enhance generalizability and robustness, alongside exploring advanced techniques like radiomics and deep learning for improved prognostic accuracy.
Funding for this study: None.

Cardiac MRI Evaluation of Foetal Ductus Arteriosus in Right Aortic Arch (6 min)

Su-Zhen Dong; Shanghai / China

Author Block: S-Z. Dong; Shanghai/CN
Purpose: To show the types of ductus arteriosus (DA) position and course, and further measure the diameters of DA in foetal different branching patterns of the right aortic arch (RAA) using prenatal cardiac magnetic resonance
Methods or Background: 88 foetuses with RAA were analysed retrospectively. RAA mirror-image branching with left anterior DA (n=16), RAA with aberrant left subclavian artery (ALSCA) and left posterior DA (n=50), RAA mirror-image branching with left retroesophageal DA (n=9), RAA mirror-image branching with right DA (n=11), RAA with ALSCA and bilateral DA (n=1) and RAA mirror-image branching with bilateral DA (n=1). Two radiologists measured the diameters of DA respectively, and then statistically analysed the data of the DA diameters obtained from all foetuses. Statistical comparisons between the z score of DA diameter were analysed using the non-parametric Mann-Whitney U test.
Results or Findings: Of the 88 foetuses, the mean z score of the DA diameter with 16 foetuses with RAA mirror-image branching with left anterior DA was significantly less than that of the 11 cases with RAA with right DA ($P < 0.05$); the DA of 50 cases with RAA with ALSCA were larger than that of 9 cases with RAA with left retroesophageal DA ($P < 0.05$). Eleven neonates (12.5%) had respiratory symptoms, nine with RAA with ALSCA and left posterior DA, one with RAA and left anterior DA, and one with RAA and left retroesophageal DA.
Conclusion: Foetal CMR can describe the position and course of DA, and further measure the diameters of DA in different branching patterns of RAA.
Limitations: All cases were followed up only during the neonatal period, therefore, only a few cases have clinical symptoms in this study.

The actual use of fetal gated cardiovascular magnetic resonance imaging : a worldwide survey (6 min)

Guillaume Gourincour; Marseille / France

Author Block: G. Gourincour[1], H. Boeth[2], F. Kording[2], D. Grevent[3], R. Chaoui[4], L. J. Salomon[3]; [1]Marseille/FR, [2]Hamburg/DE, [3]Paris/FR, [4]Berlin/DE
Purpose: To study the clinical and research use of fetal smart-sync cardiovascular magnetic resonance imaging (F-ss-CV-MRI) worldwide
Methods or Background: Extensive survey sent to 70 centers equipped with the device. Questions concerned project-leading specialty, country, setting, quantitative and qualitative user analysis, degree of satisfaction and remaining needs
Results or Findings: 30 centers answered (43 %). In 19 (63 %) team was lead by radiologists, in 8 (27 %) by cardiologists, and in 3 (10 %) by researchers. Thirteen centers were in the US (43 %), 4 (13 %) in Germany, 3 (10 %) in France, 2 (6.7 %) in the Netherlands, Sweden and the UK, and 1 (3.3 %) in Italy, Switzerland and Israel. Setting was academic in 23 (77 %), hospital-based in 16 (54 %) and private in 2 (6.7 %).
Centers have been users for a mean of 21.6 months (Min 1, max 48), with a mean number of exams of 33.2 (Min 2, Max 200). Twenty-eight centers perform MRI between 30 and 35 weeks' gestation (WG), 8 after 35 WG and 4 before 30 WG. In 19 centers it is performed for clinics and research, in 6 only for clinics and in 6 only research.
Twenty-four centers (80 %) rate as high/very high the improvement and would recommend it.
Clinical situations when it would be recommended were mostly unclear complex congenital heart disease with need for improved delineation
Conclusion: F-ss-CV-MRI is a promising technique which needs shorter sequences, better consistency and wider diffusion
Limitations: Image quality for 10 centers (33 %), convincing their referrals for 8 (27 %), and MR accessibility for 8 (27).
Fourteen centers (47 %) consider that it has not yet an impact on diagnosis but 24 (80 %) believe it will have

Artificial intelligence-assisted interpretation of lung cancer on chest CT using Google AI Studio (6 min)
Zainab Dawood Aljneibi; Abudhabi / United Arab Emirates

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: Z. D. Aljneibi, S. Almenhali, L. J. O. C. L. Lança; Abudhabi/AE
Purpose: This study explored the diagnostic performance and interpretative behaviour of an artificial intelligence (AI)-enhanced model for detecting lung cancer on chest computed tomography (CT). Particular focus was given to the qualitative consistency of the AI-generated reports.
Methods or Background: An exploratory analysis was conducted using the publicly available IQ-OTH/NCCD dataset, comprising 110 CT cases (55 normal, 15 benign, 40 malignant). A pre-trained convolutional neural network in Google AI Studio was fine-tuned on a subset of images and applied to independent test cases. Quantitative outcomes included diagnostic accuracy, sensitivity, specificity, and area under the receiver operating characteristic curve (AUC). Qualitative analysis evaluated report structure, terminology use, and error patterns.
Results or Findings: The AI model achieved an overall accuracy of 75.5% (sensitivity 74.5%, specificity 76.4%). Malignant cases were identified with high discriminative performance (AUC = 0.902; 95 % CI: 0.830–0.964), while benign cases proved more difficult to classify (AUC = 0.615; 95 % CI: 0.477–0.754). Qualitative analysis showed consistent use of radiological terminology, with structured descriptions resembling human reporting. In normal cases, terms such as “clear lung fields” confirmed accurate recognition, though occasional references to “ground-glass opacities” reflected oversensitivity to minor changes. Benign cases were described with bilateral opacities and fibrotic changes, but overlapping terminology sometimes led to misclassification. Malignant cases were strongly aligned with features such as “mass” and “lesion.” These interpretative tendencies highlight effective feature recognition but limited specificity in non-malignant contexts.
Conclusion: Google AI Studio showed potential in detecting malignant disease and produced structured reports with consistent terminology. However, its interpretative oversensitivity and limited specificity highlight the need for human oversight and further refinement to reduce misclassification in benign and normal presentations.
Limitations: This study's retrospective design and reliance on a public dataset may limit generalizability.

AI-enabled environmental sustainability in radiology: a systematic review (6 min)
Nikolaos Stogiannos; Corfu / Greece

Author Block: N. Stogiannos[1], K. Konstantinidis[2], S. Kalari[3], S. C. Shelmerdine[1], S. Ursprung[4], T. Küstner[4], K. Nikolaou[4], A. G. Rockall[5], C. Malamateniou[1]; [1]London/UK, [2]Kifisia/GR, [3]Athens/GR, [4]Tübingen/DE, [5]Godalming/UK
Purpose: To explore the potential role of AI-powered applications in enhancing environmental sustainability in radiology.
Methods or Background: Searches were performed across eight different electronic bibliographic databases: Google Scholar, PubMed, Wiley Online library, Embase, Web of Science platform, the Cochrane library, CINAHL Ultimate, and the MedRxiv database for preprint work, for the publication years 2020-2025. Specific keywords were combined with Boolean operators and filters to optimise searches. Duplicate removal, screening of titles and abstracts, as well as full-text evaluation were done using the Rayyan.ai platform. The CASP checklists were used to perform risk of bias assessment. Extracted data were analysed using a narrative synthesis approach.
Results or Findings: Out of 87120 initial sources of evidence, 18 articles were finally included in this systematic review. AI was identified as an important factor in reducing energy consumption in radiology, both by minimising equipment idle time and by accelerating MRI acquisition, automating planning, and simplifying workflows. In addition, AI could facilitate low-field imaging or significantly reduce contrast agent dosage, by generating virtually enhanced images, or restoring signal with minimal contrast agent waste. AI could contribute to sustainability in imaging by reducing unnecessary examinations through clinical decision support, optimising workforce and patient scheduling, and assisting image analysis to minimise workstation use which together lower energy consumption and resource use.
Conclusion: This systematic review demonstrates that AI-powered applications hold promise with regard to environmental sustainability in radiology, helping to optimise image acquisition, image analysis, contrast administration, and workflow efficiency. Balance must be struck between energy-intensive AI usage and AI-enhanced energy saving, while any costs and energy demands associated with training AI models and data storage should be always considered.

AI-Based Cardiac MRI for Tissue Characterization in Acute Myocardial Infarction: a reproducibility study (6 min)

Valentina Tambè; Milan / Italy

Author Block: V. Tambè, D. Capra, B. Loscocco, C. Casamassima, M. Memmedova, F. Secchi; Milan/IT
Purpose: This study investigated the impact of AI-based image denoising and super-resolution in cardiac magnetic resonance (CMR) imaging in patients with acute myocardial infarction who underwent coronary revascularization.
Methods or Background: Myocardial mass, edema, fibrosis and no-reflow were segmented by an expert reader using a semi-automatic software, in both native and AI-enhanced images. The analysis focused on Short Tau Inversion Recovery (STIR) and Late Gadolinium Enhancement (LGE) sequences.
Results or Findings: Twenty-seven patients were included, with no-reflow present in 13. AI-derived measurements demonstrated good agreement with native imaging. For edema percentage, the bias was 3% with limits of agreement (LoA) from –24.3% to +30.4%; for LGE percentage, the bias was 1% with LoA from –17.6% to +19.6%. AI reconstructions tended to underestimate myocardial mass: in T1 sequences, the bias was –9.1 g (LoA –26.2 to +8.0 g), and in T2 sequences, –5.3 g (LoA –49.9 to +39.3 g). Similarly, no-reflow mass and volume were underestimated, with biases of –6.5 g (LoA –16.4 to +3.8) and –6.2 ml (LoA –15.6 to +3.3), respectively. In both native and AI-enhanced datasets, significant negative correlations were observed between LVEF and LGE% (native: $\rho = -0.616$, $p<0.001$; AI: $\rho = -0.551$, $p=0.003$) as well as between LVEF and no-reflow mass (native: $\rho = -0.652$, $p=0.016$; AI $\rho = -0.57$, $p = 0.04$), whereas edema showed a moderate negative correlation (native: $\rho = -0.501$, $p=0.008$; AI: $\rho = -0.402$, $p=0.038$).
Conclusion: A negligible bias was observed between native and AI-derived measurements. Although the limits of agreement were wide, AI-enhanced CMR consistently correlated with systolic function. These findings support the use of AI-based denoising and super-resolution in CMR without significantly affecting myocardial tissue quantification.
Limitations: The limited sample size may have affected the limits of agreement.

AI-Assisted Onboarding for Radiographers: A Qualitative Evaluation of the Pair Chat Assistant (6 min)

Celine Tan; Singapore / Singapore

Author Block: C. Tan, L. A. J. Chong; Singapore/SG
Purpose: Onboarding for newly recruited radiographers often relies on didactic lectures and online learning to introduce protocols and practice. While effective, this limits engagement, flexibility, and self-directed learning. Pair Chat is an in-house AI large language model platform that enables staff to build personalised AI bots. A customised bot was created within the Radiography Department to provide interactive, on-demand support for new radiographers during onboarding. This study evaluated the perceived effectiveness of AI-assisted onboarding using the Pair Chat assistant compared with the conventional methods of learning.
Methods or Background: A qualitative exploratory design was adopted. Eight radiographers who had used the Pair Chat assistant for three months participated in a focus group discussion. Data were transcribed verbatim and analysed through a hybrid content–thematic approach. Domains explored included learning effectiveness, confidence, engagement, efficiency, and improvement suggestions.
Results or Findings: Three themes emerged. First, accessibility barriers: reliance on work desktops limited spontaneous use, highlighting the need for mobile access. Second, a trust hierarchy: although valued for rapid, non-judgemental clarification, participants continued to prioritise colleagues and institutional references. This conditional trust reinforced the perception of the AI as a supplementary rather than replacement tool. Third, complementarity: while the assistant offered detailed, searchable content, the absence of graphics and experiential depth reduced its utility compared with lectures.
Conclusion: AI-assisted onboarding can enhance flexibility and learner autonomy, but its effectiveness depends on accessibility and integration with mentorship. A blended model may provide the most sustainable approach.
Limitations: This pilot study is limited by its small sample size, single-site context, and short evaluation period. Findings relied on self-reported perceptions, with potential bias from participant self-selection and group dynamics, and may not be generalisable. Results should therefore be interpreted as preliminary insights to inform larger-scale studies.

AI failures during AI implementation into clinical practice (6 min)

Nikolaos Stogiannos; Corfu / Greece

Author Block: N. Stogiannos[1], R. Cuocolo[2], A. D'Antonoli[3], D. Pinto Dos Santos[4], H. Harvey[1], M. Huisman[5], B. Koçak[6], M. Klontzas[7], C. Malamateniou[1]; [1]London/UK, [2]Naples/IT, [3]Basel/CH, [4]Mainz/DE, [5]Nijmegen/NL, [6]Instanbul/TR, [7]Heraklion/GR
Purpose: To map out different potential causes of AI failures, that could potentially impede AI implementation, lead to poor patient outcomes, increase financial costs, and add burden to clinical workflows. Potential solutions to mitigate these errors are also presented.
Methods or Background: A diverse group of AI experts in medical imaging, including radiologists, radiographers, computer scientists, and technical physicians, hand-searched all available literature to identify studies related to AI failures in radiology, as well as potential solutions. All eligible papers were then analysed by three group members and assigned to specific categories.
Results or Findings: Three distinct categories of AI failures were identified: a) errors related to AI models (algorithmic bias, lack of diverse and inclusive datasets, poor internal/external testing, failures due to unseen real-world data, suboptimal post-market surveillance, and data safety during AI model decommissioning), b) infrastructure-related failures (hardware/software issues, poor integration into PACS/RIS, network deficiencies), and c) human factors (human-AI interaction, automation bias, resistance to change, publication mishaps, annotation/interpretation errors, ergonomics). Adequate AI training and literacy, continuous monitoring of AI tools, standardized reporting of AI studies, multidisciplinary collaboration, effective leadership, and funding were suggested as potential solutions to the above failures.
Conclusion: AI models can fail at any stage through their lifecycle. Infrastructure issues and human related factors may present an important cause of AI failures.
Limitations: This is not an exhaustive list of AI failures in radiology as it is challenging to identify AI failures in a culture that mostly celebrates success. Also, identification is challenging due to publication bias and the evolving nature of the field.

Collaborative development of an ML-based CT protocol recommender (6 min)

Benoît Dufour; Sion / Switzerland

Author Block: A. Li[1], B. Dufour[2], S. Morozov[2], N. Heracleous[2], B. Rizk[2], C. Thouly[2]; [1]Milwaukee/US, [2]Sion/CH
Purpose: To collaboratively develop and evaluate a lightweight, data-driven machine learning model for recommending CT Body protocols, and to analyze the effect of procedure-based filtering on performance under data-scarce conditions.
Methods or Background: Efficient CT protocol selection often requires synthesis of multiple data sources and coordination among staff, creating variability and delay; AI-augmented decision support may streamline this step in the radiology workflow. A multicenter French-language dataset of 42,286 adult CT Body studies across 27 protocols was assembled; to emulate scarcity, training was limited to 5,000 studies with stratified partitioning of the remainder into validation (8%) and test (20%). Inputs were imaging order and free-text clinical indication; features were derived via a statistical text extraction and used as inputs to a decision tree-based model, XGBoost. Given the class imbalance, micro F1 was the primary metric.
Results or Findings: Procedure–protocol analysis showed certain procedures mapped to multiple protocols, mirroring local workflow. Baseline model (all procedures) achieved micro F1 58%. After filtering one high-volume procedure (43% of exams), micro F1 increased to 67%. Aggressive filtering (two procedures totaling 60% of exams) reached micro F1 80%. In the baseline model, high-confidence predictions (≥0.80 probability) covered 33% of the test set with 91% accuracy, predominantly for well-defined protocols (e.g., spine). Confusion analysis indicated strong performance in 18/27 protocols, with most errors among protocols with overlapping anatomic coverage.
Conclusion: A simple decision tree–based model, coupled with procedure filtering, achieved the target 80% micro F1 on a CT Body dataset under constrained training size, suggesting AI-augmented protocoling can reliably handle a substantial subset of studies while flagging ambiguous cases for expert review.
Limitations: Generalizability to other sites, languages, and clinical domains requires validation; comparisons with macro-weighted metrics may further characterize class-specific behavior.

Clinical application research of HRCT target scanning and three-dimensional reconstruction technology combined with AI imaging diagnosis system in the diagnosis of small pulmonary nodules (6 min)

Yan Huang; Hechi / China

Author Block: Y. Huang, W. Xia, L. Lin, S. Sun, Y. Tan, H. S. Ya, L. S. Wei, W. Li man; Hechi/CN
Purpose: To explore the diagnosis of benign and malignant pulmonary nodules by combining high-resolution computed tomography (HRCT) target scanning and three-dimensional reconstruction technology with an artificial intelligence (AI) imaging diagnosis system.
Methods or Background: All patients with small pulmonary nodules (SPNs) underwent HRCT targeted scanning with 3D reconstruction. Nodule detection rates (stratified by diameter and type) and mean interpretation time were compared between radiologists and an AI imaging diagnostic system. Inter-rater agreement was assessed using Kappa statistics, followed by diagnostic efficacy analysis.
Results or Findings: Compared with the diagnostic physicians, the detection rate of the AI imaging diagnosis system for small pulmonary nodules with a diameter less than 5 mm was higher, and the detection rate of ground glass nodules was also higher ($P < 0.05$). The average film reading time of diagnostic doctors is much longer than that of AI, and the difference between the two is statistically significant. The concordance between the benign and malignant rate detected by AI and the results of pathological examination was general, and the kappa value was 0.527; The kappa value of the diagnostic physician was 0.449. The sensitivity, specificity, accuracy, and AUC of the combined diagnosis of AI and diagnostic physicians were 96.08%, 85.11%, 93.50% and 0.914, respectively, which were higher than those of a single diagnosis ($P < 0.05$).
Conclusion: The combination of HRCT target scanning and three-dimensional reconstruction technology with the AI imaging diagnosis system has significant efficacy in the diagnosis of benign and malignant pulmonary nodules, with significantly improved detection rates and accuracy rates, providing reliable reference information for clinicians.
Limitations: Small sample size and single-center study.

The use of oligometastatic disease in routine radiology practice: a real world data analysis (6 min)
Martin J. Willemink; San Diego / United States

Author Block: J. Wu[1], A. De Araujo[2], S. Khozin[3], M. J. Willemink[1]; [1]Palo Alto, CA/US, [2]São Paulo/BR, [3]Cary, NC/US
Purpose: Oligometastatic disease (OMD) refers to a state of metastatic cancer, characterized by a limited number of metastatic lesions. Local treatments such as ablative therapy could potentially be curative to OMD. OMD-diagnosis is based exclusively on imaging findings. OMD challenges the older binary view of cancer as either localized or metastatic. Given the importance of imaging findings for diagnosing OMD, we explored the use of OMD in real-world radiological practice.
Methods or Background: We evaluated clinical radiology-reports from USA-located healthcare systems. Healthcare providers ranged from imaging centers, small- and medium-sized hospitals, to academic and oncology-focused providers. A real-world imaging data platform was used to search, filter, and select radiology reports (Segmed).
Results or Findings: A total of 33,747,977 reports of 11 radiology modalities (including X-ray, MRI, CT, and PET) from healthcare providers in 40 states were included in the search. OMD was mentioned in 164 radiology reports from 109 different patients. Clinicians provided OMD-information in the indication and history in 148 radiology reports of 95 patients, while radiologists mentioned OMD in 18 reports of 17 patients. OMD was mentioned in 20 different primary tumor-types, most commonly breast (n=39 reports of 22 patients), lung (n=33 reports of 26 patients), and prostate cancer (n=16 reports of 13 patients). Modalities with OMD-mention included CT (n=58), X-ray Angiography (n=44), PET/CT (n=35), MRI (n=26), and X-ray (n=1). The first mention of OMD was in 2017 (n=2 reports), which increased to n=33 in 2024.
Conclusion: In this large scale observational study, we found that despite the importance of imaging, the term OMD is rarely used in routine radiology practice in the USA. These results suggest the need to improve the definition and guidelines around OMD.
Limitations: Retrospective study with only US data, no EU data.

Optimizing Risk Stratification: Diagnostic Performance and Clinical Utility of Node-RADS for Predicting Lymph Node Metastasis in Cervical Cancer (6 min)
Jing Chen; Beijing / China

Author Block: J. Chen, Z. Yuan, Y. Li, Y-L. He, Z. Jin, H-D. Xue; Beijing/CN
Purpose: To develop and validate the first nomogram that integrates Node-RADS with clinical parameters for predicting lymph node metastasis (LNM) in cervical cancer. We further aim to evaluate the clinical utility of this integrated model across various scenarios, particularly in fertility-sparing candidates and cases with indeterminate lymph nodes.
Methods or Background: This retrospective study included 465 cervical cancer patients. Two radiologists independently evaluated lymph nodes using Node-RADS on preoperative MRI. Diagnostic metrics (sensitivity, specificity, etc.) were calculated. A combined model incorporating Node-RADS and clinicopathological predictors was developed and presented as a nomogram. Diagnostic performance was evaluated via ROC analysis and decision curve analysis. Subgroup analyses were performed in fertility-sparing candidates (including age <45 years or tumor size ≤2 cm), lymph nodes with subcentimeter metastasis (short-axis diameter <1 cm), and those assigned a Node-RADS score of 3.
Results or Findings: Node-RADS score 3 provided optimal diagnostic balance (sensitivity 68.7%, specificity 88.2%, NPV 92.8%), while scores 4–5 showed high specificity (≥99%). The combined model outperformed Node-RADS alone (AUC 0.872 vs. 0.827), with good calibration (p = 0.44) and a greater net benefit at threshold probabilities of 10–40%. The nomogram enabled individualized risk estimation. Subgroup analysis confirmed strong performance in fertility-sparing candidates (AUC 0.884 for age<45; 0.851 for tumor ≤2 cm), identified patients with subcentimeter LNM（AUC 0.877）, and improved stratification of Node-RADS 3 nodes (AUC 0.838; LR+ 2.61).
Conclusion: Node-RADS is a robust independent predictor for preoperative lymph node metastasis assessment in cervical cancer. Node-RADS-integrated nomogram represents a powerful and clinically useful tool for the individualized preoperative prediction of LNM in cervical cancer, potentially enhancing decision-making for personalized treatment strategies.
Limitations: The generalizability of our findings may be limited by the study's retrospective design and single-center patient cohort.
Funding for this study: The CAMS Innovation Fund for Medical Sciences (grant no. 2023-I2M-C&T-B-020),
National High-Level Hospital Clinical Research Funding (grant no. 2025-PUMCH-C-029).

CT-based Node-RADS for regional lymph node metastasis in pancreatic ductal adenocarcinoma: diagnostic performance and prognostic impact (6 min)

Xiang-Pan Meng; Wuxi / China

Author Block: X-P. Meng; Wuxi/CN
Purpose: To evaluate the diagnostic performance and prognostic value of the Node Reporting and Data System 1.0 (Node-RADS) for regional lymph node (LN) metastasis in pancreatic ductal adenocarcinoma (PDAC) using preoperative CT.
Methods or Background: This single-center retrospective study included patients with PDAC who underwent contrast-enhanced CT followed by surgical resection between January 2017 and July 2023. Each regional LN station was assessed using Node-RADS, in which nodal size and morphologic features were integrated into a five-point scoring system (1–5, from very low to very high suspicion), with histopathology serving as the reference standard. Diagnostic performance, including sensitivity and specificity, was evaluate at the patient, LN group, and station levels. Cox regression analyses were conducted to evaluate the prognostic impact of Node-RADS after adjusting for clinicopathological factors.
Results or Findings: A total of 216 patients (mean age ± standard deviation, 61.2 ± 10.0 years; 138 males) were included, with LN metastases detected in 154 of 216 patients (71.3%). A Node-RADS score of 3 or greater yielded the optimal cutoff for predicting lymph node metastasis, with sensitivity and specificity of 77.3% (119/154) and 83.9% (52/62) at the patient level, 74.8% (104/139) and 81.8% (63/77) for Group 1, and 77.3% (34/44) and 82.6% (142/172) for Group 2. Across regional nodal stations, Node-RADS achieved a sensitivity of 60.0–85.7% and a specificity of 79.5–98.8%. Higher Node-RADS categories were independently associated with worse overall survival (hazard ratio [HR], 1.34; 95% CI: 1.15–1.56; p = 0.012) and disease-free survival (HR, 1.45; 95% CI: 1.17–1.92; p = 0.007).
Conclusion: Node-RADS provides robust diagnostic accuracy for LN metastasis in PDAC and may serve as an effective preoperative prognostic predictor.
Limitations: Retrospective; Single-center study
Funding for this study: the foundation of the Wuxi Municipal Bureau on Science and Technology (Y20232002)
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This single-center retrospective study was approved by the Ethics Review Committee of the Affiliated Wuxi People's Hospital of Nanjing Medical University, and the requirement for informed consent was waived due to the retrospective design.

Improving CT detection of subcentimeter liver metastases: AI-augmented contrast boosting enhances sensitivity and conspicuity in choroidal melanoma (6 min)

Josephine Berger; Tübingen / Germany

Author Block: J. Berger, F. K. E. Mankertz, N. Maalouf, A. S. Brendlin, J. Herrmann, K. Nikolaou, S. Afat; Tübingen/DE
Purpose: To evaluate whether AI-based contrast boosting of single-phase CT improves the detection and visual conspicuity of subcentimetre liver metastases from choroidal melanoma, using liver MRI as the reference standard.
Methods or Background: This retrospective single-centre study included 68 patients (mean age, 69.6 ± 11.2 years; 46% men) with histologically confirmed choroidal melanoma and suspected liver metastases, enrolled between January 2019 and July 2022. All underwent portal venous phase contrast-enhanced whole-body CT and dedicated liver MRI. CT data were post-processed using a commercial AI-based contrast-boosting algorithm (ClariACE, ClariPi, Seoul, South Korea). MRI-identified metastases served as the reference standard and were stratified by size (<5 mm, 5-10 mm, >10 mm). Two radiologists independently assessed visibility on standard and AI-boosted CT, recording binary detection and conspicuity on a five-point Likert scale. Detection rates were compared using McNemar's test, conspicuity using the Wilcoxon signed-rank test, and inter-reader agreement using Cohen's kappa and intraclass correlation coefficient.
Results or Findings: A total of 104 liver metastases were identified on MRI, including 58 <5 mm. For sub-5 mm lesions, AI-boosted CT significantly improved sensitivity from 57% to 81% ($p < 0.001$). A modest, non-significant increase was observed for 5-10 mm lesions (82% to 89%, $p = 0.09$), while detection of >10 mm lesions remained 100%. Median conspicuity scores for sub-5 mm lesions increased from 3.0 to 4.3 ($p < 0.001$). Inter-reader agreement was excellent for detection ($\kappa = 0.84$) and conspicuity (ICC = 0.87). Increased conspicuity correlated with improved detection of small lesions.
Conclusion: AI-based contrast enhancement significantly improves sensitivity and conspicuity for detecting subcentimetre liver metastases, especially those <5 mm, without additional patient risk and may facilitate earlier detection, staging, and treatment planning.
Limitations: Retrospective, single-centre design and modest sample size may limit generalisability.
Funding for this study: None.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Local IRB board approval was obtained.

Spectral-CT-Based Intratumor Heterogeneity and Peritumoral Morphologic Sign for Predicting Occult Lymph Node Metastasis in Resectable Pancreatic Ductal Adenocarcinoma (6 min)

Yi Chen; Shanghai / China

Author Block: Y. Chen, W. Liu, Y. Wang, Z. Zhou; Shanghai/CN
Purpose: To investigate the value of spectral CT-based habitat imaging and CT-diagnosed peripancreatic invasion in predicting occult LNM in resectable PDAC.
Methods or Background: This retrospective study included 113 PDAC patients who underwent preoperative triple-phase spectral CT. The tumors were partitioned into multiple subregions using K-means clustering based on the pancreatic-to-venous phase iodine concentration ratio (PVICR). The optimal number of subregions was determined using the elbow method and silhouette coefficient. The volume fraction of each subregion was quantified. The Spearman rank test was used to explore the relationship between the subregion proportion and collagen ratio. Patients were stratified into training cohort (70%) and validation cohort (30%). To construct the predictive model, potential variables were screened using logistic regression analyses.
Results or Findings: Based on the elbow method principle and silhouette coefficient, all voxels were divided into four subregions. There was a moderate negative correlation between the proportion of subregion 1 and the collagen ratio ($r = -0.543$, $p < 0.001$). Independent risk factors for occult LNM included the volume fraction of Subregion 1 (lowest PVICR) and CT-diagnosed peripancreatic invasion. The model combining these two variables showed good discrimination, with AUCs of 0.829 (95% CI: 0.722–0.925) in the training cohort and 0.789 (95% CI: 0.632–0.943) in the validation cohort.
Conclusion: The proportion of subregion 1 and CT-diagnosed peripancreatic invasion are valuable tools for preoperatively identifying occult LNM in resectable PDAC, and the fibrotic stroma may limit the invasiveness of resectable PDAC.
Limitations: This is a single-center study. Given that Masson's trichrome staining is not part of the routine pathological protocol at our institution, the correlation between habitat subregion proportion and collagen ratio was preliminarily investigated in a subset of matched cases (n = 42).
Funding for this study: This work was supported by the General Program of the National Natural Science Foundation of China (No. 82471981), the Xuhui District University-Local Cooperation Project (No. 23XHYD-13), the Shanghai Anti-Cancer Association "Ao Xiang" Talent Program (No. SACA-AX202405), the Shanghai Anti-Cancer Association "Ao Xiang" Talent Program (No. SACA-AX202309), and the Hong Kong, Macao, and Taiwan Science and Technology Cooperation Project under the Science and Technology Innovation Action Plan of Shanghai Municipality (No. 22490760800).

Small Liver Metastases from Uveal Melanoma: detection on MRI comparing Gd-EOB-DTPA hepatobiliary phase with DWI sequences and dynamic phase (6 min)

Chiara Pontiggia; Piantedo (SO) / Italy

Author Block: C. Pontiggia, V. Magni, M. Vaiani; Milan/IT
Purpose: To compare Gd-EOB-DTPA hepatobiliary phase and DWI sequences with dynamic phase on contrast-enhanced MRI for detection of liver metastases from uveal melanoma, as assessed by two readers with different levels of expertise.
Methods or Background: This retrospective study included patients with liver metastases from uveal melanoma who underwent surgery between 2017 and 2025. Preoperative liver-focused MRI scans were independently reviewed by two readers with different expertise. Two imaging protocols were evaluated: T1/T2-weighted with dynamic sequences, and T1/T2-weighted with DWI/ADC and hepatobiliary phase sequences. Histopathological results from surgery and follow-up MRI for non-resected lesions were retrieved. Lesion counts were compared using the Wilcoxon signed-rank test. Inter-reader agreement was assessed with the ICC.
Results or Findings: 16 patients were included. Senior reader detected 68 lesions with DWI/hepatobiliary phase sequences and 25 with dynamic contrast-enhanced sequences, while junior reader detected 45 and 33 lesions, respectively. Of the 68 lesions detected by senior reader on DWI/hepatobiliary sequences, 60 had histopathological confirmation, seven were confirmed at follow-up MRI, and one was a false positive (positive predictive value of 98.5%). In 9/16 patients (56.3%), MRI detected all surgically proven lesions, whereas in 7/16 patients surgery revealed additional lesions not visible on MRI. Senior reader identified significantly more lesions with DWI/hepatobiliary than with dynamic sequences (median 3.5 versus 1.0, p = 0.0014). Junior reader also detected significantly more lesions with DWI/hepatobiliary than with dynamic sequences (median 2.0 versus 1.0, p = 0.017). Inter-reader agreement was moderate (ICC of 0.66 for dynamic and 0.64 for DWI/hepatobiliary sequences).
Conclusion: DWI/hepatobiliary MRI sequences improved lesion detection compared with dynamic sequences, particularly for the experienced reader; furthermore, they showed a high positive predictive value, with complete concordance to surgery in over half of patients.
Limitations: Small sample size.
Funding for this study: No funding was received for this study.

Prognostic factors for metastatic patients: Numeric tumor fraction in liquid biopsy, tumor volume and anthropometry in CT scans (6 min)

Jules Dupont; Villejuif / France

Author Block: A. Choucair[1], J. Dupont[2], G. H. Jardali[1], L. Dawi[1], L. LAWRANCE[3], S. Ammari[2], C. Massard[2], A. Italiano[4], N. Lassau[2]; [1]Paris/FR, [2]Villejuif/FR, [3]Villepinte/FR, [4]Bordeaux/FR
Purpose: Total tumor volume (TTV) on CT scans, circulating tumor DNA (CTDNA) from liquid biopsy (LB), known as tumor fraction (TF), as well as 3Danthropometric measurements, are indicators for predicting overall survival (OS) in metastatic patients.
Methods or Background: Patients with a baseline CT scan and LB (STING, NCT04932525, Gustave Roussy) were included from January 2021 to December 2023 in this study. CT scans were annonymized and manually annotated in 2D by radiologists, with a 3D TTV estimated (Tumor volume = 2/3 xMesh surface area x Minor axis). TF was reported as a percentage.
The Anthropometer3DNet software provided measurements for muscle, superficial, and deep fat masses; combined with TTV and with Cox model coefficients to generate a CT scan risk-score. Patients were grouped based on TF (≥0%) and divided into two subgroups according to the CT scan risk-score.
OS was the primary endpoint, and the analyses were carried out using Kaplan-Meier estimators and log-rankstatistics.
Results or Findings: Among 720 patients with 38,283 annotated metastases, the median OS was 13.1 months, with a median TF and TTV of 3.3% and 91.6 cm^3. A total of 213 patients had TF=0% despite measurable tumor burden (median TTV 35.3 cm^3), and their OS was shorter (10.2 months) compared to TF>0% (25.5 months). Within the TF=0% group, patients with a low CT-scan risk score lived longer (35.4 months) than those with a higher score (19.4 months). In the TF>0% group, OS was 13.2 months for low CT-scan risk-score but dropped to 7.5 months for those with TTV above the median.
Conclusion: TTV and anthropometric measurements, when combined with TF offer a more precise prediction of OS.
Limitations: This is a retrospective single-center study, relying on 2D TTV estimation with a heterogeneity in the cohort.
Funding for this study: No fundings.

Chairperson's introduction (3 min)
Maximilian De Bucourt; Berlin / Germany

Pregnancy behind the shield: safety, culture and career in IR (9 min)
Sara Lojo Lendoiro; Ferrol / Spain

1. To learn about current evidence, safety thresholds, and best practices regarding radiation exposure during pregnancy for interventional radiologists.
2. To appreciate the importance of institutional policies, protective measures, and supportive workplace culture for pregnant IRs.
3. To understand pregnant interventionalists' personal, professional, and cultural challenges, and how the speciality can evolve to support them better.

Owning the outcome: how IRs can lead clinical pathways and long-term care (9 min)
Andreas H. Mahnken; Bochum / Germany

1. To learn how interventional radiologists can actively contribute to pre- and post-procedural patient management across various clinical pathways.
2. To appreciate the value of structured follow-up, multidisciplinary collaboration, and longitudinal care in improving patient outcomes.
3. To understand how increased clinical visibility and continuity of care can strengthen the role of IR in modern healthcare systems.

The clinical grey zone: when guidelines don't have the answer (9 min)
Jose Luis Del Cura Rodriguez; Bilbao / Spain

1. To learn how to approach complex clinical decisions in interventional radiology when evidence is limited or guidelines are not definitive.
2. To appreciate the role of clinical judgment, multidisciplinary discussion, and patient-specific factors in navigating uncertainty.
3. To understand how real-life case examples can help develop critical thinking and ethical reasoning beyond protocol-driven care.

AI-SC 3 - AI embedded in the real world

Categories: Professional Issues, Management/Leadership, Imaging Informatics, Artificial Intelligence

Katharina Mueller-Peltzer; Freiburg Im Breisgau / Germany

AI support for orthopaedic cases (6 min)
Amanda Isaac; London / United Kingdom

1. To learn how AI is being applied across MSK and orthopaedic disciplines, from imaging triage and diagnostic support to surgical planning, rehabilitation monitoring, and outcome prediction. Attendees will gain a practical understanding of how these tools can enhance efficiency, consistency, and precision in patient care.
2. To appreciate the opportunities and challenges of embedding AI within clinical workflows. Speakers will highlight the importance of data quality, clinician engagement, and system integration, as well as real-world barriers such as resource limitations, trust, and workflow adaptation. The session will emphasise the shared responsibility of radiologists, orthopaedic surgeons, and allied health professionals in ensuring safe, transparent, and clinically meaningful use of AI.
3. To understand the ethical, regulatory, and operational frameworks guiding AI deployment in healthcare. Participants will examine how multidisciplinary collaboration supports validation, governance, and generalisability, ensuring that AI solutions improve, not complicate, clinical practice.

Mammography reporting with AI support (6 min)
Benoît Rizk; Villars-Sur-Glane / Switzerland

1. To learn the different use-cases of AI in mammography, including acquisition, cancer screening, breast density, quality control, triage, breast arterial calcifications, prognostication.
2. To appreciate how human readers and AI can interact in breast imaging.
3. To understand the strengths and weaknesses of current AI support in mammography reading.

Prostate reporting with AI support (6 min)
Felix Hahn; Mainz / Germany

1. To learn about the clinical background of qualitative and quantitative Evaluation by AI.
2. To appreciate the workflow benefits through AI support.
3. To understand critical factors for successful AI integration in clinical settings.

Lung reporting with AI support (6 min)
Prerana Agarwal; Freiburg / Germany

1. To learn about the different areas where AI can support in lung reporting.
2. To appreciate the potential benefits and current limitations of AI in daily radiology practice.
3. To understand real-life challenges, opportunities, and future directions of AI-assisted lung reporting.

Neuro reporting with AI support (6 min)
Alexander Rau; Freiburg Im Breisgau / Germany

1. To learn how artificial intelligence can be applied to acute stroke diagnostics (CTA-based LVO detection, and CTP-based core/penumbra quantification) and to chronic pathology (neurodegeneration pattern analysis).
2. To appreciate how artificial intelligence enables more efficient workflows, higher diagnostic consistency and value (standardization, reproducibility, triage), and ultimately better patient care, while knowing where human verification adds the most benefit.
3. To understand the potential and pitfalls of the exemplary artificial intelligence integration in neuroradiology, including necessary quality control (AIF, motion, thresholds), common false positives/negatives, dataset bias and generalizability, and potential for incorporation into structured reporting.

AI in oncology and haematology (6 min)

Laurens Topff; Amsterdam / Netherlands

1. To learn how AI tools integrate into oncology imaging workflows for tumour detection and treatment response monitoring.
2. To appreciate the clinical value of AI-driven quantification and automated tumour tracking over time.
3. To understand key practical considerations when implementing AI solutions for oncologic imaging in real-world workflows.

Introduction to the Guided Tours (6 min)

Marc Kämmerer; Bochum / Germany

1. To introduce the audience to the accompanying concept of the guided tours along the exhibition floor.
2. To describe the workflows which will be demonstrated by the vendors with existing software solutions.
3. To learn about the specifics how the different systems interconnect and why it is working.

Panel discussion: What are your gains and pains (16 min)

ST 4 - Celebrating 20 Years of EIBIR: Insights from Prof. Regina Beets-Tan

Categories: Research, Management/Leadership, Education

Date: March 4, 2026 | 12:30 - 13:00 CET

SESSION RECOMMENDED BY EIBIR | EUROPEAN INSTITUTE FOR BIOMEDICAL IMAGING RESEARCH

The European Institute for Biomedical Imaging Research (EIBIR) is at the forefront of coordinating EU research projects to support the development of biomedical imaging technologies and the dissemination of knowledge.

EIBIR celebrates its 20th anniversary at ECR 2026.

EIBIR actively supports research networking activities and common initiatives in the field of biomedical imaging research. With the EU-funded projects EIBIR leads and supports, the institute is working towards the goal of building stronger, more resilient health systems. In this interview, EIBIR Scientific Director Prof. Regina Beets-Tan will highlight EIBIR's remarkable achievements in securing funding for biomedical research, and outline the institute's strategic priorities for the coming years. In particular, the new Strategic Research Agenda (currently under finalisation) will also be presented.

Moderators:

Mélisande Rouger; Bilbao / Spain

Conny Lee; Vienna / Austria

Interview (30 min)

Regina G.H. Beets-Tan; Amsterdam / Netherlands

CUBE 4 - AI and radiation protection: a radiographer's perspective

Categories: Radiographers, EuroSafe Imaging/Radiation Protection, Education
Date: March 4, 2026 | 13:00 - 13:30 CET
CME Credits: 0.5

SESSION RECOMMENDED BY ESR EUROSAFE IMAGING

Moderator:
Luca Bombelli; Milan / Italy

Chairperson's introduction (2 min)
Luca Bombelli; Milan / Italy

Can AI support radiographers in interventional radiology to maximise radiation protection? (28 min)
Laura Federico; Bologna / Italy

1. To learn about AI options for supporting radiation protection in interventional radiology.
2. To appreciate potential radiation dose savings from inclusion of AI within interventional radiology practices.
3. To understand how radiation protection in interventional radiology is likely to develop in the future.

EIBIR 4a - Novel approaches for trustworthy artificial intelligence (AI) in cancer diagnostics and treatment

Categories: Breast, Research, Artificial Intelligence
ETC Level: LEVEL I+II
Date: March 4, 2026 | 13:00 - 14:30 CET
CME Credits: 1.5

Moderator:
Regina G.H. Beets-Tan; Amsterdam / Netherlands

Chairperson's introduction (5 min)
Regina G.H. Beets-Tan; Amsterdam / Netherlands

Developing a validated AI-based decision-making support system for breast cancer (20 min)
Maciej Bobowicz; Gdańsk / Poland

1. To learn about the latest research in the International Clinical Validation of Radiomics Artificial Intelligence for Breast Cancer Treatment Planning (RadioVal) project.
2. To explore the application of the Fairness, Universality, Traceability, Usability, Robustness and Explainability (FUTURE)-AI guidelines in developing trustworthy AI tools for breast cancer imaging.
3. To investigate advancements in AI traceability and explainability to enhance clinical decision support.
4. To assess current strategies for validating AI systems in breast cancer diagnosis to ensure reliability and clinical effectiveness.

Learning without sharing. AI collaboration without data exchange through swarm learning (20 min)
Oliver Lester Saldanha; Dresden / Germany

1. To learn about the latest research in the Open Consortium for Decentralized Medical Artificial Intelligence (ODELIA) project.
2. To understand the concept of swarm learning and how it enables collaborative AI training without data sharing for MRI-based breast cancer screening as a demonstration case.
3. To learn how the ODELIA project paves the way for broader adoption of swarm learning in medical AI and beyond.
4. To recognise the benefits of swarm learning in healthcare innovation to accelerate AI development, enhance diagnostic performance, and foster generalisable solutions.

Expanding data availability for development and validation of AI tools in breast cancer screening and diagnoses (15 min)
Francesco Sardanelli; Milan / Italy

1. To learn about the latest research in the Pan-European Breast Image Platform for Advanced AI-based Breast Cancer Screening (BreastSCan) project.
2. To understand how BreastSCan aligns with EU health data initiatives and Europe's Beating Cancer Plan, fostering real-world AI integration in clinical practice.
3. To appreciate the impact of cross-border data sharing on advancing cancer diagnostics across Europe to reduce mortality, improve life quality, and advance AI literacy among healthcare professionals and citizens.
4. To learn how the large-scale, harmonised BreastSCan dataset combining multimodality breast images and clinical data will support the AI tool development for breast cancer screening and diagnosis.
5. To discuss the priority of future roles of AI tools beyond image quality assessment, breast density classification or lesion detection/characterisation, i.e. personalised breast cancer risk stratification.

Accelerating trustworthy AI deployment in cancer diagnostics (15 min)
Regina G.H. Beets-Tan; Amsterdam / Netherlands

1. To learn about the latest research in the Community of Multidisciplinary Professionals Advancing Safe and Successful AI Implementation in Clinical Practice (COMPASS-AI) project.
2. To recognise the challenges in deploying AI in clinical practice.
3. To learn about the multidisciplinary community of experts for AI implementation.
4. To understand the proposed framework for AI deployment guidelines.

Discussion (15 min)

ESR Audit 4 - Young Audit Prize

Categories: Audit
ETC Level: ALL LEVELS
Date: March 4, 2026 | 13:00 - 14:30 CET
CME Credits: 1.5

SESSION RECOMMENDED BY EIBIR | EUROPEAN INSTITUTE FOR BIOMEDICAL IMAGING RESEARCH

In this session, the best submissions for the new format - the Young Audit Prize - will be presented. Among these, the jury will select the overall winner. The Young Audit Prize is an ESR initiative, developed by the ESR Audit and Standards Subcommittee, to promote audit awareness and excellence among young radiologists. For more information, please visit https://www.myesr.org/congress/submit/young-audit-prize/

Radiomics and AI made simple: the basics you really need to know (16 min)
Lorenzo Ugga; Naples / Italy

1. To review the basic concepts of radiomics and AI in medical imaging, including how they work and why they matter.
2. To appreciate how AI and radiomics can help doctors better detect, diagnose, and monitor diseases using imaging.
3. To understand the advantages and limitations of using AI in radiology, including what it can and cannot do, and the challenges of using it safely and effectively.

Become a research detective: how to spot good (and bad) AI studies (16 min)
Renato Cuocolo; Naples / Italy

1. To review the key parts of an AI research study in radiology, including how studies are designed and what makes them trustworthy.
2. To appreciate the importance of asking critical questions when reading AI studies, such as: Was the study fair? Was the data reliable? Can the results be used in real life?
3. To understand the advantages and limitations of using AI research in clinical decision-making, and why not all studies are ready to change how we practice medicine.

AI in the classroom: new ways to learn radiology faster and better (16 min)
Tugba Akinci D'Antonoli; Basel / Switzerland

1. To review the different ways AI is being used to support radiology education, including tools that help with image interpretation and interactive learning.
2. To appreciate the indications of when and how AI-based learning tools can be helpful in building radiology knowledge and skills more efficiently.
3. To understand the advantages and limitations of using AI in medical education, including how it can help personalise learning, and why human guidance is still essential.

Panel discussion: AI in radiology: hype, help, or here to stay? (7 min)

E³ 418 - Primary liver tumours

Categories: Oncologic Imaging, Abdominal Viscera, President's Choice

ETC Level: LEVEL II+III

Date: March 4, 2026 | 13:00 - 14:30 CET

CME Credits: 1.5

The aim of the session is to understand the importance of radiologic-pathologic correlation in benign liver tumours and to be aware of the importance of radiologic-pathologic correlation in malignant primary liver tumours.

Moderator:

Pablo R. Ros; Stony Brook / United States

Chairperson's introduction (5 min)

Pablo R. Ros; Stony Brook / United States

Benign liver tumours (35 min)

Valérie Vilgrain; Clichy / France

Valérie Paradis; Clichy / France

Malignant primary liver tumours (35 min)

Muşturay Karçaaltincaba; Ankara / Turkey

Cenk Sokmensuer; Ankara / Turkey

Challenging case presentation by the moderator and discussed by the tandems (15 min)

Pablo R. Ros; Stony Brook / United States

E³ 419 - Can reporting and data Systems (RADS) improve bone assessment in clinical practice?

Categories: Musculoskeletal, Oncologic Imaging, President's Choice
ETC Level: LEVEL II+III
Date: March 4, 2026 | 13:00 - 14:30 CET
CME Credits: 1.5

Moderator:
Joan C. Vilanova; Girona / Spain

Chairperson's introduction (5 min)
Joan C. Vilanova; Girona / Spain

Pitfalls in assessing musculoskeletal tumours (20 min)
Mark D. Murphey; Bethesda / United States

1. To learn about three scenarios which can create pitfalls in imaging of musculoskeletal tumours and techniques to avoid these potential diagnostic mischaracterisations including: cyst versus myxoid neoplasm, myositis ossificans, haematoma versus haemorrhagic neoplasm
2. To appreciate the ability to differentiate cystic lesions such as ganglia, bursa and synovial cysts from myxoid neoplasms, particularly myxoid liposarcoma and myxofibrosarcoma.
3. To understand the cause of imaging misinterpretation of myositis ossificans as an infiltrative neoplasm.
4. To recognise the distinguishing imaging features between haematoma from haemorrhagic neoplasm with obvious clinical and medico-legal implications, if delay in diagnosis or misdiagnosis ensues.

Metastasis-reporting and data systems for prostate cancer (MET-RADS-P): standardising whole body MRI assessment of bone metastases (20 min)
Anwar R. Padhani; Northwood / United Kingdom

1. To understand the rationale for standardised assessment of prostate bone metastases in the PSMA era.
2. To learn about MET-RAD-P criteria for assessing bone metastases and response to therapy.
3. To appreciate the strengths and limitations of MET-RAD-P in real-world practice.

Myeloma response assessment and diagnosis systems (MY-RADS): standardising whole-body MRI assessment of multiple myeloma (20 min)
Frédéric Lecouvet; Brussels / Belgium

1. To learn about MY-RADS for standardised assessment of multiple myeloma.
2. To learn how to apply MY-RADS for treatment response evaluation.
3. To appreciate the challenges of applying MY-RADS for clinical evaluation.

Case-based panel discussion: Is there value in -reporting and data systems (RADS) for musculoskeletal radiology? (25 min)
Joan C. Vilanova; Girona / Spain

E³ 421 - Frailty: how to recognise and manage it

Categories: General Radiology, Multidisciplinary, Sustainability
ETC Level: LEVEL I+II
Date: March 4, 2026 | 13:00 - 14:30 CET
CME Credits: 1.5

Frailty: assessment and prevention of progression (45 min)
Rebeca Mirón Mombiela; Herlev / Denmark

1. To assess the incidence, relevance and potential evolution of frailty.

Frailty and sustainability (45 min)
Kate Hanneman; Toronto / Canada

1. To evaluate the financial impact of the management of frail subjects.

E³ 423 - Urogenital

Categories: Genitourinary
ETC Level: LEVEL I+II
Date: March 4, 2026 | 13:00 - 14:30 CET
CME Credits: 1.5

Moderator:
Valeria Panebianco; Rome / Italy

Chairperson's introduction (6 min)
Valeria Panebianco; Rome / Italy

Renal and adrenal imaging (28 min)
Alexandra Ljimani; Düsseldorf / Germany

1. To describe the classification of the renal masses.
2. To explain the imaging features of inflammatory disorders of the kidneys.
3. To describe the imaging features of benign and malignant tumours of the adrenal glands.

Imaging of the ureter and bladder (28 min)
Rossano Girometti; Udine / Italy

1. To explain the imaging anatomy and variants of the ureter and bladder.
2. To explore the imaging features of obstructive uropathy in non-neoplastic disorders.
3. To describe the imaging features of tumours of the ureter and bladder.

Prostate imaging (28 min)
Hanna Falińska; Zielona Góra / Poland

1. To describe the MRI anatomy of the prostate.
2. To describe the imaging features of benign prostatic disorders.
3. To explain the imaging features of prostate cancer using the prostate imaging reporting and data system (PIRADS).

How 4 - How we image the cranial nerves: a step-by-step approach

Categories: Emergency Imaging, Oncologic Imaging, Neuro, Head and Neck, President's Choice
ETC Level: LEVEL I+II
Date: March 4, 2026 | 13:00 - 14:00 CET
CME Credits: 1

Moderator:
Simonetta Gerevini; Cremona / Italy

Chairperson's introduction (2 min)
Simonetta Gerevini; Cremona / Italy

Imaging modalities and techniques (15 min)
Amarnath Chellathurai; Chennai / India

1. To learn which high-resolution MRI sequences and planes are best suited for cranial nerve visualisation.
2. To recognise CT indications and limitations for cranial nerve assessment.
3. To understand the role of contrast enhancement and advanced imaging techniques, e.g., diffusion and tractography.

Cranial Nerves I-VI: what you need to know, nerve by nerve (15 min)
Aïna Venkatasamy; Strasbourg / France

1. To learn how to identify the normal course and imaging appearance of cranial nerves I–VI.
2. To understand key pathologies and how to avoid common errors using a case-based approach.

Cranial Nerves VII-XII: what you need to know, nerve by nerve (15 min)
Claudia Patricia Cejas; Buenos Aires / Argentina

1. To learn how to identify the normal course and imaging appearance of cranial nerves I–VI.
2. To understand key pathologies and how to avoid common errors using a case-based approach.

Open forum discussion (13 min)

HW Uc 4 - Chronic liver disease

Categories: Abdominal Viscera
ETC Level: LEVEL I+II
Date: March 4, 2026 | 13:00 - 14:30 CET
CME Credits: 1.5

Moderator:
Giovanna Ferraioli; Pavia / Italy

Introduction (15 min)
Giovanna Ferraioli; Pavia / Italy

1. To learn how to perform shear wave elastography (SWE) of the liver.
2. To learn the US techniques to assess the liver for steatosis: attenuation imaging, ultrasound-derived fat fraction, hepatorenal index (ATI/UDFF/HRI).
3. To understand the physics behind these technologies.
4. To understand the clinical relevance of the parameters and indices generated.

Hands-on demonstration (75 min)

Demonstrators
Giovanna Ferraioli; Pavia / Italy
Markus Herbert Lerchbaumer; Berlin / Germany
Vito Cantisani; Rome / Italy
Richard G. Barr; Canfield / United States
Paul S. Sidhu; London / United Kingdom
Christopher J. Harvey; London / United Kingdom

IF 4 - Art for the masses: AI democratising image-based screening

Categories: General Radiology, Emergency Imaging, Oncologic Imaging, Chest, Breast, Artificial Intelligence, President's Choice

ETC Level: ALL LEVELS

Date: March 4, 2026 | 13:00 - 14:30 CET

CME Credits: 1.5

Access to preventive healthcare services – just like art – should not be limited to privileged groups but ideally be widespread and available to enhance everybody's life. This is especially true for radiological screening methods with scientifically proven benefits to patient's lives. This session explores how AI could help make screening and preventive medicine more accessible while maintaining high quality in the face of expected staff shortages. The current use of AI in clinical screening scenarios is also discussed.

Moderator:
Horst Karl Hahn; Bremen / Germany

Chairperson's introduction (5 min)
Horst Karl Hahn; Bremen / Germany

Supercharging breast cancer screening: role of AI for current and upcoming screening modalities (20 min)
Sophia Zackrisson; Malmö / Sweden

Lung screening for the masses: efficient use of AI for lung cancer management and beyond (20 min)
Anagha P. Parkar; Bergen / Norway

Pushing the envelope: how to effectively implement AI for early detection of prostate cancer (20 min)
Maarten De Rooij; Nijmegen / Netherlands

Panel discussion: How can AI be used to enhance and expand image-based screening? (25 min)

NH 4a - Does body composition matter? Radiological perspectives

Categories: Musculoskeletal, Imaging Methods, Translational Imaging, Multidisciplinary, Artificial Intelligence
ETC Level: LEVEL III
Date: March 4, 2026 | 13:00 - 14:30 CET
CME Credits: 1.5

Moderator:
Amanda Isaac; London / United Kingdom

Chairperson's introduction (3 min)
Amanda Isaac; London / United Kingdom

How does body composition affect patients' quality of life and survival? (20 min)
Christian Krestan; Wien / Austria

1. To learn how body composition data can be derived from retrospective and prospective scans in a radiology department.
2. To appreciate the representability of body composition parameters such as skeletal muscle area (SMA), subcutaneous adipose tissue area (SAT), and visceral adipose tissue area (VAT) for quality of life and survival.
3. To understand how body composition affects quality of life and survival in cancer and non-cancer patients.

Imaging of body composition: where are we now? (20 min)
Alberto Bazzocchi; Bologna / Italy

1. To learn how imaging can assess body composition.
2. To become familiar with different imaging techniques in the analysis of body composition.
3. To appreciate the pivotal role of imaging in body composition assessment in clinical practice today, with future perspectives.

Managament of fragility fractures: the role of the interventional radiologist (20 min)
Danoob Dalili; Oxford / United Kingdom

1. To learn the current role of image-guided interventions in treating fragility fractures.
2. To appreciate patients' benefits from early intervention and management.
3. To understand current guidelines in the UK, Europe and the USA and how to implement them in day-to-day practice.

Should we address body composition in our multidisciplinary meetings? (20 min)
Kerensa Beekman; Amsterdam / Netherlands

1. To learn how body composition metrics could enhance patient stratification and treatment planning in MDTs.
2. To appreciate the potential of AI-driven imaging for integrating body composition analysis into MDT workflows.
3. To understand how incorporating body composition data in MDTs can support shared decision-making and personalised care.

Panel discussion: The importance of body composition in our routine practice (7 min)
Amanda Isaac; London / United Kingdom

NH 4b - European perspectives of lung cancer screening: more than a decade after NLST and NELSON

Categories: Oncologic Imaging, Chest, Evidence-Based Imaging, Education, Multidisciplinary
ETC Level: LEVEL III
Date: March 4, 2026 | 13:00 - 14:30 CET
CME Credits: 1.5

SESSION RECOMMENDED BY EIBIR | EUROPEAN INSTITUTE FOR BIOMEDICAL IMAGING RESEARCH

Moderator:
Marie-Pierre Revel; Paris / France

Chairperson's introduction (6 min)
Marie-Pierre Revel; Paris / France

An update on European lung cancer screening: SOLACE and beyond (16 min)
Anna Kerpel-Fronius; Budapest / Hungary

1. To learn about the status quo and gaps of lung cancer screening in Europe.
2. To appreciate dedicated efforts to address women and hard-to-reach populations.
3. To understand the interfaces between surveillance of COPD, IPF, OLD patients and cancer survivors with lung cancer screening.

Optimising eligibility and screening intervals (16 min)
Harry J. De Koning; Rotterdam / Netherlands

1. To understand the characteristics of individuals eligible for current lung cancer screening programmes in Europe.
2. To understand the importance of adapting screening intervals.
3. To discuss the rationale for screening or not screening individuals with no smoking history.

Additional findings in lung cancer screening: balancing burdens and possible benefits (16 min)
Annemiek Snoeckx; Zandhoven / Belgium

1. To understand the difference between individual and population-based screening.
2. To understand the impact of reporting additional findings.
3. To learn about the potential of a "lung and cardiac health check" using low-dose CT.

Training radiologists in lung cancer screening: ESTI perspective (16 min)
Helmut Prosch; Vienna / Austria

1. To learn about the necessity to train radiologists for lung cancer screening.
2. To appreciate the comprehensive approach of the ESTI lung cancer screening certificate.
3. To understand the requirements for training other disciplines along the lung cancer screening pathway.

Panel discussion: Challenges for Europe-wide implementation of lung cancer screening. How to make it accessible, affordable and successful (20 min)

OF 4R - The future of neuroimaging: innovations every radiographer should know

Categories: Neuro, Radiographers, Contrast Media
Date: March 4, 2026 | 13:00 - 14:00 CET
CME Credits: 1

Moderator:
Pica Blackburn Andersen; Kolding / Denmark

Chairperson's introduction (5 min)
Pica Blackburn Andersen; Kolding / Denmark

What's next: emerging clinical needs in neuroimaging (10 min)
Andrea Rossi; Genoa / Italy

1. To identify emerging clinical demands in neuroimaging, evolving diagnostic challenges and patient care priorities.
2. To describe how technological innovations (e.g., AI, techniques, functional imaging) are addressing these new clinical needs.
3. To reflect on the evolving role of radiographers in adapting to future neuroimaging practices, emphasising continuous learning and interdisciplinary collaboration.

Quantitative brain imaging: where are we now? (10 min)
Christos Tsiotsios; Limassol / Cyprus

1. To understand the current landscape of quantitative brain imaging key modalities and measurable biomarkers.
2. To recognise the clinical value of quantitative data in supporting diagnosis, monitoring disease progression, and guiding treatment.
3. To identify the radiographer’s role in acquiring, processing, and imaging data analysis, and how this role is evolving with technology.

Pushing the limits of MRI for brain imaging (10 min)
Andrea Cradock; Dublin / Ireland

1. To understand the latest technological advancements in MRI that enhance brain imaging resolution and capabilities.
2. To identify the emerging neuroimaging techniques and innovations that are shaping the future of brain diagnostics.
3. To recognise the clinical implications and potential impacts of these innovations on patient care and radiographer practice.

Time is brain: technology empowered by expertise in interventional neuroradiology (10 min)
Rogério Mira Lopes; Canedo / Portugal

1. To understand the need for specialised training of radiographers in interventional neuroradiology.
2. To identify innovations in neurointerventional imaging in the angio suite.
3. To apply effective radiation protection measures for patients and staff.

Open forum discussion (15 min)

PA 4 - Generational differences in communicating/receiving news about errors

Categories: General Radiology, Professional Issues, Students, Management/Leadership, Education, President's Choice
ETC Level: LEVEL I+II
Date: March 4, 2026 | 13:00 - 14:30 CET
CME Credits: 1.5

Moderators:
Steve Ebdon-Jackson; Reading / United Kingdom
Ioana Andreea Gheonea; Craiova / Romania

Chairpersons' introduction (5 min)
Steve Ebdon-Jackson; Reading / United Kingdom
Ioana Andreea Gheonea; Craiova / Romania

Tailoring communication: why radiologists must adapt their approach for different age groups (15 min)
Ioana Andreea Gheonea; Craiova / Romania

1. To understand how personal background (such as education, age, sex, and personal situation) influences how people respond to the same information.
2. To understand generational differences in expectations and communication.
3. To learn how to experiment with and implement personalised communication styles.

Considerations when providing information to different generational groups on their imaging procedures (15 min)
Caroline Justich; Vienna / Austria

1. To learn how the perception of healthcare varies among different generations.
2. To appreciate the diverse ways to meet communication needs and how to support them effectively.
3. To understand the significant role AI will play in the future of healthcare.

Patient trust in young radiologists: examining perceptions of credibility (15 min)
Mihai-Alexandru Ene; Craiova / Romania

1. To understand how perceptions of age and experience influence patient trust towards radiologists.
2. To appreciate young radiologists' communication challenges when discussing diagnostic uncertainties or errors with patients.
3. To learn effective strategies that young radiologists can adopt to strengthen credibility and improve patient trust across generational groups.

Considerations when providing information to different generational groups on errors and uncertainties (15 min)
Steve Ebdon-Jackson; Reading / United Kingdom

1. To consider generational differences and their impact on receiving information.
2. To recognise that patients may not fully appreciate the uncertainties associated with radiology.
3. To explore approaches to discussing errors and uncertainties with patients.

Panel discussion: How can we adjust our approaches so that age is not a barrier to good communication? (25 min)

RPS 403 - Inflammation, immunometabolism and cardiac imaging

Categories: Imaging Methods, Research, Cardiac
Date: March 4, 2026 | 13:00 - 14:30 CET
CME Credits: 1.5

Moderator:
Iacopo Carbone; Rome / Italy

The role of cardiac computed tomography and echocardiography in diagnosis of infective endocarditis (6 min)
Ana Čedomir Petkovic; Belgrade / Serbia

Author Block: A. Č. Petkovic, N. Menkovic, O. Petrovic, I. Bilbija, D. Stanisavljevic, S. Putnik, B. Ivanovic, R. Maksimović; Belgrade/RS
Purpose: Infective endocarditis (IE) is rare disease with high mortality rate and rising incidence, requiring timely and precise diagnosis in order to choose appropriate therapy. Imaging of morphologic lesions is integrative part of diagnosis. Artifacts and patient's habitus make echocardiography difficult to visualize advanced-form IE. Cardiac computed tomography (CCT) constantly shows an additive diagnostic value due to high spatial resolution of cardiac anatomy. Joint application of both diagnostic tests improves overall sensitivity and specificity in diagnosing IE.
Methods or Background: Diagnostic study of 83 patients who satisfied category of definite and possible IE, based on modified Duke's criteria 2015, was conducted at University Clinical Center of Serbia, between May 2013 and April 2023. Patients underwent transthoracic echocardiography (TTE), transesophageal echocardiography (TEE), and CCT. We analyzed valvular and paravalvular IE lesions in three imaging methods and compared them to surgical or autopsy findings. We calculated sensitivity, specificity, diagnostic accuracy, and positive and negative predictive value of imaging tests individually and jointly used.
Results or Findings: We examined 78 patients and analyzed 85 valves (70 native, 13 prosthetic, and 2 corrected due to Ozaki procedure, central shunt and 4 pacemaker leads). As single test, sensitivity and specificity of CCT, TTE, and TEE for valvular lesions were 91.6/20%, 65.5/57.9%, and 60/84%, and paravalvular lesions were 100/0%, 46/10.5%, and 14.7/100%. When combined together, sensitivity and specificity for valvular lesions rose to 96.6/0% and paravalvular lesions to 100/0%. We also analyzed the diagnostic performance for each test in single and mutual application, per specific IE lesion.
Conclusion: CCT in comparison to TTE and TEE shows better diagnostic performance in detection of valvular and paravalvular lesions. In joint application, there is a statistically significant difference in performance compared to their single use.
Limitations: Not applicable.
Funding for this study: No funding was provided for this study.

Pericoronary Adipose Tissue Attenuation in Patients with Spontaneous Coronary Artery Dissection According to Emotional or Physical Triggers: Insights from the INSIGHT-SCAD Study (6 min)
Chiara Martini; Parma / Italy

Author Block: C. Martini, M. Covani, F. L. Gurgoglione, M. Della Bella, G. Cicala, L. Vignali, M. De Filippo, G. Niccoli, E. Solinas; Parma/IT
Purpose: To evaluate whether pericoronary adipose tissue (PCAT) attenuation, a marker of vascular inflammation, differs according to the type of trigger (emotional vs. physical) in patients with spontaneous coronary artery dissection (SCAD), and to explore the potential link between emotional stress, vascular inflammation, and SCAD pathophysiology.
Methods or Background: Inflammation may play a pivotal role in predisposing vascular fragility to spontaneous coronary artery dissection (SCAD). PCAT attenuation, derived from coronary computed tomography angiography (CCTA), is a recognized imaging biomarker of coronary inflammation. This analysis, part of the INSIDE-SCAD study, included patients with SCAD who underwent CCTA within 24 hours of the index event and had a clearly identifiable trigger. Patients were stratified by trigger type (emotional vs. physical). PCAT attenuation was measured in culprit and non-culprit vessels.
Results or Findings: Twenty-five SCAD patients were included (mean age 55±11 years; 80% female). Emotional triggers were reported in 17 patients (68%), and physical triggers in 8 (32%). Obesity was more prevalent in patients with physical triggers (62.5% vs. 5.9%, p=0.010), while Type 2 dissections were more frequent in the emotional trigger group (64.7% vs. 25.0%, p=0.040). Patients with emotional triggers exhibited significantly higher PCAT attenuation compared to those with physical triggers in the culprit vessel (−61.6 vs. −70.9 HU, p=0.019), LAD (−59.7 vs. −70.0 HU, p=0.023), and RCA (−66.7 vs. −75.4 HU, p=0.005).
Conclusion: Patients with SCAD showed elevated PCAT attenuation, particularly in cases associated with emotional triggers. These findings suggest that vascular inflammation may represent a predisposing factor for SCAD and that autonomic dysregulation may contribute to this inflammatory state.
Limitations: - Small sample size
- Observational sub-study design
- Selection bias (trigger-defined inclusion)
- Absence of a control group
- Lack of follow-up and outcome data
Funding for this study: Nothing to disclose
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Protocol number of approval by the Ethics Committee of the University Hospital of Parma (AOUPR): 605/2023/OSS/AOUPR SIRER ID 6728

External Validation and CMR Optimization of the 2025 ESC Myocarditis Guideline Risk Stratification Strategy (6 min)

Yining Wang; Beijing / China

Author Block: Y. Wang, M. Lu; Beijing/CN
Purpose: To externally validate the myocarditis risk stratification proposed in the 2025 European Society of Cardiology (ESC) guideline. A further aim was to determine whether cardiovascular magnetic resonance (CMR) parameters, specifically replacing late gadolinium enhancement (LGE) segment count with quantitative LGE extent and adding extracellular volume (ECV), could improve prognostic discrimination. The feasibility of a CMR-only risk stratification approach was also evaluated.
Methods or Background: We retrospectively included 308 patients with CMR-diagnosed acute myocarditis. We compared: (a) the original ESC 2025 three-tier model; (b) Model 1, substituting LGE extent for LGE segment count (threshold ≥9.5%, ROC-derived); (c) Model 2, adding ECV (threshold ≥37.5%) to refine low/intermediate risk; and (d) Model 3, a CMR-only three-tier scheme using ESC-defined LVEF categories together with dichotomized LGE extent and ECV. Risk discrimination was assessed by Kaplan–Meier analysis and Cox regression.
Results or Findings: A total of 55 major adverse cardiac events (17.9%) were observed during a median follow-up of 3.0 years. In the original ESC 2025 model, high-risk patients were effectively identified (HR 7.26, p=0.006), but intermediate vs. low risk was not significant (HR 1.79, p=0.467). In Model 1, both intermediate (HR 4.53, p=0.046) and high-risk groups (HR 16.93, p<0.001) were significantly different from low risk. In Model 2, prognostic separation further improved (intermediate HR 6.55, p=0.013; high HR 20.83, p<0.001). In Model 3 (CMR-only), risk stratification remained robust (intermediate HR 3.92, p=0.002; high HR 14.11, p<0.001). Model 2 achieved the highest C-index (0.787).
Conclusion: While the ESC 2025 scheme reliably identifies high-risk patients with myocarditis, quantitative LGE extent and ECV provide meaningful incremental value for distinguishing low and intermediate risk. A CMR-only stratification is feasible and shows robust prognostic separation.
Limitations: Single-center retrospective design; potential variability in CMR acquisition and analysis.

Evaluation of the Diagnostic Performance of Iodine Maps Derived from a Dual-Layer CT for the Diagnosis of Pericarditis (6 min)

Ludovica Rosa Maria Lanzafame; Messina / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: L. R. M. Lanzafame, D. Masi, G. Ascenti, S. Mazziotti, T. D'Angelo; Messina/IT
Purpose: To evaluate the diagnostic performance of iodine maps generated from dual-layer spectral CT in detecting pericarditis.
Methods or Background: Patients with and without pericardial effusion who underwent coronary computed tomography angiography (CCTA) between February 2023 and December 2024 using a dual-layer spectral CT scanner were retrospectively enrolled. Regions of interest (ROIs) were positioned on the pericardial layers in the iodine maps to quantify iodine concentration (mg/mL). Furthermore, pericardial thickness was measured in both spectral and conventional reconstructions. Pericardial thickness was assessed in both spectral and conventional reconstructions. The diagnostic accuracy of iodine concentration and pericardial thickness in identifying pericarditis was assessed using the European Society of Cardiology (ESC) clinical criteria as reference standard.
Results or Findings: The study included 105 patients. The median iodine concentration in patients with pericarditis was 1.79 mg/mL [IQR:1.11–2.24], significantly higher than in negative patients (0.55 mg/mL [IQR:0.42–0.66]; p<0.0001). On conventional reconstructions pericardial thickness was 3.5 mm [IQR:2.7–4.2] in positive patients and 1.2 mm [IQR:1.15–1.3] in negative patients (p<0.0001). On iodine maps, corresponding values were 2.7 mm [IQR: 2.3–3.7] and 1.2 mm [IQR:1.1–1.3] (p<0.0001). Iodine maps achieved an AUC of 0.99 (95%CI:0.94–0.99), with 93.9% sensitivity (95%CI:79.8–99.3) and 95.8% (95%CI: 88.3–99.1) specificity, for a threshold of iodine concentration >0.82 mg/mL. For a pericardial thickness >1.6 mm, iodine maps showed an AUC of 1.00 (95%CI:0.97–1.00), with 100% sensitivity (95%CI:89.4–100) and 100% specificity (95%CI:95.0–100). Conventional reconstructions demonstrated an AUC of 1.00 (95%CI:0.95–1.00), with 100% sensitivity (95%CI:89.4–100) and 100% specificity (95%CI:90.5–100) in case of pericardial thickness >1.8 mm.
Conclusion: Spectral iodine maps demonstrated excellent diagnostic accuracy in detecting pericarditis based on iodine concentration and pericardial thickness.
Limitations: Retrospective, single-center design with modest sample size, exclusive use of dual-layer spectral CT.
Funding for this study: This research received no external funding.
Has your study been approved by an ethics committee? Yes

Improved Reclassification of In-Stent Restenosis Using Ultra-High-Resolution Photon-Counting Detector-CT: An Intra-Individual Comparative Study (6 min)

Costanza Lisi; Milan / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: C. Lisi[1], F. Catapano[1], S. Figliozzi[1], L. S. Politi[1], A. Laghi[1], M. Francone[2]; [1]Milan/IT, [2]Rome/IT
Purpose: To compare ultra-high-resolution photon-counting CT (UHR-PCD-CT) with energy-integrating detector CT (EID-CT) and standard-resolution PCD-CT for intra-individual evaluation of coronary stent patency.
Methods or Background: This prospective single-center study enrolled 51 patients (mean age, 64.5 ± 9.2 years; 16 women) with 67 coronary stents between November 2024 and April 2025. Patients were randomized to EID-CT plus coronary CT perfusion (n=26; 31 stents) or EID-CT plus UHR-PCD-CT (n=25; 36 stents). Image quality, diagnostic confidence, blooming index, and lumen diameters were compared among EID-CT, standard-resolution (SR) PCD-CT, and UHR-PCD-CT. In-stent restenosis (ISR) was defined as ≥50% stenosis and/or inducible ischemia. Radiation exposure was recorded. Statistical analyses included chi-square, t-test, Mann–Whitney U, and Cohen's κ.
Results or Findings: Subjective image quality rated "excellent" was higher with UHR-PCD-CT (88.9%) vs SR-PCD-CT (45.2%, p<0.001) and EID-CT (22.6%, p<0.001). Internal lumen diameter was significantly larger with UHR-PCD-CT (2.65 ± 0.30 mm) vs SR-PCD-CT (2.40 ± 0.32 mm, p<0.01) and EID-CT (2.13 ± 0.36 mm, p<0.0001). Blooming artifacts decreased from 55.3% (EID-CT) and 42.8% (SR-PCD-CT) to 29.5% with UHR-PCD-CT (p<0.0001). Good/excellent diagnostic confidence (Likert 3–4) was achieved in 94.4% of UHR-PCD-CT stents vs 61.1% (SR-PCD-CT, p<0.001) and 41.9% (EID-CT, p<0.001). All stents <3 mm were assessable with UHR-PCD-CT vs 65% with EID-CT. Radiation dose of UHR-PCD-CT (12.0 ± 2.8 mSv) was comparable to EID-CT plus CTP (11.5 ± 2.5 mSv; p=0.42).
Conclusion: UHR-PCD-CT markedly improves lumen visualization, reduces blooming artifacts, and increases diagnostic confidence in coronary stent evaluation, particularly for stents <3 mm, with radiation exposure comparable to combined EID-CT and CT perfusion.
Limitations: Single-center design and modest sample size. Lack of systematic invasive coronary angiography validation and of long-term clinical outcomes.

Noncalcified Coronary Plaque Burden Mediates the Association of Hepatic Steatosis With Major Adverse Cardiovascular Events: Insights from the PROMISE Trial (6 min)

Jan Michael Brendel; Cambridge / United States

Author Block: J. M. Brendel[1], T. Mayrhofer[1], N. Kerkovits[1], S. Ersözlü[1], M. Kolossvary[2], M. T. Lu[1], M. Ferencik[3], P. Douglas[4], B. Foldyna[1]; [1]Boston, MA/US, [2]Budapest/HU, [3]Portland/US, [4]Durham/US
Purpose: To investigate whether HS is related to plaque volume, plaque burden, and MACE, and whether coronary plaque composition mediates the relationship between HS and MACE.
Methods or Background: Hepatic steatosis (HS) has been linked to major adverse cardiovascular events (MACE) independently of other cardiovascular risk factors and the extent of coronary artery disease. However, the association between HS, advanced plaque measures, and MACE remains unclear.

A central core laboratory analyzed PROMISE participants randomized to the CT arm. HS was assessed on non-contrast CT using standard hepatic and splenic attenuation methods. Coronary CT angiography was used to quantify total, calcified, noncalcified, and low-attenuation plaque volume and burden (% vessel volume). Multivariable regression and mediation analyses assessed relationships between HS, plaque components, and MACE (death, myocardial infarction, unstable angina hospitalization; median follow-up 25 months, IQR: 18–33).
Results or Findings: Among 3,637 patients (60.6±8.2 years, 51.4% female), 25.5% had HS and were slightly younger, more often male, had more cardiovascular risk factors, and a higher MACE rate (4.1% vs. 2.5%), all $p<0.05$. After adjustment for clinical risk factors, HS was associated exclusively with greater noncalcified plaque burden (NCPB, β 1.25%; 95%CI 0.02–2.49; $p=0.047$). HS conferred increased MACE risk independent of atherosclerotic cardiovascular disease risk score, obesity, obstructive stenosis, and NCPB (aHR 1.69; 95%CI, 1.12–2.54; $p=0.012$). NCPB accounted for 11% of the association between HS and MACE.
Conclusion: HS is linked to greater NCPB and to MACE, independent of clinical risk factors and advanced CT plaque measures. HS should be considered when stratifying cardiovascular risk and may inform medical therapy.
Limitations: Median follow-up of just over 2 years limits the ability to assess long-term outcomes.

Application of Ultra-High-Resolution Photon-Counting CT for Coronary Stenosis Assessment in Patients with Severe Coronary Calcification (6 min)

Lichen Ren; Zhengzhou / China

Author Block: L. Ren, Z. Yonggao; Zhengzhou/CN
Purpose: To compare the diagnostic performance of ultra-high-resolution (UHR) and standard-resolution (SR) coronary CT angiography (CCTA) using photon-counting detector CT (PCD-CT) against invasive coronary angiography (ICA) in patients with severe coronary calcification.
Methods or Background: This prospective study was approved by the institutional review board. Consecutive patients with severe coronary calcification (Agatston score ≥300 in a single coronary vessel) referred for ICA were enrolled. All patients underwent PCD-CT CCTA within 3 days prior to ICA. Based on the same raw data, images were reconstructed using UHR (slice thickness 0.2 mm; increment 0.2 mm; Bv72) and SR (slice thickness 0.6 mm; increment 0.4 mm; Bv44). The most severe stenotic segments were measured for lumen diameter and percent diameter stenosis on CT. ICA with quantitative coronary angiography served as the reference standard. Intraclass correlation coefficients (ICC) and mean measurement errors were calculated. Sensitivity and specificity were determined using a ≥50% stenosis threshold.
Results or Findings: Thirty-six patients (mean age 64±8 years, 10 women) with 40 stenoses were analyzed; 27 (68%) had ≥50% stenosis. UHR yielded more accurate measurements than SR. Mean absolute error of DS% was 6% (95% CI: 5–8) with UHR vs 12% (95% CI: 9–16) with SR ($P<0.01$). For MLD, mean error was 0.5 mm vs 1.7 mm, respectively ($P<0.01$). At the ≥50% threshold, sensitivity and specificity were 100% and 90% with UHR vs 75% and 50% with SR ($P<0.05$). Agreement with QCA was superior for UHR (ICC=0.92, 95% CI: 0.86–0.96) compared with SR (ICC=0.78, 95% CI: 0.66–0.87; $P<0.01$).
Conclusion: In patients with severe coronary calcification, UHR-CCTA provided more accurate quantitative assessment and higher diagnostic performance than SR, offering a more reliable basis for clinical decision-making.
Limitations: Small sample

Diagnostic performance of coronary CT angiography to diagnose acute spontaneous coronary artery dissection (6 min)

Lukas Jakob Moser; Zürich / Switzerland

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: L. J. Moser[1], T. T. Demmert[1], K. Klambauer[1], V. Mergen[1], B. Stähli[2], R. Manka[1], M. Eberhard[1], C. Templin[3], H. Alkadhi[1]; [1]Zürich/CH, [2]Zurich/CH, [3]Greifswald/DE
Purpose: The purpose of this study was to evaluate the performance of coronary CTA for the diagnosis of acute SCAD.
Methods or Background: This prospective single-center study included 52 patients with SCAD confirmed by invasive coronary angiography (ICA) and 70 patients with chest pain but without SCAD (control group), who all underwent coronary CTA. Two independent readers evaluated coronary CTA for SCAD, including vessel abnormalities and myocardial hypodensity. Accuracy, sensitivity, and specificity with 95% confidence intervals (CI) were calculated using ICA as the reference standard. Coronary CTA imaging features of SCAD were correlated with diagnostic confidence using multivariable regression analysis. Interreader agreement was determined by Cohen's Kappa.
Results or Findings: Patient-level sensitivity of coronary CTA to diagnose SCAD ranged from 52% (CI:38%-66%)-58% (CI:43%-71%), with a specificity of 97% (CI:90%-100%) and accuracy of 78% (CI:69%-85%) and 80% (CI:72%-87%) for both readers (Kappa=0.891). Sensitivity and accuracy were higher for proximal (sensitivity 67% (CI:38%-88%) and 73% (CI:45%-92%); accuracy 93% (CI:87%-97%) and 94% (CI:89%-98%)) than for distal SCAD (sensitivity 40% (CI:26%-56%) and 49% (CI:34%-64%); accuracy 76% (CI:68%-83%) and 80% (CI:71%-86%)), while specificity was high irrespective of location (97%; CI:91%-99%, resp.100%). Additional myocardial hypodensity increased readers' confidence (beta coefficient -0.38; p=0.11 for reader 1, and beta coefficient of -0.90; p=0.004 for reader 2) and sensitivity (71% (CI:57%-83%) and 65% (CI:51%-78%), respectively), while reducing specificity (both 91%, CI:82%-97%).
Conclusion: Coronary CTA has a poor sensitivity for the diagnosis of SCAD, while specificity is high irrespective of SCAD location. Patients with coronary CTA positive for SCAD might be deferred from ICA after careful consideration and when conservative management is intended.
Limitations: The limitations of the study are as follows: Single center study. Different generations of CT scanners. Not all patients in the control cohort underwent ICA.
Funding for this study: No funding was received for this study.

CMR-derived Left Atrial Strain Provides Incremental Prognostic Value in Kawasaki Disease (6 min)

Ling-yi Wen; Chengdu / China

Author Block: Z. Zhou, L-y. Wen, S. Azhe, L. Hu, Y. Zhu; Chengdu/CN
Purpose: To evaluate the role of CMR-derived Left Atrial (LA) strain in prognostic assessment in patients with Kawasaki disease (KD) and to investigate their incremental value beyond coronary artery lesions and late gadolinium enhancement (LGE).
Methods or Background: The prospective study analyzed 214 KD patients (median age, 5.5 years [IQR, 3.4-7.7 years]; 142 male) who under CMR examination. Clinical composite endpoint events included cardiac death, decreased left ventricular systolic function, cardiac cerebral ischemic syndrome, syncope, readmission for treatment due to chest pain, and malignant arrhythmias. Cox survival analysis was used to assess the association between variables and time to the end points. C index and chi-square value were used to determine the incremental value of LA strain.
Results or Findings: During a median follow-up of 32.1 months (IQR, 20.2–46.3 months), 33 of 214 (15.4%) patients experienced clinical composite endpoint events. Multivariable Cox regression analysis of Model 1 (including coronary thrombosis and LGE positive), revealed that both soronary thrombosis (HR: 3.007; 95% CI: 1.114–8.121; P = 0.03) and LGE positive (HR: 4.104; 95% CI: 1.471–11.453; P = 0.007) were independent predictors for the clinical composite endpoint. Multivariate Cox regression of Model 2 (including Model 1 and εe), showed that εe was independent predictors of the clinical composite endpoint events (HR: 0.972; 95%CI: 0.945–0.999, P=0.042). Compared with Model 1, Model 2 showed a significantly higher chi-square value (57.36 vs. 52.46, P<0.001) and C index (0.73 vs. 0.66, P<0.001).
Conclusion: εe was the independent predictor of clinical composite endpoint events. Moreover, εe provides incremental value to coronary thrombosis and LGE positive in predicting clinical composite endpoint events.
Limitations: The primary limitation of this study is its small single-center sample size.
Funding for this study: This work was supported by the National Natural Science Foundation of China (82471970), Sichuan Science and Technology Program (2024YFFK0258).

Extracardiac Thoracoabdominal Atherosclerotic Plaque Burden in Heart Transplant Candidates is not Associated with Cardiovascular Standard Modifiable Risk Factors (6 min)

Nicola Giannotti; Sydney / Australia

Author Block: T. R. Readford[1], M. Ugander[2], P. Kench[1], G. Figtree[1], J. Nadel[1], N. Giannotti[1]; [1]Sydney/AU, [2]Solna/SE
Purpose: Contemporary strategies for detection and management of atherosclerosis focus on controlling Standard Modifiable Risk Factors (SMuRFs) including diabetes, hypertension, hyperlipidaemia, and smoking. However, it is unclear if extracardiac thoracoabdominal atherosclerotic plaque burden is associated with SMuRFs.

The purpose of this study was to compare extracardiac thoracoabdominal atherosclerotic plaque burden by computed tomography angiography (CTA) between patients with and without SMuRFs among heart transplant candidates with ischaemic or non-ischaemic cardiomyopathy (ICM, NICM).
Methods or Background: This study was a retrospective, single-centre observational study. Heart transplant candidates with ICM or NICM undergoing thoracoabdominal CTA were matched for age and sex. Patients were classified as those with SMuRFs or SMuRF-less based on medical records. Extracardiac thoracoabdominal non-calcified and calcified plaque was classified as present or absent across 80 arterial segments per patient.
Results or Findings: Among included patients (n=167, median [interquartile range] age 58 [53-63] years, 16% female, 51% NICM), 40 patients (24%) were SMuRF-less (ICM: 16/82 (20%), NICM: 24/85 (28%), age 56 [50-67] years). Overall, out of 13,360 arterial segments, 1,746 (13%) were affected by atherosclerotic plaque (9 [4-15] segments per patient). Compared to NICM, ICM had higher total plaque burden (11 [7-18] vs 6 [3-11] segments per patient, $p<0.001$). However, SMuRF-less patients showed no difference in non-calcified, calcified, and total plaque burden compared to patients with SMuRFs among all patients (ICM+NICM) ($p>0.17$ for all), and within the ICM and NICM groups, respectively ($p>0.30$ for all).
Conclusion: The burden of extracardiac thoracoabdominal atherosclerotic plaque does not differ among heart transplant candidates that are SMuRF-less or those with SMuRFs, regardless of underlying ICM or NICM. Prevalence of SMuRFs is not an effective marker to determine the need to screen for extracardiac atherosclerotic plaque among heart transplant candidates.
Limitations: Retrospective observational design.
Funding for this study: No funding was received for this study.

Photon-Counting CT at Radiography Equivalent Dose: Impact on Quantitative Lung Parameters (6 min)
Jonas Kroschke; Zurich / Switzerland

Author Block: J. Kroschke[1], B. J. Kerber[1], O. Von Stackelberg[2], F. Ensle[1], L. Jungblut[1], M. O. Wielpütz[3], T. Frauenfelder[1], H-U. Kauczor[4], O. Weinheimer[4]; [1]Zurich/CH, [2]Mannheim/DE, [3]Greifswald/DE, [4]Heidelberg/DE
Purpose: Photon-counting computed tomography (PCCT) enables dose reductions to levels comparable to chest radiography, which is of clinical interest for applications such as lung cancer screening. However, quantitative CT (QCT) metrics may be altered at ultra-low dose (ULD). This study evaluated the impact of dose reduction on lung QCT.
Methods or Background: In 101 patients (mean age 61.0±12.5 years), non-contrast low-dose (LD-CT, CTDIvol: ~0.64±0.15 mGy) and radiography-comparable ULD-CT (~0.11±0.03 mGy) scans were acquired in the same session on PCCT, with LD-CT as reference. Using YACTA software fully automated QCT analysis was performed on images reconstructed with a soft kernel (Br36u, strength level 3) for lung parenchyma and a hard kernel (Bl64u, strength level 3) for airways. Two expert readers assessed image quality, emphysema, and airway wall features.
Results or Findings: ULD-CT showed a 66.5% increase in noise for Br36u and 63.9% for Bl64u, reflected in lower visual image quality ($p<0.001$, $\kappa=0.59$). Automated airway segmentation decreased (−41.4, $p<0.001$), consistent with fewer visible generations ($p<0.001$, ICC=0.81). Wall percentage remained stable across dose levels, with no significant differences in visually assessed wall thickening (R1 $p=0.89$, R2 $p=0.20$).
At ULD, mean lung density (MLD) was reduced 13.5 HU ($p<0.001$; $r^2=0.93$), leading to a lower 15th percentile (Perc15: −20.2 HU, $p<0.001$; $r^2=0.93$). Applying a sponge model correction for volume differences decreased bias (MLD: −12.5 HU; Perc15: −19.9 HU) and improved correlations ($r^2=0.97$–0.98). Visually, emphysema extent was consistently underestimated at ULD ($p<0.001$, $\kappa=0.92$).
Conclusion: PCCT at radiography-comparable dose alters QCT metrics, particularly lung density and emphysema quantification. While sponge model correction mitigates these effects, both automated and visual emphysema assessments remain biased, highlighting limitations of the conventional −950 HU cut-off at ULD.
Limitations: Single-center, single-vendor study with limited patient numbers. No HR-CT as reference standard.
Funding for this study: No external funding was provided for this study.

Quantitative Assessment of Idiopathic Inflammatory Myopathy-Associated Interstitial Lung Disease Using Photon-Counting CT: Comparison of Standard-Dose and Tin-Filtered Low-Dose Protocols (6 min)
Zhenchen Zhu; Beijing / China

Author Block: Z. Zhu[1], K. Xu[1], L. Nicodeme[2], Q. Wang[1], L. Song[1], Z. Jin[1]; [1]Beijing/CN, [2]Vienna/AT
Purpose: The accurate quantification of interstitial lung disease (ILD) in idiopathic inflammatory myopathies (IIM) is critical for prognosis but is limited by the radiation dose constraints of conventional CT. This study aimed to evaluate the clinical utility of photon-counting CT (PCCT)-derived quantitative parameters for ILD severity assessment in IIM, comparing standard-dose (SD) and tin-filtered low-dose (LD) protocols.
Methods or Background: In this prospective single-center study, outpatients with IIM-ILD underwent consecutive SD (120 kVp) and LD (Sn100 kVp) PCCT scans between September 2023 and November 2024. Images were reconstructed with 1.0-mm slice thickness. Quantitative ILD features were extracted using an EU-MDR–approved deep learning software. Fibrosis extent was defined as the sum of reticulation, honeycombing, and bronchiectasis. Visual scoring was performed for severity classification. Comparisons were analyzed using Bland–Altman and receiver operating characteristic analyses; correlation tests were assessed with Spearman's rank correlation coefficients.
Results or Findings: A total of 48 adults with IIM-ILD (40 females; mean age, 53.88 ± 11.13 years) were included. LD scans achieved a substantial dose reduction (CTDVol, 0.77 vs 5.40 mGy) while maintaining high agreement with SD (net differences <1% for all parameters). Low-dose protocols slightly underestimated fibrotic changes, with a mean net difference of -0.64% (95% LOA: −1.83% to 0.54%), whereas they overestimated the extent of ground-glass opacity, with a mean net difference of 0.98% (95% LOA: −1.27% to 3.24%). The reticulation was strongly correlated with FVC% (rho_max = –0.615, P<0.001) and DLCO% (rho_max = –0.726, P<0.001). The total ILD burden strongly distinguished limited from extensive disease (AUCs, 0.876 to 0.881).
Conclusion: LD protocols markedly reduce radiation exposure without compromising accuracy. PCCT provides a reliable and reproducible quantitative assessment of ILD severity in IIM and has the potential to improve longitudinal monitoring in IIM-ILD.
Limitations: None.
Funding for this study: No funding was provided for this study.

Photon-Counting CT-based Lung Ventilation and Perfusion Metrics: Reference Ranges and Regional Variability in 103 Healthy Subjects (6 min)

Hoen-oh Shin; Hannover / Germany

Author Block: J. Dittrich[1], C. Van den Berg[1], S. Scharm[1], C. M. Schaefer-Prokop[2], S. Dettmer[1], F. Wacker[1], G. H. Pöhler[1], H-o. Shin[1]; [1]Hannover/DE, [2]Amersfoort/NL
Purpose: To establish normative reference ranges for photon-counting CT (PCCT)-derived pulmonary ventilation and perfused blood volume (PBV) in healthy adults, using pulmonary function tests (PFTs) as the clinical reference standard.
Methods or Background: In this prospective, single-centre study (December 2022 - April 2024), 103 healthy adults underwent spirometry-guided inspiratory and expiratory contrast-enhanced PCCT in supine position. Automated lobar segmentation was performed using TotalSegmentator. CT-derived total lung capacity (CT-TLC), residual volume (CT-RV), and vital capacity (CT-VC) were compared with corresponding PFT metrics.
Ventilation (%) was quantified as the relative air-volume change between inspiration and expiration from nonlinearly registered virtual non-contrast images, normalised to inspiratory lung volume. PBV was calculated from inspiratory datasets, normalised to left atrial iodine attenuation, and corrected for lung inflation by fixing mean parenchymal attenuation at -850 Hounsfield Units. Reference ranges were expressed as mean ± standard deviation and 5th-95th percentiles. Associations with sex, age, lung region, and gravitational orientation were statistically analysed.
Results or Findings: The final cohort included 91 participants (mean age, 53±12 years; 49 men). CT-derived lung volumes were lower than corresponding PFT values but strongly correlated (CT-TLC r=0.89; CT-RV r=0.80; CT-VC r=0.82). Mean ventilation was 59.5 ± 8.5% (42.1%-72.5%), normalised mean PBV was 12.4 ± 2.5% (8.8%-16.8%).
PBV was higher in women than men (P=0.03), and both ventilation and PBV declined with age (P<0.001). Regionally, ventilation was higher in lower versus upper lobes (P=0.003), whereas PBV was higher in upper versus lower lobes (P=0.01). Both parameters exhibited a dorsal>ventral gradient (P<0.001).
Conclusion: This study defines normative reference ranges for PCCT-derived lung ventilation and PBV in healthy adults. Both parameters are influenced by demographic and regional factors and demonstrate characteristic gravitational gradients.
Limitations: Single-centre design; no assessment of scan-rescan repeatability.
Funding for this study: Part of the study was funded by DigiStrucMed (Else-Kröner-Foundation).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was approved by the German Federal Office for Radiation Protection (BfS) and by the local ethics committee of Medical School Hannover (number 10077_BO_S_2021 StrSchVO).

Ultra-high-resolution photon-counting CT in the assessment of interstitial lung disease in systemic sclerosis (6 min)

François-joseph FERETZ; Marcq-en-Barœul / France

Author Block: F-j. FERETZ, Y. Gaillandre, A. Hutt, S. Khung, P. Felloni, B. Longere, C. V. Gkizas, J-B. Faivre, F. A. Pontana; Lille/FR
Purpose: To compare the detection and characterization of interstitial lung disease (ILD) elementary lesions in systemic sclerosis using ultra-high-resolution (UHR) photon-counting detector CT (PCCT) versus high-resolution CT (HRCT) from a third-generation dual-source energy-integrating detector CT.
Methods or Background: This retrospective study included 22 patients with systemic sclerosis and ILD (15 women; mean age: 62.8 years), each undergoing both HRCT and PCCT-UHR for follow-up with clinical and functional stability between scans. HRCT parameters: collimation 2×96×0.6 mm; pitch 2; Sn150kV; 150 mAs with automatic modulation; 1 mm slices; 512² matrix; Bl57 kernel; iterative reconstruction (ADMIRE level 4). PCCT-UHR parameters: collimation 2×120×0.2 mm; pitch 2; Sn100kV or Sn140kV depending on body habitus; automatic tube current modulation (IQ level 36); 0.2 mm slices; 1024² matrix; Bl60 kernel; QIR level 4. Image analysis included tracheal noise measurement and qualitative scoring (0-3 scale) of ground-glass opacities, intralobular reticulations, bronchiectasis, bronchiolectasis, and honeycombing on 1 mm slices.
Results or Findings: The mean interval between scans was 33 ± 25 months. Despite higher image noise with PCCT-UHR (67.14 ± 13.18 HU vs 33.63 ± 5.81 HU; $P < 0.0001$), overall image quality was subjectively superior ($P = 0.0348$). PCCT-UHR yielded significantly improved visualization of ground-glass opacities ($P = 0.0003$), intralobular reticulations ($P = 0.0045$), bronchiectasis ($P = 0.0001$), and bronchiolectasis ($P = 0.0002$), with no significant difference for honeycombing ($P = 0.125$). Radiation dose was significantly lower with PCCT-UHR (CTDIvol: 2.35 ± 0.82 mGy; DLP: 77.64 ± 25.38 mGy·cm) compared to HRCT (CTDIvol: 3.35 ± 1.01 mGy; DLP: 116.77 ± 33.45 mGy·cm; $P = 0.0008$).
Conclusion: Ultra-high-resolution PCCT enables more accurate and lower-dose detection of early fibrotic changes in systemic sclerosis-related ILD, potentially improving disease monitoring and therapeutic decision-making.
Limitations: Monocentric retrospective study

A Novel Quadruple-Low Photon-Counting CT Protocol for Lung Cancer Chest Imaging: A Feasibility Study (6 min)

Xiaofei Yang; Zhengzhou / China

Author Block: X. Yang, J. Gao; Zhengzhou/CN
Purpose: To assess the diagnostic quality of chest CT images acquired using a photon-counting detector CT (PCD-CT) with quadruple-lows protocol (low radiation dose, injection rate, volume, and concentration of agent) in patients with lung cancer.
Methods or Background: This prospective study included patients with lung cancer undergoing PCD-CT and those undergoing energy-integrating detector CT (EID-CT)between July and September 2024. Participants, who were matched in terms of age, sex, and body mass index, underwent PCD-CT (quadruple-lows protocol: 2.0 mL/s injection rate, 1.0 mL/kg of 320 mg iodine/mL) and EID-CT(conventional protocol: 3.0 mL/s, 1.2 mL/kg of 350 mg iodine/mL). Radiation doses and renal function were recorded. Two radiologists independently evaluated the subjective image quality and lesion imaging features (lobulation, spiculation, pleural retraction, vacuole, and vessel convergence). The lesion and parenchymal metrics (signal-to-noise ratio[SNR], and contrast-to-noise ratio[CNR]) were assessed via quantitative analysis. Statistical data were compared using t-test and Mann–Whitney U test.
Results or Findings: Among 240 participants (mean age, 61.0±9.6; males, 65%), PCD-CT with the quadruple-lows protocol reduced the radiation dose by 55.1%(effective dose: 3.5±0.9 vs. 7.8±2.0 mSv; $P < 0.001$) while lowering contrast agent injection rate, volume, and concentration by 33.3%, 20.9%, and 8.6%, respectively, and reducing contrast-induced nephropathy(CIN)incidence by 5% compared with EID-CT. PCD-CT also exhibited significantly higher objective SNR and CNR in lung lesions and parenchyma across all scanned phases ($P < 0.001$), with superior subjective image quality scores($P < 0.001$) and increased diagnostic confidence for all lung cancer imaging features($P < 0.05$).
Conclusion: PCD-CT with the quadruple-lows protocol can significantly reduce the radiation dose, contrast agent usage, and CIN incidence while enhancing image quality and diagnostic confidence in lung cancer imaging features.
Limitations: Single-center study included a Chinese population, which may limit the generalizability of the results.

Low-dose photon-counting CT for IM-ILD: Preserving detection of key pulmonary abnormalities with reduced radiation (6 min)

Kepei Xu; Beijing / China

Author Block: K. Xu, Z. Zhu, L. Song; Beijing/CN
Purpose: To evaluate whether low-dose photon-counting CT (PCD-CT) can preserve the detection of key pulmonary abnormalities related to interstitial lung disease (ILD) while reducing radiation exposure, and to explore the incremental value of thinner-slice low-dose images.
Methods or Background: We prospectively enrolled patients with inflammatory myopathy–associated ILD patients(IM-ILD) who underwent same-day standard-dose (SD) PCD-CT and low-dose (LD) PCD-CT between October 2023 and November 2024. Four image series—SD-1.0 mm and LD-1.0 mm/0.4 mm/0.2 mm—were assessed for subjective image quality, noise, and visualization of normal structures using a 5-point Likert scale. Subsequently, two thoracic radiologists further evaluated the presence and confidence of ILD-related findings, including ground-glass opacity with reticulation (GG+R), ground-glass opacity with traction bronchiectasis (GG+B), and honeycombing.
Results or Findings: Fifty patients were included (mean age 53 ± 11 years; 9 males). The mean effective dose was significantly lower for LD vs SD (0.32 ± 0.07 mSv vs 2.25 ± 0.56 mSv; $p < 0.001$). Although SD showed better results than LD in overall image quality and image noise ($p < 0.05$), detection rates for GG+R, GG+B, consolidation, and honeycombing showed no significant differences across the four series, except for GG+B between SD-1 mm and LD-0.2 mm. Reader confidence was also comparable, except for lower confidence in GG+B on LD-0.2 mm. Thinner LD-0.4 mm images provided incremental detection in a small number of cases of GG+B missed on 1 mm images, whereas LD-0.2 mm showed no added benefit.
Conclusion: Low-dose PCD-CT substantially reduced radiation exposure while still providing good capability in detecting ILD-related pulmonary abnormalities compared with standard-dose PCD-CT, with thinner slices offering additional diagnostic value.
Limitations: The sample size was relatively small.

Systemic Sclerosis-Associated Interstitial Lung Disease: A Comparison of Automated Lung Texture Analysis in Photon-Counting-Detector and conventional Energy-Integrating- Detector CT (6 min)

Jasmin Happe; Aarau / Switzerland

Author Block: J. Happe[1], C. Bruni[2], L. Jungblut[1], N. Landini[3], C. Blüthgen[1], A. R. Larici[3], T. Frauenfelder[1], O. Distler[2], J. Kroschke[1]; [1]Zürich/CH, [2]Zurich/CH, [3]Rome/IT
Purpose: To investigate whether the superior image quality of photon-counting detector CT (PCD-CT) facilitates the application of automated lung texture analysis (LTA) for detecting interstitial lung disease (ILD) in systemic sclerosis (SSc) compared to conventional energy-integrating detector CT (EID-CT).
Methods or Background: 186 patients with systemic sclerosis (SSc), who had undergone clinically indicated EID-CT or PCD-CT, were included. Matching was performed based on comparable demographical and rheumatological profiles to ensure comparability. Visual ILD assessment by three expert radiologists served as the reference standard. Image quality was assessed both subjectively using Likert-scales and objectively by measuring signal-to-noise ratios (SNR). Quantitative ILD features and disease extent were extracted using LTA based on the CALIPER algorithm (Imbio). Diagnostic accuracy was evaluated through ROC-AUC analysis.
Results or Findings: LTA-based ILD-assessment showed higher AUC for PCD-CT than EID-CT in detecting ILD (PCD-CT AUC: 0.846 vs. EID-CT AUC: 0.772) and specific ILD features, including groundglass opacities, reticulation, and honeycombing. However, EID-CT showed higher AUCs than PCD-CT in detecting extensive ILD (>20% lung involvement; AUC = 0.978 vs. 0.842). Despite reduced radiation exposure, PCD-CT still delivered comparable SNR alongside improved image quality rating scores.
Conclusion: LTA demonstrated acceptable to excellent AUC values for ILD detection on both, PCD-CT and EID-CT scans, with PCD-CT-based LTA consistently achieving superior AUCs in detecting individual ILD features in systemic sclerosis. Notably, LTA models trained on EIDCT data performed robustly when applied to PCD-CT images. Accordingly, the improved image quality and reduced radiation dose of PCD-CT support its potential for longitudinal ILD monitoring using LTA. Nonetheless, further multicenter validation is necessary to confirm these findings.
Limitations: Post-hoc-analysis with the use of visual assessment by experienced thoracic radiologists as the reference standard for LTA-derived parameters, due to the lack of pathological confirmation.
Funding for this study: No funding was provided for this study.

Photon-Counting Detector CT vs. Energy-Integrating Detector CT for Pulmonary Nodule Diagnosis: A Comparative Evaluation with Radiologist and Automated Detection Software (6 min)

Ming Zhang; Shanghai / China

Author Block: M. Zhang, B. Kun, L. Zhifei, H. K. Zhang, J. Shen, K. Liang; Shanghai/CN
Purpose: To compare the image quality and diagnostic performance of photon-counting detector CT (PCCT) with energy-integrating detector CT (EID-CT) for pulmonary nodule diagnosis by using both radiologist assessment and computer-assisted diagnosis (CAD).
Methods or Background: Thirty-four patients were retrospectively included (EID-CT, n=17; PCCT, n=17). All chest CTs were acquired at 120 kVp with automatic tube current modulation. Both EID-CT and PCCT images were reconstructed using hybrid iterative reconstruction (HIR) with 512×512 and 1024×1024 matrices. A radiologist recorded radiation dose and evaluated image quality using a five-point scale (1=non-diagnostic, 5=excellent). Solid (SN), ground-glass (GGN), and part-solid (PSN) nodules were independently identified by both a radiologist and CAD. Nodule detection performance was evaluated across the four image groups, using a blinded senior radiologist's assessment of all available reconstructions served as the reference standard.
Results or Findings: There were no significant differences in baseline characteristics (gender, age, BMI) or nodule distribution between the groups (P>0.05). The effective radiation dose with PCCT was 70.2% lower than with EID-CT (2.94±0.49 vs. 9.85±1.13mSv; p<0.05). PCCT (HIR, 1024×1024) achieved the highest subjective image quality, significantly outperforming the best-performing EID-CT at the same matrix size (4.82±0.39 vs. 3.88 ± 0.49, p<0.05). For all three nodule types, PCCT outperformed the best-performing EID-CT (HIR, 1024×1024) for both the radiologist and CAD. Radiologist detection rates on PCCT were 88.1%(37/42), 92.3%(12/13), and 100%(2/2) for SN, GGN, and PSN, respectively; CAD on PCCT achieved 100.0% across all subtypes, versus 75.4%(43/57), 77.8%(14/18), and 50.0%(1/2) for the radiologist and 64.9%(37/57), 100.0%(18/18), and 50.0%(1/2) for CAD on EID-CT.
Conclusion: PCCT provides higher spatial resolution and lower radiation dose, as confirmed by both radiologist evaluation and automated detection software, supporting its clinical value for pulmonary nodule detection.
Limitations: Small sample size; limited number of part-solid nodules.

Comparative lung perfusion analysis in chronic thromboembolic pulmonary hypertension with V/Q-SPECT and photon-counting CT (6 min)

Matthias Moeskes; Hannover / Germany

Author Block: M. Moeskes[1], T. Derlin[2], A. M. Hunkemöller[1], C. M. Schaefer-Prokop[3], J. Eckstein[1], B. C. Meyer[1], J. Vogel-Claussen[1], F. Wacker[1], H-o. Shin[1]; [1]Hannover/DE, [2]Bad Oeynhausen/DE, [3]Amersfoort/NL
Purpose: The purpose of this study was to compare quantitative lung perfusion assessment using photon-counting computed tomography (PCCT) with ventilation/perfusion single-photon emission computed tomography (V/Q-SPECT), the current reference standard, in patients with suspected or confirmed chronic thromboembolic pulmonary hypertension (CTEPH).
Methods or Background: This retrospective, single-centre study included twenty-three patients (13 men, ten women; mean age 67.9 ± 10.7 years) who underwent both PCCT and V/Q-SPECT between 01.10.2021 and 31.12.2024. Lobar and whole-lung perfusion were quantified using PCCT-derived perfused blood volume maps and V/Q-SPECT perfusion images. Lung and lobe segmentation was performed with an artificial intelligence-based tool. Perfusion values were normalised (95% confidence interval z-score scaling). Agreement between modalities was analysed with Pearson correlation and Bland–Altman analysis, and perfusion defect volumes were compared across thresholds.
Results or Findings: Whole-lung mean perfusion correlated strongly between PCCT and V/Q-SPECT ($r = 0.72$, $p < 0.05$). Lobar correlations ranged from $r = 0.62$ in the middle lobe to $r = 0.85$ in the left lower lobe. PCCT yielded slightly higher mean perfusion values (0.50 ± 0.04) compared to V/Q-SPECT (0.49 ± 0.09). Bland–Altman analysis showed a bias of +0.015 with limits of agreement from –0.13 to +0.16. Perfusion defect volume correlation was moderate, with whole-lung $r = 0.60$ and lobar $r = 0.49$–0.77. Image quality was affected by venous contrast artefacts in PCCT and respiratory misregistration in V/Q-SPECT.
Conclusion: PCCT-based perfusion imaging demonstrates high concordance with V/Q-SPECT, supporting its potential as a comprehensive single-modality approach for functional and anatomical evaluation of CTEPH.
Limitations: The limitations of the study are its single-centre, retrospective design and the relatively small sample size.
Funding for this study: No funding was received for this study.

Normalized iodine concentrations derived from photon counting computed tomography: Correlation of histopathological features of lung cancer subtypes (6 min)

Marwin-Jonathan Sähn; Minden / Germany

Author Block: M-J. Sähn, E. Topal, J. Ottemöller, R. I. Danebrock, J. Borggrefe, A. S. Surov; Minden/DE
Purpose: Photon counting computed tomography (PCCT) is a novel imaging modality able to measures iodine concentration within tumors. However, correlations between iodine concentration and histopathological features are not well established in lung cancer. This study aims to adress the issue.
Methods or Background: NSCLC (adenocarcinoma, squamous cell carcinoma) cases were evaluated using standardized protocols for measuring normalized iodine concentration (NIC) in PCCT and correlated it with Ki67 proliferation rate, number of tumor cells per unit area („cell count"), tumor proportion score (TPS), combined positive score (CPS), and immune cell (IC) score. SCLC NIC was correlated with Ki67 proliferation rate. All NICs were tested for subtype differences via Wilcoxon test. Interobserver reliability was assessed using intraclass correlation coefficients (ICCs).
Results or Findings: A total of 92 cases (NSCLC n=58, SCLC n=34) were included. The ICCs showed excellent inter-observer consistency for iodine concentration measurements in both NSCLC and small-cell lung cancer (SCLC). Correlation analysis revealed no significant association between iodine concentration and Ki67 proliferation rate, TPS, CPS, IC score or cell count in most tumor subtypes. However, a weak, statistically siginificant positive correlation was found with TPS in adenocarcinoma (0.21, p=0.007). No significant difference in iodine concentration between lung cancer subtypes was observed.
Conclusion: Our study demonstrates excellent interobserver consistency for measuring iodine concentration using PCCT in NSCLC and SCLC. While limited correlation with histopathological features was observed, the results suggest that iodine concentration may be useful to predict TPS in adenocarcinoma.
Limitations: Retrospective study.
Funding for this study: None.

Clinical-Radiomics Nomogram Based on Dual-Energy CT for Differentiating Benign and Malignant Solid Pulmonary Nodules with External Validation (6 min)

Yu Wang; Shanghai / China

Author Block: Y. y. Wang, H. Wu, Y. Wang, X. Yu; Shanghai/CN
Purpose: To investigate the added value of multiparametric dual energy CT (DECT) radiomics integrated with clinical-radiological features for noninvasive differentiation of benign and malignant solid pulmonary nodules (SPNs), with emphasis on external validation and diagnostic performance in sub-centimeter nodules.
Methods or Background: This retrospective study enrolled 441 patients with pathologically confirmed SPNs who underwent preoperative DECT (IQon CT and CT7500, Philips Healthcare), divided into training (n=252), internal test (n=112), and external test (n=77) cohorts. Radiomics features were extracted from conventional and virtual monoenergetic images (40 and 70 keV), and material decomposition images (including iodine density (ID), Z-effective atomic number (Zeff), electron density (ED) maps) in arterial (AP) and venous phases (VP). Logistic regression constructed radiomics models, and combined clinical-radiomics model was visualized as a nomogram. Subgroup analysis was performed by nodule size (≤10 mm vs >10 mm), and diagnostic accuracy was compared with that of two radiologists.
Results or Findings: A total of 441 SPNs (112 benign, 329 malignant) were included. The optimal radiomics model, comprising features from ID in VP and Zeff in both AP and VP, achieved area under the curve (AUC) of 0.835, 0.804, and 0.772 in the training, internal, and external cohorts, respectively. The combined model (age, lobulation, and 10 radiomic features) outperformed the clinical-radiological model in all cohorts (AUC: 0.889 vs 0.816; 0.865 vs 0.795; 0.823 vs 0.742; p<0.05). It maintained strong performance for ≤10 mm and >10 mm nodules, with AUC of 0.875 and 0.888 (internal test) and 1.000 and 0.794 (external test).
Conclusion: A DECT-based multiparametric radiomics model integrated with clinical radiological features enables accurate and noninvasive differentiation between benign and malignant SPNs, including sub-centimeter nodules.
Limitations: Retrospective design may introduce selection bias.

With Great Power Comes Great Optimisation: Photon-Counting CT vs Energy-integrating CT in CT pulmonary angiography (6 min)

Carole Ridge; London / Ireland

Author Block: A. Al-Jabir, C. Ridge, T. R. Semple; London/UK
Purpose: To evaluate radiation dose in CT pulmonary angiography (CTPA) on photon-counting CT (PCCT) versus energy-integrating CT (EID), combining meta-analysis with institutional data stratified by BMI.
Methods or Background: A systematic review of MEDLINE and Embase identified studies reporting dose metrics for PCCT and EID-CT. A random-effect model was used for pooled mean differences.

At our institution, consecutive CTPA data was analysed from a PCCT scanner (NAEOTOM Alpha; n=44) and a dual-source EID scanner (SOMATOM Force; n=565). Dose-length product (DLP) was extracted from diagnostic chest series only, and patients were stratified by WHO body mass index (BMI) categories.
Results or Findings: Meta-analysis review of four institutional series (n = 372) confirmed significantly lower doses with PCCT (pooled mean DLP: 113 vs 156 mGy·cm (SMD: −0.70, 95% CI −1.18 to −0.23, p = 0.004), although highly heterogeneous (I^2 = 82%).

In our institutional experience, both delivered doses within accepted DRLs across BMI groups.
Median DLP was modestly lower with PCCT (110, IQR 45.7) than EID (122, IQR 98.6; p=0.256), with the difference most pronounced in obese patients (156 [IQR 54, n=7] vs 193 [IQR 121.8, n=113]; p=0.054).

Elevated BMI remained the main driver of dose, with both systems showing greater variability at extremes of weight; outliers disproportionately inflated means. Both scanners possess high tube power, enabling excellent image quality but also risking higher exposures at extremes of weight if protocols are not carefully adapted.
Conclusion: Both PCCT and EID systems delivered radiation doses that remained well within acceptable limits across all BMI categories.
PCCT trended toward dose reductions, most evident in obese patients.
However, high BMI continues to challenge dose efficiency; with both systems offering substantial tube power, real-world benefit depends on BMI-adapted protocol optimisation.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study.

The Power of Photon-Counting CT in Pulmonary Sarcoidosis (6 min)

Leandra Piscopo; Civitavecchia / Italy

Author Block: L. Piscopo[1], G. Rea[2], A. G. Fois[1], D. Turilli[1], G. De Paula[1], L. M. Fattacciu[1], E. Solinas[1], S. Masala[1], M. Scaglione[1]; [1]Sassari/IT, [2]Napoli/IT
Purpose: Sarcoidosis is a multisystem granulomatous disease, and the lung is the most commonly affected organ. The aim of this prospective study was to assess the morphological performance of Photon-counting CT (PCCT), with dual reconstruction kernel (HR and soft tissue kernels) in patients with pulmonary sarcoidosis, focusing on its diagnostic accuracy, radiation dose reduction, ultra-high-resolution (UHR) and spectral capabilities.
Methods or Background: Forty consecutive patients with pulmonary sarcoidosis underwent PCCT at our institution. Two chest radiologists blinded the imaging reports and functional data. Detailed evaluation of the granulomatous alterations with HRCT imaging (nodular, ground glass opacity, consolidative reticular, fibrosing) was the object of the radiological evaluation with the further aim of identifying elements of sub-millimetric detail (intercepted excellently by the PCCT) that could increase the diagnostic power. Radiation dose indices (CTDIvol, DLP, effective dose) were compared with standard energy-integrating detector CT (EID-CT).
Results or Findings: PCCT with its iterative algorithm reconstruction and UHR protocols (0.4 mm, with select reconstructions at 0.2 mm), provided a sharper depiction of parenchymal microstructures, interlobular septa, nodules, fibrotic changes, and pleural abnormalities. Compared to EID-CT, PCCT significantly enhanced the diagnostic accuracy with great potential in predictive value, while the radiation dose analysis demonstrated a 30–50% reduction in CTDIvol and effective dose.
Conclusion: PCCT provides significant advantages in granulomatous disorders, particularly in pulmonary sarcoidosis. Its UHR morphological detail, using 0.25 mm isotropic voxels, facilitates clear visualization of tiny micronodules near 0.5 mm and subtle early fibrotic reticulations in order to reduce the radiant load, expand spectral/quantitative potential, and improve its diagnostic accuracy and positive predictive value. Therefore, PCCT could improve the staging, therapy monitoring, and future integration into precision imaging pathways for granulomatosis lung diseases.
Limitations: Lack of standardization for new imaging method technology.
Funding for this study: This research received no external funding
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was conducted according to the guidelines of the Declaration of Helsinki. The local Institutional review board approved the study. The Ethical Committee's approval was obtained (2022030).

High-Resolution Ultra-Low-Dose Photon-Counting CT in Lung Nodule Assessment: Application Value and Comparative Analysis with Standard-Dose EID-CT (6 min)

Xiaoyu Tong; Chengdu / China

Author Block: X. Tong[1], J. Sun[1], J. Zhou[1], Y. Li[2], M. Jiang[3], L. JIE[1], B. Li[3], X. Liang[2]; [1]Chengdu/CN, [2]ShangHai/CN, [3]ShenYang/CN
Purpose: To analyze the image quality and diagnostic performance of high-resolution ultra-low-dose photon-counting CT (PCCT) in evaluating lung nodules with varying sizes and densities, and perform a comparative analysis with standard-dose energy-integrating detector CT (EID-CT). The ultimate goal is to verify the superiority of high-resolution ultra-low-dose PCCT in lung nodule imaging and its potential for clinical application.
Methods or Background: Fifteen spherical nodules, covering five diameters (3 mm, 5 mm, 8 mm, 10 mm, 12 mm) and three density levels (100 HU, -630 HU, -800 HU), were randomly embedded in a commercial lung phantom and scanned. High-resolution low-dose scanning was performed using PCCT (NeuViz P10); while standard-dose scanning was conducted with EID-CT (NeuViz Epoch+). Lung nodules were automatically detected using CAD software and subsequently evaluated in terms of contrast-to-noise ratio (CNR). Differences among scanning protocols were assessed using repeated measures ANOVA.
Results or Findings: The effective dose of PCCT was 0.524 mSv, compared with 2.425 mSv for EID-CT, corresponding to an approximately 78.4% reduction in radiation dose. For data reconstructed at 512 matrix size, PCCT showed higher CNR than EID-CT at both 512 ($t = 4.812$, $p = 0.001$) and 1024 ($t = 4.743$, $p = 0.001$) matrix sizes. Similarly, for data reconstructed at 1024 matrix size, PCCT showed higher CNR than EID-CT at both 512 ($t = 3.691$, $p = 0.006$) and 1024 ($t = 3.166$, $p = 0.013$) matrix sizes.
Conclusion: Despite approach 80% decrease in radiation dose, PCCT remains superior to large-matrix EID-CT when evaluating lung nodules and overall image quality, This finding strongly indicates that PCCT holds great potential as a reliable substitute for standard-dose EID-CT in applications like lung nodule assessment.
Limitations: These findings require further validation across diverse parameter settings and in vivo.
Funding for this study: No funding was received for this study.

Désirée Deandreis; Villejuif / France

Multiplex immunofluorescence and oscillating gradient spin echo (OGSE) identification of different molecular subtypes of brain glioma tumor microenvironment T lymphocyte infiltration (6 min)
Wanjun Hu; Lanzhou / China

Author Block: W. Hu[1], J. Zhang[1], K. Ai[2]; [1]Lanzhou/CN, [2]Xi An/CN
Purpose: To investigate whether OGSE-derived microstructural imaging parameters—including cell diameter, intracellular volume fraction, and extracellular diffusivity—can noninvasively characterize the infiltration status of $CD4^+$ and $CD8^+$ T lymphocytes in brain gliomas, given their critical role in tumor progression, immune response, and patient outcome.
Methods or Background: A total of 350 patients with clinically suspected gliomas were enrolled in this prospective study, and 210 patients were finally enrolled based on postoperative histopathological findings (IDH-Wild: 98; IDH-Mutation: 112), all of whom underwent magnetic resonance OGSE sequences one week prior to the operation and obtained HE staining of tumor tissues and multiple immunofluorescence staining of CD4+ and CD8+ T lymphocytes by multiple immunofluorescence staining; subsequent calculation of quantitative parameters based on the OGSE sequence (cell diameter,Vin, Dex); and analysis of the number of positives, area of positives and subsequent calculation of cell density, cell diameter. Measurement data were analyzed by t-test and Mann-Whitney test with Chi2 for dichotomous/categorical variables.
Results or Findings: The demographic data (age, gender, tumor location) of all patients were not statistically significant. the OGSE quantitative indexes fin□d and Dex were significantly correlated with CD4+ and CD8+ T lymphocyte densities and diameters, with the correlation coefficients of r=0.745, 0.684, and 0.769, respectively, P<0.001. IDH-Wild gliomas with CD4+ and CD8+ T-lymphocyte infiltration were higher than IDH-Mutation, P<0.005.
Conclusion: OGSE microstructural imaging can identify CD4+ and CD8+ T lymphocyte expression in the tumor microenvironment of different molecular subtypes of gliomas, and OGSE quantitative parameters can characterize the infiltration status of CD4+ and CD8+ T lymphocytes.
Limitations: This study is limited by its single-center design and the absence of genomic data to validate the imaging-based assessment of T-cell infiltration. Multicenter studies and integration with molecular analyses are needed to further confirm these findings.
Funding for this study: This study has received funding by the Youth Science and Technology Foundation of Gansu Province (25JRRA623), Gansu Province Clinical Research Center for Functional and Molecular Imaging. Grant (No. 21JR7RA438). Key Project of Gansu Province United Research Foundation (No. 25JRRA1266).

Hybrid PET-MRI for Comprehensive Tumor Characterization: Advancing Precision Oncology (6 min)
Aditya Chauhan; Bangalore / India

Author Block: A. Chauhan; Bangalore/IN
Purpose: To assess the clinical value of hybrid PET-MRI in oncology by integrating molecular and structural imaging for improved tumor characterization, treatment planning, and response assessment.
Methods or Background: Conventional imaging often requires separate PET-CT and MRI examinations, leading to increased radiation exposure, cost, and limited integration of metabolic with anatomical data. Hybrid PET-MRI combines the functional sensitivity of PET with the superior soft-tissue contrast and multiparametric capabilities of MRI. In this study, 60 oncology patients (brain, head & neck, pelvic, and pediatric tumors) underwent hybrid PET-MRI. Parameters analyzed included standardized uptake values (SUVmax, SUVmean), diffusion-weighted imaging (ADC values), and dynamic contrast-enhanced MRI perfusion metrics. Diagnostic accuracy was compared with PET-CT and standalone MRI.
Results or Findings: PET-MRI demonstrated superior lesion delineation in brain and pelvic tumors, with improved tumor-to-background contrast compared to PET-CT. Multiparametric integration allowed differentiation between treatment-induced changes (necrosis, fibrosis) and active disease in 85% of equivocal cases. In pediatric oncology, PET-MRI reduced radiation dose by over 60% compared to PET-CT. Clinicians reported higher confidence in treatment response assessment, particularly in gliomas and cervical cancers.
Conclusion: Hybrid PET-MRI offers comprehensive tumor characterization by uniting molecular, structural, and functional information in a single examination. This modality has the potential to redefine oncology imaging by improving diagnostic accuracy, reducing radiation exposure, and personalizing therapy strategies.
Limitations: High cost, limited availability, and longer acquisition times remain barriers to widespread adoption. Further multicenter trials are required to validate clinical and economic impact.
Funding for this study: Not Applicable

Multicentre Analysis of Focal Bone Uptake on [18F]PSMA-1007 PET/CT in Prostate Cancer – Comparative Effectiveness of PSMA-RADS v2.0 vs bone uptake metastatic probability (BUMP) score (6 min)

James Henry Robert Cairns; Leeds / United Kingdom

Author Block: J. H. R. Cairns[1], S. J. Arain[1], A. Challapalli[2], A. Bahl[2], T. Ali[3], J. Sage[4], R. Frood[1], G. Petrides[3], A. Scarsbrook[1]; [1]Leeds/UK, [2]Bristol/UK, [3]Newcastle/UK, [4]Oxford/UK
Purpose: Prostate-specific membrane antigen (PSMA) PET/CT is widely used in prostate cancer management. Indeterminate bone lesions (IBLs) remain a diagnostic challenge when using [18F]PSMA-1007. The study compared the bone uptake metastatic probability (BUMP) score - a composite model combining imaging and clinical parameters with PSMA Reporting and Data System (PSMA-RADS) Version 2.0 for predicting skeletal metastases in IBLs.
Methods or Background: [18F]PSMA-1007 PET/CT scans from three tertiary cancer centres were retrospectively analysed. Bone lesions with focal PSMA uptake were evaluated. For each lesion SUVmax, CT-derived mean Hounsfield unit and androgen deprivation therapy status were recorded to calculate the BUMP score. Lesional PSMA-RADS scores were determined by experienced radiologists. Ground truth was established using follow-up imaging, prostate specific antigen (PSA) kinetics and multidisciplinary consensus. Receiver operating characteristic (ROC) analysis was used to assess diagnostic performance of both methods.
Results or Findings: In total 136 patients (median age 70.5) with 427 bone lesions were analysed; 58.8% (n=251) of lesions were metastatic. Median SUVmax for malignant lesions was 7.55 (Interquartile range (IQR) 10.3) versus 3.53 (IQR 1.51) for benign lesions. BUMP achieved an area under the ROC curve (AUROC) of 0.81 (95% confidence interval (CI): 0.78 - 0.85) with an optimal threshold at 0.125 yielding an F1 score of 0.77. PSMA-RADS 2 outperformed BUMP with higher sensitivity and specificity (98% and 96%, versus 74% and 75% respectively). In equivocal PSMA-RADS 3 lesions (n=44), BUMP had reduced discriminative power (AUROC 0.61, 95%: CI 0.40-0.79).
Conclusion: BUMP performed well in predicting metastases but underperformed compared to expert PSMA-RADS assessment. In equivocal lesions BUMP offered limited value, highlighting importance of expert interpretation.
Limitations: Retrospective design, limited subgroup power and reliance on clinical rather than histopathological ground truth.
Funding for this study: No specific funding was obtained for this study.

Personalized SUVmean–Based Semiautomatic PSMA PET/CT Segmentation Predicting 12–Month Progression in mCRPC Patients Undergoing [177Lu]Lu–PSMA–617 Therapy (6 min)

Warissara Jutidamrongphan; Hat Yai / Thailand

Author Block: W. Jutidamrongphan[1], J. Hu[1], J. Wang[1], Y. Chen[1], Y. Rakvongthai[2], R. Seifert[1], K. Shi[1], A. Rominger[1], A. Afshar-Oromieh[1]; [1]Bern/CH, [2]Bangkok/TH
Purpose: Appropriate patient selection is crucial for effective [177Lu]Lu–prostate–specific membrane antigen (PSMA) radioligand therapy (RLT) in metastatic castration–resistant prostate cancer (mCRPC). While quantitative tumor burden assessment from PSMA PET/CT is prognostically valuable, its accuracy depends on segmentation methodology. This study compares fixed SUV 4 thresholding (SUV_4) with personalized SUVmean–based segmentation (SUV_MEAN) for predicting 12–month disease progression.
Methods or Background: This single–center study retrospectively analyzed 51 mCRPC patients treated with [177Lu]Lu–PSMA–617. Pre–treatment PSMA PET/CT was performed with [68Ga]Ga–PSMA–11 (n=6) or [18F]F–PSMA–1007 (n=45). Whole–body molecular tumor volume (MTV), total lesion uptake (TLU), and total lesion quotient (TLQ) were derived using both segmentation methods. Progression–free survival (PFS) was assessed with Cox regression; 12–month progression was evaluated using LASSO–penalized multivariable logistic regression.
Results or Findings: Mean age was 70.6 years (range 54–89); median PSA 264 ng/mL (range 1.6–6946); median treatment cycles 4 (range 1–11). At 12 months, 27 patients (53%) progressed. Both high MTV_4 and MTV_MEAN were associated with shorter PFS (HR 2.50 [95% CI 1.30–4.80], p=0.006), as were high TLU_4 and TLU_MEAN (HR 2.02 [1.06–3.85], p=0.032). For 12–month progression prediction, the SUV_MEAN–based model (MTV_MEAN, treatment cycles, baseline PSA) achieved superior performance with AUC 0.923 (95% CI 0.849–0.996) and cross–validated AUC 0.842 (0.691–0.993), with MTV_MEAN as the only significant PET–derived predictor. No SUV_4–derived metrics achieved significance in the final model.
Conclusion: Personalized SUV_MEAN segmentation provides superior prognostic performance compared to fixed SUV_4 thresholding for predicting early progression after [177Lu]Lu–PSMA–617 RLT. By incorporating patient–specific tumor uptake patterns, SUV_MEAN generates more clinically representative and reproducible tumor burden metrics. Validation in larger multicenter cohorts could improve patient selection and provide a standardized foundation for AI–driven prognostic tools.

Multicentre Evaluation of Detection Accuracy of [^{68}Ga] PSMA PET/CT in Prostate Cancer Patients with Rising PSA Levels (6 min)

Palak Wadhwa; Delhi / India

Author Block: F. Binti Yusof[1], P. Mohan[2], T. H. Tan[1], A. Faez Bin Mohamed Ridhwan[1], N. Binti Mohd Shahrom[1], H. Siew Ping[1], N. Yee Lian[1], H. Mahajan[2], P. Wadhwa[2]; [1]Kuala Lampur/MY, [2]Delhi/IN
Purpose: This study aimed to assess the diagnostic value of [^{68}Ga] PSMA PET/CT imaging in patients with rising PSA levels, within the context of prostate cancer evaluation.
Methods or Background: A retrospective, cross-sectional observational study was conducted at a multi-centre level by Sunway medical center, Kuala Lampur, Malaysia and Mahajan Imaging & Labs, Safdarjung Development Area, New Delhi, India following institutional ethics approval. 138 subjects diagnosed with prostate adenocarcinoma were recruited from both the centers, exhibiting a range of PSA levels and Gleason scores between 6 and 9. All the patients underwent scans using the uMI 780 and uMI550 system (United Imaging Healthcare, Shanghai, China).
Results or Findings: Patients were categorized into five PSA subgroups: ≤0.2 ng/mL (4%), 0.2–1 ng/mL (4%), 1–3 ng/mL (5%), 3–10 ng/mL (19%), and >10 ng/mL (68%). PSMA-avid lesions were detected in 127 of the 138 scans (92%), and these were considered positive. Detection rates based on PSA levels were: 87.5%, 75.0%, 70.0%, 96.3%, and 96.4%, respectively. In addition to the prostate bed, PSMA uptake was observed in lymph nodes (32%), bone (28%), liver (2%), and thoracic structures (6%). A statistically significant correlation was found between PSA levels and the maximum standardized uptake value (SUVmax) in prostate bed lesions (p = 0.32).
Conclusion: The findings highlight the efficacy of PSMA PET/CT in detecting prostate cancer lesions across a spectrum of PSA levels and Gleason scores, including low-grade and low-PSA cases. PSMA PET/CT emerges as a sensitive and reliable imaging modality for prostate cancer detection, capable of identifying lesions with high SUVmax even at low PSA concentrations. These results underscore its potential in the early diagnosis of prostate cancer and in guiding therapeutic decision-making.

Quantitative PSMA PET Biomarkers for Predicting Response to ^{177}Lu PSMA Therapy in Prostate Cancer: A Systematic Review and Meta-Analysis (6 min)

Iman Kiani; Tehran / Iran

Author Block: I. Kiani[1], M. A. Siri[1], M. Babaei[1], S. Mohammadzadeh[1], S. Mohammadi[1], J. Calais[2], A. Salavati[2]; [1]Tehran/IR, [2]Los Angeles, CA/US
Purpose: Lutetium-177 radiopharmaceutical therapy targeting prostate-specific membrane antigen (PSMA RPT) (177Lu-PSMA-617) therapy has emerged as a promising targeted radioligand treatment for metastatic castration-resistant prostate cancer (mCRPC). This systematic review and meta-analysis aims to evaluate the predictive value of PSMA PET biomarkers for response to 177Lu-PSMA therapy in mCRPC patients.
Methods or Background: A systematic search was conducted across PubMed, Scopus, Web of Science, and Embase databases to identify studies evaluating quantitative PSMA PET parameters as predictors of response to 177Lu-PSMA therapy. Hazard ratios (HRs) and 95% confidence intervals (CIs) for quantitative PSMA PET parameters were extracted and synthesized using random-effects meta-analysis. Heterogeneity was assessed using I2 statistics, and publication bias was evaluated via funnel plots and Egger's test.
Results or Findings: A total of 23 studies met the inclusion criteria. Among PSMA PET parameters, SUVmean, tumor volume (TV), or total lesion PSMA (TL)emerged as significant predictors of overall survival OS, progression free survival (PFS), and prostate specific antigen (PSA) response. The pooled HR for SUVmean in predicting OS was 0.93 (95% CI: 0.90–0.96, I2=92.8%), while TV showed an HR of 1.37 (95% CI: 1.27–1.47, I2=4.7%), and TL had an HR of 1.04 (95% CI: 1.03–1.05, I2=16.1%). Additionally, SUVmax demonstrated limited predictive value (HR: 0.99; 95% CI: 0.99-1.00, I2=49.3%) .
Conclusion: Our findings indicate that SUVmean, TV, and TL derived from PSMA PET imaging could serve as valuable prognostic biomarkers for predicting response to 177Lu-PSMA therapy. Future studies should aim to integrate PET biomarkers with clinical and biochemical parameters.
Limitations: The high heterogeneity indicates variability in imaging protocols and patient selection across studies. Current data regarding standardized imaging protocols and the effect of the interval between the last therapy cycle and imaging remain insufficient.

Ga-68 PSMA PET–Derived SUVpeak and TLG Predict Early Response After Two Cycles of Lu-177 PSMA I&T (6 min)

Subhash Chand Kheruka; Muscat / Oman

Author Block: S. C. Kheruka, S. Al Rashdi, N. A. Almaymani, A. Al Balushi, A. Jain, N. M. Al Makhmari, H. Al Saidi, T. Al Raii, K. Al Riyami; Muscat/OM
Purpose: This study aims to determine whether quantitative Ga-68 PSMA PET/CT metrics predict early response on the follow-up scan after two cycles of Lu-177 PSMA I&T in men with mCRPC.
Methods or Background: This is a single-centre retrospective study (n=14). Each patient underwent baseline Ga-68 PSMA PET/CT and a follow-up scan after cycle 2 (28 paired scans). Quantification (syngo.via): SUVmax, SUVmean, SUVpeak; metabolic tumour volume (MTV); total lesion glycolysis (TLG=SUVmean×MTV); and intratumoural heterogeneity (SD of SUV). Primary metabolic response: ≥30% reduction in both SUVpeak and TLG (PERCIST-inspired). Secondary: ≥30% MTV reduction and change in SD(SUV). The association between baseline SUVmean and response was tested with Fisher's exact.
Results or Findings: 12/14 (85.7%) achieved the primary response, with large median declines (SUVpeak −63.2%, TLG −69.4%). 8/14 (57.1%) met the ≥30% MTV-reduction threshold (median −41.5%). 10/14 (71.4%) showed SD(SUV) decreases (median −58.9%), indicating less heterogeneity. Baseline SUVmean >7.0 was linked to sustained metabolic response (p=0.02). Two non-responders exhibited stable or increasing values in SUVmean, SUVpeak, and TLG, and they progressed according to RECIST 1.1 criteria. Overall, SUVpeak and TLG were the most sensitive early markers, with MTV and SD (SUV) providing complementary information on tumour burden and texture.
Conclusion: Quantitative Ga-68 PSMA PET metrics—especially SUVpeak, TLG, and baseline SUVmean—serve as practical indicators for predicting and monitoring response after two cycles of Lu-177 PSMA I&T. Embedding a simple reporting rule (baseline SUV mean context plus early ≥30% reductions in SUVpeak and TLG) can support early decision-making and personalise therapy, while MTV and SD (SUV) add volumetric and heterogeneity insights for follow-up assessments.
Limitations: Small, single-centre retrospective cohort; no absorbed-dose modelling or survival endpoints; PERCIST-inspired thresholds rather than strict SULpeak; potential variability in lesion segmentation and reconstruction across scans.
Funding for this study: This research received no external funding. Imaging, radiopharmaceuticals, and data analysis were performed within routine clinical service and departmental resources.

Tailored PET/MRI Protocol and Quantitative Tumour Regression Grading for Assessing Treatment Response in Locally Advanced Rectal Cancer Post-Neoadjuvant Chemoradiotherapy (6 min)

PAWAN GULABRAO SHINKAR; Hyderabad / India

Author Block: P. G. SHINKAR[1], P. Wadhwa[2], C. S. Keerthi[1], L. Somepalli[1], D. Kumar[2], M. Vamsy[1]; [1]Hyderabad/IN, [2]Delhi/IN
Purpose: To evaluate the predictive value of integrated PET/MRI parameters—SUVmax, T2-weighted (T2W) signal, diffusion-weighted imaging (DWI) apparent diffusion coefficient (ADC)—for assessing treatment response in locally advanced rectal cancer (LARC) after neoadjuvant chemoradiotherapy (nCRT), and to propose a PET/MRI-based tumour regression grading system (pmrTRG).
Methods or Background: Fifty LARC patients underwent 18F-FDG PET/MRI before and after nCRT. Post-treatment T2 signal, DWI signal, quantitative biomarkers (SUVmax, ADC), and their percentage changes (ΔSUVmax, ΔADC) were analyzed. Group comparisons, ROC analysis, and logistic regression assessed predictive value. A pmrTRG system was developed based on imaging metrics.
Results or Findings: Pre-treatment SUVmax was higher in non-responders compared to complete responders ($p < 0.05$), while pre-treatment ADC values showed no statistically significant difference between the groups. Post-treatment, complete responders demonstrated markedly lower SUVmax (2.1 ± 0.7 vs. 6.8 ± 2.0; $p < 0.001$) and higher ADC values (1.58 ± 0.18 vs. $1.27 \pm 0.14 \times 10^{-3}$ mm²/s; $p < 0.001$). Both ΔSUVmax and ΔADC were strong predictors of response ($p < 0.001$). Post-treatment SUVmax and ΔSUVmax both achieved AUCs of 0.996, post-treatment ADC 0.891, and ΔADC 0.762, with the combined model providing the highest AUC of 0.998.
Conclusion: A tailored PET/MRI protocol combining functional and anatomical metrics accurately predicts treatment response and enables individualized tumour regression grading in LARC after nCRT.

FDG PET/CT Biomarkers Beyond Deauville: Added Value of Dmax and MTV in Predicting Outcome in Lymphoma (6 min)

Yulduzkhan Dauytova; Almaty / Kazakhstan

Author Block: Y. Dauytova, Z. J. Zholdybay, Z. Zhakenova, Z. M. Amankulov, A. Dyo, L. Aitzhanova, M. S. Telkhazhaeyeva; Almaty/KZ
Purpose: To assess the added prognostic value of MTV and Dmax beyond the Deauville score in predicting progression-free survival (PFS) in lymphoma patients
Methods or Background: 18F-FDG PET/CT is indispensable in the management of lymphoma. While the Deauville 5-point scale remains the cornerstone for response assessment, it often fails to capture the full biological heterogeneity of disease. Novel quantitative biomarkers such as metabolic tumor volume (MTV) and the maximum distance between the two most metabolically active lesions (Dmax) may provide complementary insights into tumor burden and dissemination.
We retrospectively evaluated 120 patients with newly diagnosed Hodgkin and non-Hodgkin lymphoma who underwent baseline and interim ^18F-FDG PET/CT. MTV was derived from semi-automated segmentation, and Dmax was calculated as the Euclidean distance between the most distant FDG-avid lesions. Patients were stratified into high vs. low MTV and Dmax groups. Kaplan–Meier and multivariate Cox analyses were performed with PFS as the primary endpoint.
Results or Findings: Patients with high baseline Dmax (>30 cm) and high MTV had significantly inferior outcomes. The 2-year PFS was 82% in the low-Dmax group versus 48% in the high-Dmax group ($p < 0.01$), and 80% versus 50% for low vs. high MTV ($p < 0.01$). On multivariate analysis, both Dmax and MTV remained independent predictors of PFS beyond interim PET response. The combined model (Deauville + MTV + Dmax) achieved superior risk stratification, identifying a subgroup with poor prognosis despite negative interim PET findings.
Conclusion: MTV and Dmax extend the prognostic power of FDG PET/CT beyond the Deauville scale. Their integration into routine reporting can refine risk stratification and support personalized treatment strategies in lymphoma.
Limitations: N/a

Longitudinal integrated diagnostics in GEP-NET patients undergoing PRRT (6 min)

Christian Alexander Dascalescu; Munich / Germany

Author Block: F. Herr, C. A. Dascalescu, R. Ebner, M. L. Schnitzer, J. Ricke, M. Heimer, M. Brendel, R. Werner, C. C. Cyran; Munich/DE
Purpose: To evaluate the prognostic value of integrated clinical and laboratory biomarkers for longitudinal overall survival (OS) prediction in patients with gastroenteropancreatic neuroendocrine tumors (GEP-NETs) undergoing [177Lu]Lu-DOTA-TATE peptide receptor radionuclide therapy (PRRT).
Methods or Background: In this retrospective single-center study, 178 patients with histologically confirmed, well-differentiated (Grade 1–2) GEP-NETs treated with PRRT between 2012 and 2023 were included. Clinical and laboratory parameters (BMI, CRP, albumin, leukocytes, erythrocytes, hemoglobin, platelets, NSE, CgA) were collected at baseline, follow-up 1 (FU1; after 2 cycles), and follow-up 2 (FU2; after 4 cycles). Optimal cut-offs were determined using maximally selected rank statistics. Univariate and multivariate Cox regression analyses were performed; model performance was assessed by Harrell's concordance index (C-index) and Akaike Information Criterion (AIC). Kaplan–Meier analysis with log-rank testing was applied.
Results or Findings: Median OS across the cohort was 70.1 months after a median follow-up of 60.8 months. At FU1, albumin ≤ 4.1 g/dL and CgA > 299 ng/mL were independent predictors of shorter OS. At FU2, albumin ≤ 4.5 g/dL, NSE > 29.1 ng/mL, and CgA > 179 ng/mL retained independent prognostic value. Models combining these biomarkers showed superior prognostic accuracy (C-index up to 0.77) compared with single-parameter approaches. Kaplan–Meier analyses confirmed significant separation between high- and low-risk groups.
Conclusion: Longitudinal assessment of albumin, NSE, and CgA provides independent and complementary prognostic information in PRRT-treated GEP-NET patients. Integration of these biomarkers into multivariable models improves OS prediction beyond baseline or single-marker assessment, supporting their role in personalized follow-up and treatment planning.
Limitations: Retrospective, single-center design; external validation in multicenter cohorts is required.
Funding for this study: No
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective single-center study was approved by the local ethics committee (approval number 19–027). Due to the retrospective nature, informed consent was waived.

Value of pre-operative 18F-FDG-PET/CT in restaging NSCLC patients after neoadjuvant immunochemotherapy (6 min)

Daria Kifjak; Vienna / Austria

Author Block: D. Kifjak, M. J. Hochmair, A. Korajac, S. Pochepnia, R-I. Milos, A. Hoda, K. Sinn, L. Beer, H. Prosch; Vienna/AT
Purpose: To evaluate the clinical impact of pre-operative 18F-FDG-PET/CT in non-small cell lung cancer (NSCLC) patients who received neoadjuvant immunochemotherapy.
Methods or Background: This retrospective analysis included 68 potentially operable NSCLC patients (39 female, 29 male) who were treated with neoadjuvant immunochemotherapy and underwent subsequent pre-operative 18F-FDG-PET/CT for surgical planning. Histological subtypes included 42 adenocarcinomas and 26 squamous cell carcinomas. Pre-operative 18F-FDG-PET/CT scans after neoadjuvant immunochemotherapy were assessed for new metastatic disease and their influence on treatment decisions. Patient treatment decisions, including surgical resection and reasons for non-operative management, were reviewed.
Results or Findings: Of the 68 patients, 62 underwent surgical resection. Six patients did not undergo surgery. Among these, one patient was found to have new osseous metastases in the pelvis on pre-operative 18F-FDG-PET/CT, that were only detected on the metabolic PET component, which excluded surgery and therefore altered the treatment decision. Five patients did not undergo surgery for reasons unrelated to 18F-FDG-PET/CT findings: one declined surgery, one was excluded by multidisciplinary tumor board decision due to a large primary tumor, one was referred for radiotherapy because of N3 disease, and in two patients surgical resection was technically not feasible. Thus, pre-operative 18F-FDG-PET/CT changed the treatment strategy in only one patient (1.5%).
Conclusion: While the current National Comprehensice Cancer Network (NCCN) guidelines recommend contrast-enhanced CT with optional 18F-FDG-PET/CT for restaging prior to surgery, our results suggest that pre-operative 18F-FDG-PET/CT may not be warranted, raising an ethical dilemma regarding addional costs, radiation exposure and patient burden given its minimal impact on treatment decision-making.
Limitations: This was a retrospective analysis of a relatively small cohort size.
Funding for this study: The financial support by the Austrian Federal Ministry for Digital and Economic Affairs, the National Foundation for Research, Technology and Development and the Christian Doppler Research Association is gratefully acknowledged.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Approved by the institutional ethics committee (EC No: 1521/2015).

Functional Imaging Modalities in Multiple Myeloma: Comparative Diagnostic Performance of Whole-Body MRI, FDG and FCH PET/CT (6 min)

Gürsan Kaya; Ankara / Turkey

Author Block: G. Kaya[1], O. Kodaz[2], A. E. Yıldız[2], S. Akın[2], P. Ozgen Kıratlı[2]; [1]Yozgat/TR, [2]Ankara/TR
Purpose: Recent ESMO-EANM guidelines recognize ^{18}F-FDG-PET/CT and whole-body diffusion-weighted MRI (WB-MRI) as key imaging modalities in multiple myeloma (MM), while ^{18}F-Fluorocholine-(FCH)-PET/CT has emerged as a potentially more sensitive alternative. However, no prior study has directly compared all three modalities in the same cohort. This study aimed to evaluate the diagnostic yield of FCH PET/CT, FDG PET/CT, and WB-MRI in newly diagnosed MM patients and correlate imaging findings with laboratory and histopathological markers.
Methods or Background: This retrospective approved-study included 7 adults with newly diagnosed MM (median age: 63). All underwent WB-MRI, FDG-PET/CT, and FCH-PET/CT within four weeks. PET scans were evaluated using IMPeTUs criteria; WB-MRI was scored semi-quantitatively. Lesion- and patient-based analyses were performed. SUVmax and ADC were recorded for three target lesions per patient.
Results or Findings: FCH-PET/CT and WB-MRI detected disease in all patients(100%), outperforming FDG-PET/CT (positive in 6/7). FCH identified significantly more lesions than FDG or WB-MRI ($p = 0.005$), especially in diffuse marrow involvement. FDG showed better performance in cases with low CD138 expression. Imaging patterns varied markedly, even in similar disease phenotypes. SUVmax and ADC values showed weak correlation ($r < 0.4$). FDG Deauville scores correlated strongly with urinary kappa light chains, while FCH scores correlated with focal WB-MRI lesion counts and lower ADC values. Interestingly, higher β_2-microglobulin levels were inversely associated with FCH scores. WB-MRI findings correlated with urinary lambda light chains and protein levels in patients with focal lesions.
These findings underscore FC- PET/CT's translational potential as a sensitive and widely accessible tool in MM staging.
Conclusion: FCH-PET/CT provided the most extensive disease detection, particularly in diffuse marrow infiltration. The complementary nature of FCH, FDG, and WB-MRI imaging suggests value in combined multimodality approaches.
Limitations: Retrospective nature, small cohort.
Funding for this study: This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

Evaluation of standardized uptake value (SUV) and apparent diffusion coefficient (ADC) as prognostic imaging parameters for primary Ewing Sarcoma in hybrid 18F-FDG-PET/MRI (6 min)

Marcel Alexander Drews; Essen / Germany

Author Block: M. A. Drews, A. Milosevic, S. Zensen, M. Opitz, L. Umutlu, W. Fendler, K. Herrmann, U. Dirksen, B. M. Schaarschmidt; Essen/DE
Purpose: Ewing sarcoma (EwS) is the second most prevalent malignant bone tumour among paediatric and juvenile patients. Due to its highly malignant character, an accurate diagnosis is crucial to determine most suitable treatment and to identify patients with unfavourable courses as early as possible. In this context, hybrid 18F-FDG-PET/MRI combines high-contrast morphological information with functional diffusion imaging and metabolic data which could deliver valuable prognostic information for treatment response and survival prediction. Therefore, we evaluated correlations between ADC and SUV as established parameters for tumour cellularity and metabolic activity and Salzer-Kuntschik scale(SKS) for treatment response as well as overall survival(OS) in this rare entity.
Methods or Background: In a monocentric retrospective study, 39 patients with histopathologically proven EwS who underwent 18F-FDG PET/MRI before therapy start were evaluated(14female, median age 16yrs [IQR:11-23]). A polygonal region of interest was drawn encompassing the entire primary tumour mass on fused PET/MR images to determine SUVmax and SUVmean and copied onto the ADC maps to quantify ADCmean and ADCmin. Dependencies between these parameters and SKS were analysed using Spearman's correlation coefficients and Hazard ratio was used for OS.
Results or Findings: A strong inverse correlation between SUVmax and ADCmean(ρ=-0.709,$p<0.001$) and SUVmean and ADCmean(ρ=-0.689,$p<0.001$) was observed. Furthermore, moderate correlations between SKS and SUVmax(ρ=0.502,p=0.009), SUVmean(ρ=0.389,p=0.049) and ADCmean(ρ=-0.425,p=0.03) were seen as well as correlations between OS and SUVmax(HR:5.324,95%-CI 1.065-26.615,p=0.042) and SUVmean(HR: 5.558,95%-CI 1.114-27.733,p=0.037).
Conclusion: Our study demonstrates a strong correlation between metabolic activity(SUV) and tumour cellularity(ADC) in EwS. SUVmax and SUVmean can further be used as prognostic markers for neoadjuvant treatment response and OS, while ADCmean also correlates inversely with treatment response but does not deliver complementary information.
Limitations: Limitations lie in the retrospective design and small patient number, but which is high for this rare entity.
Funding for this study: Marcel Drews received funding by the Junior Clinical Scientist Program at the University of Essen Medical School to carry out this project.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Approval by the local ethics committee was obtained and the need for informed consent was waived due to the retrospective nature of this study (application number: 24-11729-BO; approval date: 23.02.2024).

RPS 407 - Bladder cancer and ureteral cancer imaging

An artificial intelligence framework based on contrast-enhanced CT for predicting postoperative recurrence risk in non-muscle-invasive bladder cancer: a multicenter study (6 min)
Jialu Wu; Inner Mongolia Autonomous Region / China

Author Block: J. Wu, J. Li, J. Han, R. Liu; Inner Mongolia Autonomous Region/CN
Purpose: To determine whether the deep learning model based on automatic segmentation of CT images can provide a robust prediction of postoperative recurrence for non-muscle-invasive bladder cancer (NMIBC).
Methods or Background: Preoperative CT scans were retrospectively acquired in patients with surgically proven NMIBC at multiple centers from January 2015 to May 2023. Follow-up was extended until May 2025, and cases were categorized as recurrent or nonrecurrent based on
postoperative outcomes. The proposed framework comprised four modules, including a 3D tumor segmentation model by 3D-UNet, a deep learning feature extraction module by Swin Transformer, a clinical-radiological feature screening module, and a fully-connected classification module that combines features from different sources. The predictive performance of the model was evaluated based on discrimination, calibration, and clinical usefulness.
Results or Findings: The training data set was comprised of 310 patients from three centers, and 115 and 72 patients were included in the two external test data sets. The average Dice coefficient of the 3D-UNet automatic segmentation network in the test sets was 0.88 and 0.83. Subsequently, the model's ability to predict the risk of postoperative recurrence was evaluated. The integrated model exhibited excellent performance with AUCs of 0.92 in the training set, 0.85 and 0.88 in the external validation set, along with satisfactory calibration across all cohorts ($P>0.05$). Furthermore, the integrated model significantly outperformed both the clinical-radiological model and deep learning model ($P<0.05$).
Conclusion: The integrated model based on clinical features and deep learning features focusing on NMIBC patients undergoing the transurethral resection of bladder tumor(TURBT), accurately identifies cases at high-risk of postoperative recurrence, which outperformed the clinical-radiological feature model.
Limitations: This is a retrospective study and we only included NMIBC with a pathological diagnosis after TURBT, with some selection bias.
Funding for this study: This work was supported in part by the Key Scientific Research and Development Achievement Transformation Programme of the Department of Science and Technology of the Inner Mongolia Autonomous Region (2025YFSH0050); and partially supported by the Public Hospital Research Joint Fund Programme of Inner Mongolia Medical University (2023GLLH0086, 2024GLLH0013).

Utility of nacVI-RADS for Predicting Pathological Complete Response After Chemoradiotherapy in Muscle-Invasive Bladder Cancer (6 min)
Kenichi Fukui; Adachi-ku Tokyo-to / Japan

Author Block: K. Fukui[1], M. Kobayashi[1], S. Yoshida[1], Y. Arita[2], K. Yamagiwa[1], J. Tsuchiya[1], Y. Fujii[1], U. Tateishi[1]; [1]Tokyo/JP, [2]San Francisco, CA/US
Purpose: Accurate post-treatment imaging evaluation remains a key challenge in muscle-invasive bladder cancer (MIBC), particularly for assessing the effect of chemoradiotherapy (CRT) in the context of bladder-sparing strategies. To pathologically validate CRT response, analysis of a patient cohort who underwent partial or radical cystectomy after CRT is required. This study evaluated the effectiveness of nacVI-RADS on multiparametric MRI for predicting pathological complete response (pCR) after CRT and explored its potential role in standardized post-treatment assessment to guide bladder-preserving management.
Methods or Background: In this single-center retrospective study, 73 patients with non-metastatic MIBC who underwent CRT (40 Gy) followed by cystectomy and had multiparametric MRI both pre-TURBT and post-CRT were included. Two board-certified radiologists with genitourinary subspecialty experience (9 and >10 years), blinded to pathology, independently assigned nacVI-RADS on post-CRT MRI. Diagnostic performance for predicting pCR was assessed using a prespecified threshold of nacVI-RADS <3; inter-reader agreement was quantified with Cohen's κ.
Results or Findings: Median age was 70 years; 30% were female. Clinical stages were T2 55%, T3 43%, and T4 3%. Radical and partial cystectomy were performed in 37% and 63%, respectively. pCR occurred in 67% (49/73). Patients with nacVI-RADS <3 had significantly higher pCR rates than those with ≥3 (reader 1: 81% vs 42%, p=0.002; reader 2: 77% vs 46%, p=0.021). For predicting pCR, sensitivity/specificity of nacVI-RADS <3 were 78%/63% (reader 1) and 80%/50% (reader 2). Inter-reader agreement was almost perfect (κ=0.84).
Conclusion: To our knowledge, this is the first study to validate nacVI-RADS as a reproducible imaging biomarker for pathological response assessment after CRT. These results support its potential role in standardized post-treatment MRI evaluation and in guiding bladder-preserving strategies in MIBC.
Limitations: Retrospective single-center design with a modest cohort and a fixed CRT dose regimen.
Funding for this study: No funding was received for this study.

Optimizing Multi-b-Value DWI Quantitative Parameters for Assessing Detrusor Muscle Invasion and Histological Grade in Bladder Tumors (6 min)

Yunyun Shang; Kunming / China

Author Block: Y. Wu, X. Zhu, Y. Shang, C. Liu, Y. Tong, L. Ai, Z. Xiaolong; Kunming/CN
Purpose: Given bladder tumors' high incidence, malignancy, and invasiveness, traditional VI-RADS scoring, based on morphology, inadequately captures tumor microstructure. This study innovatively evaluates MRI multi-b-value DWI parameters' predictive power for muscular invasion and histological grading in bladder urothelial carcinoma, exploring their synergy with VI-RADS.
Methods or Background: Prospectively, 160 patients with suspected bladder masses underwent conventional MRI and multi-b-value DWI (11 b-values, 0-2000 s/mm²). Among them, 106 pathologically confirmed cases (age 68±11 years, 84.9% male) were analyzed. Using iCareSpinx software, entire lesion volumes were delineated to compute 15 diffusion parameters from six non-Gaussian models (CTRW, DKI, FROC, IVIM, SEM, SE). Statistical tests compared parameter differences between groups with varying muscular invasion and pathological grades. Binary logistic regression constructed combined diagnostic models, and ROC curves with AUC values evaluated diagnostic performance.
Results or Findings: Significant differences were observed in CTRW-ADC, DKI-ADC, IVIM-D slow, SEM-ADC, SM-ADC, SM-Theta, and monoADC for discriminating muscular invasion and pathological grading (all $P < 0.05$). Individually, these parameters showed moderate AUCs (0.704-0.779 for invasion, 0.629-0.712 for grading). VI-RADS alone had AUCs of 0.774 (95% CI: 0.681-0.867) for invasion and 0.720 (95% CI: 0.621-0.818) for grading. Combining parameters with VI-RADS improved AUCs (e.g., 0.870 for invasion with four parameters, outperforming traditional monoADC-VI-RADS combination's 0.845; 0.849 for grading, outperforming 0.765).
Conclusion: MRI multi-b-value DWI quantitative parameters offer clinical value in assessing bladder urothelial tumor invasiveness and grading. While their individual efficacy is limited, their combination with VI-RADS significantly enhances diagnostic performance, providing a more reliable tool.
Limitations: Firstly, the single-center study has a relatively small sample size. Secondly, not delineating smaller or unclear-boundary lesions may omit some. However, volume-based delineation minimizes this bias. Additionally, post-processing times for some models are lengthy, necessitating further optimization to enhance clinical practicality.

VI-RADS quality score: reproducibility validation study (6 min)

Luca De Giacomo; Rome / Italy

Author Block: L. De Giacomo, A. Dehghanpour, A. Borrelli, G. Bincoletto, M. Pecoraro, V. Panebianco; Rome/IT
Purpose: To retrospectively validate the reproducibility of the recently proposed Vesical Imaging Quality Score (VI-RADS QS) for multiparametric magnetic resonance imaging (mpMRI) of the bladder, assessing inter-reader agreement across radiologists with different levels of expertise.
Methods or Background: One hundred consecutive bladder mpMRI examinations acquired at 1.5T and 3T scanners were retrospectively retrieved and anonymized. Three radiologists with varying experience in genitourinary imaging (expert, intermediate, beginner) independently scored each examination according to the VI-RADS QS, which stratifies image quality as inadequate, adequate, or optimal per sequence (T2-weighted, diffusion-weighted, and dynamic contrast-enhanced) and overall. Inter- and intra-reader agreement were measured using Gwet's AC1 statistics.
Results or Findings: Preliminary analyses are expected to show moderate to substantial inter-reader agreement for the overall VI-RADS QS (anticipated Gwet's AC1 ≈ 0.50–0.70), with higher reproducibility among expert readers compared to beginners. Per-sequence agreement is projected to be higher for DWI and DCE compared to T2-weighted imaging, reflecting the key role of these sequences in bladder cancer staging.
Conclusion: This retrospective study on 150 bladder mpMRI examinations will provide the first validation of the VI-RADS Quality Score, demonstrating its reproducibility across readers of varying expertise. Adoption of the VI-RADS QS may facilitate protocol optimization, harmonize reporting across institutions, and strengthen the reliability of bladder MRI in multidisciplinary decision-making.
Limitations: Small sample size; single center retrospective study

Added value of synthetic MRI in refining VI-RADS for predicting muscle-invasive bladder cancer (6 min)

Zihui Zhao; Nanjing / China

Author Block: Z. Zhao, X-G. Peng; Nanjing/CN
Purpose: To evaluate the diagnostic value of synthetic MRI (SyMRI)-derived T1 and T2 values in predicting muscle-invasive bladder cancer (MIBC) and assess the feasibility of integrating them into biparametric MRI VI-RADS (bpVI-RADS).
Methods or Background: This prospective, dual-center study included 36 patients with histologically confirmed urothelial carcinoma who underwent standardized bladder MRI. Two radiologists independently assigned bpVI-RADS scores based on T2WI and DWI, blinded to pathological. Discrepancies were resolved by another senior radiologist. Tumor volumes were manually delineated on SyMRI-derived maps to extract T1 and T2 values. Two modified models (bpVI-RADS+T1 and bpVI-RADS+T2) were developed by adjusting bpVI-RADS scores based on predefined T1 or T2 thresholds. Diagnostic performance was compared among original and modified scoring systems using ROC analysis.
Results or Findings: Thirty-six patients (mean age: 71.25 ± 10.27 years, 22.2% MIBC) were enrolled in this study. MIBC lesions showed significantly lower T1 and T2 values than non–muscle-invasive bladder cancer (NMIBC). Optimal cutoff values for differentiating MIBC from NMIBC were 1370 msec for T1 (sensitivity: 87.5%, specificity: 89.3%) and 113 msec for T2 (sensitivity: 87.5%, specificity: 100%). Among all scoring methods, bpVI-RADS+T2 achieved the highest diagnostic performance at the ≥3 cutoff, with higher specificity (89.3% vs. 67.9%, p=0.031), accuracy (91.7% vs. 75.0%, p=0.031), and AUC (0.993 vs. 0.900, p=0.048) compared to bpVI-RADS. The bpVI-RADS+T1 showed non-significant AUC improvement (0.973 vs. 0.900, P = 0.144).
Conclusion: Incorporating SyMRI-derived T2 values into the bpVI-RADS framework significantly enhances diagnostic performance for predicting MIBC.
Limitations: First, the modest sample size and limited MIBC cases may reduce statistical power and generalizability. Second, inter-center variations in MRI equipment and software could have introduced bias despite high reader consistency. Finally, the modified thresholds were derived from this cohort without external validation, warranting cautious clinical application.

Optimizing VI-RADS: Tumor Contact Length for Precise Bladder Cancer Staging (6 min)

Divyansh Gupta; Jaipur / India

Author Block: D. Gupta, A. Bhandari, N. Gupta; Jaipur/IN
Purpose: To investigate VI-RADS diagnostic performance on multiparametric MRI for predicting detrusor muscle invasion in bladder cancer, with histopathology as gold standard, and evaluate tumor contact length (TCL) as a quantitative biomarker for equivocal cases.
Methods or Background: This prospective cross-sectional study enrolled 70 patients with suspected bladder masses undergoing 3.0T Mp-MRI prior to transurethral resection (June 2023-July 2024). Inclusion criteria: gross hematuria and untreated bladder cancer. Exclusion criteria: prior treatment, MRI contraindications, or elevated creatinine. Imaging protocol included T2-weighted imaging, diffusion-weighted imaging with ADC mapping, and dynamic contrast-enhanced sequences. VI-RADS scoring used standardized algorithms with DWI as dominant sequence. TCL was measured as maximum curvilinear tumor-bladder wall interface on T2-weighted images. Statistical analysis included ROC analysis, Youden index optimization, and multivariate logistic regression.
Results or Findings: The cohort comprised 44 patients (62.9%) with non-muscle-invasive bladder cancer (NMIBC) and 26 patients (37.1%) with muscle-invasive bladder cancer (MIBC). VI-RADS (≥3 threshold) achieved 96.2% sensitivity, 84.7% specificity, 89.7% accuracy, and 95.5% negative predictive value. Diffusion-weighted imaging showed superior individual sequence performance (92.5% sensitivity, 88.1% specificity). TCL (≥3.2cm threshold) demonstrated 96.2% sensitivity, 94.6% specificity, and 98.6% accuracy. Within challenging VI-RADS 2-3 intermediate cases (n=36), TCL integration achieved 89% sensitivity, 95% specificity, and 94% accuracy. Multivariate analysis confirmed VI-RADS ≥3 (OR 4.2, $p<0.05$) and TCL (OR 8.7, $p<0.01$) as independent predictors.
Conclusion: VI-RADS provides highly accurate bladder cancer staging. TCL integration transforms equivocal intermediate-risk lesions into definitive clinical decisions, fundamentally improving patient management using standard imaging protocols.
Limitations: single-center design, moderate sample size, predominance of urothelial carcinoma, and dependence on TURBT reference standard with inherent sampling variability.
Funding for this study: The authors received no specific funding for this work

Dual-layer detector spectral CT parameters for differentiating low-grade and high-grade bladder urothelial cancer and predicting muscular invasion (6 min)

Jian Lv; Guilin / China

Author Block: J. Lv[1], R. X. Mu[1], X. Li[1], W. Zheng[1], P. Yang[1], X. Liu[2], X. Qin[1], X. Zhu[3]; [1]Guilin/CN, [2]Guangzhou/CN, [3]Baise/CN
Purpose: To evaluate the diagnostic efficacy of dual-layer detector spectral CT (DLCT) in distinguishing low-grade (LG) from high-grade (HG) bladder urothelial cancer and in predicting muscular invasion (MI).
Methods or Background: A total of 116 patients (74 HG, 42 LG) who underwent preoperative DLCT scan were retrospectively included. Quantitative parameters included iodine density (ID) and extracellular volume (ECV) fractions in the arterial (AECV), venous (VECV), and equilibrium (EECV) phases were calculated. ECV was calculated as (1–hematocrit) × (lesion iodine concentration / blood pool iodine concentration). Univariate and multivariate regression analysis were performed to construct the combined diagnostic mode for predicting bladder cancer grading, as well as MI versus non muscular invasion (NMI) within HG and LG tumors, respectively. ROC analysis was used to assess diagnostic performance.
Results or Findings: V-ID, AECV, VECV, and EECV significantly differentiated HG from LG tumors, with AUCs of 0.801, 0.727, 0.770, and 0.833, respectively. Tumor calcification was identified as a risk factor, achieving an AUC of 0.638. The combined diagnostic model significantly improved the discriminative performance for HG versus LG bladder cancer, yielding an AUC of 0.891 (sensitivity 0.905, specificity 0.833). For predicting MI within HG tumors, heterogeneous muscular enhancement (HME) at VMI 40 keV, VECV and EECV served as predictors, with AUCs of 0.733, 0.692, and 0.714, respectively. The combined model for MI prediction achieved an AUC of 0.788 (sensitivity=0.800, specificity=0.708) within HG tumors. No spectral parameters demonstrated statistically significant difference in predicting MI within the LG subgroup.
Conclusion: DLCT-derived parameters, particularly ECV, allow reliable differentiation between low- and high-grade bladder urothelial carcinoma and provide valuable prediction of muscular invasion in HG tumors.

Diagnostic performance of Intravoxel Incoherent Motion MRI In Diagnosis and Assessment of Invasiveness of Urothelial Bladder Carcinoma (6 min)

Mona Shawky Korkor; Mansoura / Egypt

Author Block: M. S. Korkor; Mansoura/EG
Purpose: The aim of the current study is to evaluate the role of intravoxel incoherent motion (IVIM) MRI and apparent diffusion coefficient (ADC) map in differentiating muscle invasive from non-muscle invasive bladder carcinomas.
Methods or Background: Urinary bladder cancer is a common malignancy. Preoperative accurate judgement of the degree of tissue invasion is crucial to determine the plan of therapy. The current study included 83 patients with bladder cancer. We included patients with clinical and ultrasonographical suspicion of bladder cancer. Patients with contraindications to MRI study as those with cardiac pacemaker, metallic implants or those received neoadjuvant chemotherapy were excluded. All patients were prepared and examined in the supine position using 3-Tesla MRI machine. The protocol included 3 main sequences: high resolution T2WI and DWI with post processing ADC map (b value = 1000). Additional IVIM sequences were performed with axial multiple b values DWI (b values = 0, 10, 25, 50, 75, 100, 150, 200, 400, 600, 800, 1000, 1400 s/mm2).
Regarding IVIM parameters: the D, D* and F were measured and assessed for the mass and wall beside mass. In addition, the ADC values of mass and wall beside mass were analyzed. All values were correlated to the histopathological findings.
Results or Findings: Values of both D (true diffusion coefficient) and ADC were lower in muscle invasive carcinomas than non-invasive masses with p values < 0.001 and 0.001, respectively.
Conclusion: IVIM MRI parameters and ADC map can be utilized to detect the degree of tissue invasion by bladder cancer.
Limitations: • Being a single center study.
• The analyzed parameters are obtained from single region of interest (ROI) that may not fully reflect the information of the whole tumor.
Funding for this study: No funding.

INcidence of malignant ureteric obStruction In patienTs with non-organ confined abdominopElvic malignancy (INSITE MUO) a multi-centre observational study (6 min)

Oliver Llewellyn; Edinburgh / United Kingdom

Author Block: O. Llewellyn[1], J. Blackmur[1], J. Aning[2], N. Shaida[3], M. Bagkeris[4], T. Barrett[3], A. Laird[1], .. BAUS Oncology[1], .. UNITE Collaborative[1]; [1]Edinburgh/UK, [2]Bristol/UK, [3]Cambridge/UK, [4]London/UK
Purpose: Interventional radiologists and Urologists commonly encounter malignant ureteric obstruction (MUO). Capturing this patient population is challenging due to the pan-cancer aetiology. The aim of this study was to estimate the incidence of MUO in advanced abdominopelvic cancer and provide groundwork for further prospective work.
Methods or Background: National multicentre observational research study using national Interventional Radiology and Urology stakeholder networks (UNITE & BAUS). 24 sites contributed HRA approved, RCR funded study. Study teams contained at least one post-FRCR Trainee/Consultant.
Cases of advanced cancer involving the abdomen and cases of MUO were identified by trainees filtering reports. To do this, a standardised list of CT examination protocols involving the abdomen/pelvis over a 4 week study period was acquired at each site. Pseudonymised data was collected centrally from sites using the REDCap platform.
Results or Findings: 6781 abdominopelvic malignancy cases were identified. 2972 cancers were classified as advanced. 1387 cases missing TNM data were excluded from this interim analysis. The incidence of MUO in advanced cancer was 5.2% and the prevalence of was 9.8%. Survival analysis (Kaplan-Meier) indicated a protective influence of intervention (nephrostomy or stent) on overall survival in MUO in advanced cancer, p = 0.049. Intra-abdominal involvement from cancers originating outside the abdomen represented the largest proportion of the advanced intra-abdominal cancers (22.7%). The most common cause for MUO was prostate cancer (18.1%).
Conclusion: The incidence of MUO in patients with advanced abdominopelvic cancer was 5.2% and the prevalence of was 9.8%. Intervention (nephrostomy or ureteric stent) in MUO in advanced cancer appears to have a protective effect on overall survival.
Limitations: Observational study methodology

Preliminary evaluation of 5T MRI for bladder imaging: feasibility and image quality (6 min)

Zihui Zhao; Nanjing / China

Author Block: Z. Zhao, X-G. Peng; Nanjing/CN
Purpose: To evaluate the feasibility and image quality of ultra-high-field 5T MRI for bladder imaging.
Methods or Background: This prospective study included 6 healthy volunteers undergoing 5T MRI and 7 bladder cancer patients undergoing 3T MRI between June and July 2025, with one patient scanned at both field strengths, yielding 14 bladder MRI datasets. Imaging sequences included T1-weighted, T2-weighted, and diffusion-weighted imaging (DWI). All participants drank 300–500 mL of water 40 minutes before scanning or voided 1–2 hours beforehand, with intravenous spasmolytic administered 15 minutes prior. Three experienced radiologists independently evaluated T2WI and DWI sequences using a 5-point Likert scale for bladder distension, artifacts, tumor–bladder wall interface clarity (or bladder wall clarity in volunteers), and overall image quality (a weighted composite score of the above metrics, on a 5-point scale). 5T images were compared with 3T images.
Results or Findings: Among 5T scans, 6/7 (85.7%) achieved optimal bladder distension, 1/7 (14.3%) showed notable artifacts, and all 7 (100%) exhibited clear bladder wall or tumor–bladder wall interface details. Notably, two volunteers prepared via waiting 1–2 hours after voiding showed almost no artifacts. Compared with 3T MRI, 5T MRI demonstrated marginally superior overall image quality (4.4±0.6 vs. 3.7±0.7, p=0.065), with better bladder distension, clearer bladder wall details, and fewer artifacts, although differences did not reach statistical significance ($p > 0.05$). Visual assessment in one patient scanned on both field strengths confirmed better image quality at 5T.
Conclusion: Ultra-high-field 5T MRI shows excellent feasibility for bladder imaging, with trends toward improved anatomic delineation and artifact reduction over 3T.
Limitations: The study is limited by a small, unevenly distributed sample, and most results were not statistically significant. Larger prospective studies are needed to confirm the clinical value of 5T bladder MRI.
Funding for this study: This study has received funding by National Natural Science Foundation of China (82272064), Jiangsu Provincial Science and Technique Program (BK20221461), Zhongda Hospital Affiliated to Southeast University, Jiangsu Province High-Level Hospital Pairing Assistance Construction (zdlyg08), Postgraduate Research & Practice Innovation Program of Jiangsu Province (KYCX23_0323 and KYCX22_0297).

MRI-based Intratumoral Heterogeneity Quantification Accessing Early Neoadjuvant Treatment Response in Bladder Cancer (6 min)

Lingmin Kong; Guangzhou / China

Author Block: L. Kong, Y. Qin, H. Wang; Guangzhou/CN
Purpose: To develop a quantitative measure of Intratumoral Heterogeneity (ITH) on pretreatment MRI scans and test its performance for predicting pathologic complete response (pCR) after neoadjuvant treatment (NAT) in bladder cancer (BCa)
Methods or Background: Pretreatment MRI scans, including contrast-enhanced (CE) and non-contrast-enhanced (NE) T1-weighted images (WI), were retrospectively acquired in patients with BCa who received NAT followed by surgery from April 2020 and August 2024. Tumor regions on MRI scans were clustered and integrated with global pixel distribution patterns to calculate ITH scores. Multivariable logistic regression analysis was used to identify variables associated with pCR, and significant variables, including clinicopathologic variables and ITH index, were combined into a predictive model for which performance was assessed using the area under the receiver operating characteristic curve (AUC).
Results or Findings: Among the 74 patients, the median age was 64 years (IQR: 57, 71); with 61 (82%) being male. Forty patients (54%) achieved pCR. The combined model showed good performance for predicting pCR to NAT in the training data set (AUC, 0.976) and test data sets (AUC, 0.875).
Conclusion: ITH analysis on pre-therapeutic CE- and NE-MRI demonstrated promising predictive ability for NAT responsiveness prior to treatment initiation.
Limitations: All patients in this study were recruited from single center, which need a further verification of the generalizability of the findings. Second, in this study, the use of manual tumor delineation was time consuming and also could affect the stability and repeatability of radiomic features. In future, it is imperative to employ an automated tumor segmentation method.
Funding for this study: This study received funding from the following sources: National Natural Science Foundation of China (Nos. 82372075, 82371911), Natural Science Outstanding Youth Fund Project of Guangdong province, China (No. 2024B1515020061)

The role of multiparametric MRI and VIRADS in the preoperative differentiation of Ta and T1 bladder cancer (6 min)

Merve Nur Tasdemir; Giresun / Turkey

Author Block: M. N. Tasdemir, U. Eryürük, S. Aslan; Giresun/TR
Purpose: To assess multiparametric MRI's utility, using VI-RADS and quantitative metrics – ADC, Tumor Contact Lenght (TCL) – , for distinguishing Ta from T1 stage non-muscle-invasive bladder cancer (NMIBC).
Methods or Background: This retrospective study enrolled patients with histopathologically confirmed NMIBC (2021–2025) who underwent mpMRI. Index tumors were evaluated using mp-VIRADS, and ADC values and TCL were measured. ROC analysis determined optimal cut-offs for ADC and TCL. The Mann-Whitney U and chi-square tests compared continuous variables and VI-RADS associations, respectively.
Results or Findings: Among 157 patients (83 Ta, 74 T1), T1 tumors exhibited significantly lower mean tumor ADC (1136 vs. 1326 $x10^{-3}$ mm^2/s) and mean normalized ADC (0.47 vs. 0.55), and higher mean TCL (30.4 vs. 14.0 mm, all $p<0.001$). ROC analysis for Ta-T1 discrimination yielded AUCs of 0.72 for tumor ADC (cut-off: 1216, sensitivity 79%, specificity 74%), 0.72 for normalized ADC (cut-off: 0.51, sensitivity 79%, specificity 68%), and 0.75 for TCL (cut-off: 17 mm, sensitivity 66%, specificity 79%), identifying TCL as the strongest discriminator. T1 stage tumors were significantly more frequent with higher mpVIRADS scores, with a prevalence of 22.2% (6/27) for score 1, 46.7% (42/90) for score 2, 52.4% (11/21) for score 3, 66.7% (6/9) for score 4, and 90.0% (9/10) for score 5 ($p < 0.001$).
Conclusion: MpMRI effectively differentiates Ta from T1 NMIBC. Both VI-RADS system and quantitative assessments are valuable, with TCL being the most potent discriminator. These findings underscore mpMRI's pivotal role in preoperative planning.
Limitations: This was a retrospective study.
Funding for this study: None.

Decoding seizure recurrence post epilepsy surgery: Insights from pre- and post-operative MRI and advanced imaging (6 min)
Tom Mishael; Vellore / India

Author Block: T. Mishael, A. Jasper, H. A. Vanjare, B. T S, J. H. Prasad D; Vellore/IN
Purpose: To determine the role of pre- and post-operative MRI, including advanced imaging techniques, in predicting seizure recurrence after epilepsy surgery, and to identify imaging biomarkers that correlate with long-term outcomes.
Methods or Background: We retrospectively reviewed 102 patients who underwent temporal or extra-temporal epilepsy surgery with ≥12 months follow-up. Pre-operative imaging included 3T MRI (3D T1, FLAIR, T2, DTI), arterial spin labelling (ASL) perfusion, MR spectroscopy (MRS), and fMRI in selected cases. Post-operative MRI was obtained at early (≤72 h) and/or delayed (3–12 mo) intervals. Imaging features—extent of resection (EOR), residual lesions, gliosis, hippocampal remnants, tract integrity, perfusion asymmetry, and functional connectivity—were correlated with Engel/ILAE outcomes using Cox regression and Kaplan–Meier analysis.
Results or Findings: At 24 months, 38% (39/102) experienced seizure recurrence.
Post-operative predictors: Incomplete resection (24%) predicted recurrence (HR 2.4, p=0.006). Residual hippocampal tail remnants (31%) increased risk (HR 1.9, p=0.02). Gliosis was frequent (63%) but non-specific.
Pre-operative predictors: ASL hypoperfusion (HR 2.1, p=0.01), reduced NAA/Cr on MRS (OR 2.7, p=0.03), and reduced hippocampal–default mode connectivity on fMRI (p=0.04) were associated with recurrence.
A Composite Imaging Score (CIS) stratified patients into risk groups with distinct seizure freedom rates: 78% (low risk), 54% (intermediate), 29% (high) (log-rank p<0.001).
Among patients undergoing re-surgery, 58% achieved Engel I–II outcomes.
Conclusion: Integrating pre- and post-operative MRI with advanced imaging improves prediction of seizure recurrence. A composite imaging framework offers a practical tool for risk stratification and personalised follow-up.
Limitations: Single-center design, incomplete availability of advanced imaging for all patients, and variable surgical techniques may limit generalizability. Prospective multi-center validation is warranted.
Funding for this study: This study did not receive any grant or external funding.

Decoupled Temporal BOLD-CSF Signaling and Free Water Elevation Predict Cognitive Impairment in Temporal Lobe Epilepsy: A Multimodal NODDI-fMRI Study (6 min)
Xiaona Xia; Qingdao / China

Author Block: X. Xia[1], Q. Ren[1], X. Meng[1], K. Xue[2], F. Long[2]; [1]Qingdao/CN, [2]Shanghai/CN
Purpose: To evaluate glymphatic system (GS) functional alterations using global and temporal BOLD-CSF couplings, and to assess microstructural alterations via NODDI parameters, in patients with temporal lobe epilepsy (TLE). We further evaluated their associations with cognition and predictive value for mild cognitive impairment (MCI).
Methods or Background: From January 2024 to May 2025, 71 TLE patients (19 Drug-resistant epilepsy (DRE) ,52 non-DRE) and 49 age- and sex-matched healthy controls (HCs) underwent 5T MRI, including resting-state fMRI and NODDI. BOLD-CSF couplings (gBOLD-CSF and tBOLD-CSF) were computed to assess GS dynamics, while NODDI metrics (global/temporal isotropic volume fraction [isovf], intracellular volume fraction [icvf], and orientation dispersion [od]) quantified microstructural changes. Montreal Cognitive Assessment (MoCA) scores assessed cognition. Partial Spearman's correlations examined associations between metrics and MoCA, adjusting for confounders. Forward stepwise logistic regression developed a model to predict MCI, with receiver operating characteristic (ROC) analysis evaluating performance.
Results or Findings: TLE patients showed lower MoCA scores (p=0.014), reduced global isovf (p<0.001), and elevated global icvf (p=0.016) and od (p<0.001) versus HCs. Post-hoc analyses revealed DRE subgroup exhibited decreased tBOLD-CSF coupling and T_icvf, with increased T_isovf, compared to non-DRE subgroup, (all adjusted p<0.05)(Fig.1). MoCA positively correlated with gBOLD-CSF (r=0.474) and tBOLD-CSF (r=0.436; both FDR-p<0.001) in TLE patients (Fig.2). The combined model (tBOLD-CSF, T_isovf, epilepsy duration) predicted MCI with AUC=0.891 (sensitivity=95.0%, specificity=72.0%), outperformingtBOLD -CSF coupling (p<0.05) (Fig.3).
Conclusion: BOLD-CSF decoupling and NODDI alterations reflect GS dysfunction and microstructural damage in TLE, serving as potential biomarkers for early cognitive decline detection and MCI prediction.
Limitations: The single-center design and potential influence of antiepileptic drug may bias the GS assessments.

Ethics committee - additional information: The study involving human subjects received approval from the Ethics Committee of Qilu Hospital of Shandong University (KYLL-qdql2020070).

Sub-voxel quantitative susceptibility mapping for assessing whole-brain magnetic susceptibility in temporal lobe epilepsy: A preliminary study (6 min)

Zihuan Huang; Guangzhou / China

Author Block: Z. Huang, Y. Li, N. Zhu, L. Mazu, J. Chu; Guangzhou/CN
Purpose: This study aims to use the recently proposed sub-voxel QSM, namely APART-QSM, to simultaneously quantify the paramagnetic and diamagnetic susceptibility sources in temporal lobe epilepsy (TLE).
Methods or Background: In this retrospective analysis, a total of 52 healthy subjects (HCs) and 68 patients with TLE were recruited. According to the ILAE 2020 definition, the patients were divided into 30 non-refractory, 31 refractory TLE and 7 patients were lost to follow-up. APART-QSM could distinguish the paramagnetic susceptibility map (Xpara) and diamagnetic susceptibility map (Xdia).
Results or Findings: In the voxel-wise analysis, compared with HCs, TLE patients exhibited deceased Xpara and increased Xdia in a large scale of brain regions. Remarkably, refractory TLE demonstrated significantly decreased Xpara and increased Xdia in both thalamus relative to non-refractory TLE. Decreased Xdia was found in the left supramarginal gyrus in refractory TLE patients compared to non-refractory cohorts (all FDR-q < 0.05 & cluster extent > 100 voxels). No significant differences were observed in disease duration between patient groups. The log-transformed seizure frequency is higher in refractory TLE than that in non-refractory patients (ln [seizure frequency] 0.31 ± 0.34 vs 0.80 ± 0.67, P = 0.001). In the patient cohorts, the disease duration was negatively correlated with Xpara in the left thalamus (r = -0.284, P = 0.026), right thalamus (r = -0.367, P = 0.004) and positive with Xdia in the right thalamus (r = 0.395, P = 0.002). The log-transformed seizure frequency is negatively correlated with Xdia in the left supramarginal gyrus (r = -0.258, P = 0.045).
Conclusion: The sub-voxel QSM offers significant insights into the magnetic susceptibility perturbation of the whole brain in TLE patients.
Limitations: This work is lacking of pathological evidence.

Cortical Structural Parameters and Cognitive Performance in Juvenile Myoclonic Epilepsy: A Surface-Based Morphometry Study (6 min)

Osman Aykan Kargin; Istanbul / Turkey

Author Block: O. A. Kargin, R. Ozun Kargin, A. Ceyhan Dirican, H. D. Atakli; Istanbul/TR
Purpose: Juvenile myoclonic epilepsy (JME) is the most prevalent idiopathic generalized epilepsy syndrome, with a typical onset at adolescence. Beyond seizures, JME has increasingly been recognized as a condition involving widespread cognitive dysfunction, particularly affecting memory, executive functions, and attention. This study aimed to investigate cortical structural alterations in JME using surface-based morphometry and to explore their relationship with cognitive performance, with the goal of identifying potential imaging biomarkers.
Methods or Background: Fifty-five patients with JME and 65 healthy controls matched for age, sex, and educational status underwent high-resolution 3D T1-weighted brain MRI. Cortical thickness, sulcal depth, gyrification index, and fractal dimension were extracted using the CAT12/SPM pipeline. Cognitive functions were assessed with a comprehensive neuropsychological battery covering multiple domains including memory, verbal fluency, attention, executive functions, and psychomotor speed. Vertex-wise analyses were conducted using threshold-free cluster enhancement (TFCE). All models were adjusted for age, educational status, depression/anxiety scores, and Euler number.
Results or Findings: Compared to controls, JME patients exhibited significant cortical thinning and increased gyrification, most prominently in perirolandic and medial prefrontal cortices, extending to frontal, parietal, and occipital regions (pFWE<0.001). These effects remained robust after controlling for global mean cortical thickness. Correlation analyses demonstrated moderate positive associations between cortical thickness in frontal regions and cognitive performance, particularly in memory, verbal fluency, and executive domains (pFWE<0.05, r≤0.57).
Conclusion: Our findings highlight region-specific cortical alterations in JME that extend beyond global effects, linking frontal structural abnormalities to clinically relevant cognitive deficits. These results support the role of surface-based morphometric parameters as promising neuroimaging biomarkers of cognitive impairment in JME.
Limitations: This is a cross-sectional study without longitudinal follow-up.
Funding for this study: No funding was received for this study.

From Static to Dynamic: Multiscale Connectivity Features of Resting-State Brain Network Reconfiguration in SeLECTS (6 min)

Xu Chen; Zunyi City / China

Author Block: X. Chen, L. Song, A. j. Zhang, X. Yang, L. Jiang; Zunyi City/CN
Purpose: To reveal network-level functional reconfiguration in children with self-limited epilepsy with centrotemporal spikes (SeLECTS) by integrating static functional connectivity (sFNC), dynamic functional connectivity (dFNC), and hidden Markov model (HMM) analysis.
Methods or Background: Sixty-one children with SeLECTS and sixty-nine healthy controls (HCs) underwent resting-state fMRI. Independent component analysis identified 34 components, 15 of which were matched to six canonical networks. sFNC was computed from full time series. dFNC was assessed using sliding-window and k-means clustering. And the HMM was applied to resolve dynamic brain activation states.
Results or Findings: The sFNC analysis showed significantly reduced connectivity within the DAN (IC_31–IC_32 and IC_32–IC_33) in SeLECTS compared to HCs. The dFNC analysis identified four recurrent states. In state 1 (IC_32–IC_33) and state 3 (IC_31–IC_32), both reflecting intra-DAN connectivity, SeLECTS showed significantly reduced connectivity compared to HCs. No group differences were found in states 2 and 4. State 2 was characterized by more balanced connectivity and showed fewer fractional windows and shorter mean dwell time in SeLECTS. In contrast, States 1 and 3 represented two extreme connectivity patterns, respectively reflecting low integration and over-integration. The HMM analysis also identified four dynamic states, including distinct extremes of brain network activation—one with markedly increased activation and another with globally reduced activation. Additionally, SeLECTS exhibited prolonged dwell time in a state characterized by suppressed DAN activity.
Conclusion: This study indicates that persistent disruption of DAN connectivity may underlie resting-state network abnormalities in SeLECTS. Imbalanced connectivity states revealed by dFNC and HMM from distinct dynamic perspectives further support network reorganization in SeLECTS.. This static-to-dynamic integrated analysis offers new perspectives on its neuropathological mechanisms.
Limitations: Limitations include cross-sectional design, lack of EEG-fMRI, and uncontrolled medication effects potentially confounding connectivity findings.
Funding for this study: This work was supported by the National Natural Science Foundation of China (Grants No. 82160328), Natural Science Foundation of Guizhou Province (Project No. Qiankehejichu-ZK [2021] yiban 479, Qiankehejichu-ZK [2022] yiban 582), Scientific and Technological Innovation Talent Team for Functional Imaging and Artificial Intelligence Applications in Guizhou Province (Project: QKHRC- CXD(2025)047).

Focal Cortical Dysplasia IIb Type: correlation of histological data with typical MRI patterns during epileptological scanning (6 min)

Alina Vyacheslavovna Smirnova; Saint Petersburg / Russia

Author Block: A. V. Smirnova, D. Rudenko; Saint Petersburg/RU
Purpose: To assess the concordance between typical MRI patterns and histologically confirmed FCD IIb, and to determine the diagnostic value of these imaging features.
Methods or Background: A total of 93 patients (minimum age in both groups — 3 years) who underwent surgical treatment for focal cortical dysplasia were included in the study. Histopathological examination revealed: FCD type I — 37 cases, FCD type IIb — 56 cases. All patients underwent preoperative MRI on 3T scanners with HARNESS protocols and high-resolution T2-weighted sequences (slice thickness 0.6–1.0 mm), with a focus on detecting the transmantle sign.
Results or Findings: The transmantle sign was detected on MRI in 36/56 patients with FCD IIb (64.3%; 95% CI: 50.9–76.0%) and in none of the patients with FCD type I. Demographic data: FCD IIb group — mean age: 17.2 ± 6.4 years (range: 3–32 years), females: 57.1%; FCD I group — mean age: 19.5 ± 7.2 years (range: 3–35 years), females: 51.4%. The difference between groups was statistically significant (Fisher's exact test, $p < 0.0001$). Sensitivity — 64.3%, specificity — 100%, positive predictive value (PPV) — 100%, negative predictive value (NPV) — 65.5%.
Conclusion: The transmantle sign demonstrates high specificity (100%) for FCD IIb, with statistically significant differences compared to FCD type I ($p < 0.0001$). However, its moderate sensitivity (64.3%) means that absence of the sign on MRI, even with 3T scanners and HARNESS protocols, does not rule out the diagnosis. Comprehensive preoperative evaluation integrating clinical and electrophysiological data remains essential.
Limitations: N/A
Funding for this study: N/A

Deep learning-based MRI volumetric analysis in epilepsy patients with hippocampal sclerosis: a two-center study (6 min)

Aakaar Kapoor; Delhi / India

Author Block: H. Anand[1], A. Kapoor[2], L. H P[1], H. G. K B[1], P. B P[1], A. Kapoor[2], R. Kanotra[3], D. Singh[2], D. Kumar[2]; [1]Bengaluru/IN, [2]New Delhi/IN, [3]Gilbert, AZ/US
Purpose: To evaluate the diagnostic accuracy of a deep learning-based volumetric analysis tool in epilepsy patients with hippocampal sclerosis (HS) across two centers, and to determine which brain regions exhibit the most significant volumetric changes compared to healthy controls (HC).
Methods or Background: This two-center study included 40 subjects:20 patients with MRI-confirmed HS and 20 HC. MRI data were acquired on 3T systems (uMR 780, United Imaging Healthcare,Center-1; and MAGNETOM Skyra, Siemens Healthineers,Center-2). Volumetric analysis was performed using the cascaded weakly supervised confidence integration network (CINet), which applies weak supervision and confidence integration for accurate brain region segmentation. Regions of interest included the hippocampus, amygdala, entorhinal cortex, parahippocampal gyrus, thalamus, and temporal neocortex. A recursive feature elimination pipeline identified discriminative volumetric markers. Classification of HS versus HC was performed using Support-Vector Machine (SVM) and Random-Forest (RF) with 5-fold cross-validation.
Results or Findings: HS patients demonstrated volumetric reductions relative to HC, reflecting both focal hippocampal pathology and broader network involvement. The hippocampus showed the most pronounced atrophy (mean-reduction 27.4%, $p < 0.001$), followed by the amygdala (21.6%, $p < 0.01$). Moderate but significant reductions were observed in the entorhinal-cortex (15%) and parahippocampal gyrus (18%) (both $p < 0.05$). Extra-temporal regions including the thalamus (10%) and temporal neocortex (14%) also showed significant volume loss ($p < 0.05$). RF classifier achieved an accuracy of 93.3%, while SVM reached 91.3%. Feature selection consistently identified hippocampal and amygdala volumes as the strongest predictors of HS.
Conclusion: This two-center pilot study demonstrates that CINet-based volumetric analysis reliably detects HS-associated brain changes, with RF providing superior classification performance. The integration of deep learning, feature selection, and supervised classifiers offers a robust framework for objective and generalizable epilepsy diagnostics.
Limitations: Small cohort.

Retrospective Evaluation of Hippocampal Morphology in Temporal Lobe Epilepsy: Toward Interpretable and Automated Detection of Sclerosis (6 min)

Thu Minh Chau Nguyen; Hanoi / Vietnam

Author Block: T. M. C. Nguyen; Hanoi/VN
Purpose: Hippocampal sclerosis (HS) is the most frequent pathological finding in temporal lobe epilepsy (TLE) but may be subtle or missed on conventional MRI, limiting pre-surgical decision-making. HipUnfold, an automated surface-based morphometry tool, has shown promise for HS detection and lateralisation. However, prior work focused mainly on volumetry and asymmetry indices. We extended this approach using unsupervised clustering of shape features and compare imaging-derived clusters with histopathological severity.
Methods or Background: We retrospectively included 30 unilateral HS patients who underwent surgical resection and 30 age- and sex-matched controls. Preoperative T1-weighted MRI was processed using HipUnfold to reconstruct hippocampal surfaces and extract structural features (volume, thickness, gyrification, curvature). Morphological features were compared across sclerotic, contralateral, and control hippocampi. Principal component analysis (PCA) was applied to shape-normalized features, followed by unsupervised k-mean clustering.
Results or Findings: HS patients showed significant reductions in hippocampal volume (−24.6%, $p < 0.001$) with decreased gyrification (−25.6%, $p < 0,0001$) and increased mean curvature (+9.55%, $p < 0.05$). PCA explained 84.4% of variance and identified three clusters: Cluster 1 (n = 17) with severe atrophy and curvature change, and Cluster 2 (n = 29) with milder alterations and Cluster 3 (n=10) with preserved morphology, likely corresponding to non-sclerotic hippocampi. Cluster membership corresponded closely with histopathological grading of sclerosis, providing greater diagnostic granularity than volumetry or asymmetry alone.
Conclusion: Though HipUnfold is validated for HS detection, our study demonstrates that unsupervised clustering of surface features captures HS phenotypes aligned with histopathological sclerotic severity, offering added interpretability for presurgical planning in TLE
Limitations: This pilot study had a modest sample size, which limits statistical power and cluster stability. Most surgical cases showed clear HS on imaging, introducing selection bias.. Larger prospective studies with broader anatomical coverage are needed for validation.
Funding for this study: This study received no external funding.

Correlation of morphological features of the arcuate and uncinate fasciculi to language lateralization: a combined fMRI and DTI study (6 min)

Jiyeon Yoo; Vienna / Austria

Author Block: J. Yoo, R. Stepponat, F. Fischmeister, G. Kasprian; Vienna/AT
Purpose: Understanding the organization of language functions is one of the most rigorously researched neuroscientific topics, as it carries significant importance in clinical settings, such as preoperative planning in neurosurgery, and disease comprehension in neurological disorders.
In our combined DTI tractography and fMRI study, we aim to determine whether experts who work closely with the above-mentioned imaging methods can identify the correct language lateralization solely with DTI tractography in TLE patients as well as healthy controls.
Methods or Background: We performed a questionnaire study with experts who routinely work with DTI tractography as well as fMRI in patients. The experts were shown randomized, partially mirrored images of DTI tractographies of the arcuate and uncinate fasciculi and then attempted to determine the language lateralization based on the images. The results were further validated by calculating the inter-rater variability. Furthermore, fMRI- and DTI-laterality indices (LI) were correlated in order to validate our data.
Results or Findings: The exploratory preliminary results show a correlation of the arcuate fascicle structure to the fMRI LI as proven by previous studies. Furthermore, certain visual qualities of the arcuate fascicle such as a dense, highly organized fiber structure spanning between the temporal and frontal lobe showed to be a visual marker for language lateralization to the same side.
Conclusion: The preliminary results suggest that an evaluation by experts of language lateralization solely by DTI tractography is possible. This finding can help clinicians determine language lateralization or increase their confidence in identifying the dominant hemisphere when fMRI is unavailable or the patient is not able to perform fMRI.
Limitations: Due to the distribution of language laterality by fMRI, atypically lateralized patients are under-represented and further investigation with a larger pool of atypically lateralized patients may be needed.

Stability of spontaneous brain activity and functional connectivity in Subcortical gray matter using test-retest ultrahigh field 7-Tesla resting-state functional magnetic resonance imaging (6 min)

Hasan M H Sbaihat; Bochum / Germany

Author Block: H. M. H. Sbaihat, B. Bellenberg, A. K. Roenneke, B. Krieger, D. Müller, C. Lukas; Bochum/DE
Purpose: Reliable biomarkers are needed in psychiatry and neurology to improve diagnosis and treatment. While the reliability of resting-state (RS) fMRI has been studied at standard field strengths, it remains underexplored at ultrahigh field (UHF) strengths such as 7 Tesla. This study evaluated the stability of spontaneous brain activity (RSA) and functional connectivity in subcortical gray matter (SCGM), regions central to cognition, emotion, and memory. We assessed RSA with the amplitude of low-frequency fluctuations (ALFF), local connectivity with regional homogeneity (ReHo), and global connectivity with degree centrality (DC).
Methods or Background: Sixteen healthy participants (mean age = 25.3 ± 2.0 years) were selected from a publicly available dataset (Gorgolewski et al., 2015). fMRI and T1-weighted images were acquired on a Siemens MAGNETOM 7T scanner in two sessions one week apart. Preprocessing was performed, and then ALFF, ReHo, and DC were computed in native space for each session. Test–retest reliability was assessed using Lin's concordance correlation coefficient across SCGM regions, including the amygdala, basal ganglia, caudate, hippocampus, insula, pallidum, putamen, and thalamus.
Results or Findings: Our results indicate moderate-to-strong stability across all selected subcortical gray matter regions, except for the RSA in pallidum. The amygdala, insular cortex, and thalamus demonstrated strong reliability across ALFF, DC, and ReHo. The basal ganglia and caudate were moderately stable for ALFF and ReHo but strong for DC. The hippocampus and putamen showed moderate stability across all measures, while the pallidum exhibited weak ALFF stability but moderate DC and ReHo.
Conclusion: RS measures of SCGM exhibit generally moderate-to-strong stability. These findings support the potential of ultrahigh-field 7T fMRI for reliably assessing spontaneous brain activity and connectivity in subcortical regions, providing a foundation for future biomarker development in psychiatry and neurological disorders.
Limitations: Not applicable.

Fetal MRI of suspected cortical malformations: predicting epileptogenic outcomes (6 min)

Stefanie Chambers; Vienna / Austria

Author Block: S. Chambers, S. Glatter, L. Krepler, T. Dorittke, J. Binder, M. Weber, D. Prayer, G. Kasprian; Vienna/AT
Purpose: Predictions of epileptogenicity are often biased by inferring risk retrospectively from symptom onset. Fetal MRI allows identification of malformations of cortical development (MCD) before clinical manifestation. We present a preliminary analysis of the epileptogenicity of suspected MCD in prenatal MRI, validated through postnatal follow-up. Our aim is to stratify epilepsy risk by MCD subtype and location, providing less biased estimates to support the transition from reactive to preemptive, disease-modifying interventions.
Methods or Background: We retrospectively reviewed fetal MRIs performed at the Medical University of Vienna (2005–2024) with suspected MCD. Scans included T2-weighted sequences in three planes at 1.5/3T, with ≥1 year postnatal follow-up. Two neuroradiologists independently assessed primary MCD features (e.g., schizencephaly, polymicrogyria, dysplasia) and lesion location. Clinical outcomes included epilepsy and/or neurodevelopmental delay. Group comparisons used chi-squared/Fisher's exact tests; stepwise logistic regression assessed multivariable effects.
Results or Findings: Forty-four cases (18 female) were included with mean follow-up of 6.3 years. Sixteen patients (36.4%) developed epilepsy and 19 (43.2%) neurodevelopmental delay. Microlissencephaly and dysgyria were strongly associated with epilepsy (both $p=0.013$), with frontal lobe involvement being the strongest predictor (OR=13, $p<0.001$), remaining significant in multivariable regression. Combining location to pathology, schizencephaly also reached significance ($p=0.013$), whereas periventricular nodular heterotopia and hippocampal malrotation showed nonsignificant associations.
Conclusion: Our exploratory, preliminary analysis highlights the epileptogenicity of microlissencephaly, dysgyria, and frontal lobe involvement, while schizencephaly and polymicrogyria may be less predictive in a univariate analysis than assumed. Our findings support the questionable epileptogenicity of periventricular nodular heterotopia and suggest possible two-hit mechanisms.
Limitations: The limitations are the small sample size and consequent difficulty of disentangling co-occurring features, a multi-center study is currently ongoing. Furthermore, our assessment is limited to early-onset epilepsy due to the mean follow-up period of 6 years.
Funding for this study: No funding was received for this study.

AI-Augmented MRI and EEG Connectomics for Localizing Epileptogenic Networks (6 min)

Aditya Chauhan; Bangalore / India

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: A. Chauhan; Bangalore/IN
Purpose: Accurate localization of epileptogenic zones is critical for surgical success in drug-resistant epilepsy, yet conventional MRI and EEG often provide incomplete information. This study investigates an artificial intelligence (AI) framework that integrates MRI-based structural and functional connectomics with EEG data to enhance presurgical mapping.
Methods or Background: A cohort of 72 patients with drug-resistant focal epilepsy underwent 3T multiparametric MRI (structural MRI, diffusion tensor imaging, resting-state fMRI) and scalp EEG. Radiomics and graph-theoretical features were extracted from MRI, while functional connectivity metrics were derived from EEG. These multimodal datasets were integrated using a supervised machine learning pipeline (random forest and support vector classifier), trained on postsurgical outcome as ground truth.
Results or Findings: The AI-integrated model achieved an accuracy of 87% in localizing epileptogenic networks, outperforming MRI-only (72%) and EEG-only (68%) models. Notably, connectomic features capturing disrupted hub regions in the temporal and frontal lobes were strongly predictive of seizure recurrence risk. Surgical resections guided by AI-predicted zones correlated with improved seizure freedom rates (Engel Class I outcomes in 79% vs. 61% with standard planning).
Conclusion: AI-driven integration of MRI and EEG connectomics provides a robust tool for identifying epileptogenic zones, enhancing presurgical planning, and improving clinical outcomes in drug-resistant epilepsy.
Limitations: Single-center design and modest sample size may limit generalizability. Future work should validate the framework in multicenter datasets and explore real-time clinical deployment.

What you see is not always what you get - MRI-Based Ganglionic Eminence Volumetry Challenges Subjective Assessment in CNS Anomalies (6 min)

Marlene Stuempflen; Vienna / Austria

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: M. Stuempflen, P. Kienast, V. Schmidbauer, M. Weber, J. Tischer, T. Dorittke, J. Binder, D. Prayer, G. Kasprian; Vienna/AT
Purpose: Failure of fetal interneuron migration arising from the ganglionic eminence (GE) may lead to a wide spectrum of neuropsychiatric and neurodevelopmental disorders. Early detection of anomalies may improve the MRI phenotyping of neurodevelopmental diseases. This atlas-based fetal MRI study aimed to quantitatively assess development of and alterations in GE volume in fetuses with previously diagnosed abnormal GE volumes based on subjective assessment only.
Methods or Background: This retrospective study investigated 17 fetuses (20 fetal MRIs, mean gestational age 26.3 weeks, SD 3.3) with subjectively enlarged ganglionic eminence with concurrent structural central nervous system anomalies based on assessment of experienced fetal neuroimaging experts. Three-dimensional volumetry was performed based on super-resolution fetal MRI and compared to age-matched neurotypical controls (94 fetuses, 100 MRIs, mean gestational age 27.2 weeks, SD 3.6).
Results or Findings: Only 25% were found to include patients with GE hyperplasia, while 60% were found to show normal and 15% smaller GE volumes than healthy references. Most patients (80%) were found to have increased total brain volume - mostly due to high ventriculomegaly (75%). Brain parenchyma volume was enlarged in only 20%. No correlation was found between GE volumes and volumes of ten other substructures of the fetal head.
Conclusion: The study highlights the unreliability of expert visual assessment of GE size, despite excellent examination conditions and emphasizes the necessity of three-dimensional volumetry. Specifically in patients with structural CNS anomalies quantitative fetal neuroimaging will serve as an emerging tool for deep phenotyping, which identifies abnormalities within the GE prior to the structural emergence of cortical malformations.
Limitations: The findings of this study should be confirmed in larger patients cohorts and histological studies, which were unavailable due to the in vivo nature of this study.
Funding for this study: None.

Kevin Cronin; Dublin / Ireland
Huadan Xue; Beijing / China

Evaluating the use of complementary therapies amongst patients undergoing radiotherapy in Malta (6 min)
Karen Borg Grima; Naxxar / Malta

Author Block: K. Borg Grima, A. Xuereb; Msida/MT
Purpose: Complementary therapies (CTs) are increasingly recognised for their potential to improve quality of life in oncology care. However, evidence regarding their awareness, utilisation, and acceptance among Maltese cancer patients remains limited. This study aimed to assess patient awareness, explore demographic influences, and evaluate willingness to use CTs within the state oncology hospital.
Methods or Background: A cross-sectional, non-experimental, prospective research was conducted with patients undergoing radical radiotherapy. A self-designed questionnaire, incorporating both quantitative and limited qualitative components, was distributed to 140 eligible participants. Ninety-one completed responses were analysed (65% response rate). Data was processed using IBM SPSS® version 27. Chi-square, Kruskal–Wallis, and Friedman tests were applied to evaluate associations between demographics and CT use, with statistical significance set at $p<0.05$.
Results or Findings: Over half of the participants (57.8% females; 42.2% males) reported prior use of CTs. Younger patients (76.9% aged 18–47 years) and those with tertiary education (82.6%) were most likely to use CTs. Awareness of at least one CT was reported by 88% of respondents, with massage (68.1%), yoga (58.2%), dietary supplements (46.2%), and meditation (46.2%) being the most commonly cited. Willingness to use CTs if offered freely within the hospital was expressed by 95.6% of patients. The Friedman test indicated the strongest agreement that a wider range of CTs should be available in Malta (mean 4.27), and that more patient education is required before using such additional therapies.
Conclusion: The findings highlight strong awareness, favourable attitudes, and clear demand for CT integration within oncology services in Malta. Younger and better-educated patients were most likely to utilise CTs. Implementation may improve holistic cancer care and patient wellbeing, while promoting patient education on additional cancer therapies.
Limitations: Study limitations included a reduced participant sample size, limiting generalisability.
Funding for this study: No funding was used for this study

Knowledge and Perceptions of MRI Safety: A Cross-Sectional Survey Among Healthcare Professionals and the General Population (6 min)
Matteo Garziera; Thiene / Italy

Author Block: M. Signorini[1], M. Garziera[2], D. Cerchiaro[2], S. Fontani[1], B. Bragagnolo[2], G. Iannucci[2], V. Iurilli[2]; [1]Rovigo/IT, [2]Vicenza/IT
Purpose: To evaluate the level of knowledge and perceptions regarding MRI safety among healthcare professionals and the general population, identifying well-understood topics and critical misconceptions, in order to inform targeted educational strategies.
Methods or Background: A cross-sectional online survey was developed (Google Forms) and distributed between June–August 2025 via hospital networks and social media. The questionnaire comprised demographic items, a self-assessment of knowledge (5-point Likert scale), 13 core safety questions and 6 advanced safety questions. Respondents were categorized as: radiologists, radiographers (TSRM), non-radiologist physicians, other healthcare workers, students, and general population. Data were analyzed with χ^2 tests, Kruskal–Wallis, Spearman correlation, and logistic regression.
Results or Findings: A total of 524 valid responses were collected: 30% general population and 70% healthcare professionals. Overall, healthcare workers achieved significantly higher accuracy than the general population across all 13 core questions ($p<0.001$, large effect sizes). Radiologists obtained the highest mean accuracy (72.4%), followed by radiographers (66.8%) and non-radiologist physicians (61.2%), while other healthcare workers (54.1%) and students (58.7%) scored lower. Critical knowledge gaps emerged across all groups regarding removal of contact lenses (<30% correct) and recognition of common transient effects (≤13%). Logistic regression confirmed radiologists were significantly more likely to answer correctly on advanced items such as ventriculo-peritoneal shunts (OR 2.85, $p<0.001$) and long-term effects (OR 2.12, $p=0.005$). Self-perceived knowledge correlated with actual accuracy among professionals ($\rho=0.14$, $p=0.009$), but not in the general population.
Conclusion: Substantial differences exist between professionals and laypersons, and across professional subgroups, in MRI safety knowledge. While radiologists demonstrate the highest competence, recurrent misconceptions persist in all categories, underscoring the need for targeted educational initiatives.
Limitations: Convenience sampling via online distribution may introduce selection bias; self-reported professional categories were not externally verified.

Structured SimZones in CT education: enhancing clinical reasoning with immersive simulation (6 min)

Eleonora Stefani; Treviso / Italy

Author Block: E. Stefani[1], M. Centenaro[1], R. P. P. Almeida[2]; [1]Padova/IT, [2]Esch-sur-Alzette/LU
Purpose: Traditional CT education often emphasizes technical competence, with limited opportunities to practice decision-making and clinical reasoning. The SimZones framework (Roussin & Weinstock, 2017) provides a structured pathway of increasing complexity for simulation-based learning. Its integration with immersive high-fidelity technologies may enhance diagnostic judgment and bridge the gap between classroom and clinical environments. To evaluate the effectiveness of a structured CT simulation program based on the SimZones model in strengthening clinical reasoning and operational confidence among undergraduate radiography students.
Methods or Background: Four immersive simulation sessions focusing on CT modules were delivered to 24 second- and third-year students. The program was designed within SimZones 2 and 3 and included pre-briefing, guided scenarios, and reflective debriefing. Effectiveness was assessed using the validated Italian version of the Simulation Effectiveness Tool–Modified (SET-M). Data analysis included descriptive statistics of 19 items and correlation across cognitive, technical, and decision-making domains.
Results or Findings: Overall SET-M scores were high (mean 2.4/3). Decision-making achieved a mean of 2.41, while debriefing received the highest rating (2.55). A strong correlation ($r = 0.75$) was observed between pre-briefing quality and the ability to manage complex scenarios. Moderate correlations ($r = 0.68$) were found between technical knowledge, patient safety, and decision-making autonomy. Qualitative feedback highlighted increased situational clinical reasoning, confidence, and awareness of professional roles.
Conclusion: Structured CT simulation based on the SimZones framework, combined with immersive technologies, effectively enhances clinical reasoning and confidence in radiography students. This approach strengthens the educational impact of simulation, bridging academic learning with clinical practice, and offers a sustainable, replicable model for next-generation radiography education.

Personalised CT/MRI Placements: Tailored Clinical Training (6 min)

Angie Devetti; Udine / Italy

Author Block: A. Devetti, S. Da Dalt; Udine/IT
Purpose: This project details the implementation and evaluation of a personalised, advanced clinical placement model in CT and MRI for undergraduate radiographers. The overarching objective is to deepen and specialise students' practical proficiency in both modalities whilst fostering reflective self-assessment and self-efficacy.
Methods or Background: The advanced placement, structured as a mixed-modality block following two standard, dedicated 6-week continuous blocks in CT and MRI, is collaboratively designed with each student upon demonstrating high foundational competence and autonomy. This phase shifts emphasis from core principles to refining advanced skills in areas of high clinical relevance or student interest (3T prostate MRI, DECT urography, cardiac imaging). Learning objectives are deliberately flexible, adapting to the host clinical site's available caseload. Students who achieved lower prior performance primarily focus on consolidation of core competencies.
Results or Findings: The preliminary introduction of this personalised model suggests a marked increase in student engagement and the acquisition of highly targeted, specialised technical skills. The individualised learning pathways allowed high-performing students to effectively manage and contribute to advanced procedures, exceeding standard undergraduate placement outcomes. Conversely, the tailored objectives successfully remediated skill deficits in lower-performing cohorts.
Conclusion: The personalised, mixed-modality placement represents a sophisticated pedagogical evolution in radiographer training. By linking specific learning objectives to prior performance and individual inclination, this approach ensures maximal clinical exposure relevance and promotes the development of highly capable and motivated practitioners.
Limitations: The model's efficacy, tested on a small cohort of 16 students, was inherently restricted by clinical site casemix and operational flow, potentially limiting exposure to every pre-agreed objective. To counteract inherent self-report bias in the final reflective assessment, the students' individual reports were robustly cross-referenced with the summative evaluation provided by experienced placement mentors.

Radiographers' Role and Practice in Suspected Cases of Child Physical Abuse in Malta (6 min)

Emma Buttigieg; Xewkija, Gozo / Malta

Author Block: E. Buttigieg, J. L. Portelli; Msida/MT
Purpose: Radiographers are frequently among the first healthcare professionals to encounter patients presenting with signs or injuries that may be indicative of physical abuse. The purpose of this study was to examine the role and current clinical practices of radiographers in Malta in the detection and management of Suspected Child Physical Abuse (SCPA).
Methods or Background: From a target population of 44 radiographers working in the A&E department of the public general hospital and/or public health centres in Malta, 36 (81.88%) completed an online questionnaire developed for this study.
Results or Findings: Most radiographers (66.7%) had encountered SCPA, with 47.2% reporting occasional cases. All recognised physical and behavioural indicators, however 83.4% reported limited familiarity with radiological signs of SCPA, indicating potential training gaps. While 61.1% identified the detection and reporting of SCPA as part of their professional duties, only 41.7% were aware of a legal obligation to report, and 63.9% lacked knowledge of departmental protocols. Although 77.8% stated they would report suspected cases, confidence varied: 77.8% felt competent in producing high-quality images for legal proceedings, whereas 55.6% reported only moderate competence in providing court testimony. Training gaps were notable, with half indicating they had never received formal training and 66.7% unaware of available training opportunities. Nevertheless, 83.3% valued specialised training in SCPA, with 94.4% supporting mandatory periodic training programmes.
Conclusion: Radiographers play a pivotal role in safeguarding children, but variability in knowledge, awareness, and radiographic interpretation, may impede timely intervention. While most acknowledged their responsibilities and demonstrated understanding of SCPA, gaps in knowledge and familiarity with procedural frameworks were evident. Structured education, targeted training, and clear protocols are needed to strengthen radiographers' contribution to multidisciplinary child protection.
Limitations: As a single-centre, cross-sectional study, the findings may not be generalisable.
Funding for this study: None

AIMIROE - Artificial Intelligence in Medical Imaging and Radiation Oncology (MIRO) Education: A European Survey (6 min)

Hendrik Garbrand Erenstein; Groningen / Netherlands

Author Block: H. G. Erenstein[1], R. G. L. Decoster[2], J. Menzinga[1], N. Stogiannos[3], C. Malamateniou[3]; [1]Groningen, Gr/NL, [2]Brussels/BE, [3]London/UK
Purpose: AI is reshaping Medical Imaging Radiation Oncology (MIRO), but limited awareness and education hinder adoption. This EuSoMII-led study, in collaboration with EFRS, identifies EU-based AI programs for MIRO and aims to centralize them on an accessible platform to support ethical use, compliance, and professional growth.
Methods or Background: A Qualtrics-based electronic survey was developed and piloted with six MIRO-professionals to collect data on European AI course characteristics (e.g. format and delivery, content, and audience target audience). Ethical approval was granted by KU Leuven (Ref: G-2024082214). The survey was disseminated via snowball sampling through social media, and mailing lists of EuSoMII and EFRS between September 16, 2024, and January 16, 2025.
Results or Findings: This study identified 30 MIRO-related AI courses across Europe. Most (55.2%) were offered by universities, with industry and professional bodies contributing 20.7% and 17.2%. Courses targeted radiographers, medical physicists, and radiologists (40–60%), mainly at EQF7 level (42.9%). Most were standalone (76.7%), online (53.3%), and free (43.3%), with nearly half lasting under a week. English was the primary language (76.7%), and 80% were openly accessible.
Conclusion: Short AI courses for MIRO professionals across Europe offer accessible entry points but often lack depth and hands-on experience. Expanding formats, multilingual access, and global inclusivity, especially in low-resource settings, are essential for meaningful, practical, and equitable AI integration.
Limitations: The study used self-reported data and snowball sampling, which may have introduced selection bias and limited course coverage. Conducting the survey in English may have excluded non-English responses and overlooked multilingual offerings. Course details were based on publicly available information, and rapid changes in AI education may affect the relevance of findings.
Funding for this study: No external funding was received for this study.

Transformative e-learning to enhance radiographers' care of older adults: outcomes from a multi-module educational course (6 min)

Amanda Er; Singapore / Singapore

Author Block: A. Er, L. H. Sng; Singapore/SG
Purpose: With a rapidly ageing population, radiographers are increasingly caring for older adults who require unique physical and cognitive considerations. Yet, radiography curricula often provide limited training in this area, potentially compromising patient-centred care. This study evaluated the effectiveness of a transformative e-learning course in enhancing qualified radiographers' knowledge, communication strategies, and reflective practices when caring for older adult patients.
Methods or Background: A total of 189 radiographers from a Singapore healthcare cluster completed a two-hour, four-module self-directed e-learning course. The programme was grounded in transformative learning theory, encouraging participants to challenge assumptions and engage in reflective practice. Knowledge was assessed through pre- and post-course multiple-choice questions, and learning effectiveness was analysed using paired t-tests. Additionally, open-ended reflective responses were subjected to thematic analysis to capture qualitative insights into changes in practice.
Results or Findings: Knowledge scores improved significantly, rising from a mean of 76.8% pre-course to 96.0% post-course ($p<0.001$). Thematic analysis of reflective responses revealed four dominant themes: patient communication and rapport building, compassionate care approaches, workplace challenges and adaptations, and professional growth and self-reflection. Together, these findings suggest both cognitive and attitudinal benefits of the intervention.
Conclusion: A short, theory-informed e-learning course produced significant improvements in radiographers' knowledge and reflective practice when caring for older adults. While participants highlighted the value of communication and compassion, tensions between best practice and workplace time constraints remain an ongoing barrier to implementation.
Limitations: Voluntary participation introduced self-selection bias, limiting generalisability of findings.
Funding for this study: Funding was provided by the SingHealth Duke-NUS Radiological Sciences Clinical Programme (Project No.: 10/FY2023/P1/03-A18).

Person-centred care education in practice: students' and academics' evaluation of a postgraduate radiography module (6 min)

Emily Skelton; London / United Kingdom

Author Block: R. Van de Venter[1], E. Skelton[2], B. Potts[2], C. J. C. Parish[2], N. Shiner[3], E. Hyde[2], J. St John-Matthews[2], B. Ohene-Botwe[2], C. Malamateniou[2]; [1]Port Elizabeth/ZA, [2]London/UK, [3]Keele/UK
Purpose: To evaluate a new postgraduate educational module delivered by a UK-based University designed to empower radiographers with the knowledge, skills, and confidence to embed person-centred approaches to care provision within the clinical practices.
Methods or Background: A qualitative, online survey consisting of six open-ended questions was developed to capture perspectives from students enrolled on the module, and teaching faculty delivering the module. Participants were also asked about what improvements could be made to future iterations of the module. An inductive, open, and descriptive coding approach was utilised, informed by a social constructivist epistemology and relativist ontology. Responses were received from sixteen participants (n=10 enrolled students, n=6 teaching faculty).
Results or Findings: Four themes were developed from the qualitative analysis: 1) Stimulating a culture of person-centred care: strengths of the module; 2) Module aspects that limited relatability and learning; 3) The ideal person-centred care module: suggestions for improvement, and 4) Becoming champions of person-centred care: reflection on the module impact. Collectively, these themes represented how participants felt empowered to apply theoretical knowledge acquired during the module to implement person-centred care approaches within their own radiography practices, and support colleagues within their clinical departments.
Conclusion: Focused educational modules may be an effective strategy to help develop a culture of person-centred care in radiography environments. The findings of this evaluation will inform future iterations of the module, and may be used to develop other educational interventions focussed on person-centred care in different clinical contexts.
Limitations: Self-selection of participants may incur bias in the findings by over- or under-representing specific perspectives. The small sample size and focus on a unique educational module may limit generalisability of the findings outside of this study.

A focus group study of student experiences of an Interprofessional Education Workshop (IPE) for learning about dementia together (6 min)

Niamh Moore; Cork / Ireland

Author Block: J. Keane, N. Moore, M. F. Mcentee, C. Rainey, L. McLaughlin, T. O'Sullivan, J. O'Neill, P. C. Murphy, A. England; Cork/IE
Purpose: Dementia encompasses a group of disorders characterised by progressive cognitive decline that significantly impairs daily functioning, most notably memory and problem-solving abilities. Inter-professional education (IPE) involves learners from multiple disciplines engaging collaboratively to enhance understanding of roles and approaches to care. This qualitative focus group study aimed to evaluate the effectiveness of an IPE workshop in improving communication and role recognition in the management of dementia.
Methods or Background: A half-day workshop on dementia care was delivered to healthcare students from eleven disciplines (medicine, nursing, dentistry, physiotherapy, radiography, radiation therapy, audiology, speech and language therapy, pharmacy, occupational therapy, and paramedicine). The workshop employed a multimodal approach, integrating lectures, small-group discussions, and case-based learning. Post-workshop, a number of participants engaged in inter-professional online focus groups, and the data were analysed using Braun and Clarke's thematic analysis framework.
Results or Findings: Two focus groups comprising eleven participants from five healthcare disciplines were conducted in November 2024, six weeks following the workshop. Thematic analysis identified four overarching themes: (1) awareness of disciplinary roles in dementia care, (2) the importance of teamwork and interprofessional communication, (3) the influence of patient advocacy and awareness, and (4) communication skills for supporting people with dementia.
Conclusion: This workshop was regarded as highly beneficial, offering valuable inter-professional learning opportunities and highlighting the importance of patient advocacy in educational contexts. While only minor adjustments in timing and broader disciplinary inclusion were suggested, participants reported improved understanding of role boundaries, communication challenges, and care for people with dementia
Limitations: Not all disciplines were represented in the focus groups.

Global Classrooms: Virtual Exchange Strengthens Students' Ethical and Patient Safety Competence (6 min)

Bodil T Andersson; Ahus / Sweden

Author Block: B. T. Andersson[1], J. Gardling[1], H. Muller[2], I-K. Sebelego[2]; [1]Lund/SE, [2]Bloemfontein/ZA
Purpose: 1. Understand the Global Implementation of Virtual Classes in Ethics and Patient Safety.
2. Identify the Advantages of Virtual Learning in Ethics and Patient Safety Education .
3. Explore Effective Strategies for Managing Virtual Classes in Ethics and Patient Safety.
Methods or Background: Radiographers play a pivotal role in upholding patient safety and ethical standards in medical imaging. To foster global dialogue on these critical issues, a university in South Africa and a university in south of Sweden, conducted a series of collaborative virtual classes in 2024. Students engaged in scenario-based discussions on “patient safety” and “ethics of care from a global perspective”. This study evaluates radiography students’ perceptions of these international educational virtual collaborations. Following the virtual sessions, first-year (n = 88) and second-year (n = 80) radiography students completed an online survey. The instrument consisted of nine Likert-scale questions (five-point scale) that assessed technical performance, participation, engagement, and learning outcomes. Two open-ended questions gathered qualitative feedback on experiences and suggestions for improvement.
Results or Findings: Over 80% of participants reported actively contributing opinions during the classes. Quantitative results showed that more than 80% of students agreed or strongly agreed with all nine positive survey statements. Qualitatively, the analysis revealed a strong alignment of ethical values between the two international student cohorts. Key suggestions for improvement included allocating more time for peer interaction and using smaller breakout groups to facilitate deeper discussions.
Conclusion: Virtual international collaborations are an effective tool for promoting global knowledge exchange in radiography education. It significantly strengthen students’ capacity to integrate best practices in patient safety and ethics into their professional development.
Limitations: Reduced Interpersonal Interaction and limited opportunities for face-to-face debate, emotional expression, and observing professional behavior in practice.

Radiographers as knowledge translators (6 min)

Marco De Summa; Roma / Italy

Author Block: M. De Summa, S. Spinosa; Roma/IT
Purpose: To investigate radiographers’ role as knowledge translators in Italian hospitals by mapping their activities bridging technological innovation and clinical practice, identifying factors that facilitate or impede research integration and evaluating training programmes that improve competence and confidence in adopting emerging technologies.
Methods or Background: Radiology evolves rapidly due to technological advances, yet a gap persists between theory and clinical practice. Radiographers often make decisions based on experience rather than evidence, and knowledge translation in radiology remains nascent. A multicentre mixed-methods study will combine a questionnaire survey (~300 participants), semi-structured interviews with radiographers and trainers and ethnographic observation of intra-hospital training. Quantitative data will be analysed descriptively and by regression; qualitative data will undergo thematic analysis.
Results or Findings: The study expects to identify three radiographer profiles: expert facilitators engaged in communities of practice; clinical pragmatists with strong practical skills but limited evidence use; and digital learners interested in AI but lacking experience. Organisational support, protected training time and mentoring are anticipated facilitators, whereas resource constraints and absence of formal updating pathways may emerge as barriers. Combined training interventions (webinars, mentorship and simulations) should improve confidence and knowledge translation.
Conclusion: Radiographers act as vital knowledge translators, ensuring innovations are adopted safely and effectively. Developing knowledge translation skills within intra-hospital training can reduce the theory–practice gap, foster evidence-based practice and encourage integration of AI. Communities of practice, mentoring and interdisciplinary collaboration reinforce the radiographer’s identity as a mediator between technology and patient care and support sustainable service delivery overall.
Limitations: The study relies on self-reported data and observations from a limited number of hospitals; findings may not generalise to all settings. As this is a prospective design, actual outcomes may differ from expectations.

From preparation to perception in rectal MRI: Improving patient experiences with self-administered micro-enemas (6 min)

Lyanne Molenaar; Amsterdam / Netherlands

Author Block: L. Molenaar, M. A. van der Lubbe, M. De Haan, K. P. Chupetlovska, R. Beets-Tan, D. M. J. Lambregts; Amsterdam/NL
Purpose: A micro-enema is known to improve image quality on rectal MRI (particularly DWI) by reducing gas-induced artefacts. However, little is known about the patient burden of this preparatory step. This study aimed to assess and improve patient experience when self-administrating a micro-enema before rectal MRI.
Methods or Background: At our institution, patients are routinely instructed to self-administer a micro-enema before rectal MRI. During an initial 4-month period (Period A), patients completed a questionnaire assessing discomfort (none, mild, severe) and provided feedback with suggestions for improvement. Based on results of this questionnaire, corrective actions were taken. The questionnaire was repeated in a subsequent period (Period B) to assess the impact of these improvements. Two board-certified radiologists analyzed the presence of DWI artefacts (none/non-significant vs. clinically significant) to confirm the micro-enema's effect on image quality.
Results or Findings: 83 patients completed the questionnaire (27 in period A, 56 in period B). In period A, 33% of patients reported mild discomfort, versus 21% in period B. The majority of patients reported no discomfort (67% in period A, 77% in period B). Main causes of discomfort were suboptimal toilet facilities (15%), fear of incorrect administration (11%), and concerns about leakage during MRI (7%). Many patients, especially in period A, did not understand the micro-enema's purpose. After improving facilities and patient information, complaints about toilets ceased, and anxiety about administration dropped to 5%. Image quality was high, with 96% of cases showing no clinically significant artefacts.
Conclusion: This study shows that a self-administered micro-enema is generally well-tolerated by patients and leads to good image quality. Clear instructions, patient support, and adequate facilities enable this step to be successfully integrated into routine protocols.
Limitations: Relatively small an unequally sized patient cohorts.
Funding for this study: None.

Radiographers' awareness and patients' needs on risk-benefit communication in nuclear medicine: A Cross-Sectional Study (6 min)

Nicole Agius; Floriana / Malta

Author Block: K. Borg Grima, N. Agius; Msida/MT
Purpose: Limited research exploring radiographers' communication practices in NM was found, despite European regulations requiring radiation risk disclosure to patients. This study evaluated radiographers' awareness and practices in risk-benefit communication, alongside patient expectations and needs, within nuclear medicine (NM). The focus was on cardiac stress scans and routine 18F-FDG PET/CT examinations performed in Malta, where a single NM centre services the national population.
Methods or Background: A quantitative, prospective, cross-sectional design was employed, complemented by qualitative elements. Two anonymous questionnaires were distributed: one to radiographers (n= 9) and one to patients (n=57). The radiographers' survey assessed demographics, training, knowledge of radiation risks, and communication practices, while the patients' survey examined understanding, clarity of information provided, and unmet informational needs. Data were analysed using SPSS v29, chi-squared tests for categorical associations and content analysis for open-ended responses.
Results or Findings: Discrepancies were identified between radiographers' awareness and knowledge, and patients' stated needs. While 96.5% of patients found the language used to be clear, only 10.5% fully understood that benefits outweighed risks. All radiographers expressed interest in further training, with 55% highlighting that structured education would improve their confidence levels in communication. Barriers to information giving included limited time, fear of alarming patients, lack of standardised materials and training. Patients frequently requested more information on radiation exposure to themselves, relatives, and the general public.
Conclusion: Despite radiographers' intention to communicate risk-benefit information, knowledge gaps and inconsistencies persist within the local scenario resulting in patient misunderstandings. Standardised communication protocols, visual aids, plain-language explanations and continuous professional development are needed to ensure accurate, patient-centred risk-benefit discussions in NM and PET/CT.
Limitations: Overall there was a low response rate to the patients' questionnaire, therefore results cannot be generalised to the entire target population.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the university of Malta research ethics committee (reference number: FHS – 2024 – 00417).

Impact of flow rate on Patient comfort, extravasation incidence and allergic-like reactions during administration of iodinated contrast media at room temperature: CATCHY III Trial (6 min)

Lion Stammen; Maastricht / Netherlands

Author Block: L. Stammen, C. R. Jeukens, T. Flohr, J. E. Wildberger, L. Brandts, B. Martens; Maastricht/NL
Purpose: The randomized CATCHY I trial and the subsequent large follow-up CATCHY II found no benefit of pre-warming iodinated contrast media (CM) over room-temperature administration regarding patient comfort, extravasation, or allergic-like reactions. However, as both used relatively low injection flow rates, applicability to higher flow rates remains uncertain. This study examines patient comfort, extravasation, and allergic like reactions when administering CM at room temperature with high flow rates.
Methods or Background: This retrospective study included consecutive outpatients undergoing Coronary CT Angiography (May-October 2025); from August onward, a new CM protocol applied higher flow rates. CM injections (300mgI/ml, room temperature) were performed via an 18-gauge needle (GFR=103ml/min), using weight-adapted protocols. Post-scan, patients rated comfort (5-point Likert scale, excellent-very poor), pain (no/mild, moderate, severe), and any side feelings (yes/no). Technicians reported extravasations or allergic like reactions. Low-flow (2-4 ml/s) and high-flow (7-10 ml/s) groups were compared using the Mann-Whitney U test or the Fisher's exact test.
Results or Findings: Preliminary results indicated no significant differences between the low flow rate group (n=15) and the high flow rate group (n=14) regarding comfort (p=.949) and pain score (p=.683). Side feelings showed no significant differences, accept for heat sensation, where 92.9% of the participants in the high flow rate group reported to feel a heat sensation, compared to only 46.7% in the low flow rate group (p=.014).
Conclusion: These preliminary findings indicate that using higher flow rates when administering CM at room-temperature does not increase the incidence of extravasation or allergic-like reactions, and has no significant impact on comfort or pain scores, although patients are more likely to experience a heat sensation.
Limitations: Single-center study and small sample size due to preliminary results.
Funding for this study: This study received no funding

RPS 415 - Technical innovations in vascular imaging

Categories: Research, Vascular, Multidisciplinary
Date: March 4, 2026 | 13:00 - 14:30 CET
CME Credits: 1.5

Moderator:
Patrick Krumm; Tübingen / Germany

In Vitro and In Vivo Stability Assessment of the Investigational, Macrocyclic Gadolinium-Based Contrast Agent Gadoquatrane (6 min)
Stephan Gruendemann; Berlin / Germany

Author Block: S. Gruendemann, T. Frenzel, J. Lohrke, J. Boyken, G. Jost, M. Berger, H-F. Ulbrich, H. Pietsch; Berlin/DE
Purpose: Gadoquatrane is a tetrameric extracellular macrocyclic gadolinium-based contrast agent (GBCA) with a T1 relaxivity of 11.8 L/(mmol Gd*s) at 1.41 T in human plasma, which has been submitted for regulatory approval in several countries. This study evaluated its stability in comparison with approved macrocyclic GBCAs in vitro and in vivo.
Methods or Background: All assays were conducted at equimolar Gd concentrations. Dissociation kinetics were measured for gadoquatrane, gadoteridol, gadobutrol, gadoterate, and gadopiclenol at pH 1.2 and 37°C using a complexometric assay. Stability in human plasma at pH 7.4 and 37°C was analyzed by ion exchange chromatography with ICP-MS. Rats received a single injection of gadoquatrane, gadobutrol, or gadopiclenol (0.6 mmol Gd/kg; human equivalent 0.1 mmol Gd/kg), and Gd distribution in bone was quantified by laser ablation ICP-MS one week later.
Results or Findings: At pH 1.2, dissociation half-lives were 28.6 days (gadoquatrane), 14.2 days (gadopiclenol), 2.7 days (gadoterate), 14.1 h (gadobutrol), and 2.2 h (gadoteridol). After 15 days in plasma (pH 7.4), no detectable Gd release was observed for gadoquatrane or gadoterate, while gadobutrol, gadoteridol, and gadopiclenol released 0.12%, 0.20%, and 0.20%, respectively. In rats, bone marrow Gd levels were similar across compounds (2.3-3.0 nmol/g). In epiphysis, concentrations were 1.2 nmol/g for gadoquatrane and gadobutrol, and 2.2 nmol/g for gadopiclenol. In diaphysis, levels were 0.5, 1.0, and 2.7 nmol/g, respectively. Elemental imaging showed lowest Gd in mineralized bone for gadoquatrane (<1 nmol/g) compared to gadobutrol and gadopiclenol.
Conclusion: Gadoquatrane demonstrated the highest kinetic inertness under acidic conditions and no measurable Gd release under physiological conditions in plasma. Its high stability was supported by very low Gd concentrations in mineralized bone in rats.
Limitations: These preclinical data do not allow direct conclusions regarding safety in humans.

One-year follow-up of gadolinium presence and distribution in rat bones: Evaluation of the novel, high-relaxivity contrast agent gadoquatrane compared to gadopiclenol and gadobutrol (6 min)
Hubertus Pietsch; Berlin / Germany

Author Block: G. Jost, J. Boyken, J. Lohrke, S. Gruendemann, H. Pietsch; Berlin/DE
Purpose: There is ongoing scientific research on the presence of gadolinium (Gd) in bones after administration of Gd-based contrast agents (GBCAs). Gadoquatrane is a novel, macrocyclic GBCA with significantly higher r1-relaxivity, enabling MRI at reduced Gd dose. Gadoquatrane is in clinical development and was recently investigated in phase III studies at a dose of 0.04 mmol Gd/kg. Our study evaluates the presence of Gd in rat femurs compared to standard doses of gadopiclenol and gadobutrol.
Methods or Background: Rats (Wistar-Han, n=40 per GBCA) received a single intravenous injection of gadoquatrane (0.24 mmolGd/kg), gadopiclenol (0.3 mmolGd/kg) or gadobutrol (0.6 mmolGd/kg), representing human doses of 0.04, 0.05 and 0.1 mmol Gd/kg, respectively. After a treatment-free period of 1,4,22 and 52 weeks the Gd concentrations of the dissected femur (n=10 rats) were measured by inductively coupled plasma mass spectrometry (ICP-MS) and laser-ablation ICP-MS imaging (LA-ICP-MS).
Results or Findings: The Gd concentrations in bone epiphysis and diaphysis were comparable after administration of gadobutrol and gadopiclenol, whereas 2-to 6-fold lower concentrations were observed after injection of gadoquatrane. All GBCAs showed a limited Gd wash-out over the one-year follow up. In bone diaphysis the Gd concentration (geometric mean in nmol/g) after 1 and 52 weeks was 0.2±1.4 and 0.2±1.3 (gadoquatrane), 1.0±1.9 and 0.6±1.9 (gadopiclenol), 0.6±1.8 and 0.5±1.2 (gadobutrol). LA-ICP-MS imaging revealed different Gd distribution patterns. A local accumulation of Gd in the cortical bone was present after injection of gadopiclenol, which was barely visible after injection of gadobutrol. No local accumulation was detected for gadoquatrane.
Conclusion: The presence and distribution of Gd in the rat femur after a single injection of human equivalent clinical Gd doses differ among the three GBCAs. For gadoquatrane considerably lower Gd concentrations without local accumulations were detected.
Limitations: Preclinical study

First imaging results of a non-metallic aortic stent graft for MRI (6 min)

Franz Wegner; Lübeck / Germany

Author Block: F. Wegner[1], M. R. Meyer[2], V. Gesché[3], P. Borm[4], A. Dell[1], G. Männel[1], D. Wendt[1], T. Friedrich[1], M. M. Sieren[1]; [1]Lübeck/DE, [2]Duisburg/DE, [3]Aachen/DE, [4]Düsseldorf/DE
Purpose: Commercially available endovascular stents are typically manufactured from metals. Due to their ferromagnetic properties, these devices can cause significant imaging artefacts, potentially limiting follow-up assessments with MRI and posing challenges for future MRI-guided EVAR procedures. The aim of this study was to develop a non-metallic aortic stent graft and evaluate its imaging characteristics in MRI.
Methods or Background: The stent struts were printed in a Z-shaped configuration using a custom-built 3D-printer with PEEK polymer filaments. The printer employed a rotational principle to apply the polymer onto a tubular graft textile. The stent graft was placed via a tube of 20 mm in diameter in a 3D-printed aortic phantom (material: Vero/Agilus, Shore 70A). The phantom was filled with gadolinium-based contrast agent (dilution 1:200) and subsequently imaged using a clinical MRI-scanner. To evaluate potential stent artefacts, the SNRs inside the stent and outside the stent were calculated. The stent strut thickness displayed on MR-images was measured at six locations and averaged.
Results or Findings: The rotational printing process enabled a stable connection between the stent struts and the textile. The resulting stent measured 30 mm in outer diameter and 100 mm in length. The strut thickness was measured by a caliper to be 1.6 mm. After the placement in the phantom, the stent fully expanded and showed no macroscopic loss of integrity. The stent struts were clearly delineable in MRI with a measured strut thickness of 1.7 ± 0.1 mm. The SNR inside the stent was 86.4 and outside 88.1, indicating no relevant stent-induced artefacts.
Conclusion: A non-metallic stent graft can be successfully manufactured using a rotational 3D-printing process with PEEK polymer, enabling artefact-free stent imaging in MRI.
Limitations: Only static measurements have been performed.

Development of a degradable stent marking technology for Magnetic Particle Imaging (6 min)

Patrick Elfers; Lübeck / Germany

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: P. Elfers[1], K. Lüdtke-Buzug[2], A. Malhotra[2], J. Ackers[2], J. C. Engster[2], D. Melenberg[2], M. Ahlborg[2], T. Friedrich[2], F. Wegner[1]; [1]Lübeck/DE, [2]Luebeck/DE
Purpose: Magnetic Particle Imaging (MPI) is a preclinical imaging modality on the verge to first human studies. It is based on the real-time visualisation of magnetic nanoparticles (MNPs). MPI is particularly well suited for cardiovascular imaging and enables artefact-free imaging of stent lumina. To visualise stents during MPI-guided interventions and to prevent interferences during follow-up examinations, a bioresorbable coating is required that degrades after a defined period. The aim of this work was to develop a coating based on polylactic acid (PLA) and MNPs to make stents temporarily visible in MPI.
Methods or Background: Glass capillaries were coated with a PLA-MNP-mixture by dip-coating. The degradation of the coating was investigated in a static water bath experiment at 37 °C. For this purpose, each sample was stored individually in a glass vial filled with isotonic saline solution. Ten different exposure durations (one hour to 28 days) were investigated and the samples were removed for analysis at the respective time. Before and after the water bath, the samples were dried, weighed, their MPI signal was measured, and their morphology was examined by using micro-CT.
Results or Findings: A continuous mass reduction of the markers was observed after exposure to the water bath (approx. 6 % after one hour, approx. 90 % after 28 days). Micro-CT showed only a slight volume decrease, whereas cavities formed inside the markers with increasing exposure time. A detectable MPI signal was present throughout the entire observation period.
Conclusion: PLA seems to be a suitable polymer for degradable stent markers. The observed properties provide a promising basis for future applications of MPI in cardiovascular and periinterventional imaging.
Limitations: The samples were investigated under static conditions only. Flow experiments are required to transfer the results.
Funding for this study: This work was supported in part by the Clinician Scientist Program of the University of Lübeck under Grant CS10-2021. The Fraunhofer IMTE and this work are supported by the EU, the State Schleswig-Holstein, Germany, and by Internal Programs (Grants 12420002/LPWE1.1.1/1536, 12524009/LPW21L/2.2/262 and 139–600251).

Valve stent crimper enables faster reloading compared to the traditional tourniquet technique - Bench-top testing of a novel approach for PMEG reloading (6 min)

Peter Osztrogonacz; Budapest / Hungary

Author Block: P. Osztrogonacz, J. Csőre, A. Szentiványi, Á. Bérczi, A. Hüttl, C. Csobay-Novák; Budapest/HU
Purpose: During physician-modified endograft (PMEG) preparation, reloading the stent graft into its delivery sheath is a time-sensitive step. Traditionally, this is performed using the tourniquet (T) technique. At our quaternary aortic referral center, valve stent crimper (C) has emerged as a potential alternative, offering a controlled and possibly more reproducible method.
Our study aimed to compare the C and T techniques in terms of reloading time.
Methods or Background: A Medtronic Valiant 38x200mm thoracic stent graft was reloaded a total of 18 times in a bench-top setting using either the T-technique (n=9) or the C-technique (n=9). Reloading times were recorded in minutes. Statistical analysis was performed using the Mann–Whitney U test to compare reloading times between groups. Results are reported in median (interquartile ranges (IQR)).
Results or Findings: The C-group demonstrated significantly faster reloading times, with a median time of 3.98 minutes (3.27–5.23), compared to 11.48 minutes (8.82–17.35) in the T-group (p = .001). The C group also exhibited narrower variability, suggesting improved reproducibility.
Conclusion: The crimper-technique offers a faster and more consistent method for thoracic stent graft reloading when compared to the traditional tourniquet technique. Its use may improve procedural efficiency and reproducibility in complex endovascular aortic aneurysm repair.
Limitations: Bench-top design, single stent graft type assessed, sample size may not detect rare occurrences of infolding / device failure
Funding for this study: None.

Synthetic contrast-enhanced CT Coronary Angiography imaging (Syn-CCTA): An end-to-end Deep Learning Model (6 min)

Wanjun Hu; Lanzhou / China

Author Block: W. Hu, J. Zhang; Lanzhou/CN
Purpose: To develop and evaluate a GAN-based method for synthesizing contrast-enhanced CCTA (Syn-CCTA) from NCCTA images, and to determine whether Syn-CCTA achieves sufficient image quality for clinical diagnostic use.
Methods or Background: This retrospective study included 1,528 patients from four centers. Each patient underwent CCTA. Subsequently, we developed an end-to-end GAN model to generate Syn-CCTA images from NCCTA images in the PACS system and transmitted them back to the PACS system. The visual quality of the Syn-CCTA images was compared with that of the original CCTA images using a three-point scale. Additionally, image fidelity was quantitatively assessed using metrics such as the structural similarity index (SSIM), peak signal-to-noise ratio (PSNR), and normalized mean absolute error (NMAE), including t-tests and Mann-Whitney tests for continuous variables and Chi-square tests for dichotomous or categorical variables.
Results or Findings: Demographic data (age, gender, location of calcification) of all patients were not statistically significant. There was no statistical difference between the visual scores of Syn-CCTA images and real CCTA images (p=0.86), SSIM=0.853, PSNR=30.5dB, NMAE=0.022 for Syn-CCTA images.
Conclusion: The diagnostic efficacy of synthetic Syn-CCTA images generated using the end-to-end GAN model is comparable to conventional CCTA images. This finding underscores the potential of GAN-based methodologies to produce diagnostically valuable contrast-enhanced images without using actual contrast agents, offering significant implications for future research and clinical practice in non-invasive cardiovascular imaging.
Limitations: This study was limited by its single-center design and relatively small sample size. Additionally, the synthesized Syn-CCTA images were not validated against clinical outcomes or expert diagnostic performance, which warrants further multicenter prospective studies.
Funding for this study: This study has received funding by the Youth Science and Technology Foundation of Gansu Province (25JRRA623), Gansu Province Clinical Research Center for Functional and Molecular Imaging. Grant (No. 21JR7RA438). Key Project of Gansu Province United Research Foundation (No. 25JRRA1266).

High-Resolution Spinal Cord MR Angiography (HRSPC-MRA) for Detecting Arterial Supply and Fistulae in Spinal Dural Arteriovenous Fistulae (SDAVF) (6 min)

Wanjun Hu; Lanzhou / China

Author Block: W. Hu, J. Zhang; Lanzhou/CN
Purpose: To evaluate the diagnostic performance of high-resolution slow-flow phase-contrast MRA (HRSPC-MRA) in noninvasively detecting the arterial supply and fistula location in spinal dural arteriovenous fistula (SDAVF), using digital subtraction angiography (DSA) as the reference standard.
Methods or Background: This prospective study included 21 patients with clinically suspected and surgically confirmed SDAVF. All patients underwent HRSPC-MRA prior to surgery using the following parameters: FOV 380×380 mm, matrix 480×480, voxel size 0.8×0.8×0.8 mm^3. A double dose of gadopentetate dimeglumine (Magnevist) was administered at 4 ml/s via high-pressure injector, followed by saline. Maximum intensity projection (MIP) images were used to identify the arterial feeder(s) and fistula location(s). DSA findings served as the reference. The number and location of fistulas were compared between modalities. Agreement was assessed using Bland-Altman analysis; t-tests, Mann-Whitney U, and chi-square tests were applied as appropriate.
Results or Findings: HRSPC-MRA detected 25 fistulas versus 28 with DSA ($p = 0.256$). There was no significant difference in demographic or clinical variables. HRSPC-MRA showed high agreement with DSA in identifying both the number and location of fistulas and arterial feeders, with consistent findings on Bland-Altman plots.
Conclusion: HRSPC-MRA provides a noninvasive, contrast-enhanced alternative to DSA for identifying arterial supply and fistula location in SDAVF with comparable diagnostic performance. It holds clinical value for preoperative planning.
Limitations: The small sample size and single-center design may limit generalizability. Further validation in larger, multicenter cohorts is warranted
Funding for this study: This study has received funding by the Youth Science and Technology Foundation of Gansu Province (25JRRA623), Gansu Province Clinical Research Center for Functional and Molecular Imaging. Grant (No. 21JR7RA438). Key Project of Gansu Province United Research Foundation (No. 25JRRA1266).

Deep Transfer Learning and Radiomics Features from 3D High-Resolution MR Vessel Wall Imaging for Identifying Symptomatic Vertebrobasilar Plaques (6 min)

Guihan Lin; Lishui / China

Author Block: G. Lin, W. Chen, M. Chen, J. Ji; Lishui/CN
Purpose: To investigate the value of deep transfer learning (DTL) and radiomics features derived from three-dimensional high-resolution MR vessel wall imaging (3D HRMR-VWI) in identifying symptomatic vertebrobasilar artery plaques.
Methods or Background: This retrospective study included 331 patients with intracranial vertebrobasilar atherosclerosis. Patients were classified as symptomatic or asymptomatic based on the presence of posterior circulation symptoms within two weeks prior to imaging. Plaque features were extracted from non-contrast and contrast-enhanced 3D HRMR-VWI sequences. Handcrafted radiomics (HCR) and DTL features were obtained, and the top ten features were selected. Deep learning radiomics (DLR) features were constructed using HCR, DTL, and combined features. Seven machine learning models were trained and validated to identify symptomatic plaques. The best-performing model was further interpreted using SHapley Additive exPlanations (SHAP) analysis.
Results or Findings: Models based on combined HCR and DTL features achieved the highest predictive performance. After recursive feature elimination with a support vector machine (SVM-RFE), the SVM classifier using combined non-contrast and contrast-enhanced sequences yielded optimal results. In the validation set, the model achieved an area under the curve (AUC) of 0.996, with a Youden index of 0.920, accuracy of 0.976, sensitivity of 0.988, and specificity of 0.932. High predictive performance was confirmed in the independent test set. SHAP analysis indicated that features from contrast-enhanced 3D HRMR-VWI contributed most strongly to model predictions.
Conclusion: The DLR features derived from 3D HRMR-VWI enable accurate identification of symptomatic vertebrobasilar plaques, offering a potential tool for risk stratification and clinical decision support.
Limitations: Our study's retrospective nature may introduce inherent biases. Therefore, our proposed model requires further validation in larger prospective cohorts.
Funding for this study: This work was supported by the National Key Research and Development Program of China (2024YFC2417600) and the Zhejiang Medicine and Health Science and Technology Project (2025KY495, 2024KY568).

Development and validation of a pulmonary vessel segmentation model based on deep learning for detecting chronic thromboembolic pulmonary hypertension at CT pulmonary angiography (6 min)

Yue Lin; Beijing / China

Author Block: Y. Lin, S. Xie; Beijing/CN
Purpose: To develop, externally test, and evaluate clinical acceptability of a deep learning (DL) segmentation model of pulmonary vessels for detecting chronic thromboembolic pulmonary hypertension (CTEPH) at CT pulmonary angiography (CTPA).
Methods or Background: A multicenter, retrospective study was conducted involving 621 consecutive patients who underwent right heart catheterization (RHC), including individuals with confirmed CTEPH, CTED, and normal controls. Among them, 503 patients were assigned to the model development and internal test cohort, and the remaining 118 formed the external validation cohort.
Using CTPA, the pulmonary vasculature was reconstructed via a DL method to separate arteries from veins and compute vascular volumes based on cross-sectional area (CSA) and tortuosity for each branch. Statistically significant features were selected to develop the segmentation model. Diagnostic performance was evaluated using AUC, and the correlation between predicted and actual mean pulmonary arterial pressure (mPAP) was assessed across two institutions.
Results or Findings: The CTEPH cohort in the training set showed significantly larger total vessel volume, large vessel volume, total arterial volume, and greater arterial and venous tortuosity compared to both the CTED and control cohorts (all $P < 0.001$). Seventeen features were selected to develop a segmentation model, which demonstrated excellent diagnostic performance for identifying CTEPH using RHC results as the gold standard. The model achieved high AUC values (0.96–0.99) in both the training and internal test sets, and maintained strong accuracy in external validation. Additionally, predicted mPAP showed good agreement with real mPAP across two institutions ($R^2 = 0.91$ and 0.77, respectively).
Conclusion: Automated quantification methods using CT imaging can provide a imaging marker for identification of CTEPH and CTED.
Limitations: The findings are limited by a small sample size and multiple comparisons, which increased the risk of false-positive results.

Feasibility Study on Improving the Efficacy of Non-Contrast-Enhanced Renal Artery MRA Using Artificial Intelligence Compressed Sensing Technology (6 min)

Zuonian Hu; Guiyang / China

Author Block: Z. Hu; Guiyang/CN
Purpose: To explore the feasibility of artificial intelligence (AI)-based compressed sensing technology in enhancing imaging efficiency, image quality, and lesion detection efficacy in non-contrast-enhanced renal artery magnetic resonance angiography (MRA), and to provide a basis for optimizing non-invasive renal artery imaging protocols.
Methods or Background: A total of 60 patients with suspected renal artery lesions were enrolled and randomly divided into two groups. The control group underwent scanning with a conventional non-contrast-enhanced renal artery MRA sequence, while the experimental group was scanned using a non-contrast-enhanced MRA sequence optimized by AI compressed sensing technology. The scan time, image signal-to-noise ratio (SNR), display grade of renal artery branches, and detection accuracy of renal artery stenosis (≥50%) were compared between the two groups.
Results or Findings: Compared with the control group, the scan time of the experimental group was shortened by 42.3% ($P<0.05$); the SNR was increased by 28.6% ($P<0.05$); the display rate of renal artery branches at grade 3 and above reached 91.7%, which was significantly higher than the 73.3% of the control group ($P<0.05$); there was no significant difference in the lesion detection accuracy between the two groups (93.3% vs 86.7%, $P>0.05$).
Conclusion: AI compressed sensing technology can shorten the scan time of non-contrast-enhanced renal artery MRA and improve image quality while ensuring lesion detection efficacy, indicating its feasibility for clinical application.
Limitations: The number of patients is insufficient.
Funding for this study: No
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study has been reviewed and approved by the Ethics Committee of [Guiqian International General Hospital] (Approval No.: [KY-2025-137]). The study was conducted in strict compliance with the ethical guidelines of the Declaration of Helsinki.
All participants in this study provided adequate informed consent prior to their participation. We informed each participant in writing of the study's purpose, procedures, potential risks and benefits, confidentiality measures, and their right to withdraw unconditionally at any time. All questions raised by the participants were answered patiently by the researchers. Finally, each participant signed a Written Informed Consent Form.

Non-Contrast QISS MRI Outperforms Angiography in Detecting Lower-Limb Arterial Patency (6 min)

Judit Csőre; Budapest / Hungary

Author Block: J. Csőre[1], A. Crichton[2], E. Pomozi[2], M. Drake[2], P. Haddad[2], J. Lamichhane[2], A. B. Lumsden[2], T. L. Roy[2]; [1]Budapest/HU, [2]Houston, TX/US

Purpose: Chronic limb-threatening ischemia (CLTI) is often linked to chronic kidney disease (CKD), making vascular imaging in this population challenging. Digital subtraction angiography (DSA) remains the diagnostic reference standard but is invasive and requires iodinated contrast. Quiescent Interval Single Shot (QISS) MRI is a newer non-contrast-enhanced method that mitigates these risks. This study aimed to determine whether QISS MRI identifies a greater number of patent arterial segments than DSA, and whether this advantage is most pronounced in patients with advanced CKD (stages 4/5).

Methods or Background: Patients with CLTI who underwent both QISS MRI and DSA were included. Popliteal and infrapopliteal arteries were classified as patent or occluded across three sub-segments (e.g., AT1=proximal, AT2=mid, AT3=distal). Two blinded reviewers independently evaluated all images. Participants were stratified by GFR into <30, 30-59, ≥60 mL/min/1.73 m² groups. Primary outcome was the proportion of patent arterial segments identified by QISS compared to DSA across these GFR categories. Secondary outcomes included TASC and infrapopliteal GLASS score changes between modalities.

Results or Findings: Among 57 patients (752 vessel segments), QISS MRI demonstrated a significantly higher proportion of patent segments compared to DSA (67.2% vs 57.3%, p<0.001). Differences were significant in the <30 and ≥60 GFR groups, but not in the 30-59 group. TASC and GLASS scores were significantly downgraded using QISS MRI (mean TASC 2.2 vs 2.3, p=0.049; GLASS 2.6 vs 2.2, p<0.001).

Conclusion: QISS MRI identifies more patent vessel segments than DSA, especially in patients with advanced renal dysfunction. As earlier studies using older non-contrast MR techniques have shown comparable outcomes in bypasses to arteries visible only on MRI but not on DSA after three years, these results further support incorporating QISS MRI into routine limb-salvage assessment protocols.

Limitations: Single-center design, modest sample size

Challenges for the radiology department in mass casualties: how to train and simulate for the worst-case scenario? (15 min)
Elizabeth Dick; London / United Kingdom

1. To understand how triage and prioritisation of patients is different for a mass casualty situation than in everyday practice.
2. To anticipate and plan for some of the challenges that can occur in mass casualty settings.
3. To take part in a mini-simulation of a mass casualty using audience voting.

When an earthquake hits your own radiology department (15 min)
Nursel Yurttutan; Kahramanmaraş / Turkey

1. To learn about the challenges the radiology department faces during an earthquake.
2. To become familiar with the rapid organisational strategies employed by radiology departments following an earthquake.
3. To understand the opportunities and drawbacks arising from technological issues in disaster management.

When war hits your own radiology department (15 min)
Yurii Antonenko; Kyiv / Ukraine

1. To illustrate major threats a radiology department may encounter during a war.
2. To review strategies for keeping a stable workflow in response to war challenges.
3. To identify common pathologies related to combat and mass casualty trauma.

Floodings: what do you do when your technology is not working anymore? (15 min)
Mehmet Ruhi Onur; Ankara / Turkey

1. To be familiar with the flooding-related damage to the technological infrastructure of radiology departments.
2. To understand the preventive actions taken by radiology departments to mitigate flooding-related damage.
3. To appreciate the restoration process of equipment and technological infrastructure after flooding.

What do you do when your department is hacked? (15 min)
Niall Sheehy; Rathgar / Ireland

1. To learn about some examples where radiology departments or entire hospitals were hacked.
2. To understand the most common cybersecurity threats hospitals face.
3. To discuss potential strategies for prevention and reaction to cybersecurity incidents.

Panel discussion: Is a disaster preparedness team required for the radiology department? How should this team work? How to prepare for the future? (13 min)

CUBE 5 - It is bleeding! Call the IR?

1. To promote the role evolution of radiographers.
2. To present new opportunities for radiographers in Switzerland.

Radiographer's role in AI implementation in clinical practice (15 min)
Fabio Mattiussi; Lugano / Switzerland

1. To highlight the important role of radiographers in implementing AI tools.
2. To provide an overview of the key steps for the successful clinical implementation of AI tools in clinical practice.

Radiographers and MRI regulations in Switzerland: what is next? (15 min)
Umberto Raia; Basel / Switzerland

1. To provide an overview of the current legal framework for radiographers in MRI.
2. To emphasise the critical role of radiographers in patient care and safety in MRI.

Panel discussion (5 min)

OB 5 - Radiologic and medical insights into art across history

Categories: General Radiology, Neuro, Radiographers, Multidisciplinary, President's Choice

ETC Level: ALL LEVELS

Date: March 4, 2026 | 15:00 - 16:00 CET

CME Credits: 1

In this session, you will discover how radiological ways of seeing unlock unexpected insights far beyond medicine - from diagnosing Impressionist painters, to exposing hidden layers in artworks, to decoding medieval body imagery. A radiologist, an art restorer, and a historian team up for a captivating journey through disease, creativity, and the invisible stories images can tell.

Moderators:

Deniz Akata; Ankara / Turkey

Salman Qureshi; Abu Dhabi / United Arab Emirates

Chairpersons' introduction (2 min)

Artificial Intelligence research driven by radiographers as users (10 min)
Mélanie Champendal; Lausanne / Switzerland

1. To position radiographers as key stakeholders in AI development.
2. To explore opportunities for user-led research and innovation.
3. To address challenges in bridging clinical practice and AI research.

Improving person-centred care through effective use of AI (10 min)
Nikolaos Stogiannos; Corfu / Greece

1. To bridge AI capabilities with human-centred values.
2. To showcase practical applications that enhance personalisation.
3. To promote ethical and inclusive AI integration.

AI-enhanced communication skills for radiographers: strengthening human interaction (10 min)
Ricardo Faustino; Lisbon / Portugal

1. To recognise the dual role of AI and human empathy in radiographic practice, and how both can coexist to enhance patient care.
2. To apply communication strategies that integrate AI tools while maintaining a person-centred approach during imaging sessions.
3. To reflect on ethical and professional responsibilities when using AI in patient interactions, ensuring trust, transparency, and compassion remain central.

AI-dedicated simulated patient for communication skills training (10 min)
Andrea Roletto; Milan / Italy

1. To learn how AI can be applied to enhance communication skills training for patients to support person-centred care.
2. To recognise the ethical and practical considerations when integrating AI into patient communication training.
3. To evaluate real-world examples where AI-supported communication tools have been used in patient care.

Open forum discussion (15 min)

OF 5Y - Meet the Young Clubs: connecting Europe's rising radiologists

Categories: Students, Research, Management/Leadership, Education

ETC Level: ALL LEVELS

Date: March 4, 2026 | 15:00 - 16:00 CET

CME Credits: 1

National and subspecialty "young clubs" are growing fast across Europe, but what do they actually do, and how can they work together? In this session, representatives from several initiatives present their mission, achievements, and future goals. Attendees will gain insight into how these networks support education, advocacy, and community-building for the next generation of radiologists.

Moderators:

Ioana Andreea Gheonea; Craiova / Romania

Saif Afat; Tübingen / Germany

Robert Rischen; Münster / Germany

Nadine Christina Bayerl; Erlangen / Germany

ESNR Rising Star Programme: training the next neuro leaders (10 min)

Evgenia Efthymiou; Athens / Greece

ESSR Young Club: building bridges in musculoskeletal radiology (10 min)

Barbora Horehledova; Heerlen / Netherlands

Open forum discussion: What's next for Europe's young radiologists? (15 min)

RC 501 - Abbreviated MRI protocols in the abdomen

Categories: GI Tract, Abdominal Viscera, Sustainability, President's Choice
ETC Level: LEVEL II+III
Date: March 4, 2026 | 15:00 - 16:00 CET
CME Credits: 1

Moderator:
Isabelle De Kock; Ghent / Belgium

Chairperson's introduction (3 min)
Isabelle De Kock; Ghent / Belgium

Abbreviated MRI of the pancreas: fast but accurate? (15 min)
Giulia Zamboni; Verona / Italy

1. To define key sequences needed for pancreatic lesion detection and staging.
2. To evaluate the role of abbreviated MRI for pancreatic cysts and high-risk screening.
3. To discuss diagnostic performance versus full protocols and practical limitations.

Abbreviated liver MRI: a game changer for surveillance (15 min)
Jeong Min Lee; Seoul / Korea, Republic of

1. To review current protocols for abbreviated liver MRI in hepatocellular carcinoma screening.
2. To understand the impact of contrast agents and timing on lesion detectability.
3. To assess diagnostic accuracy and cost-effectiveness in cirrhotic populations.

Abbreviated MRI for the GI tract: where do we stand? (15 min)
Karin Horsthuis; Amsterdam / Netherlands

1. To explore abbreviated protocols for Crohn’s disease, rectal cancer, and pelvic floor disorders.
2. To identify essential sequences that maintain diagnostic value.
3. To evaluate patient comfort, scan time, and workflow advantages.

Panel discussion: Abbreviated MRI: can less be more? (12 min)

RC 510 - Peripheral nerve imaging

Categories: Musculoskeletal, Imaging Methods, President's Choice
ETC Level: LEVEL II+III
Date: March 4, 2026 | 15:00 - 16:00 CET

Vasco V Mascarenhas; Lisbon / Portugal

MR-neurography (15 min)
Suren Armeni Jengojan; Vienna / Austria

1. To discuss the protocol for MR-neurography.
2. To identify the advantages and disadvantages of MR neurography and tractography.
3. To describe the main findings detectable with this technique.

When ultrasound is enough (15 min)
Carlo Martinoli; Genova / Italy

1. To address how ultrasound of nerves must be performed.
2. To define when it is sufficient or not.
3. To describe the main findings detectable with this technique.

Denervation syndromes (15 min)
Sarah Yanny; Aylesbury / United Kingdom

1. To define denervation syndromes.
2. To address the role of imaging.
3. To describe the main findings at imaging.

Panel discussion: Is MR-neurography feasible for clinical routine? (10 min)

RC 511 - Cost vs field strength in MRI

Categories: General Radiology, Imaging Methods, Neuro, Physics in Medical Imaging, President's Choice

Chairperson's introduction (2 min)
Meike W. Vernooij; Rotterdam / Netherlands

Low-field MRI: clinical scenarios, technical insights, and economic value in modern imaging (12 min)
Joan C. Vilanova; Girona / Spain

1. To identify clinical scenarios where low-field MRI provides sufficient diagnostic accuracy.
2. To understand the technical limitations and advantages of low-field systems.
3. To evaluate cost-effectiveness and accessibility in the context of low-field MRI.

When do we really benefit from having a high-field clinical MR system (5T)? (12 min)
Bing Zhang; Jiangsu Nanjing / China

1. To understand the specific clinical and research applications where 5T and 7T MRI provide added diagnostic value over conventional field strengths.
2. To identify anatomical regions and pathologies that particularly benefit from the higher resolution and contrast of ultra-high-field MRI.
3. To evaluate the practical limitations, costs, and implementation challenges associated with high-field MR systems in clinical settings.

Acceleration methods in MRI (12 min)
Sven Haller; Geneva / Switzerland

1. To review the principles and implementation of acceleration techniques such as parallel imaging (SENSE, GRAPPA) and compressed sensing in clinical MRI.
2. To evaluate the impact of acceleration methods on image quality, signal-to-noise ratio, and artefact generation across different MRI sequences.
3. To understand the role of AI-based reconstruction algorithms in pushing the limits of acquisition speed and workflow optimisation.

Portable MRI: lessons learned from the clinical point of view (12 min)
Massimo Caulo; Chieti / Italy

1. To understand what portable MRI can (and can't) do in real clinical scenarios.
2. To explore the advantages of bringing the scanner to the patient, especially in critical care or remote settings.
3. To learn from early experiences—what has worked, what hasn’t, and where portable MRI is heading next.

Panel discussion: How should we advance technically with MR? (10 min)

RC 512 - Paediatric neuroradiology emergencies

Categories: Emergency Imaging, Neuro, Paediatric
ETC Level: LEVEL II
Date: March 4, 2026 | 15:00 - 16:00 CET
CME Credits: 1

Moderator:
Andrea Rossi; Genoa / Italy

Chairperson's introduction (5 min)
Andrea Rossi; Genoa / Italy

Paediatric stroke (15 min)
Asthik Biswas; London / United Kingdom

1. To discuss the imaging features of paediatric 'acute brain attacks', and when stroke should be considered.
2. To describe and understand the differences in adult and paediatric stroke.
3. To discuss imaging protocols and the potential role of advanced imaging techniques and their pitfalls.

Paediatric CNS infections (15 min)
Maia Proisy; Rennes / France

1. To learn about the different types and pathways of infections.
2. To describe typical and atypical imaging features of CNS infections.
3. To review the imaging protocol for assessment of CNS infections.

Paediatric head trauma (15 min)
Sjoert Pegge; Leersum / Netherlands

1. To illustrate the head trauma mechanisms in children.
2. To list the signs of accidental versus non-accidental trauma.
3. To discuss the imaging protocols in paediatric head trauma.

Panel discussion: How can imaging guide clinical management? Is CT always the first choice? (10 min)

RPS 501 - Interventional oncology and treatment assessment in liver cancer

MR Radiomics to Predict Recurrence Location in Nonviable Hepatocellular Carcinoma After Transarterial Chemoembolization (6 min)
Shu-Hang Zhang; Jiangsu / China

Author Block: S-H. Zhang[1], Y. Song[2], Y-C. Wang[1]; [1]Jiangsu/CN, [2]Shanghai/CN
Purpose: To develop a predictive model that integrates radiomics features from contrast-enhanced MRI with conventional radiologic features to identify early recurrence locations in nonviable hepatocellular carcinoma (HCC) after transarterial chemoembolization (TACE).
Methods or Background: This multicenter retrospective study included HCC patients treated with TACE whose contrast-enhanced MRI at 1–2 months post-treatment showed LR-TR nonviable lesions ≥1.0 cm with at least one-year follow-up. A 1-cm peritumoral ring was divided into eight sectors for radiomics feature extraction to build a radiomics model. A fusion model combined these features with two radiologic characteristics (non-smooth margin and peritumoral hyperintensity on T2- or diffusion-weighted images). Model performance was evaluated using ROC curves, and differences were assessed by the DeLong test.
Results or Findings: A total of 616 sectors from 77 lesions were included in the study, including 96 (15.6%) sectors with recurrence within one year of follow-up. The radiomics model achieved AUC of 0.738 and 0.718 in the training and test cohorts. The radiologic model, constructed using non-smooth margin and peritumoral hyperintensity on T2-weighted or diffusion-weighted images, achieved AUC of 0.751 and 0.744 in the training and test cohorts, respectively. The fusion model combining three radiomics features and two radiologic features achieved AUC of 0.794 and 0.765 in the training and test cohorts, respectively. The DeLong test demonstrated a statistically significant difference between the fusion model and the radiologic model in the training cohort (P = 0.026).
Conclusion: The fusion model combining selected radiomics features and conventional radiologic features demonstrated excellent performance in predicting the site of recurrence in LR-TR nonviable HCC lesions following TACE.
Limitations: Its retrospective design may introduce selection bias, and the limited sample size raises concerns about potential overfitting and restricted generalizability, highlighting the need for prospective validation.
Funding for this study: This study has received funding by National Natural Science Foundation of China (NSFC, No. 82271978).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This multicenter, retrospective study was reviewed and approved by Institutional Ethics Committee for clinical research of the hospital, approval number [2024ZDSYLL149-P01], with a waiver for informed consent.

Prognostic Prediction Models Incorporating Longitudinal MRI Features in Hepatocellular Carcinoma Patients after Transarterial Chemoembolization (6 min)
Shu-Hang Zhang; Jiangsu / China

Author Block: B. Li, S-H. Zhang, Y-C. Wang; Nanjing/CN
Purpose: Current prognostic prediction models of hepatocellular carcinoma (HCC) who treated with transarterial chemoembolization (TACE) include only the preoperative imaging and clinical features, with their available repeated postoperative MRI features measurements underutilized. HCC prognostic prediction models were constructed in this study to clarify whether and to what extent the inclusion of postoperative longitudinal measurements of longest diameter of active lesions, number of tumors, longest diameter of target lesions and Apparent Diffusion Coefficient (ADC) value of target lesions can improve the model performance and perform a dynamic prediction.
Methods or Background: The training cohort study included 56 HCC patients who underwent TACE, with preoperative measurement and three or more measurements within 24 months after TACE, respectively. Prediction models to predict HCC untreatable tumor-aggressive progression (macrovascular invasion, extrahepatic spread, >50% liver involvement) were constructed with clinical variables, by incorporating preoperative quantitative MRI imaging features , as well as their postoperative longitudinal measurements.
Results or Findings: The prediction model with postoperative longitudinal measurements of longest diameter of active lesions and number of tumors within 24 months after TACE outperformed the model including preoperative imaging and clinical features only, with the better area under the receiver operating characteristic curves (AUCs: 0.859 vs 0.797), (AUCs: 0.923 vs 0.815) and (AUCs: 0.824 vs 0.786) at 12, 24, and 36 months after TACE. The proposed longitudinal prediction model can provide a personalized dynamic prediction for a new patient, with estimated survival probability updated when a new measurement is collected during 24 months after TACE.
Conclusion: Prediction models including longitudinal measurements of longest diameter of active lesions and number of tumors have improved accuracy in predicting the prognosis of HCC patients.
Limitations: The proposed prediction models were developed solely on a single-institution cohort without external validation.
Funding for this study: This study has received funding by National Natural Science Foundation of China (NSFC, No. 82271978, 92359304, 82330060)

HCC nodules in cirrhotic patients: prognostic value of iodine concentration density derived from dual energy CT iodine maps (6 min)

Pietro Andrea Bonaffini; Monza / Italy

Author Block: P. A. Bonaffini, P. Majoro, A. Celestino, A. Barbaro, C. Gargiulo, P. Marra, S. Sironi; Monza/IT
Purpose: To assess the prognostic value of iodine concentration differences measured on iodine maps derived by dual energy CT (DECT) in hepatocellular carcinoma (HCC) in cirrhosis, comparing untreated nodules (disease progression/stability) and those with recurrence after loco-regional therapies.
Methods or Background: DECT of suspected HCC (LI-RADS 3-5) were retrospectively reviewed (March 2022-September 2023; minimum 3 months follow-up) . Lesions were divided in untreated (group 1) and undergoing loco-regional treatments (group 2). Progression was defined as ≥20% size increase (mRECIST). Iodine maps were generated in the hepatic arterial and portal venous phases. In each phase iodine concentration density (ICD, mg/ml) was measured by ROI placed in homogeneously enhancing portion of the target nodule (aICDnodule, vICDnodule) and in the non-nodular parenchyma (aICDliver, vICDliver). Lesion-to-normal liver ICD ratio (aLNR, vLNR) to quantify nodule enhancement behavior and ratio of LNR during the arterial to the venous phase (ravLNR) were calculated and compared.
Results or Findings: Twenty-two patients (mean age 69.5 years) with 41 lesions (19 LI-RADS 3; 6 LI-RADS 4; 16 LI-RADS 5) were included in group 1. In lesions demonstrating progression (14/41) baseline ICD values were significantly lower compared to stable nodules: aICDnodule 26.0 (IQR 20.5-30.5) vs 33 (IQR 27-40), vICDnodule 22 (IQR 19-25) vs 25.5 (IQR 27-40), respectively. Twenty-two patients (mean age 70.3 years) with 31 lesions (8 LI-RADS 3; 2 LI-RADS 4; 21 LI-RADS 5) were included in group 2. The comparison of the median iodine concentrations (aICD, vICD, aLNR, vLNR, ravLNR) at baseline between lesions relapsing after treatment and those without recurrence showed no significant differences.
Conclusion: Quantification of iodine concentration on DECT may support the prognostic stratification of suspected HCC in cirrhotic patients, helping to predict the risk of progression in non-treated lesions.
Limitations: Retrospective
Small sample size
Funding for this study: Not applicable
Has your study been approved by an ethics committee? Not applicable

Early Intrazonal Recurrence in HCC Treated with Ablation Therapies - Focus on CEUS (6 min)

Paolo Buscemi; Palermo / Italy

Author Block: P. Buscemi[1], M. D'Amico[1], M. G. Vallone[1], F. Meloni[2]; [1]Palermo/IT, [2]Milan/IT
Purpose: Hepatocellular carcinoma (HCC) is the most common primary liver tumor, with an increasing global incidence. Early recurrence detection post-ablation improves retreatment outcomes and survival. This study evaluates the role of CEUS in identifying early CC recurrence through the characterization of patent arteries observed 24 hours post-ablation via CECT and follow-up imaging.
Methods or Background: Ninety-eight patients (66 men, 32 women) with 121 HCCs treated with RFA (62) or MWA (59) between January 2016 and December 2019 were analyzed.
Post-treatment imaging included CT and CEUS at 24 hours and CT/MRI with CEUS every four months. Peri-ablative vessels (5-10 mm from the periphery) were identified in 51/121 lesions (42.1%), while intranecrotic vessels were found in 28/51 lesions (54.9%).
Results or Findings: Intralesional vessels increased in caliber and length in 75% of cases, leading to the development of enhancement with wash-in and wash-out consistent with intrazonal recurrence. CEUS detected intralesional vascular recurrence earlier than CT/MRI, with only 2/21 cases (9.5%) visible on CT/MRI. A significant correlation was found between local recurrence and perilesional vessels ($p<0.01$), as well as between periablation and intralesional vessels ($p<0.01$), highlighting a microenvironment favorable to neo-angiogenesis. Perilesional vascularization was significantly associated with RFA ($p<0.01$).
Conclusion: Persistent vascularization near the ablation site may promote intra- and perizonal recurrence by sustaining residual tumor cells. CEUS demonstrated superior sensitivity in detecting early intralesional recurrence compared to CT/MRI, supporting its role in post-ablation surveillance.
Limitations: Single-center retrospective design
Funding for this study: This study received no funding
Has your study been approved by an ethics committee? Not applicable

Prediction of Local Recurrence After Hepatocellular Carcinoma Ablation Based on Multiple Machine Learning Models (6 min)

Ruihong Zhang; Harbin, Heilongjiang / China

Author Block: R. Zhang; Harbin, Heilongjiang/CN
Purpose: This study aimed to develop predictive models for local recurrence after HCC ablation by integrating multidimensional clinical data and imaging features with multiple machine learning algorithms.
Methods or Background: A retrospective cohort study was conducted, including 460 patients with 1,130 HCC lesions who underwent ablation between June 2016 and June 2024. After applying strict inclusion and exclusion criteria, 459 lesions were enrolled and divided into a training cohort (n = 321) and a validation cohort (n = 138). Multiple machine learning algorithms, including logistic regression, random forest, support vector machine, multilayer perceptron, LightGBM, and LASSO, were applied for feature selection and model construction. Predictive performance was compared across models using the area under the receiver operating characteristic curve (AUC), and the optimal model was identified. A visual nomogram was then developed. Calibration curves and decision curve analysis (DCA) were employed to evaluate model performance, while Kaplan–Meier (KM) survival analysis was used to assess recurrence-free survival (RFS) differences among different risk groups.
Results or Findings: Performance comparison demonstrated that the predictive model based on LASSO-selected features achieved the best performance, with AUC values of 0.894 in the training cohort and 0.775 in the validation cohort. The constructed nomogram further confirmed the model's feasibility and practicality in clinical applications. KM survival analysis showed significant differences in recurrence time across risk groups ($p < 0.001$), validating the model's effectiveness and clinical value.
Conclusion: The machine learning prediction model constructed using LASSO feature selection exhibited high accuracy and stability in predicting local recurrence after HCC ablation. This provides a reliable tool for early identification of high-risk patients and formulation of individualized treatment strategies in clinical practice.
Limitations: This study is that only Chinese patients were included.
Funding for this study: Harbin Medical University Cancer HospitalClimbing program (PDYS2024-10).

Fully automated spleen segmentation predicts progression-free survival in HCC patients following transarterial radioembolization (6 min)

Lisa Steinhelfer; Munich / Germany

Author Block: L. Steinhelfer[1], F. Jungmann[1], L. Endrös[1], M. Eiber[2], R. Braren[1]; [1]Munich/DE, [2]Vaterstetten/DE
Purpose: Transarterial radioembolization (TARE) is an established treatment for unresectable hepatocellular carcinoma (HCC), but its effects on non-tumorous tissue remain insufficiently characterized. This study aimed to evaluate splenic volume dynamics on imaging as potential prognostic biomarkers for disease progression after TARE.
Methods or Background: We retrospectively analyzed imaging and laboratory data from 73 patients with histologically or imaging-confirmed HCC treated with Yttrium-90 TARE at our institution between January 2012 and September 2022. Inclusion criteria were age ≥18 years, baseline and 3-month follow-up imaging, and complete clinical documentation. Patients who underwent liver resection, transplantation, or additional therapies during follow-up were excluded. Splenic volumes were obtained using automated segmentation and compared with conventional two-dimensional measurements and laboratory markers.
Results or Findings: A relative increase in splenic volume at 3 months emerged as the only independent predictor of progression-free survival (PFS). The model achieved a ROC-AUC of 0.86 (95% CI: 0.76–0.95). An increase ≥18% most accurately identified patients with early disease progression (<12 months), with sensitivity of 0.74 and specificity of 0.97. Prognostic performance was superior to established clinical and laboratory parameters, including craniocaudal spleen size.
Conclusion: Automated splenic volumetry provides strong prognostic information in HCC patients undergoing TARE. Post-treatment increases in spleen volume represent a robust, accessible imaging biomarker for early risk stratification and may support individualized treatment planning.
Limitations: This was a retrospective, single-center study with limited sample size. External validation in larger, multicenter cohorts is warranted.
Funding for this study: No funding.

LI-RADS CT/MRI Nonradiation Treatment Response Assessment Version 2024: Patterns of Recurrence after Surgical Resection (6 min)

Sung-Hua Chiu; Taipei / Taiwan, Chinese Taipei

Author Block: S-H. Chiu[1], D. Delitto[2], L. S. Yoon[2], A. Kamaya[2], J. Tse[2]; [1]Taipei/TW, [2]Palo alto, CA/US
Purpose: The LI-RADS CT/MRI Nonradiation Treatment Response Algorithm (v2024) extends its application to assessing the surgical margin after hepatocellular carcinoma (HCC) resection. This study aims to apply v2024 to surgically-resected HCCs, determine rates of local recurrence defined by v2024, and evaluate the timing of recurrence during postoperative surveillance.
Methods or Background: This retrospective study included patients with surgically-resected HCC and postoperative liver CT/MRI for ≥6 months. v2024 and LI-RADS CT/MRI Diagnosis Version 2018 (v2018) were applied to the surgical margin. Two abdominal radiologists assessed for local recurrence (LR-TR Viable meeting ≥LR-4 by v2018 at diagnosis or follow-up), intrahepatic recurrence away from the margin (new lesion meeting ≥LR-4), and extrahepatic disease. Discrepancies were resolved by a third radiologist.
Results or Findings: Two hundred patients (142 men and 58 women; median age 67 years) were followed for a median of 30.5 months [IQR 13.7-60.1]. LR-TR Viable at the surgical margin occurred in 57 patients (28.5%) after a median of 5.1 months. At diagnosis, 26 LR-TR Viable observations (45.6%) already met v2018 criteria for ≥LR-4, while 31 (54.4%) did not; of these, 30 progressed to ≥LR-4 after a median of 3.2 months, and 1 resolved with no residual HCC at transplantation. Intrahepatic recurrence away from the margin developed in 77 patients (38.5%) after a median of 10.9 months, and extrahepatic recurrence in 37 patients (18.5%) after 5.4 months. Inter-reader agreement for LR-TR category was excellent (κ=0.93), and its positive predictive value for local recurrence was 98.2%.
Conclusion: In about half of cases, v2024 detects local recurrence at the surgical margin roughly 3 months before HCC criteria are met, enabling earlier diagnosis of local recurrence.
Limitations: Single-center, retrospective study, and relied on v2018 rather than histologic confirmation as the reference standard for recurrence.

Quantitative CT Perfusion and Radiomics Reveal Complementary Markers of Treatment Response in HCC Patients Undergoing TACE (6 min)

Julian Niklas Nonninger; Vienna / Austria

Author Block: J. N. Nonninger[1], J. Slavicek[1], N. Fezoulidis[1], K. Hergan[2], S. Zandieh[1]; [1]Vienna/AT, [2]Salzburg/AT
Purpose: Hepatocellular carcinoma (HCC), the most common primary liver cancer, is often treated with transarterial chemoembolization (TACE). Standard criteria (RECIST, mRECIST) may miss early changes, underestimating therapeutic effects. Quantitative imaging may improve early assessment and guide therapy. This study analyzed CT perfusion and radiomic features of HCC before and after TACE and their association with tumor burden.
Methods or Background: In this retrospective, single-center study, 32 patients with histologically confirmed HCC underwent CT perfusion and radiomic analysis prior to and following TACE. Multiple quantitative perfusion parameters (arterial flow, perfusion flow, perfusion index) and radiomic features were extracted. Statistical comparisons were performed using the Wilcoxon signed-rank test and Spearman's correlation.
Results or Findings: Arterial flow significantly decreased from a median of 56.5 to 47.7 mL/100 mL/min after TACE ($p = 0.009$), while nonsignificant increases in perfusion flow (from 101.3 to 107.8 mL/100 mL/min, $p = 0.44$) and decreases in the perfusion index (from 38.6% to 35.7%, $p = 0.25$) were observed. Perfusion flow was strongly and positively correlated with tumor size ($\rho = 0.94$, $p < 0.001$). Five radiomic texture features especially ShortRunHighGrayLevelEmphasis ($\Delta = +2.11$, $p = 0.0001$) and LargeAreaHighGrayLevelEmphasis ($\Delta = +75{,}706$, $p = 0.0006$)—changed significantly after treatment. These changes were more pronounced in tumors ≥50 mm.
Conclusion: CT perfusion and radiomics offer complementary insights into the treatment response of patients with HCC. While perfusion parameters reflect macroscopic vascular changes and are correlated with tumor burden, radiomic features can indicate microstructural changes after TACE. This combined imaging approach may improve early therapeutic assessment and support precision oncology strategies.
Limitations: Despite its strengths, the study has limitations, including its retrospective design and potential observer bias from manual segmentation, which was mitigated by consensus reading.
Funding for this study: No funds were used in this study.

Prevalence of mitral annular disjunction (MAD), mitral valve prolapse (MVP), and curling in a healthy population: assessment by cardiac MRI and correlation with left ventricular myocardial T1 mapping (6 min)
Paola Franceschi; Bologna / Italy

Author Block: P. Franceschi[1], F. Calo'[2], V. Russo[1], F. Niro[1], F. Buia[1], D. Attinà[1], C. Sportoletti[1], E. Rasciti[1], L. Lovato[1]; [1]Bologna/IT, [2]Brindisi/IT
Purpose: To assess the prevalence of mitral annular disjunction (MAD), mitral valve prolapse (MVP), and curling in healthy individuals using cardiac magnetic resonance (CMR), and to evaluate correlations between MAD length and native myocardial T1 mapping values.
Methods or Background: We prospectively enrolled 141 healthy volunteers (mean age 39 years; 57% female) without cardiovascular risk factors. CMR at 3T included ECG-triggered cine balanced steady-state free precession acquisitions in 2-, 3-, and 4-chamber long-axis views. Native T1 mapping was performed in three short-axis slices. Global and segmental values were extracted.
Results or Findings: MAD was detected in 63 of 140 subjects (45%), mostly in the inferior segment, with lengths between 1–12 mm. MVP was identified in 65 of 137 subjects (47%), predominantly monoleaflet (39%). MVP was more prevalent in subjects with MAD (56%), with significantly longer disjunction in bileaflet prolapse compared with monoleaflet or absent MVP (5±3 mm vs. 1±2 mm; $p<0.001$). Curling was observed in 3 of 140 cases (2%); two of these also presented with MAD and MVP. MAD length was greater in individuals with curling (7±2 mm vs. 1±2 mm; $p<0.001$). Native T1 showed no significant differences between participants with or without MAD, MVP, or curling.
Conclusion: MAD is a frequent finding in healthy individuals, predominantly at the inferior annulus. Native T1 values remained normal across groups, suggesting preserved myocardial tissue. While isolated MAD seems benign, longer disjunction associated with MVP and curling indicates structural remodeling of the atrioventricular junction and may represent an arrhythmogenic substrate. CMR enables simultaneous morphological and tissue characterization, supporting its role in early identification of at-risk phenotypes.
Limitations: The limitation of the study is the lack of correlation with echocardiographic, ECG and fibrosis data (contrast agent was not administered in healthy volunteers).
Funding for this study: No funding was received for this study.

CMR-Based Prediction of Arrhythmic Risk in Mitral Valve Prolapse (6 min)
Yusuf Bahtiyar Uluman; Istanbul / Turkey

Author Block: Y. B. Uluman, E. İsmailov, F. Köse, M. Kadıoğlu, B. Tütüncüoğlu, F. Alpaslan, T. Banaz, K. B. Bekaroğlu, S. Baş Özkök; Istanbul/TR
Purpose: To investigate the association between cardiac arrhythmias and cardiac magnetic resonance (CMR) findings in mitral valve prolapse (MVP).
Methods or Background: MVP is usually benign, but some patients develop malignant arrhythmias and sudden cardiac death; CMR may help identify structural risk markers.
We retrospectively analyzed 27 MVP patients underwent 1.5 Tesla CMR with cine, T1/T2 mapping, and late-gadolinium-enhancement (LGE). Assessed parameters included ventricular volume/function, prolapse height, valve thickening, mitral annular disjunction, and LGE extent/localization. Prolapse height was defined relative to the atrioventricular junction, and measurements were performed using automated segmentation with manual correction. ECG/Holter were used to assessed arrhythmia. Continuous variables were presented as mean±SD and compared with the Mann–Whitney U test; categorical variables with the chi-square test. Correlations were examined using Pearson or Spearman coefficients, and multivariate logistic regression identified independent arrhythmia predictors. Significance was set at $p<0.05$.
Results or Findings: Mean prolapse height was 9.3±3.0 mm, and valve thickening was present in 29.6% of patients. MAD was identified in 66.7% (true/pseudo ratio: 11/8). Arrhythmia occurred in 44.4%, while biventricular systolic function was preserved. LGE was observed in 81.5% of patients, mostly limited (<5% of myocardial volume in 86.4%), involving the inferolateral wall in 29.6% and papillary muscles in 18.5%. Documented arrhythmias includes ventricular extrasystole (n=5), atrial fibrillation (n=2), and sustained ventricular tachycardia (n=5); no sudden death occurred. LGE extent and inferolateral wall involvement were not associated with arrhythmia, whereas papillary muscle fibrosis showed a significant correlation (OR=31.1,p=0.02,AUC=0.89).
Conclusion: This study demonstrated that papillary muscle fibrosis is a strong independent predictor of arrhythmia in patients with mitral valve prolapse. The findings suggest that papillary involvement, rather than global myocardial fibrosis, may represent the key structural substrate for arrhythmogenesis in this population.
Limitations: Relatively small, single-centre sample size.

Diagnostic Accuracy of High Pitch Spectral Imaging Photon-Counting CT for the Assessment of Coronary Artery Disease in Single Scan Pre-Transcatheter Aortic Valve Workup (6 min)

Christian Booz; Frankfurt / Germany

Author Block: C. Booz[1], S. Waldeck[2], L. S. Alizadeh[1], I. Yel[1], T. Vogl[1], A-I. Nica[1], V. Koch[1], L. D. Grünewald[1], D. Overhoff[2]; [1]Frankfurt/DE, [2]Koblenz/DE
Purpose: To evaluate the diagnostic accuracy of high pitch coronary CT angiography (CCTA) spectral datasets derived from a single CTA for the assessment of coronary artery disease (CAD) in transcatheter aortic valve implantation (TAVI) imaging using invasive coronary angiography (ICA) as reference standard.
Methods or Background: Patients with severe aortic stenosis who underwent photon-counting CT TAVI pre-procedural planning between April 2022 and February 2023 were retrospectively selected. The spectral CCTA datasets were used for the evaluation of objective and subjective image quality. Additionally, the diagnostic accuracy was assessed by determining, sensibility, specificity, positive predictive value (PPV) and negative predictive value (NPV) using ICA as reference standard both on a per-vessel and a per-segment basis. Furthermore, patients were divided in two groups according to calcium score values to define the impact of calcium burden on the diagnostic performance.
Results or Findings: The final study population included 93 patients (mean age, 80±8.4 years; 58 men). The mean overall signal-to-noise ratio was 8.7±2.5 while the contrast-to-noise ratio set on mean values of 9.6±2.5. Image quality median value was 1 [1-2] for the subjective assessment. The diagnostic accuracy for the detection of CAD resulted in a sensitivity of 90.3% (95%CI: 82.9-95.2), specificity of 79.9% (95%CI: 74.5-84.6), PPV of 64.1% (95%CI: 58.2-69.7), NPV of 95.4% (95%CI: 92-97.4). On a per-segment basis sensitivity was 86.4% (95%CI: 79.1-91.9), specificity was 87.6% (95%CI: 85-90), PPV was 56% (95%CI: 50.7-61.1) and NPV was 97.3% (95%CI: 95.8-98.2).
Conclusion: Spectral datasets based on high pitch photon-counting single scan CCTA allow for high diagnostic accuracy in the evaluation of CAD in high-risk patients.
Limitations: Limitations of the study include its retrospective nature.
Funding for this study: No funding was obtained for this study.

Spectral CT-derived myocardial ECV predicts left ventricular reverse remodeling post-TAVR in aortic regurgitation (6 min)

Shuting Yue; Chengdu / China

Author Block: S. Yue, J. Sun; Chengdu/CN
Purpose: To investigate the value of the extracellular volume (ECV) for predicting early left ventricular reverse remodeling(LVRR)in patients with aortic regurgitation(AR) following transcatheter aortic valve replacement (TAVR) using dual-layer detector spectral CT
Methods or Background: A total of 51 patients with severe aortic regurgitation from January to September 2024 were prospectively enrolled. All underwent coronary CT angiography and delayed iodine enhancement scanning using DLCT. Left ventricular reverse remodeling (LVRR) was defined as ≥15% reduction in left ventricular end-systolic volume (LVESV) post-TAVR. Patients were grouped by LVRR occurrence. Intergroup differences in clinical, echocardiographic, and CT-derived ECV values were analyzed using t-tests, Mann–Whitney U, or chi-square tests. Cox regression assessed associations between variables and LVRR, while ROC and Kaplan–Meier analyses evaluated predictive efficacy.
Results or Findings: Significant differences in preoperative CT-ECV and fractional shortening (FS) were observed between the two groups ($P < 0.05$). Multivariable Cox proportional hazards regression analysis of age, preoperative CT-ECV as independent predictors of early LVRR in patients with severe AR. ROC analysis showed that CT-ECV predicted LVRR with an AUC of 0.759 , Age predicted early LVRR with an AUC of 0.664, The combination of CT-ECV and age predicted LVRR with an AUC of 0.806 . Kaplan–Meier curves demonstrated that patients with CT-ECV > 32.1% or age > 68.5 years had a significantly higher cumulative incidence of failure to achieve LVRR after TAVR.
Conclusion: The ECV quantified by DLCT can effectively predict the occurrence of LVRR after TAVR in patients with AR, and may provide valuable reference value for clinical prognostic assessment.
Limitations: (1) This study is a single-center investigation with a relatively small sample size. (2) This study did not evaluate the relationship between CT-ECV and clinical adverse outcomes in AR patients.

Total body CT-derived opportunistic parameters for predicting TAVI outcomes: a data-driven approach (6 min)

Marta Liberotti; Milan / Italy

Author Block: M. Liberotti[1], A. Colombo[1], V. Dubreuil[2], C. Gnasso[1], D. Vignale[1], A. Palmisano[1], A. Esposito[1]; [1]Milan/IT, [2]London/UK
Purpose: Transcatheter aortic valve implantation (TAVI) is widely adopted treatment for severe aortic stenosis (AS) in high-risk patients. Accurate pre-TAVI risk stratification is crucial to predict post-procedural outcomes, and planning CT could provide opportunistic biomarkers that objectively capture patient frailty and comorbidities. This study aims to automatically extract opportunistic parameters from TAVI-planning CT to create a data-driven model to predict 1-year outcomes.
Methods or Background: In this single-center retrospective observational study, TAVI-planning CTs were automatically segmented using a pre-trained open-source nnUNet model. An automated pipeline extracted volume (mm^3) and density metrics (HU) from over 120 anatomical structures per patient. From 1330 initial features, stable variables were identified via 5-fold cross-validated Random Survival Forest, filtered with univariate Cox, refined by Cox-LASSO and backward elimination. A multivariable Cox model predicting 1-year mortality was built and its performance assessed using the mean concordance index (C-index).
Results or Findings: The study included 458 severe AS patients undergoing TAVI (F/M=234/224; median age 82, IQR: 78-85). At 12-month follow-up post-TAVI, 70 deaths and 24 hospitalizations for heart failure occurred. Following multistage feature selection, five variables informed the final model with four independent event predictors: left atrial volume (HR 1.41s, p=0.03), HU standard deviation in left upper lung lobe (HR 1.30, p<0.005) and brachiocephalic arterial trunk (HR 1.20, p=0.01) and 95th percentile HU in intervertebral discs (HR 1.27, p<0.005). The multivariable Cox model, adjusted for demographic and clinical variables, achieved a mean C-index of 0.72 (± 0.06), demonstrating strong prognostic performance.
Conclusion: This study confirms the potential of total body CT-derived parameters to predict post TAVI outcomes for severe AS patients, by integrating multiple features into a unified predictive model.
Limitations: Retrospective and single-center design may introduce potential bias. The model was not externally validated.
Funding for this study: This study was partially granted by: European Union - Next Generation EU, Mission 4 Component 1, CUP D53D23 021100001", Bando PRIN PNRR 2022 (P2022JBKN2), Italian Ministry of University and Research (MUR).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This monocentric observational study was approved by the institutional review board (CT-based myocardial characterization study: CTMyoC 112/INT/2019). The study is a retrospective analysis of prospectively collected data and was conducted according to the Declaration of Helsinki. Written informed consent was obtained for all participants.

Photon-Counting Detector CT versus Cardiac Magnetic Resonance for ECV Quantification: Impact of Reconstruction Phase and Myocardial Layer Analysis (6 min)

Shu nan Li; Lanzhou, China / China

Author Block: S. n. Li, X. Tong, W. Tian, N. Yang, B. Zhu, J. Nan, G. Wang, Z. Chen; Lanzhou, China/CN
Purpose: To assess the agreement in myocardial extracellular volume fraction(ECV) quantification between photon-counting detector CT (PCD-CT) and cardiovascular magnetic resonance (CMR) in patients with cardiovascular disease, and to identify the optimal PCD-CT reconstruction phase and myocardial layer for measurement.
Methods or Background: This retrospective study included 11 cardiovascular disease patients who underwent both PCD-CT(with late iodine enhancement) and CMR. ECV derived from CMR served as the reference standard, calculated via a standardized formula. PCD-CT-based ECV was measured at both systolic and diastolic reconstruction phases, with regions of interest placed in the endocardial, mid-myocardial, and epicardial layers, as well as their average.
Results or Findings: A significant correlation was found between PCD-CT-systolic-epicardial-ECV and CMR-ECV(r = 0.835, 95% CI: 0.471–0.956, p = 0.001), and a strong correlation between PCD-CT-diastolic-endocardial-ECV and CMR-ECV (r = 0.807, 95% CI: 0.402–0.948, p = 0.003). Overall correlation was higher in systole than diastole, with PCD-CT-systolic-epicardial-ECV demonstrating the strongest correlation across all phases and layers. The mean difference between PCD-CT-systolic-epicardial-ECV and CMR-ECV was –1.856% (95% LoA: –7.068 to 3.355).
Conclusion: PCD-CT-derived ECV measurements show strong agreement with CMR,particularly when acquired during the systolic phase at the epicardial layer, supporting its potential as a clinically viable alternative for myocardial interstitial fibrosis.
Limitations: Small sample size.

Inferolateral LGE: additional clinical significance of mitral annular disjunction (MAD) in arrhythmogenesis compared with non-MAD disease (6 min)

Vanessa Vespucci; L'Aquila / Italy

Author Block: V. Vespucci, D. Boccetti, S. Ciambellini, F. Carusi, C. Confalone, S. Di Terlizzi, P. Palumbo, E. Di Cesare; L'Aquila/IT
Purpose: Mitral annular disjunction (MAD) is recognized as a potentially arrhythmogenic substrate, yet its clinical impact on disease progression and outcomes remains uncertain. Cardiac magnetic resonance (CMR) with late gadolinium enhancement (LGE) may help refine individual risk stratification in these patients. The objective of this study was to investigate the prognostic role of CMR findings in patients with MAD compared with individuals presenting a similar non-ischemic LGE phenotype but without MAD.
Methods or Background: In this retrospective-prospective study, 82 patients were enrolled and classified into three groups: MAD+/LGE- (n=26), MAD+/LGE+ (n=21), and MAD-/LGE+ (n=35, control group). The primary endpoint was the occurrence of major adverse cardiac events (MACE), defined as sudden cardiac death (SCD), uncontrolled ventricular arrhythmias (NCVA), catheter ablation or implantation of an implantable cardioverter defibrillator (ICD) or pacemaker (PMK).
Results or Findings: During a mean follow-up of 1.8 ± 1.1 years, 22 patients (32%) experienced MACE, with a comparable incidence across the three groups. Arrhythmic burden did not differ significantly among groups. Neither MAD presence/absence, MAD severity (MADmax, p=0.175), nor LGE extent (p=0.387) predicted adverse outcomes. However, MAD-/LGE+ patients showed lower GLS values, consistent with subclinical systolic dysfunction and a higher short- to mid-term MACE risk compared with MAD+/LGE+ patients (OR 4.463, 95% CI 1.506–13.230; p=0.007).
Conclusion: MAD should be regarded as a potential risk factor for arrhythmias and adverse cardiac events. Nonetheless, its prognostic weight appears lower than that of non-MAD disease with a comparable LGE phenotype.
Limitations: Study limitations include the small sample size, the retrospective–prospective design, and the absence of T1 mapping. As reported in previous studies, T1 mapping and extracellular volume (ECV) assessment could provide further insights into interstitial fibrosis and risk stratification in MAD.
Funding for this study: No fund

Right Atrial and Right Ventricular Strain in Dilated Cardiomyopathy vs. Healthy Population Controls: A Comparative CMR Analysis from Two Large Population Cohorts (6 min)

Thomas Geyer; Munich / Germany

Author Block: T. Geyer, P. Franke, B. J. Wintersperger, R. Lorbeer; Munich/DE
Purpose: Cardiovascular magnetic resonance (CMR) strain imaging is increasingly applied for functional characterization of dilated cardiomyopathy (DCM). While left-sided strain has been extensively described, large-scale reference data for right atrial and ventricular strain in healthy populations remain limited, complicating clinical interpretation. Our objective was to establish normal RA and RV strain values in cardiovascular (CV) disease–free individuals and compare them with patients with DCM from a population-based registry using harmonized imaging and post-processing protocols.
Methods or Background: We studied 162 patients with non-ischemic DCM from the German Centre for Cardiovascular Research (DZHK) nationwide multicenter databank with standardized clinical and imaging protocols. Normal reference data were derived from 400 CV disease–free participants of the population-based KORA (Cooperative Health Research in Augsburg) MRI sub-study. All underwent 1.5T or 3T CMR. RA reservoir strain (RA-RS), RA longitudinal strain (RA-LS), RV radial strain (RV-RS), RV longitudinal strain (RV-LS), and RV circumferential strain (RV-CS) were quantified using feature tracking (cvi42, Circle CVI). Group differences were assessed by multivariable linear regression adjusted for age and sex.
Results or Findings: In controls, mean values were RA-RS 50.5%, RA-LS 20.0%, RV-RS 24.9%, RV-LS 21.6%, and RV-CS 14.3%. Patients with DCM showed significant reductions in all parameters (all $p<0.001$): RA-RS 40.8% (−9.7), RA-LS 15.4% (−4.6), RV-RS 16.1% (−8.8), RV-LS 17.8% (−3.8), and RV-CS 9.2% (−5.1). The largest adjusted differences were observed for RA-RS (β=−9.7%; 95%CI −13.5 to −4.7) and RV-RS (β=−8.8%; 95%CI −10.3 to −6.2).
Conclusion: This study provides robust, population-based reference values for right heart strain and demonstrates the utility of CMR-derived strain for detecting early dysfunction in DCM. Such reference values may improve diagnostic precision and support clinical decision-making.
Limitations: Limitations include the cross-sectional design and lack of longitudinal outcome data, which may restrict prognostic interpretation.
Funding for this study: None.

Cardiac magnetic resonance evaluation of Mavacamten therapy in patients with severe hypertrophic obstructive cardiomyopathy: preliminary results (6 min)

Martina Dodaro; Rome / Italy

Author Block: M. Dodaro, L. Conia, G. Marchionni, M. Alfarano, C. Chimenti, C. Catalano, N. Galea; Rome/IT
Purpose: Hypertrophic obstructive cardiomyopathy (HOCM), characterized by left ventricular (LV) hypertrophy and systolic anterior motion (SAM) of the mitral valve, remains a clinically and therapeutically challenging disease. Mavacamten, a selective cardiac myosin inhibitor, has shown clinical and functional benefits, but its structural effects assessed by cardiac magnetic resonance (CMR) imaging are not fully defined. This study explored structural and functional changes after Mavacamten therapy using advanced CMR techniques.
Methods or Background: Twelve patients with severe HOCM and SAM were prospectively enrolled and received Mavacamten for at least 17 weeks. CMR was performed at 3T, before and after therapy, including cine balanced steady-state free precession, pre- and post-contrast Modified Look-Locker Inversion Recovery, and T1-weighted inversion recovery imaging for late gadolinium enhancement (LGE). Measurements included ventricular wall thickness, LV and right ventricle (RV) volumes, LGE, global/segmental native T1 and extracellular volume fraction (ECV). Statistical analysis was performed with paired t-tests, with significance set at $p\leq0.05$.
Results or Findings: After an average follow-up of 31±5.6 weeks, 9 of 12 patients demonstrated resolution of LV outflow tract obstruction and disappearance of SAM. Significant decreases in wall thickness were observed in septal and lateral basal-ventricular segments ($p=0.04$ and $p=0.03$), as well as in anterior and septal mid-ventricular walls ($p=0.05$ and $p=0.03$). RV anterior and inferior wall thickness also declined ($p=0.004$ and $p=0.02$). Significant reductions in indexed LV mass ($p=0.004$), RV stroke volume ($p=0.004$) and RV ejection fraction ($p=0.01$) were observed, although RV values ramained normal. No significant changes were seen in native T1, ECV, or LGE areas.
Conclusion: These preliminary data suggest that Mavacamten could induce early favorable reverse remodeling in patients with severe HOCM. Larger cohorts are required to better define myocardial tissue effects and remodeling.
Limitations: Monocentric study; small population; short-time follow-up
Funding for this study: None

A Hospital-Integrated Human-in-the-Loop Platform for Reproducible Musculoskeletal Segmentation and AI Deployment (6 min)

John Garcia-Henao; Zurich / Switzerland

Author Block: J. Garcia-Henao, N. Bünger, B. Herzog, S. Caprara; Zurich/CH
Purpose: To evaluate the Medical Imaging Research Orchestration (MIRO) platform for integrating human-in-the-loop (HITL) annotation and AI-assisted segmentation within hospital infrastructure, with a focus on improving reproducibility and collaboration in musculoskeletal imaging.
Methods or Background: The development of accurate AI-assisted segmentation models in orthopaedics requires standardized datasets, clinical validation, and reproducible workflows. The MIRO platform was developed within the MedTwins Agil.IT Trusted Research Environment (TRE) to connect hospital PACS systems with secure research storage and high-performance computing resources.
This study used the Spine Segmentation Dataset, which includes 37 cadaveric CT scans acquired at the Balgrist Research Center and the Swiss Center for Musculoskeletal Imaging. The dataset was designed to be accessible to the scientific community and serves as a benchmark for reproducible spine segmentation.
Three segmentation models, TotalSegmentator, MedSAM2, and SegmentAnyBone, were evaluated using the MIRO platform. Radiologists and surgeons accessed the images and segmentations through the MIRO web interface, enabling direct visualization, refinement, and comparison. Segmentation accuracy was measured using Dice similarity, 95th percentile Hausdorff distance, and surface Dice coefficients.
Results or Findings: TotalSegmentator provided the most consistent delineation of vertebrae. MedSAM2 achieved high performance with guided prompts, and SegmentAnyBone produced detailed segmentation in complex regions. Integration within MIRO allowed efficient dataset management, traceability of annotations, and reproducible comparison across annotators and models.
Conclusion: The MIRO platform enables secure, collaborative, and reproducible segmentation research for musculoskeletal imaging within hospital environments.
Limitations: Preliminary findings are based on early-stage evaluations; large-scale multi-institutional validation is ongoing.
Funding for this study: This study was supported by the Digitalization Initiative of the Zurich Higher Education Institutions (DIZH) under the project MedTwins Agil.IT (2024–2026).

Zero-shot performance of promptable medical images segmentation model (6 min)

Astha Jaiswal; Cologne / Germany

Author Block: A. Jaiswal, F. Meyer, L. Oberlinkels, R-U. Müller, N. Große Hokamp, L. Caldeira, T. Persigehl; Cologne/DE
Purpose: Robust segmentation of structures of interest such as organs, tumors is crucial for clinical applications including diagnosis, treatment planning, and disease monitoring. In this work, we performed evaluation of two public medical image segmentation models.
Methods or Background: We collected two datasets (DS1, DS2) from University Hospital Cologne. DS1 includes 102 3D MR-scans of 50 autosomal dominant polycystic kidney disease patients. DS2 consists of 40 MR-scans from 40 prostate cancer patients. We evaluated the performance of TotalSegmentator MRI (TS)[1] and prompt based model nnInteractive (NI)[2] for polycystic kidney segmentation in DS1 and prostate segmentation in DS2. NI was evaluated using a single interaction via a randomly inflated 2D bounding box around each kidney and around the prostate. Dice scores and Wilcoxon Signed-Rank Test were used to compare the performance.
Results or Findings: For kidney segmentation, TS resulted in dice score of 0.32±0.28 (0.03, 0.90). NI outperformed with a dice of 0.78±0.17 (0.09, 0.97)($p<.001$). Polycystic kidneys are deformed due to multiple cysts and have different appearance compared to normal kidneys. Though nnInteractive was not trained on polycystic kidney data, it captured previously unseen objects well even with single interaction. The prostate region often did not have clear boundaries, likely confusing the NI model resulting in dice of 0.80±0.14 (0.31, 0.92). For prostate segmentation, TS outperformed NI with a dice of 0.85±0.03 (0.74, 0.91)($p<.001$).
Conclusion: NI generalizes well on the new tasks and allows generating high quality segmentations with one or few interactions.
Limitations: In future, we will test NI on different datasets and with multiple interactions including different prompts.

Federated Learning for Brain Tumor Segmentation: Privacy-Preserving Multi-Institutional AI Model Development (6 min)

Elshan Abdullayev; Doha / Qatar

Author Block: E. Abdullayev; Baku/AZ
Purpose: To develop and validate a federated learning approach for automated brain tumor segmentation in MRI that maintains data privacy while leveraging multi-institutional datasets for improved model performance.
Methods or Background: This retrospective multi-center study implemented a federated learning framework across five institutions using 3,420 brain MRI scans (T2-weighted, FLAIR, T1-Gd) from patients with glioblastoma, meningioma, and metastatic lesions collected between 2019 and 2024. A 3D U-Net architecture was trained using a federated averaging algorithm, where each institution trained locally without sharing raw data. Ground truth segmentations were established by consensus of two neuroradiologists. Model performance was compared against centralized learning and single-institution models using Dice similarity coefficient (DSC), Hausdorff distance (HD95), and sensitivity/specificity metrics. Statistical significance was assessed using Wilcoxon signed-rank tests.
Results or Findings: The federated learning model achieved a mean DSC of 0.763 ± 0.124 for the whole tumor, 0.698 ± 0.156 for the tumor core, and 0.612 ± 0.189 for the enhancing tumor regions. Compared to single-institution models, federated learning showed moderate improvement in DSC (0.763 vs 0.721, p=0.023) and HD95 (8.4mm vs 11.2mm, p=0.041). Performance was slightly lower than centralized learning (DSC: 0.763 vs 0.791, p=0.031) but maintained complete data privacy. The model showed variable performance across different institutions (DSC range: 0.698-0.812), with challenges in generalizing different MRI protocols. Training convergence required 15% more iterations compared to centralized approaches due to data heterogeneity.
Conclusion: Federated learning enables the development of brain tumor segmentation models while preserving patient data privacy, though with some performance trade-offs compared to centralized approaches. Despite challenges with data heterogeneity across institutions, this method shows promise for collaborative AI development in medical imaging.
Limitations: Single time-point analysis, heterogeneous scanner types, absence of an external validation cohort, and limited tumor subtype representation.
Funding for this study: No funding received for this study.

Multimodal learning for automated segmentation and preoperative risk stratification of endometrial cancer via multi-sequence MRI (6 min)

Xiuping Nie; Hong Kong / Hong Kong SAR China

Author Block: X. Nie[1], G. Liu[2], Y. Dong[2], X. Wang[1]; [1]Hong Kong/HK, [2]Shenyang/CN
Purpose: Risk stratification in endometrial cancer (EC) is essential for treatment planning, but is currently determined by postoperative pathology. This study aims to develop and validate a multimodal learning model for non-invasive, preoperative risk prediction in EC patients using multi-sequence MRI, thereby enabling more individualized surgical and adjuvant treatment strategies.
Methods or Background: This multicenter retrospective study included 623 paired axial contrast-enhanced T1-weighted (CE-T1W) and fat-suppressed T2-weighted (FS-T2W) MRI scans obtained from EC patients across three sources. A two-stage multimodal learning framework was designed: in Stage I, the model was pretrained for 3D tumor segmentation and radiomics feature extraction; in Stage II, the model was further finetuned to integrate traditional radiomics features and multiscale deep learning image features for risk stratification into low-, intermediate-, and high-risk groups according to the ESGO/ESMO/ESP 2020 guidelines. Experiments on multicenter cohorts evaluated tumor segmentation and risk stratification with standard metrics.
Results or Findings: The proposed AI model outperformed the widely used nnUNet in 3D tumor segmentation, achieving Dice scores of 0.753 ± 0.149 on CE-T1W MRI and 0.764 ± 0.129 on FS-T2W MRI in the internal validation cohort, and maintained high accuracy in two external validation cohorts. For preoperative risk stratification, the model achieved an AUC of 0.801 (95% CI: 0.712-0.880) in the internal validation cohort, with AUCs of 0.852, 0.746, and 0.799 for the high-, intermediate-, and low-risk groups, respectively. Moreover, the performance observed in external validation cohorts (AUCs of 0.740 and 0.724) demonstrated the model's robust generalizability for risk stratification.
Conclusion: Our results highlight the model's potential to support preoperative risk stratification in EC patients, particularly by accurately identifying high-risk groups. This may aid preoperative clinical decision-making and ultimately improve patient outcomes.

Deep Learning-Based MRI Segmentation of the Uterus for Early Adenomyosis Detection Across Menstruation and Ovulation (6 min)

Chiara Tappermann; Bremen / Germany

Author Block: C. Tappermann[1], M. S. May[2], L. Siegler[2], T. Rüttinger[2], M. Fenske[2], M. B. Bauer[2], L. Kratzsch[2], S. Arndt[2], B. Lassen-Schmidt[1]; [1]Bremen/DE, [2]Erlangen/DE
Purpose: The RACOON FADEN project investigates MRI-based uterine biomarkers for early adenomyosis detection, a gynaecological condition in which endometrial tissue grows into the muscular wall of the uterus, often associated with uterine enlargement, pelvic pain, and infertility.
This research includes volumetric segmentation of the myometrium (MM), junctional zone (JZ), and endometrium (EM) during menstruation and ovulation.
Within the project, tailored deep learning models are trained to partially automate this process. Their performance should be assessed for both phases.
Methods or Background: The test dataset includes 16 females from six German university hospitals. Reference segmentations were created by medical students and reviewed by radiologists using a CuraMate workflow based on predefined guidelines.
MM, JZ, and EM were segmented up to the cervical junction on T2-weighted short-axis uterine images using motion-insensitive, multi-shot TSE BLADE sequences.
Models were trained iteratively in three rounds on additional training data, incorporating more data each time (32/98/122 samples, comprising both menstruation and ovulation phases).
Results or Findings: Model performance was measured with the Dice Similarity Coefficient (DSC), resulting in DSC 0.71 (MM), 0.68 (JZ), 0.63 (EM) during menstruation and DSC 0.66 (MM), 0.65 (JZ), 0.74 (EM) during ovulation for model 1. Model 2 achieved DSC 0.76 (MM), 0.74 (JZ), 0.75 (EM) during menstruation and DSC 0.74 (MM), 0.77 (JZ), 0.87 (EM) during ovulation. Model 3 reached DSC 0.73 (MM), 0.70 (JZ), 0.75 (EM) during menstruation and DSC 0.72 (MM), 0.73 (JZ), 0.84 (EM) during ovulation.
No significant differences were observed between paired DSC values for menstruation and ovulation (Wilcoxon signed-rank test; all $p > 0.1$).
Conclusion: Our deep learning models reliably segment MM, JZ, and EM on T2-weighted MRI during both phases, with no significant performance differences, supporting automated assessment of early adenomyosis.
Limitations: No Limitations.
Funding for this study: Funding was provided by the Bundesministerium für Bildung und Forschung via Netzwerk Universitätsmedizin (NUM 2.0, FKZ: 01KX2121).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The RACOON FADEN study was approved by the ethics committee of all participating university hospitals. The study protocol complies with the declaration of Helsinki.

MRIvals - TotalSegmentator vs MRSegmentator. Validation of major organs segmentation in abdominal scans. A comparative study (6 min)

Georgios Lappas; Athens / Greece

Author Block: G. Lappas[1], A. Afentouli[1], N. Patlakas[1], P. Giannikopoulos[1], M. Triantafyllou[2], G. I. Kalaitzakis[2], M. Klontzas[2], K. Petropoulos[1]; [1]Athens/GR, [2]Heraklion/GR
Purpose: This study aims to validate and compare the open-source TotalSegmentator 3mm (TS3MR) and MRSegmentator (MRS) models for the segmentation of major abdominal organs in Magnetic Resonance (MR) scans.
Methods or Background: The models' segmentation capability was quantified using Dice Similarity Coefficient (DSC) and Normalized Surface Distance (NSD) across four heterogeneous datasets (N≈1600 individuals & 100 scanners). Exploratory Data Analysis, including basic statistics, was performed to investigate the suitability of the datasets for benchmarking. Additionally, explainable AI (i.e., Grad-CAM maps) was utilized focusing on disentangling the black box of the model decision-making. Clinical rating of the predicted segmentations' quality was conducted by one assistant professor of radiology, and one senior radiology resident from Greek hospital scans (N=10 patients).
Results or Findings: Overall, despite the high data variability, projected in normalized volume (0.44±0.21) and intensity (0.36±0.22), both MR models can accurately segment most abdominal organs, e.g., average DSC > 90%. MRS was more accurate across all organs compared to TS3MR as DSC scores were boosted from 4% to 28% depending on sequence, pathology and anatomical region. Poorer and less robust performance was found for the gallbladder, and pancreas with an average DSC ≈ 63% for both models. Grad-CAM maps revealed the models' inconsistencies. The clinical evaluation findings showed high-quality and clinical acceptable segmentations for both models while fine-grained details were generated by MRS.
Conclusion: Both TotalSegmentator 3mm and MRSegmentator models can accurately segment most of the major abdominal organs in MR scans while the latter is more accurate across all organs and modalities.
Limitations: The available MR data presents lower variability (for scanning protocols and demographics) for kidneys, spleen and gallbladder. Segmentation of lower abdomen organs such as prostate is not supported by MRSegmentator even though routine examined.

Analyzing Machine Learning Techniques for Automated SPECT MPI Scan Segmentation (6 min)

Ahmad Tawfiq Alenezi; Kuwait / Kuwait

Author Block: A. T. Alenezi[1], E. Alawdhi[1], A. Jodeiri[2], A. Mayya[3]; [1]Kuwait/KW, [2]Tabrez/IR, [3]Latakia/SY
Purpose: This study systematically benchmarks five U-Net architectures for cardiac SPECT segmentation, each utilizing a unique encoder backbone for more accurater and faster segmentation of cardiac SPECT images.
Methods or Background: Introduction: Single-photon emission computed tomography (SPECT) myocardial perfusion imaging (MPI) is pivotal for evaluating coronary artery disease (CAD) and quantifying left ventricular function. Yet, manual delineation of myocardial regions is laborious and susceptible to inter-observer discrepancies. Deep learning, especially convolutional neural networks (CNNs), has shown promise in automating this process.
Methods: Two annotated MPI datasets were used: a small set (609 images) and a large set (5169 images) with pixel-level ground truth. Preprocessing standardized all images to 64×64 pixels, followed by augmentation (flipping, elastic distortion, noise, and contrast modifications). Five U-Net models were trained with consistent hyperparameters, each with a different encoder: CNN, MobileNet, VGG with attention, Inception, and ResNet50 with attention. Performance was evaluated using mean Intersection-over-Union (mIoU), Dice coefficient, pixel accuracy, and AUC. Additionally, a weighted ensemble was constructed by averaging the individual network outputs.
Results or Findings: On both datasets, the Inception-U-Net achieved the highest Dice (0.9656 and 0.9538) and mIoU (0.9358 and 0.9197) among single models. The ensemble U-Net surpassed all individual architectures (Dice: 0.9679 and 0.9544; mIoU: 0.9398 and 0.9205), delivering the greatest overall accuracy and lowest false negatives. While the MobileNet variant offered the quickest training, its segmentation performance was marginally lower. The Inception-based model balanced strong segmentation outcomes with clinical applicability but required more computational resources.
Conclusion: Deep learning, particularly ensemble U-Net models, enables precise, automated segmentation of myocardial regions in cardiac SPECT, minimizing manual effort and observer variability. This approach can optimize nuclear cardiology workflows and boosting reliability and throughput.
Limitations: The study was limited by the retrospective nature.
Funding for this study: This work was supported and funded by Kuwait University Research

Deep Learning (DL)-Based Detection and Segmentation of Acute Pulmonary Thromboembolism (PTE) in Computed Tomography Pulmonary Angiography (CTPA): A Clinical Validation Study (6 min)

Ekin Cinar; Izmir / Turkey

Author Block: M. A. Kamar[1], M. M. Baris[2], E. Konukoglu[3], E. Cinar[2], N. Cakir[2], T. Yonka[2], A. Ozgen Alpaydin[2], N. S. Gezer[2]; [1]İzmir/TR, [2]Izmir/TR, [3]Zurich/CH
Purpose: To clinically validate a DL model for fully automated detection and segmentation of acute PTE on CTPA, and to assess the impact of imaging artifacts and contrast enhancement quality on model performance.
Methods or Background: A total of 530 CTPA examinations (157 PTE-positive, 373 PTE-negative) were retrospectively evaluated. Emboli were manually segmented slice-by-slice by experienced radiologist to establish the ground truth. Each CTPA scan is classified by the DL model as positive or negative; then voxel-level segmentation of emboli across all slices in a fully automated end-to-end manner is performed for positive scans. The model's performance in embolus detection was evaluated. Subgroup analysis classified emboli from the main pulmonary artery to lobar branches as central, and segmental to subsegmental emboli as peripheral. False positive(FP) and false negative(FN) cases were analyzed for image artifacts and pulmonary artery attenuation (HU). Embolus volume analysis was also performed.
Results or Findings: The AI model achieved overall sensitivity of 91.7%, specificity of 92.0%, precision of 82.8%, and accuracy of 91.9%. In peripheral emboli cases (n=57), the model showed 84.2% sensitivity. In central emboli (n=100), sensitivity reached 96.0%. Among 13 FN cases, 10 were associated with technical limitations including low contrast density in the main pulmonary artery (<250HU), streak artifacts, motion artifacts, and low tube current. Similarly, 22 of 30 FP cases were linked to similar artifacts, particularly vena cava streaks and suboptimal contrast timing. Only 3 FN and 8 FP cases occurred without any identifiable artifact.
Conclusion: The DL model demonstrated high performance especially for centrally located emboli. Image artifacts and low pulmonary artery contrast enhancement significantly contributed to false results, highlighting the importance of standardized acquisition protocols for reliable AI-assisted diagnosis.
Limitations: The model's volumetric segmentation errors were primarily in small-volume thrombi.

Autosegmentation of Tumor-Bearing Bladders on CT: A Comparison of U-Net Variants and an Ensemble Model (6 min)

Li Chen; Beijing / China

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: L. Chen[1], E. Guo[1], Z. Wu[2], Z. Jin[1], G. Zhang[1], H. Xue[1], H. Sun[1]; [1]Beijing/CN, [2]Fushun/CN
Purpose: To evaluate and compare the performance of 2D U-Net, 3D U-Net, Dual Swin Transformer U-Net (DS-TransUNet), and an Ensemble Segmentation Model (ESM) for automated segmentation of tumor-bearing bladders on CT, a critical task in computer-aided diagnosis of bladder cancer (BCa).
Methods or Background: This retrospective study included 435 BCa patients (397 internal, 38 external) with manual segmentation as ground truth. Models were trained and validated through five-fold cross-validation within the nnU-Net framework. The ESM was constructed by aggregating predictions from three individual models using majority voting. Performance metrics included the Dice similarity coefficient (DSC), average surface distance, and 95th-percentile Hausdorff distance, with subgroup analyses by gender and muscle invasion status (muscle-invasive BCa / non-muscle-invasive BCa).
Results or Findings: The ESM achieved the highest DSC in both internal (0.980±0.024) and external (0.986±0.014) cohorts, significantly outperforming DS-TransUNet ($P < 0.001$) and 3D U-Net in internal validation ($P = 0.047$), and again outperformed DS-TransUNet ($P < 0.001$) and showed a marginally significant advantage over 2D U-Net ($P = 0.045$) in external validation. 3D U-Net and 2D U-Net also showed strong performance, particularly in external validation, while the DS-TransUNet model had the worst relative segmentation efficiency. Subgroup analyses confirmed stable performance of ESM across gender and tumor invasion categories.
Conclusion: The 3D U-Net excels in segmentation accuracy, while the 2D U-Net is efficient and consistent. DS-TransUNet, though promising, needs refinement for robustness. The ESM model, integrating advantages from multiple U-Net-based architectures, demonstrated optimal accuracy and robustness, highlighting its potential clinical utility.
Limitations: First, the relatively small external validation cohort potentially limits broader applicability. Additionally, cases with significant imaging artifacts were excluded, potentially affecting real-world generalizability.

RPS 508 - New developments in imaging of the oral cavity and the oropharynx

Categories: Imaging Methods, Oncologic Imaging, Head and Neck
Date: March 4, 2026 | 15:00 - 16:00 CET
CME Credits: 1

Moderator:
Carlos Buitrago Tellez; Solothurn / Switzerland

Oral Cavity Lesion Mimicker: How prevalent is the Mylohyoid Boutonnière on MRI? (6 min)
Anne Renée Juliette Péporté; Frauenfeld / Switzerland

Author Block: A. R. J. Péporté[1], J. Kostova[1], F. B. Schön[2], G. Andreisek[2], L. Diem[3], F. Wagner[4]; [1]Frauenfeld/CH, [2]Münsterlingen/CH, [3]Lucerne/CH, [4]Aarau/CH
Purpose: The mylohyoid muscle is commonly considered a continuous muscular sling, but it is frequently discontinuous, forming mylohyoid boutonnières (MHB) that can contain salivary tissue, fat, blood vessels, or lymph nodes. The MR prevalence remains largely unexplored. This study assesses the prevalence, age- dependence, anatomical distribution, and content of MHBs on MRI.
Methods or Background: A retrospective review of MRI scans of the head and neck from 294 patients between 2016 and 2020 was conducted. MR images were analyzed for the presence, location, and contents of MHBs. Inter-rater agreement from the three independent readers with different levels of experience and statistical analysis were performed to assess consistency across readers.
Results or Findings: MHBs were identified in 50.7% of individuals, with bilateral deficiencies occurring in 45.6% of cases. Most defects were located in the anterior (45.6%) and middle (51.0%) thirds of the mylohyoid muscle. The herniated content consisted predominantly of salivary tissue (69.3%), followed by fat (15.9%), and blood vessels (14.2%). No significant association was found between MHB prevalence and age. There was a high level of inter-rater agreement among all three raters regarding the presence, side, location, and content of the MHB, with no statistically significant discrepancies observed across the assessed parameters.
Conclusion: A MHB is a true and common anatomical variant, with a prevalence of 50.7% in this study, and most defects are bilateral. This knowledge aids in preventing diagnostic errors when evaluating oral cavity lesions, minimizing the need for unnecessary invasive procedures.
Limitations: This retrospective study, while involving a heterogeneous referral population and excluding about 20% of cases due to MRI artifacts, benefits from a large sample size, multi-reader interpretation, and provides valuable non-invasive anatomical assessment complementary to cadaveric data.
Funding for this study: No funding was received.

Ultra-high-frequency ultrasound (UHFUS) in oral cavity lesions: diagnostic role and correlation with histopathology (6 min)
Vittorio Patanè; Naples / Italy

Author Block: V. Patanè, A. Russo, M. C. Pezzella, R. Frnaco, S. Cappabianca, A. Reginelli; Naples/IT
Purpose: Ultra-high-frequency ultrasound (UHFUS, >22 MHz) is a novel imaging technique for the assessment of oral mucosal lesions. It provides real-time, non-invasive, radiation-free, and repeatable imaging. The aim of this study was to evaluate the role of UHFUS in the diagnostic workup of oral lesions and to compare imaging features with histopathology.
Methods or Background: Oral examinations were performed using 48–70 MHz probes (Vevo® MD, VisualSonics). The intraoral protocol included axial and sagittal scans in B-mode and C-mode with standardized presets. Lesions were assessed for location, morphology, dimensions, echotexture, echogenicity, and vascularization. Sites analyzed included tongue, lips, buccal mucosa, gingiva, and hard palate. Patients with clinically suspected benign or malignant lesions were included.
Results or Findings: Benign lesions identified included a post-traumatic lingual fibroma, an angioleiomyoma of the lower lip, a storiform collagenoma of the hard palate, and a gingival granuloma with fistulous tract. Malignant lesions comprised an early infiltrating squamous cell carcinoma, a mucoepidermoid carcinoma of the sublingual gland, and an oral squamous cell carcinoma. UHFUS findings showed good concordance with histopathology, particularly in defining lesion depth and extension.
Conclusion: UHFUS is a valuable adjunct in the diagnostic and surgical management of oral lesions. It enhances diagnostic precision, is well accepted by patients, and holds strong potential for broader clinical application as standardization improves.
Limitations: Despite its advantages, UHFUS has some limitations. The small field of view and limited penetration depth restrict its applicability to superficial mucosal and submucosal lesions. Operator experience is critical for image acquisition and interpretation, and standardized diagnostic criteria are still under development. Larger multicenter studies are needed to validate its diagnostic accuracy and establish clinical guidelines.
Funding for this study: Thi research received no fundings
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was conducted in accordance with the Declaration of Helsinki (as revised in 2013). The study's protocol was approved by the local ethics committee at the University Hospital of Campania "L. Vanvitelli" and AORN "Ospedale dei Colli", Naples, Prot. N. 325889/i/2024. 17 November 2024.

Gingival ultrasonography in evaluation of post-operative healing in post collagen tissue graft for gingival recession - A novel cohort study in a tertiary care center and teaching hospital (6 min)

Rajeshwar Balaji Venkatasubramanian; Chennai / India

Author Block: R. B. Venkatasubramanian[1], R. Sivakumar[1], V. Sai[1], R. Ramachandran[1], B. Dev[1], R. Rangasami[1], M. Lokesh[1], H. Sivakumar[2]; [1]Chennai/IN, [2]CHENNAI/IN
Purpose: To set gingival ultrasonography protocols as a screening tool to evaluate post operative healing in collage tissue graft patients for gingival recession.
Methods or Background: Gingival recession is a common condition when gingival margin moves proximally beyond cemento-enamel junction.
It can increase risk of dental carries and have cosmetic issues.
Root coverage procedures like autologous collagen tissue graft are a common surgery for gingival recession.
A cohort of 15 patients of gingival recession planned for autologous collagen tissue graft, aged 30-50, were sonographically assessed pre-operatively, 1 and 2 weeks post-op for healing assessment.
Anterior gingival thickness and vascularity(spectral Doppler) were assessed pre-op.
Surgical site echogenicity, neovascularisation status(Power and spectral Doppler) and anterior gingival thickness were assessed on post-op follow up.
Protocols were set to assess anterior gingival thickness from anterior gingival margin to interdentine papilla at incisor plane, low PRF for Doppler evaluation.
Results or Findings: All 15 patients(100%) had decreased mean anterior gingival thickness - 1.3+/-0.3 mm, demostrating high resistance flow (RI>0.7) in Doppler.
Post surgery, mean anterior gingival thickness was - 1.6+/-0.4 mm in week 1 and 1.5+/-0.2 mm in week 2.
14 out of 15 patients (93.3%) showed increased relative echogenicity on both follow up scans signifying inflammation.
One patient had ~0.5 cc persistent collection in surgical site. Post operative Doppler showed low resistance flow (RI<0.6) with decreased PSV in all cases signifying inflammation/healing.
Conclusion: Post operative intraoral/gingival ultrasonography is an effective tool to assess inflammation, post-operative changes, abscess formation and neovascularisation in post autologous collagen tissue graft, in adjunct to clinical and visual assessment. Presence of hypoechoic areas, collections, high resistance vascular flow and decreased gingival thickness are markers of poor prognosis.
Limitations: Limited sample size can be expanded to cover other dental surgeries.
Funding for this study: Self funded.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Part of MD thesis dissertation.

Interobserver agreement of Neck Imaging Reporting and Data System (NI-RADS) in MRI-based surveillance of oropharyngeal squamous cell carcinoma (6 min)

Marianna Fusina; Trento / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: M. Fusina, M. Parillo, M. Neri, M. Antolini, D. Vo, F. De Rosa, C. C. Quattrocchi; Trento/IT
Purpose: To investigate the level of agreement among radiologists with varying levels of expertise when interpreting MRI scans using NI-RADS system for monitoring oropharyngeal squamous cell carcinoma (OPSCC) patients.
Methods or Background: An observational retrospective study was conducted to analyze follow-up MRIs in patients treated for OPSCC. NI-RADS scores were assigned by five radiologists (two residents in radiology, one general radiologist and two head and neck experts). Agreement was evaluated using percentage of agreement (POA) and kappa values (κ) for NI-RADS final score and for each MRI specific feature of the NI-RADS (lymph nodes, primary tumor size, primary site signal on T2-weighted, contrast-enhanced and diffusion-weighted images). Concordance was assessed separately for the first follow-up MRI and subsequent follow-up scans.
Results or Findings: A total of 91 patients were evaluated, and each reader analyzed 218 MRI. Overall inter-reader agreement was moderate for NI-RADS score (κ = 0.53, POA = 89%) and for individual MRI features (κ = 0.42–0.52, POA = 84%–93%). Agreement was notably lower between the expert radiologist and the two radiology residents during the first follow-up MRI, particularly for assessing contrast-enhancement at the primary site (κ = 0.25–0.36, POA = 77%–90%) and lymph nodes (κ = 0.38–0.41, POA = 72%–88%).
Conclusion: MRI NI-RADS in the surveillance of OPSCC patients shows moderate agreement among readers with varying expertise, especially in the evaluation of the first post-treatment scans. Routine use of NI-RADS in clinical practice and educational programs could improve uniformity in imaging assessments.
Limitations: We included examinations from different MRI scanners within a considerable timeframe. In a limited number of instances, DWI sequences were missing because standardized head and neck imaging protocols were not in place during earlier examinations.
Funding for this study: The authors declare that no funds, grants, or other support were received during the preparation of this manuscript.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The retrospective study was approved by the institutional review board and conducted in accordance with the principles of the Declaration of Helsinki. Informed consent to participate in the study was waived due to the retrospective-observational study design.

Refining Clinical T-Staging of Oral Tongue Squamous Cell Carcinoma with Structured MRI Reporting to Guide Neoadjuvant Chemoimmunotherapy (6 min)

Jie Pan; Guangzhou / China

Author Block: J. Pan, X. Hui, L-Z. Liu, W. Huang; Guangzhou/CN
Purpose: Current T-staging for oral tongue squamous cell carcinoma (OTSCC) primarily relies on postoperative pathology, which offers suboptimal preoperative risk stratification, limiting precision in the neoadjuvant therapy era. This study aimed to optimize the clinical T-staging for OTSCC using a structured MRI reporting system and evaluate its value in guiding patient selection for neoadjuvant chemoimmunotherapy (NACI).
Methods or Background: In this retrospective study, we analyzed patients with pathologically confirmed OTSCC who underwent pretreatment MRI between January 2010 and January 2025. Based on a structured MRI report, patients were stratified into four risk groups: "Very-low-risk" (no structural invasion), "Low-risk" (hyoglossus/styloglossus invasion), "Medium-risk" (Mild structural invasion: eg., lingual artery, sulcus terminalis, sublingual gland), and "High-risk" (Severe structural invasion: eg., mylohyoid, retromolar trigone, oropharynx). Network and survival analyses were employed to assess prognostic differences. The survival benefit of NACI was specifically evaluated in the high-risk group defined by the new staging system.
Results or Findings: Among 1202 enrolled patients, the optimized T-staging system showed significantly superior risk stratification for 5-year overall survival (OS) (48.1%, 74.8%, 85.9%, 95.1% for the four groups, P <0.001) versus the current T-staging (86.9%, 77.8%, 70.4%, 53.1%, P>0.05). Crucially, high-risk patients receiving NACI had markedly better 5-year OS than those who did not (84.2% vs. 45.9%, p<0.05). The revised T-staging system showed better stratification in OS (C-index: 0.712 vs. 0.652, p < 0.05).
Conclusion: A structured MRI-based T-staging system provides superior prognostic stratification and effectively identifies high-risk OTSCC patients who derive significant survival benefit from NACI, facilitating preoperative personalized treatment planning.
Limitations: This was a retrospective, single-center study. Additionally, there is inherent subjectivity in interpreting structural invasion, although excellent inter-observer agreement was confirmed (kappa > 0.82 for all evaluated structures).
Funding for this study: The National Natural Science Foundation of China (No. 82171906) and the Guangdong Basic and Applied Basic Research Foundation (2025A1515011590, 2024A1515140147).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective study was conducted in accordance with the ethical guidelines outlined in the 1964 Declaration of Helsinki and approved by the ethics committee (approval number: B2019-047-Y02; date of approval: November 07, 2022).

High-Resolution Intraoral Ultrasound for Depth of Invasion Assessment in Early Tongue Squamous Cell Carcinoma: Technical Refinements and Validation (6 min)

Maria Paola Belfiore; Naples / Italy

Author Block: M. P. Belfiore, M. Balzano, M. Montella, G. Colella, D. Setola, D. Di Stasio; Naples/IT
Purpose: To validate the accuracy and reproducibility of high-resolution intraoral ultrasound (ioUS) in measuring depth of invasion (DOI) in early-stage oral squamous cell carcinoma (OSCC) of the tongue and to address common methodological inconsistencies in current imaging practices.
Methods or Background: Thirty-five patients (21 males, 14 females; mean age 64.7 ± 10.3 years) with histologically confirmed OSCC of the tongue (dorsal, lateral, or ventral surfaces) and clinical tumor size ≤2 cm (T1–T2) were prospectively enrolled. ioUS imaging was performed using an 18 MHz linear probe in a non-contact technique. For each patient, three high-quality images were selected based on bilateral visualization of intact epithelial margins. A horizontal DOI reference line was defined at the epithelium-connective tissue interface, and DOI was measured perpendicularly to the deepest hypoechoic area. Images with acoustic shadowing were excluded. DOI values were normalized to correct for tissue shrinkage during histopathological processing. Measurements were performed using ImageJ software. Statistical analysis included Spearman's correlation, intraclass correlation coefficient (ICC), and Mann-Whitney U test.
Results or Findings: ioUS demonstrated a strong correlation with pathological DOI (Spearman's $\rho = 0.93$; $p < 0.001$), and all lesions were correctly staged as T1 or T2, with 100% concordance with pathological staging. Normalized DOI data showed excellent reproducibility (ICC >0.90). No significant differences were found between ioUS and pathological DOI measurements ($p > 0.05$).
Conclusion: High-resolution ioUS provides accurate and reproducible measurements of DOI in early tongue OSCC, with staging performance equivalent to histopathological analysis. Technical refinements, including standardized image acquisition and definition of reference lines, are critical for clinical reliability.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study.

Preoperative prediction of perineural invasion in tongue squamous cell carcinoma with spectral detector CT-derived histogram parameters and clinical features (6 min)

Xiaomin Liu; Guangzhou / China

Author Block: H. K. Zhang[1], F. Chen[1], Y. Liao[2], X. Liu[2]; [1]Haikou/CN, [2]Guangzhou/CN
Purpose: This study aims to investigate the feasibility of preoperative prediction of perineural invasion (PNI) status in tongue squamous cell carcinoma (TSCC) using dual-layer spectral-detector CT(DLCT) histogram features and clinical features.
Methods or Background: We retrospectively analyzed 85 patients with TSCC, comprising 30 PNI-positive and 55 PNI-negative cases. All patients underwent preoperative contrast-enhanced DLCT, and spectral images (including virtual mono-energetic images at 40KeV, 70KeV, 100KeV, 130KeV, iodine density, effective atomic number, and virtual non-contrast images) were reconstructed from venous phase data. A single radiologist manually delineated the tumor region of interest (ROI) on 40-keV virtual mono-energetic images, which was propagated to other spectral images to extract seven histogram features from each image. Clinical and histogram features were compared using appropriate statistical tests (t-test, Wilcoxon, or chi-square). Feature selection involved Spearman correlation filtering (threshold = 0.9) followed by backward stepwise regression. Three predictive models—clinical, spectral-histogram, and a combined model—were developed using logistic regression. Model performance was evaluated and compared via receiver operating characteristic (ROC) analysis and DeLong's test.
Results or Findings: Pathological T-stage differed significantly between PNI-positive and negative groups ($P<0.05$). Most spectral histogram features also showed significant intergroup differences (all $P<0.05$). The clinical, spectral-histogram, and combined models achieved AUCs of 0.751 (0.653–0.849), 0.760 (0.655–0.865), and 0.828 (0.736–0.920), respectively. The spectral-histogram and combined models both significantly outperformed the clinical model ($P<0.05$).
Conclusion: The combined model integrating DLCT-derived spectral histogram features with clinical data demonstrates promising efficacy for the preoperative prediction of perineural invasion in tongue squamous cell carcinoma.
Limitations: Retrospective, single-center study with a small sample size

Prevalence and Distribution of Anterior Disc Displacement of the Temporomandibular Joint: A Retrospective MRI Study in a Large German Cohort (6 min)

Moritz Ludwig Schnitzer; Munich / Germany

Author Block: M. L. Schnitzer, F. Herr, L. Göbel, J. Rübenthaler; Munich/DE
Purpose: Craniomandibular disorders (CMD) are common musculoskeletal conditions, often linked to anterior disc displacement (ADD) of the temporomandibular joint (TMJ). MRI is the diagnostic standard of reference. This study assessed prevalence and demographic patterns of ADD in a large patient cohort.
Methods or Background: We retrospectively analyzed 512 TMJ MRI examinations (2017–2022, LMU Munich). ADD was graded: 1 (10–11 o'clock), 2 (9–10 o'clock), 3 (6–9 o'clock). Borderline cases were assigned to the higher grade.
Results or Findings: The cohort included 382 females and 130 males (mean age 40.9 ± 18.7 years). ADD was present in 63.5%: Grade 1, 20.3%; Grade 2, 10.7%; Grade 3, 32.4%. No displacement was found in 36.5%. Distribution showed polarization (Grade 0 vs. Grade 3). Bilateral symmetry occurred in 58% ($r = 0.50$, $p < 0.000005$). Females were more frequently affected by higher-grade ADD ($p < 0.001$). Younger patients showed more severe grades. A pandemic-related shift was observed, with female predominance in 2020 and male rebound in 2021.
Conclusion: ADD is frequent and shows polarized severity. Female predominance, younger age association, and pandemic-related shifts underline its multifactorial nature. MRI provides essential diagnostic and epidemiological insights.
Limitations: This retrospective, single-center study may reflect referral bias and is not fully representative of the general population. The cross-sectional design precludes causal inference between ADD severity, age, sex, and pandemic-related trends. MRI interpretation was based on categorical grading, which may oversimplify complex disc dynamics. Variability between 1.5T and 3.0T scanners, as well as interobserver differences, could influence diagnostic consistency. Clinical correlation with symptoms and treatment outcomes was beyond the study's scope, limiting assessment of functional relevance.
Funding for this study: No Third Party funding for this study

Dental radiology at a glance (6 min)

Mia Smoljan; Zagreb / Croatia

Author Block: M. Smoljan; Zagreb/HR
Purpose: The purpose of this presentation is to review the most common pathologies of the maxillofacial region, as well as their imaging characteristics on different imaging modalities, and their differentials.
Methods or Background: Dental radiology is still a relatively unfamiliar part of radiology for many radiologists, even though the maxillofacial region is seen on many neuroradiological examinations, like brain and cervical spine scans, and included in most head & neck scans. Therefore, radiologists come across different odontogenic and non-odontogenic lesions of the jaws and other pathological lesions of this area in their everyday practice.
Results or Findings: Different odontogenic and non-odontogenic lesions of maxillofacial region can be seen on X-rays, CT scans and MRIs. When analyzing brain, head, neck or cervical spine images, radiologists should pay attention to maxillofacial structures as well. Whether the indication for the radiological examination is to diagnose an already suspected dental/maxillofacial pathology or the pathology found is an incidental finding in the examination performed for other indications, the radiologists should be familiar with the nomenclature, the lesions typical for this region, and their differentials.
Conclusion: Odontogenic and non-odontogenic lesions of the jaws, as well as other maxillofacial pathologies, account for a substantial number of pathological changes visible on different radiological modalities. Adding them to the radiological reports may assist the clinicians solve the clinical inquiry and help the patient maintain their oral health.
Limitations: No limitations were identified.
Funding for this study: No funding was received.

Small Pixel Effect and Tin Effect in Energy-Integrating and in Photon-Counting CT (6 min)
Marc Kachelrieß; Heidelberg / Germany

Author Block: J. Wucherpfennig[1], L. T. Rotkopf[1], H-P. Schlemmer[1], M. Frölich[2], S. O. Schönberg[2], S. Sawall[1], M. Kachelrieß[1]; [1]Heidelberg/DE, [2]Mannheim/DE
Purpose: To evaluate the separate and combined influence of the small pixel effect (SPE) and tin prefiltration in terms of signal-to-noise ratio at unit dose (SNRD) in energy-integrating CT (EICT) and photon-counting CT (PCCT).
Methods or Background: SPE refers to higher SNRD for scans with small detector pixels versus larger pixels at the same MTF. Tin effect refers to the selective removal of low-energy photons before reaching the patient. Fully exploiting the tin effect requires adjusting tube voltages, which was not possible in our setting with the same tube voltages and spectra on both scanners. Both effects improve the SNRD. To quantify, images of semi-anthropomorphic abdomen phantoms of sizes 20×30 cm (S), 25×35 cm (M), 30×40 cm (L), and 35×45 cm (XL) were acquired with an EICT (Somatom Definition Flash, Siemens Healthineers) and a PCCT (Naeotom Alpha.Peak, Siemens Healthineers) at 140 kV and 140 kV Sn. PCCT scans were done in standard and ultra-high-resolution mode to exploit the SPE. All reconstructions within each scanner were performed with the same MTF.
Results or Findings: SPE allowed for 36% (S), 30% (M) and 6% (L) dose reduction. Tin effect in PCCT was observed only in the XL phantom, with 25% dose reduction. The unobserved tin effect in smaller phantoms and the reduced SPE in larger phantoms are presumably due to a proprietary raw-data-dependent filter implemented in the PCCT. Tin effect in EICT was consistent across all phantom sizes with a dose reduction of 20% (S), 29% (M) and 30% (L).
Conclusion: EICT benefits from the tin effect. PCCT allows to exploit the small pixel effect. Making use of the expected combined effect in PCCT, however, seems to require an adaptation of the vendor-proprietory rawdata filter.
Limitations: Findings are based on phantoms.

Effects of Pulse Pileup Correction on the Signal and Noise Characteristics in Clinical Photon-Counting CT (6 min)
Xinming Liu; Houston / United States

Author Block: X. Liu, F. Dong, K. Li; Houston/US
Purpose: In the NAEOTOM Alpha photon-counting detector CT (PCD-CT), the mean CT number of a given tissue has shown good consistency across varying dose levels. This observation has been interpreted as evidence that pulse pileups are negligible in Alpha. However, such stability in CT numbers can also result from effective pileup correction. The aim of this study was to evaluate the impact of pileup correction on the signal and noise characteristics of the Alpha PCD-CT.
Methods or Background: Images were acquired using an Alpha scanner at four tube potentials and twelve tube current settings. The vendor's pulse pileup correction was automatically applied during reconstruction. Experimental measurements included image variance, noise power spectrum (NPS), MTF, and mean HU. The dependence of each metric on tube current and dose level was analyzed.
Results or Findings: The MTF, the shape of the NPS, and the mean HU showed no significant variation with tube current or dose. However, the image variance deviated notably from the classical inverse relationship with tube current (variance $\propto$ 1/mA). Specifically, the observed variance was higher than predicted by this relationship, with the deviation becoming more pronounced at higher mA levels. At tube currents above 300 mA at 120 kV, corresponding to a flux of 1E8 counts-per-second/pixel, the variance even increased with mA. This counterintuitive behavior can only be explained by the presence of a pileup correction mechanism.
Conclusion: Pulse pileup correction was automatically applied in the Alpha PCD-CT imaging chain. This correction linearizes the mean detector counts with respect to tube current but results in elevated image noise. The correction appears to be applied on a pixel-by-pixel basis, as it does not affect spatial resolution or alter the noise texture.
Limitations: The study is based only on phantoms.

Dose and noise texture effects on lung nodule volumetry in photon counting CT (6 min)

Ioannis Sechopoulos; Nijmegen / Netherlands

Author Block: E. Pimenta[1], G. Boiset[1], G. Negro[1], M. Bettencourt[1], A. Tomal[2], L. J. Oostveen[3], M. Caballo[4], I. Sechopoulos[3], P. R. Costa[1]; [1]São Paulo/BR, [2]Campinas/BR, [3]Nijmegen/NL, [4]'s-Hertogenbosch/NL
Purpose: To evaluate the effect of noise texture at different dose levels on volumetric accuracy and precision of synthetic solid nodules (SNs) and ground-glass opacities (GGOs) imaged with photon counting CT (PCCT).
Methods or Background: A 3D-printed SN and a GGO were inserted into an anthropomorphic lung phantom. Ground-truth volumes were quantified using a µCT (U-SPECT6CThr, MILabs). The phantom was scanned five times with repositioning in a prototype PCCT system (Canon Medical Systems) at four CTDIvol levels (0.3, 0.5, 0.8 and 1.1 mGy). Images were reconstructed using hybrid iterative reconstruction (AIDR 3D/FC54 kernel).
Volumes were segmented (3DSlicer, v5.6.2) by readers blinded to the imaging parameters. Accuracy was assessed using median relative error and Bland-Altman plots. Precision was evaluated using the coefficient of variation (CV, IQR-based). Noise power spectra (NPS) were calculated from four ROIs around each nodule. Associations between volumetric performance, NPS features (area, downslope σ, peak frequency fpeak, and average frequency fave) and CTDIvol were evaluated using ordinary least squares and quantile regression (QReg, τ=0.5).
Results or Findings: SN volumetry showed strong dose-dependence for accuracy (QReg R^2=0.91; CTDIvol β=0.93, p=0.034), whereas GGO accuracy modeling was weaker (R^2=0.46). In contrast, GGO precision was dose-dependent (R^2=0.57; β=7.71, p=0.022). For SN, precision strongly correlated with NPS features (QReg R^2=0.78), including fpeak (β=−154.8, p<0.001), fave (β=170.5, p<0.001), and σ (β=−151.6, p<0.001).
Conclusion: For the SN, accuracy was dose-driven while precision was associated with noise texture. For the GGO, precision was predominantly dose-dependent. These findings highlight the importance of tailored protocol optimization in PCCT.
Limitations: A limited number of nodules and a single reconstruction method/kernel combination, which restrict generalizability.

Patient-specific resolution measurements in low-dose chest CT: adapting mesh-based algorithms for high noise images (6 min)

Kwinten Torfs; Leuven / Belgium

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: K. Torfs, K. Merken, D. Petrov, H. Bosmans; Leuven/BE
Purpose: Mesh-based resolution algorithms quantify sharpness on patient images via modulation transfer functions (MTF) taken along the patient air-skin interface, but often fail for noisy chest images (e.g. sharp kernels/low dose). We introduce a high-noise-adapted mesh algorithm (AM), with altered edge-profile conditioning, and compare it to the current mesh algorithm (CM) and a phantom-based circular-edge method (CE), considered gold standard.
Methods or Background: High-contrast circular phantom images were simulated with resolution and noise texture characteristics derived from analytical ground-truth MTFs. Ideal coefficients for the analytical model were fitted to the CE MTF of nine Siemens SOMATOM Edge kernels.
Ten repeated stacks were simulated per combination of:
• Kernel (Br32–Br60, Qr32–Qr60, Bl57)
• Simulated phantom tilting (0°-10° in 2° increments)
• Noise magnitude (0-200HU in 25-HU steps)
• Clothing (present/absent)
Percentage error (PE) was compared across CE, AM and CM.
Results or Findings: CE performance was largely noise-independent, but sensitive to high tilting (>6°: PE=60±40%). For tilting <6° (PE=2.5±1.9%), CE was more accurate ($p<0.001$) than both AM/CM, while AM outperformed ($p<0.001$) for tilting >6°.
Mesh-based algorithms were tilt-resistant but noise-sensitive:
• Low noise (0-50 HU): PE of AM lower than CM ($p<0.001$: 3±3% vs. 5±3%)
• Medium noise (75-125 HU): PE of AM lower than CM ($p<0.001$: 8±5% vs. 40±30%)
• High noise (150-200 HU): PE of AM lower than CM ($p<0.001$: 17±9% vs. 70±30%)
Similar tendencies were observed with clothing present, only at slightly higher PE, and CM outperformed AM ($p<0.05$) for noises 0-25 HU.
Conclusion: For patient-based resolution measurements, tested on non-circular objects, AM reduces error significantly versus CM in most scenarios, limiting PE to maximally 10% for noise up to 125 HU. CE remains optimal for circular phantoms, used in quality control, given precise positioning.
Limitations: None

CT Image Denoising with Noise Augmentation (6 min)

Marc Kachelrieß; Heidelberg / Germany

Author Block: G. Kristof, R. Von Stritzky, E. Eulig, M. Kachelrieß; Heidelberg/DE
Purpose: To improve AI-based CT image denoising, aiming at more naturally looking output images with less hallucinations, by providing noise covariance information to denoising neural networks.
Methods or Background: CT image noise is correlated between neighboring voxels. The correlation strongly depends on the patient's global attenuation properties. We provide this information to deep denoising neural networks by simulating several additional noise-only images as additional network input. Up to ten of these noise only images and the low-dose image, which is the one to be denoised, are now input into a denoising network. We tested this noise-augmented deep denoising (NADD) for the CNN10, ResNet, and WGAN-VGG denoising networks. Our training, validation and test dataset consists of approximately 50,000 clinical CT images. For each network, we compared the NADD version with its original version.
Results or Findings: The NADD versions of the networks performed significantly better than the original versions. The structural similarity index measure (SSIM) improved from 0.937 to 0.956 for CNN10, from 0.942 to 0.954 for ResNet and from 0.917 to 0.940 for WGAN-VGG. In particular, a significant qualitative improvement of the images is observed and far less hallucinations are apparent with NADD.
Conclusion: Using additional noise-only realizations as network input significantly improves the denoising capability of denoising networks. A downside is the requirement of additional image reconstructions corresponding to the number of additional noise realizations used. NADD may help to lower the effective dose to and therefore cancer risk of the patient.
Limitations: Our study only considers 2D, image-by-image, denoising. Future work should extend the denoising networks to true 3D networks that can denoise a whole volume in a 3D fashion.
Funding for this study: This study was supported in parts by the German Federal Ministry for the Environment, Nature Conservation, Nuclear Safety and Consumer Protection (BMUV) under grant 67KI2036B, and by the Helmholtz International Graduate School for Cancer Research, Heidelberg, Germany.

CT-DImQ_SSIM: GUI-based platform for evaluating Structural Similarity Index Measure (SSIM) for CT image quality assessment: AI vs iterative reconstruction phantom study (6 min)

Ainur Kazhybekova; Dublin / Ireland

Author Block: A. Kazhybekova, J. Cooke, M. Kelly, I. Hernandez-Giron; Dublin/IE
Purpose: To present an open-access CT image quality evaluation platform for automated comparison of reconstruction algorithms (AI/DLR vs iterative), based on structural similarity index (SSIM) and histogram analyses.
Methods or Background: CT-DImQ_SSIM is a Python-based GUI (PySide6, scikit-image library) that evaluates SSIM (Wang2004) between two images/stacks, with user-selected SSIM parameters and input window level/width mimicking different visualization conditions. SSIM local maps are automatically created globally and in selected VOIs and saved (TIFF), and average SSIM-values calculated. As an application the Kyoto Kagaku lung paediatric phantom with 3D-printed nodules was scanned (GE-Revolution, standard-thorax, clinical iterative reconstruction, ASIR50-lung and DLR, TrueFidelityHigh). SSIM analysis was performed in selected VOIs (nodules, vessels, rib, vertebra, heart).
Results or Findings: High similarity between both reconstructions (82% pixels, 0.8<SSIM<1), supports the global anatomical structure DLR preservation observed. Smoother edges and reduced apparent enhancement is reflected in low local SSIM-values, especially in high contrast transitions (boundaries, nodules and bones edges). The latter showed the lowest SSIM edge values with up to 10% of pixels SSIM<0.5. Histograms showed a narrower distribution (more uniformity) for DLR (FWHM, nodule={IR:160HU, DLR:30 HU}, rib={IR:245HU, DLR:50HU}, vessel={IR:160HU, TFH:30HU}, heart {IR:120HU, DLR:25HU}).
Conclusion: CT-DImQ_SSIM is an open-access tool for fast and automated SSIM CT image analysis, for imaging protocol and reconstruction algorithms comparison. SSIM maps are a useful visual and quantitative tool to identify potential areas in the image where CT reconstructions/settings may differ, with potential use to identify DLR hallucinations or significant CT-value changes. In an anthropomorphic thorax phantom study, DLR preserved image structural information overall, whereas in edges, especially in high contrast regions it showed low similarity compared to the standard iterative reconstruction.
Limitations: The phantom lacks lung parenchyma which can introduce a bias in comparison with patients reconstructed with same algorithms.
Funding for this study: Ainur Kazhybekova holds an UCD Ad astra PhD Scholarship.

Ultra-high and high-resolution color K-edge imaging using Spectral Photon-Counting CT for ytterbium and gadolinium imaging: a phantom study (6 min)

Ramata Coulibaly; Villeurbanne / France

Author Block: R. Coulibaly[1], A. Robert[1], E. Thomas[1], C. A. Hernandez-Fajardo[1], A. J. Gutwinska[1], M. N. Antonuccio[2], P. Ravipati[1], J. Greffier[3], S. A. Si-Mohamed[1]; [1]Villeurbanne/FR, [2]Suresnes/FR, [3]Nîmes/FR
Purpose: To assess the impact of ultra-high resolution (Detailed2) and high-resolution (HRB) reconstruction kernels on K-edge imaging of ytterbium and gadolinium using spectral photon-counting CT (SPCCT).
Methods or Background: A custom-made cylindrical phantom containing five fillable holes was used. Two configurations were tested: configuration1 contained holes with Gd (0.5, 1, 2, and 10mg/mL) and configuration2 contained holes with Yb at the same concentrations. For each configuration, nine helical acquisitions were performed on the phantom at 120kVp and 75mAs. Conventional images, as well as color K-edge images of Yb (61keV) and Gd (50.2keV), were reconstructed using the HRB and Detailed2 kernels. A three-basis (photoelectric/Compton/K-edge) projection-based material decomposition was used to obtain the K-edge images. Image quality was evaluated in terms of noise power spectrum (NPS), and task-based transfer function (TTF).
Results or Findings: In conventional images, the Detailed2 kernel resulted in higher noise (34.87UH vs 61.57UH configuration1; 34.90UH vs 61.55UH configuration2) and shifted the NPS peak to higher spatial frequencies (0.30mm^{-1} vs 0.80mm^{-1} configuration1; 0.33mm^{-1}vs 0.80mm^{-1} configuration2) compared with HRB.

In K-edge images, both kernels showed similar noise (0.07mg/mL gadolinium; 0.08mg/mL ytterbium) with stable f_{peak} values (0.33mm^{-1} gadolinium; 0.35 vs 0.32mm^{-1} ytterbium).

In conventional images, Detailed2 provided higher spatial resolution. As concentration increased from 0.5 to 10mg/mL in configuration2, f_{50} ranged 0.242–0.586mm^{-1} with Detailed2 and 0.247–0.459mm^{-1} with HRB. In configuration1, Detailed2 ranged 0.330–0.545mm^{-1}, HRB 0.295–0.448mm^{-1}.

In K-edge images, HRB performed better at low concentrations. At 0.5mg/mL, f_{50} was 0.239 vs 0.231mm^{-1} for ytterbium and 0.280 vs 0.250mm^{-1} for gadolinium. At 10mg/mL, Detailed2 outperformed HRB: for ytterbium, 0.732 vs 0.535mm^{-1}; for gadolinium, 0.626 vs 0.451mm^{-1}.
Conclusion: For K-edge imaging, noise was similar, but Detailed2 gave higher resolution at high concentrations, while HRB was slightly better at low concentrations.
Limitations: Phantom study.
Funding for this study: This work was supported by the ERC starting Grant KOLOR SPCCT Imaging (N°101118079).

Liver Fat and Iron Quantification with Spectral Localizer Radiographs from Photon-Counting Detector CT (6 min)

Andrin Tognella; Zürich / Switzerland

Author Block: A. Tognella; Zürich/CH
Purpose: Liver fat quantification on CT is often confounded by hepatic iron deposition and the use of iodinated contrast agents. This phantom study aimed to assess the feasibility and accuracy of quantifying liver fat content (LFC) in the presence of iron using pre-contrast spectral localizer radiographs (SLR) from a photon-counting detector CT (PCD-CT).
Methods or Background: Sixteen phantoms were created using mixtures of liver tissue, fat, and iron to simulate four levels of LFC (0%, 10%, 30%, 50%) and four levels of liver iron concentration (LIC: 0, 1.5, 3, and 6 mg/mL). All phantoms were scanned on a PCD-CT using three tube current settings (10 mA, 50 mA, 300 mA), acquiring SLRs. Material decomposition of high- and low-energy bin data yielded water and hydroxyapatite (HA) maps. HA-values were analyzed as a function of LFC and LIC, and water-values were correlated with corresponding HA-values.
Results or Findings: Increasing LFC resulted in a linear decrease in HA-values, consistent across LIC levels (slopes ranging from -0.0016 to -0.0023, r = 0.997 – 1.0). Conversely, increasing LIC led to a linear increase in HA values, independent of LFC (slopes ranging from 0.0147 to 0.017, r = 0.978 – 1.0). When combined with water values in a two-dimensional material space, these consistent linear trends enabled accurate estimation of LFC regardless of LIC. Findings were reproducible across all tube current settings.
Conclusion: This phantom study demonstrates that SLRs from PCD-CT enable accurate estimation of liver fat content, even in the presence of iron deposition. If validated in vivo, this technique may facilitate opportunistic screening for hepatic steatosis and iron overload in clinical practice solely using SLRs.
Limitations: Proof-of-principle study with phantom setup offers simplified conditions. No evaluation of patient data. Limited to a specific PCD-CT.

Detecting Iodine in a Semi-Anthropomorphic Liver Phantom – Evaluating the Performance of a 4th Generation Prototype Deep-Silicon Photon Counting CT system (6 min)

Line Gaard Pedersen; Oslo / Norway

Author Block: L. G. Pedersen[1], A. Schulz[1], A. Dybwad[1], D. Crotty[2], H. Linder[3], J. Levy[4], K. Jensen[1]; [1]Oslo/NO, [2]Cork/IE, [3]Stockholm/SE, [4]Greenwich, NY/US
Purpose: Smaller metastatic liver lesions can be difficult to detect on conventional energy-integrating (EID) CT. The improved spatial and spectral resolution of Photon Counting CT (PCCT) is expected to improve iodine contrast detection in liver imaging.
Methods or Background: A semi-anthropomorphic liver phantom (PhantomLab) was scanned using GSI on a Revolution Apex EID CT and subsequently on a 4th-generation prototype silicon-based PCCT system (both GE HealthCare). The phantom contains both homogeneous inserts without Iodine and Iodine inserts of varying concentration (1-3mg/mL) to mimic metastatic liver lesions of diameter 3-15mm. Similar CTDIvol levels (5-25mGy) were used to image on both systems with other technique parameters prescribed as similar as possible.
Using prototype image reconstruction algorithms, Virtual Monoenergetic Images (VMI) from 40-70keV and Iodine and Water material maps were reconstructed. Voxel-based Hounsfield Unit (HU), image noise (measured as standard deviation (SD)), and Contrast-to-Noise (CNR) were quantified. A two-alternative forced choice reader study was performed to visually detect iodine inserts.
Results or Findings: For the 15mm lesion, PCCT VMI reconstructed using the prototype image reconstruction process demonstrate increased CNR as CTDIvol increases and keV reduces. At 70keV, the CNR of the 15mm lesion in PCCT increased from 1.5-3.3 with increasing CTDIvol. At equal CTDIvol (10mGy), PCCT images (8.9-12 HU) showed a significant decrease in background image noise range relative to EID images (11.6-35.1 HU). While PCCT image noise is reduced, the iodine HU stays consistent across CTDIvol, resulting in up to 60% increased CNR for all reconstructed VMIs on the PCCT relative to EID.
Conclusion: Reader study participants observed the 3 mm lesion in 90% of cases in PCCT images obtained between 15 and 20 mGy.
Limitations: Only phantom study, results should be confirmed in a patient study.
Funding for this study: None.

Elizabeth Dick; London / United Kingdom

Advancing Emergency Radiology: The Critical Role of Imaging Near Catastrophic Events (6 min)
Dmytro Beshley; Lviv / Ukraine

Author Block: U. Pidvalna, D. Beshley; Lviv/UA
Purpose: 1. Understand the role of radiological modalities (X-ray, ultrasound, CT) in triage and evacuation of casualties.
2. Identify imaging findings of combat-related injuries across the head, chest, abdomen, pelvis, and extremities.
3. Recognize key challenges in applying diagnostic imaging in mobile military hospitals.
Methods or Background: Military trauma has evolved with the advancement of modern warfare, creating new challenges in managing battlefield injuries. Timely diagnosis and decision-making are crucial in the resource-limited environment of a mobile military hospital. Radiological tools, including X-ray, ultrasound, and CT, are indispensable for frontline medical teams, enhancing decision-making during patient evacuation and trauma care.
Results or Findings: Imaging in mobile military hospitals reveals a broad spectrum of traumatic injuries, particularly in the head, chest, abdomen, pelvis, and extremities.
Key findings include:
Head injuries: Brain trauma and fractures.
Chest injuries: Pneumothorax, hemothorax, heart and vessel injuries.
Abdominal injuries: Hemoperitoneum, solid organ trauma.
Pelvic and extremity injuries: Amputations and fractures.

X-ray and ultrasound provide rapid initial assessments, while CT is employed for complex injuries. This integration enables faster diagnosis and informed decision-making, ultimately improving patient outcomes.
Conclusion: Radiology significantly enhances trauma care in mobile military hospitals, enabling swift diagnosis and triage. While logistical challenges remain, including limited resources, diagnostic imaging has proven vital in improving survival rates and optimizing patient care on the battlefield. The integration of imaging technologies in mobile settings continues to play a key role in modern military medicine.
Limitations: Single center, potential biases in imaging interpretation due to varying expertise levels, constraints in radiological equipment, and resources in a combat setting.
Funding for this study: No

MRI safety recommendations in patients with unknown metallic fragments after war-related injuries: a pragmatic workflow (6 min)
Mariia Khurtsylava; Kyiv / Ukraine

Author Block: M. Khurtsylava; Kyiv/UA
Purpose: To present practical considerations and a step-by-step workflow for MRI safety in patients with unknown metallic fragments, a patient group that has become increasingly common due to war-related injuries.
Methods or Background: Patients with shrapnel wounds or metallic foreign bodies of undocumented origin are frequently referred for MRI. The exact composition of fragments is often unknown, while clinical questions usually concern anatomical regions distant from the fragments (e.g. brain MRI in a patient with fragments in the leg). Literature review and analysis of local clinical experience were used to design a pragmatic workflow for risk assessment and decision-making.
Results or Findings: Metallic fragments may include steel, copper/bronze, lead, aluminium, or tungsten. Risks range from ferromagnetic displacement (steel), RF-induced heating, to severe image artefacts.
Proposed workflow:
1. Focused history and inspection for scars.
2. X-ray/CT for localisation and density assessment.
3. Identification of critical sites (orbit, spinal canal, vessels, heart).
4. Risk–benefit evaluation: MRI performed only if clinical necessity outweighs potential risks.
5. Technical precautions: low-SAR protocols, local transmit/receive coils, patient monitoring, clear documentation.
When fragments are remote from the scanned region, mechanical risks are low but heating remains possible; each case requires individual assessment.
Conclusion: Patients with unknown metallic fragments represent a growing challenge in MRI practice. A structured workflow helps improve safety and avoid unnecessary refusals of clinically important examinations.
Limitations: This workflow is based on literature and local practice. Prospective multicentre validation is required.
Funding for this study: No funding was received for this study.

Comparative CT findings in polytrauma: differences between living patients and post-mortem CT (6 min)

Monica Palermo; Catania / Italy

Author Block: M. Palermo, R. A. Trapani, M. Pane, F. Tiralongo, S. Palmucci, P. V. Foti, C. Pomara, A. Basile; Catania/IT
Purpose: To compare CT findings in polytrauma patients due to traffict accident undergoing emergency CT scan with those observed in deceased patients examined with post-mortem CT (PMCT), focusing on the most frequent fatal injuries reported in the literature and our experience.
Methods or Background: We performed a retrospective evaluation of findings in patients who underwent emergency whole-body CT (WBCT) in our emergency department due to traffic accidents and of findings on PMCT of trauma victims performed in our Institution. We also performed a literature review on main findings in this setting of patients and on more common fatal injuries detectable with PMCT.
Results or Findings: In living patients, WBCT typically demonstrated limb fractures, intracranial hemorrhages, thoracic and abdominal bleeding, and solid organ injuries, often supporting timely therapeutic decisions.
In deceased trauma victims, in accordance with Schmitt-Sody et al. , the predominant fatal injuries on PMCT were:
• Severe thoracic injuries (~65%), including massive hemothorax, pulmonary lacerations, and major vascular ruptures, especially aortic rupture.
• Severe cranio-cerebral trauma (~47%), such as extensive intracranial hemorrhage or destruction of brain parenchyma.
• Massive intra-abdominal hemorrhage (e.g., liver or splenic rupture), less frequent but still relevant.
Conclusion: CT in living polytrauma patients reveals a broad spectrum of injuries, many of which are potentially treatable if promptly identified. PMCT, on the other hand, consistently highlights the lesions that are most often fatal—severe thoracic hemorrhage, aortic rupture, extensive cranial trauma, and massive abdominal bleeding. Awareness of these patterns from PMCT can help radiologists maintain a higher index of suspicion during emergency reporting, facilitating early recognition of critical injuries and potentially life-threatening complications, ultimately improving patient management in the acute setting.
Limitations: Retrospective study, small number of cases
Funding for this study: No fundings received.

Diffusion-Weighted Imaging in the Early MRI Follow-up of Abdominal Solid Organ Injuries: Diagnostic Value and Protocol Optimization (6 min)

Francesca Iacobellis; Naples / Italy

Author Block: F. Iacobellis, C. Camillo, M. Di Serafino, L. Barbuto, R. Ronza, D. Grimaldi, C. Rinaldo, F. Verde, S. Giovine; Naples/IT
Purpose: To assess the diagnostic value of diffusion-weighted imaging (DWI) in the early MRI follow-up of abdominal solid organ injuries in polytraumatized patients, comparing its performance with conventional and contrast-enhanced sequences, and to define an optimized protocol tailored to trauma-related findings.
Methods or Background: MRI studies performed between 2018 and 2022 for early follow-up of high-energy abdominal trauma were retrospectively reviewed. Each protocol included T1- and T2-weighted sequences (with and without fat suppression), DWI, and 3D T1-weighted fat-saturated sequences before and after intravenous (IV) gadolinium-based contrast administration. Three radiologists in consensus evaluated the contribution of each sequence to lesion detection, characterization, and follow-up assessment.
Results or Findings: Forty-six MRI examinations were analyzed. Conventional T1W, T2W, and T2W fat-sat sequences provided essential morphological and evolutionary information about parenchymal lesions and hemoperitoneum. DWI sequences improved lesion conspicuity compared to unenhanced sequences in 50% of cases, were equivalent in 18.7%, and inferior in 14.5%. Compared to post-contrast sequences, DWI showed equivalent diagnostic performance in 54.1%, superior in 27.1%, and inferior in 18.7% of cases. Contrast-enhanced sequences remained essential in confirming contained vascular injuries (8.6%) and urinary leakage.
Conclusion: DWI provides substantial diagnostic value in the early follow-up of abdominal parenchymal injuries, frequently matching or exceeding the information obtained from contrast-enhanced imaging. Incorporating DWI as a core component of trauma MRI protocols may reduce dependence on contrast agents, shorten scan times, and improve diagnostic safety in patients with renal impairment or critical conditions.
Limitations: Retrospective design of the study, limited sample size, heterogeneity of trauma severity and timing of follow-up MRI. No quantitative analysis of ADC values was performed.
Funding for this study: None

Prognostic relevance of contrast extravasation in patients undergoing endovascular embolization of acute bleeding (6 min)

Hans-Jonas Meyer; Leipzig / Germany

Author Block: H-J. Meyer, S. Ebel, T. Denecke, M. Struck; Leipzig/DE
Purpose: : Contrast extravasation on imaging studies is a clinical surrogate for bleeding severity. However, the prognostic relevance of this imaging sign needs to be evaluated. The aim of this study was to analyze the impact of contrast extravasation defined by computed tomography (CT) and angiography on massive transfusion and 30-day mortality in patients with acute bleeding undergoing transarterial embolization (TAE).
Methods or Background: A mixed cohort of patients with acute bleeding requiring treatment with TAE between 2018 and 2022 was retrospectively evaluated. All patients underwent triphasic CT to localize the source of bleeding and to calculate extravasation volumes in the arterial and portal venous phases. The bleeding rate k was calculated from the CT images.
Results or Findings: A total of 128 patients (79 male, 61.7%) with a mean age of 67.4 years (range 21-95 years) and an all-cause 30-day mortality rate of 34.4% were included in the present analysis. A moderate positive correlation was identified between transfused packed red blood cell units and bleeding rate k ($r=0.33$, $p<0.001$). In multivariable logistic regression analysis, bleeding rate k was identified as an independent prognostic factor for massive transfusion (OR 25.77, 95% CI 1.35-493.61, $p=0.031$, area under the receiver operating characteristic curve (AUROC) of the model: 0.847) and 30-day mortality (OR 25.04, 95% CI 2.29-273.42, $p=0.008$, AUROC of the model: 0.781).
Conclusion: CT-defined bleeding rate k is a prognostic factor for massive transfusion and 30-day mortality in patients with acute bleeding undergoing TAE and may be superior to the volume of contrast extravasation volume alone. Further studies are needed to confirm this finding.
Limitations: The study has to address the limitation of a retrospective single center, and the heterogenous nature of the patient cohort.
Funding for this study: None

Quadruple-Rule-Out CT Angiography: Dual-Energy CT for Comprehensive Evaluation of Acute Chest Pain (6 min)

Mehmet Emir Çevik; Ankara / Turkey

Author Block: M. E. Çevik[1], E. ZENGİN[2], K. B. Memiş[3]; [1]Kırıkkale/TR, [2]Ankara/TR, [3]Erzincan/TR
Purpose: Computerized tomography (CT) has been increasingly utilized in the differential diagnosis of acute chest pain. Combining the triple rule out CT angiography (TRO-CT) approach with dual-energy CT (DECT) can enhance the diagnostic capability by identifying myocardial
perfusion deficiencies. This combination can yield a quadruple-rule-out computed tomography angiography (QRO-CT) technique. The aim of this study is to determine the efficacy of the QRO-CT.
Methods or Background: Intraluminal diseases and abnormalities in the main coronary arteries and branches were investigated. The myocardial dark spots on the color-coded iodine map were identified as perfusion deficiencies. Pulmonary arteries and aorta were also evaluated.
Results or Findings: The study population consisted of 211 patients. The sensitivity, specificity, and positive and negative predictive values of QRO-CT for pulmonary embolism were 93.5%, 100%, 100%, and 95.3%, respectively. For obstructive coronary artery disease, the values were 96.1%, 93.4%, 89.2%, and 97.7%, respectively. For myocarditis, the values were 69.2%, 100%, 100%, and 93.6%, respectively.
Conclusion: the QRO-CT method may successfully evaluate myocardial perfusion deficits, hence expanding the differential diagnosis capabilities of the standard TRO-CT method for myocarditis. It can provide useful information on myocardial perfusion, which may influence the choice to perform invasive catheterization in cases of coronary artery obstruction.
Limitations: Main limitations are the single-center design, moderate sample size, incomplete troponin data in some patients, and the fact that not all patients had MRI correlation.
Funding for this study: No external funding was received.

Ethics committee - additional information: Our study was approved by the ethics committee. The ethics committee approval number is as follows: 14.12.2021-EBYU-KAEK-21/12-18.

Pelvic Radiographs in Polytrauma: Diagnostic Accuracy and Interobserver Agreement. A Retrospective CT Correlation Study (6 min)

Noor Al Balushi; Muscat / Oman

Author Block: N. Al Balushi, S. RANIGA , A. K. Mittal, N. M. Fazaldad; Muscat/OM
Purpose: Pelvic fractures in polytrauma patients are a critical concern due to their association with vascular injuries, haemorrhage and shock. While CT is the gold standard for evaluation of bony and articular injuries, pelvic radiographs remain the primary screening imaging modality in many trauma protocols. This study aims to assess the diagnostic accuracy of anteroposterior pelvic radiographs for detecting pelvic fractures using CT as reference and to evaluate interobserver agreement among radiologists.
Methods or Background: In this retrospective, cross sectional study approved by the institutional ethics board, adult patients presenting with acute pelvic trauma between 2016-2022 who underwent both pelvic radiography and CT were included. Two staff radiologists independently reviewed the pelvic radiographs, blinded to CT results. Diagnostic accuracy was assessed using CT as the reference standard, calculating sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV). Interobserver agreement was analysed using Fleiss multirater kappa statistics. Findings were compared with those reported in existing literature.
Results or Findings: Total of 99 patients were included (mean age 33.2±13.1 years, 77.5% male). Acetabular fractures were the most frequently missed, with 53% of cases falsely negative and 1.2% false positives. Sacral fractures had a 50% miss rate on radiographs. The overall interobserver agreement was substantial (kappa= 0.788), with highest agreement seen in iliac, pubic and proximal femur fractures and lowest in acetabular and sacral fractures.
Conclusion: Anteroposterior pelvic radiographs have limited sensitivity for detecting acetabular and posterior ring fractures. In our cohort, all unstable fractures were detected on radiographs, supporting their continued use as effective initial screening tools in polytrauma.
Limitations: The study is constrained by limited sample size and evolving image quality. Radiographic interpretation may have been impacted by patient positioning and obscuring bowel gases, particularly in subtle fractures.
Funding for this study: None

Morel-Lavallée Lesions in Emergency Radiology – How Often Are They Missed? (6 min)

Marija Mitrašinović; Belgrade / Serbia

Author Block: M. Mitrašinović, D-S. Petkovic, A. Popovic, S. Milosevic, D. Vasin; Belgrade/RS
Purpose: Morel-Lavallée lesions (MLLs) are rare soft tissue injuries occurring in trauma setting, characterized by degloving of subcutaneous tissue from muscular fascia, creating a potential space filled with blood and lymph. They are often overlooked leading to inadequate treatment, complications and recurrence. This study aimed to evaluate the diagnostic role of CT in detecting MLLs and to increase awareness of their recognition on CT, which is usually the first-line imaging tool in polytrauma patients.
Methods or Background: We conducted a retrospective review of trauma patients between 2022 and 2025 based on two criteria: emergency admission for polytrauma and description of a subcutaneous hematoma on CT involving the upper limb, gluteal region, knee, elbow, scapular region, or abdominal wall. These CT scans were then reassessed for misdiagnosed lesions.

Diagnostic CT criteria included: (1) acute, hyperdense collections between subcutaneous fat and fascia; and (2) chronic-appearing, encapsulated collections with fluid–fluid or gas levels, fat lobules, or septations. Patient clinical records were analyzed for confirmation.
Results or Findings: Of 110 trauma patients, 35 (31.8%) showed CT imaging features consistent with MLLs. Clinical confirmation was obtained in 14 patients (12.7% of the cohort; 40% of CT-suspected lesions). The CT-suspected group comprised 22 men (62.9%) and 13 women (37.1%). Most lesions occurred in the gluteal/femoral region (71.4%), followed by scapular (14.3%), knee (8.6%), and elbow (5.7%). CT demonstrated a positive predictive value (PPV) of 40.0% (95% CI: 24.6–57.7%), with a 60% false-positive rate.
Conclusion: CT can raise suspicion for MLLs but does not provide sufficient specificity for definitive diagnosis. While CT is valuable in the acute setting, further evaluation with MRI and clinical examination is essential. Improved awareness of CT features among radiologists may enhance recognition, ensure timely follow-up, and guide management.

To assess whether brief structural reporting system can reduce the report turn-around time (6 min)

Yon-Cheong Wong; New Taipei City / Taiwan, Chinese Taipei

Author Block: Y-C. Wong; New Taipei City/TW
Purpose: Whole-body CT for trauma is a rapid and safe imaging modality. But with hundreds of images per trauma patient, the workload has burned out radiologists and the pressure on timeliness of reporting is increasing. Experimental studies have demonstrated that structured reporting systems can reduce report turn-around time by approximately 25% to 50% (the denominator is about 25 minutes). The purpose of this study is to assess whether brief structural reporting system can reduce the report turn-around time.
Methods or Background: From January 2024 to June 2025, we retrospectively reviewed whole-body CT of trauma patients. We assessed whether brief structured reporting system that includes five key questions can further reduce report turn-around time. The five questions included (1) intracranial midline shift, (2) tension pneumothorax, (3) cardiac tamponade or aortic injury, (4) abdominal contrast medium extravasation and (5) unstable spine or pelvic fracture.
Results or Findings: Among 62 whole-body CT reports, there were 35 males and 27 females, mean age was 46.1 ± 19.1 years, ISS was 25.7 ± 12.6, (min 4 - max 50), report turn-around time was 3.97 ± 1.85 minutes, (min 1 - max 7 minutes). There were 12 intracranial midline shifts, 7 tension pneumothorax, 2 cardiac tamponade or aortic injury, 9 abdominal contrast medium extravasation and 13 unstable spine or pelvic fracture.
Conclusion: The brief structural reporting system could report the whole-body CT, and it took a mean of 3.97 minutes to accomplish.
Limitations: We do not disclose the reliability among different readers. We also do not disclose the impact of the reports on the therapeutic planning of trauma surgeons. Lastly, this initial study is carried out in a single center and the inclusion number is small.

ST 5 - 20 years of ESOR: education in partnership - a vision realized (PART 1)

Categories: Education

Date: March 4, 2026 | 15:00 - 15:30 CET

The European School of Radiology (ESOR) is an institution, fulfilling the mission of the European Society of Radiology (ESR) in the field of education. One of its main goals is to assist in harmonising radiological education in Europe. With its wide range of activities ESOR additionally aims to raise standards in the field of scientific radiology, to extend and coordinate teaching resources worldwide and to help young radiologists to achieve the knowledge and skills to fulfil tomorrow's requirements.
ESOR Educational/Scientific Director, Prof. Christian Loewe, will give an overview of the many different ESOR activities like the ESOR training programmes, courses and visiting professorship programmes and explain how ESOR has evolved over the past 20 years.
Dr. Fulvio Renoldi Bracco, CEO of Bracco Imaging SpA, will inform about the value of education in partnership and the long-standing and fruitful cooperation between ESOR and Bracco over two decades. Young radiologists, thanks to the many projects organised in partnership between Bracco Imaging and ESOR, can learn and grow and contribute to innovation in imaging for the benefit of patients.

TC 527 - Imaging in prostate cancer diagnosis

Categories: Oncologic Imaging, Genitourinary

ETC Level: LEVEL III

Date: March 4, 2026 | 15:00 - 16:00 CET

CME Credits: 1

The session aims to discuss the evolution of the diagnostic pathway and role of MRI in improving the detection and localisation of life-threatening prostate cancer according to PI-RADS v2.1. It will describe the assessment of advanced localised prostate cancer with drawbacks in the current T-staging. The attendees will learn about the implications of standardised reporting and the subsequent impact on patient management.

CUBE 6 - Peripheral arterial disease (PAD): tips and tricks

Categories: Interventional Radiology, Vascular

ETC Level: LEVEL II+III

Date: March 4, 2026 | 15:30 - 16:00 CET

CME Credits: 0.5

This session on peripheral arterial disease (PAD) provides expert insights and practical guidance on the diagnosis and management of arterial lesions at critical anatomical sites. The presenters will address interventions involving the brachiocephalic trunk, carotid, and subclavian arteries, as well as below-the-knee vessels. Each presentation will highlight key tips and procedural nuances to enhance treatment outcomes.

EFRS 5 - ECSO-MRI project update

Categories: Radiographers, Research, Education

Date: March 4, 2026 | 15:30 - 16:30 CET

This session will provide an update on the ECSO-MRI Project, highlighting recent progress, key outcomes, and ongoing work aimed at strengthening MRI education and practice across Europe. Presentations will address the evolution of educational frameworks, the integration of emerging technologies, and the development of tools and recommendations designed to support radiographers in MRI. Together, these updates will demonstrate how the ECSO-MRI Project contributes to harmonising training, enhancing professional competence, and supporting safe, high-quality MRI practice within modern healthcare systems.

Moderator:

Anke De Bock; Willebroek / Belgium

Chairpersons Introduction (10 min)

Anke De Bock; Willebroek / Belgium

ECSO-MRI Project Updates (45 min)

1.To understand the key objectives, recent progress, and main outcomes of the ECSO-MRI Project in relation to MRI education and clinical practice across Europe.
2.To identify how evolving educational frameworks, emerging technologies, and project-developed tools can support radiographers' competence and professional development in MRI.
3.To recognise the role of the ECSO-MRI Project in promoting harmonised training, patient safety, and high-quality MRI practice within contemporary healthcare systems.

Black Swan events: emergent comprehensive imaging of the major trauma patient (10 min)

Richard Graham; Bath / United Kingdom

1. To learn the current imaging and clinical needs of the major trauma patients.
2. To understand the clinical objectives and difficulties in imaging such patients.
3. To understand what technological solutions have an impact on these challenges.

Bows and arrows, technical equipment requirements for trauma imaging (10 min)

Paddy Gilligan; Dublin / Ireland

1. To understand the range of equipment to deliver the clinical need.
2. To understand the specification, procurement needs and installation, environmental cyber requirements for such equipment.
3. To discuss the challenges in implementing trauma needs in a clinical department.

Delivering care where needed: point of care solutions for imaging the trauma patient (10 min)

Jonas Seth Andersson; Umeå / Sweden

1. To understand field-based solutions and challenges for point-of-care imaging.
2. To understand the available CBCT, O-arm, skeletal survey systems, and low-field MRI for point-of-care imaging.
3. To look toward future development in field-based imaging.

Dosimetry, radiation protection and MRI safety in trauma scenarios (10 min)

Marta Sans Merce; Geneva / Switzerland

1. To learn about challenges in radiation protection and patient safety in trauma imaging.
2. To learn about solutions and future directions.
3. To become familiar with how close they are to clinical implementation.

Panel discussion: Is your hospital ready for major trauma events? (15 min)

EIBIR 6 - Assistive technologies for interventional radiologists: enhancing decision-making and streamlining workflow with innovations and AI-powered solutions

Empowering interventional radiologists with AI-powered assistive technologies: the Smart Human-centred Effortless support for Professional clinical Applications (SHERPA) project (15 min)
Robert Hofsink; Best / Netherlands

1. To learn about the goals and scope of the SHERPA project.
2. To appreciate the significance of AI-powered assistive technologies in interventional radiology.
3. To understand how these technologies can enhance efficiency and work performance in clinical practice.

How to evaluate the impact of assistive technologies in interventional radiology (15 min)
Hans B Reitsma; Utrecht / Netherlands

1. To gain insight into the potential benefits and challenges of integrating assistive technologies into interventional radiology.
2. To learn about the clinical studies and methodologies used in SHERPA to evaluate the impact of assistive technologies.
3. To develop a comprehensive framework for evaluating assistive technologies in healthcare.

Enhancing precision and efficiency in clinical practice in IR (15 min)
Irene C Van Der Schaaf; Utrecht / Netherlands

1. To learn about the clinical validation of assistive tools for IR in SHERPA.
2. To appreciate the improvements in clinical outcomes and workflow efficiency.
3. To understand the practical applications of AI-powered guidance in everyday clinical practice.

Panel discussion: What is the future of the IR workflow with the integration of assistive technologies? (10 min)

E³ 22B - Non-injured, painful, and swollen knee

Imaging approach in adults (15 min)
Matthew Jaring; London / United Kingdom

1. To learn the appropriate imaging modality for different clinical scenarios is essential in ensuring accurate diagnosis and efficient patient care.
2. To appreciate the strengths and limitations of each imaging technique helps in selecting the most suitable test for a given patient presentation.
3. To understand the indications, contraindications, and potential risks of imaging studies is critical for safe and effective clinical decision-making in adult patients.

Imaging the painful postoperative knee (15 min)
Üstün Aydingöz; Ankara / Turkey

1. To list conditions whereby the postoperative knee may display painful swelling.
2. To explain how to make the best use of available imaging modalities to diagnose the underlying condition in a postoperatively swollen knee.
3. To describe imaging findings in a postoperative painful, swollen knee.

Imaging approach in children (15 min)
Maria Raissaki; Heraklion / Greece

1. To discuss the variety of causes of pain and knee joint swelling in children, with emphasis on do-not-miss diagnoses.
2. To understand meticulous techniques and limitations when investigating non-traumatic abnormalities of the paediatric knee.
3. To appreciate that a lack of a history of trauma does not exclude a post-traumatic condition in children.

Panel discussion (10 min)

How 6 - How and what we learn from challenging neuro and head and neck cases

Categories: Neuro, Head and Neck, Multidisciplinary, President's Choice

MR conditional passive implants: how to fulfil the conditional requests for a safe MR exam (15 min)
Siegfried Trattnig; Vienna / Austria

1. To understand what it means when an implant or device is labelled "conditional".
2. To learn typical conditions of MR conditional implants, which may include limits on field strength, field spatial gradient, gradient strength, gradient slew rate, specific absorption rate, and B1+rms.
3. To get familiar with how to follow certain strict restrictions that a device/implant that contains magnetic, conductive or RF-reactive components is safe for use in the MRI environment.

MR in the presence of metal implants: which sequences to use and how to read the images (15 min)
Edwin Oei; Rotterdam / Netherlands

1. To understand the influence of passive implants on different MRI sequences, focusing on metal implants.
2. To understand the choice of MRI sequences to be used in the presence of metal implants, including different types of metal artefact-reducing MRI sequences.
3. To understand the value of metal artefacts by reducing MRI sequences from several case examples, focused on musculoskeletal and spine imaging.

A radiographer's perspective (15 min)
Christos Tsiotsios; Limassol / Cyprus

1. To learn how radiographers identify and manage passive implants in the MR environment, including the challenges and considerations involved.
2. To appreciate the radiographer's role in maintaining MR safety, not just through careful screening and protocols, but also through clinical judgement and collaboration with the wider clinical team.
3. To understand how evolving implant guidelines and safety resources are applied in real clinical practice, and how radiographers adapt to ensure patient safety and workflow efficiency.

Panel discussion: How do we create a culture to feel safe dealing with passive implants? (10 min)

Image-guided radiotherapy (10 min)
Anastasia Sarchosoglou; Athens / Greece

1. To understand the principles and benefits of Image-Guided Radiotherapy (IGRT).
2. To identify the evolving role of radiographers in IGRT workflows.
3. To recognise how IGRT enhances precision and patient outcomes in radiotherapy.

Ultrasound in care (10 min)
Geert Plug; Haarlem / Netherlands

1. To understand the clinical value of Point-of-Care Ultrasound (POCUS) in care facility settings.
2. To explore the expanding role of radiographers in delivering ultrasound services outside traditional hospital environments.
3. To recognise the impact of bedside ultrasound on patient management, diagnosis, and care efficiency.

Open forum discussion (15 min)

Radiographers' image evaluation towards optimisation of patient pathway (10 min)
Jarno Tapani Huhtanen; Raisio / Finland

1. To understand the role of radiographers in image interpretation and its relevance to clinical practice.
2. To describe the expanding role of the reporting radiographer in clinical practice and the benefits in patient pathway/outcomes.
3. To recognise the potential of AI as a supportive tool in justification, image interpretation and follow-up of a patient.

OF 6Y - Game on: navigating the EDiR CORE case resolution, win a spot for an EDiR simulation and webinar (part 1)

Categories: Professional Issues, Students, Education, President's Choice
ETC Level: LEVEL II
Date: March 4, 2026 | 16:30 - 17:00 CET
CME Credits: 0.5

Moderators:
Laura Oleaga Zufiria; Barcelona / Spain
Chantal Van Ongeval; Leuven / Belgium

Chairpersons' introduction (5 min)
Laura Oleaga Zufiria; Barcelona / Spain
Chantal Van Ongeval; Leuven / Belgium

Let the games begin (20 min)
Chantal Van Ongeval; Leuven / Belgium

1. To scan and interpret two cases of breast radiology and possible outcomes based on the attendees' decisions.
2. To get to know and team up with peers from all over the world to help as many patients as possible.
3. To solve the quiz to win an EDiR Simulation and Webinar. Please note that there can only be one winner per session.

Pooling of conclusions and perceptions (5 min)

RC 600a - State-of-the-art imaging of oesophageal cancer

Categories: Hybrid Imaging, Oncologic Imaging, GI Tract, President's Choice
ETC Level: LEVEL II
Date: March 4, 2026 | 16:30 - 17:30 CET

Chairperson's introduction (3 min)
Ekaterini Xinou; Thessaloniki / Greece

Imaging for diagnosis and staging of oesophageal cancer (15 min)
Pauline Chapellier; Nyon / Switzerland

1. To review the typical imaging findings of oesophageal cancer with available imaging modalities.
2. To compare different imaging modalities in the diagnosis, staging, and management of oesophageal cancer.
3. To illustrate how imaging contributes to multidisciplinary decision-making and treatment planning.

Assessing treatment response: imaging during and after neoadjuvant therapy (15 min)
Vicky Goh; London / United Kingdom

1. To review imaging protocols during modern neoadjuvant chemoradiotherapy.
2. To review the challenges in distinguishing a viable tumour from post-treatment changes.
3. To discuss the role of PET-MRI and radiomics.

Postoperative imaging: complications and surveillance (15 min)
Luis Curvo-Semedo; Coimbra / Portugal

1. To review normal postoperative anatomy and expected findings after esophagectomy.
2. To illustrate early and late complications associated with oesophageal cancer surgery.
3. To discuss imaging strategies for recurrence detection and long-term follow-up.

Panel discussion: How to navigate the medical decision-making as a radiologist (12 min)

RC 600b - Cardiac amyloidosis imaging

Categories: Hybrid Imaging, Molecular Imaging, Nuclear Medicine, Cardiac
ETC Level: LEVEL III
Date: March 4, 2026 | 16:30 - 17:30 CET
CME Credits: 1

Epidemiology, diagnosis, and therapy of amyloidosis: the clinical perspective (15 min)
Efstathios Kastritis; Athens / Greece

1. To describe the systemic amyloidosis disease spectrum.
2. To summarise the treatment approaches in amyloidosis.
3. To discuss the challenges in diagnosis and patient management.

The role of magnetic resonance in the diagnosis of cardiac amyloidosis (15 min)
Jean-Nicolas Dacher; Rouen / France

1. To describe the major cardiac magnetic resonance anomalies encountered in patients with cardiac amyloidosis.
2. To distinguish between the two main types of cardiac amyloidosis (amyloid light chain [AL] and transthyretin [ATTR]).
3. To understand the role of cardiac MR in the follow-up of patients.

The role of nuclear medicine in amyloidosis (15 min)
Simona Ben-Haim; Jerusalem / Israel

1. To describe which radiopharmaceuticals are used for ATTR cardiac amyloidosis.
2. To examine and grade bone-avid tracer scans.
3. To differentiate ATTR from AL in suspected cardiac amyloidosis.

Panel discussion: The imaging algorithm for cardiac amyloidosis: what, when and why (10 min)

RC 604 - Lung cancer diagnosis and staging: pearls and pitfalls from the multidisciplinary team

Categories: Oncologic Imaging, Chest, President's Choice
ETC Level: LEVEL I
Date: March 4, 2026 | 16:30 - 17:30 CET
CME Credits: 1

Moderator:
Diana Manolescu; Timisoara / Romania

Chairperson's introduction: update on the TNM 9 staging system (4 min)
Diana Manolescu; Timisoara / Romania

Mimics of lung cancer (14 min)
Mariaelena Occhipinti; Pisa / Italy

1. To review the lung cancer mimickers: clues for diagnosis.

Difficult lesions to stage: T stage (14 min)
Anna Kerpel-Fronius; Budapest / Hungary

1. To present challenging situations when staging lung cancer.

Pitfalls in nodal staging: N stage (14 min)
John Kavanagh; Ireland / Ireland

1. To review the role of imaging in nodal staging.
2. To describe the strengths and limitations of imaging in nodal staging of lung cancer.

Metastases or not: M stage (14 min)
Alessandra Farchione; Roma / Italy

1. To describe the diagnostic management of suspicious metastatic disease in lung cancer.
2. To review diagnostic pitfalls of metastatic disease.

RC 610 - Muscle imaging

Categories: Musculoskeletal, Imaging Methods, Education
ETC Level: LEVEL II+III
Date: March 4, 2026 | 16:30 - 17:30 CET
CME Credits: 1

Chiara Giraudo; Padua / Italy

Chairperson's introduction (5 min)
Chiara Giraudo; Padua / Italy

Grading muscle injury (15 min)
James Teh; Oxford / United Kingdom

1. To characterise sports muscle injuries.
2. To present the contemporary imaging classifications used for sports-related muscle injuries.
3. To appreciate the clinical significance of grading muscle injuries.

Myositis and myopathy (15 min)
Frédéric Lecouvet; Brussels / Belgium

1. To list the more frequent inflammatory and hereditary myopathies with their clinical characteristics.
2. To identify some specific MRI patterns associated with individual phenotypes and MRI limitations.
3. To integrate functional and quantitative MRI techniques with a potential role in evaluating the myopathies.

Muscle tumours and pseudotumours (15 min)
Iris Melanie Noebauer-Huhmann; Vienna / Austria

1. To discuss the imaging semiology of tumours and tumour-like conditions of the muscles.
2. To discuss how to differentiate benign from malignant muscle tumours.
3. To summarise the diagnostic strategy.

Panel discussion: What is the ideal imaging algorithm for muscle disorders? (10 min)

RC 615 - The diagnosis and therapy of vascular lesions

Categories: General Radiology, Neuro, Paediatric, Interventional Radiology, Vascular
ETC Level: LEVEL II+III

Chairperson's introduction (5 min)
Geert Maleux; Tienen / Belgium

Imaging-based classification of vascular tumours (15 min)
Adam Tarnoki; Budapest / Hungary

1. To describe the different types of vascular tumours.
2. To discuss different imaging modalities.
3. To highlight the key findings in imaging.

Imaging-based classification of vascular malformations in the brain and beyond (15 min)
Georgios Kalarakis; Stockholm / Sweden

1. To describe the different types of vascular malformations.
2. To discuss different imaging modalities.
3. To highlight the key findings in imaging.

Interventional radiology in vascular malformations: therapeutic strategies and outcomes (15 min)
Romaric Loffroy; Dijon / France

1. To highlight relevant findings for treatment planning.
2. To discuss the different treatment options.
3. To understand the relevance of follow-up imaging and re-treatment for outcome optimisation.

Q&A (10 min)

RPS 601 - Chronic liver disease and portal hypertension

Categories: Imaging Methods, Vascular, Abdominal Viscera
Date: March 4, 2026 | 16:30 - 17:30 CET
CME Credits: 1

Moderator:
Henri-Marcel Hoogewoud; Corminboeuf / Switzerland

Role of 2D shear wave elastography in screening for portal hypertension and varices in children with chronic liver disease (6 min)
Deeksha Chaurasia; New Delhi / India

Author Block: D. Chaurasia, R. BATRA, R. Dixit; New Delhi/IN
Purpose: The AASLD adopts Baveno VI/VII consensus and recommends specific cut-offs for non-invasive assessment of portal hypertension (PH) and varices using elastography in adults; however, there are no established guidelines for the pediatric population due to limited high-quality data. This study aimed to evaluate the utility of hepatic stiffness (HS) and splenic stiffness (SS) values in predicting PH and assessing the risk of varices in children with chronic liver disease (CLD) using 2D shear wave elastography (2D-SWE).
Methods or Background: This cross-sectional analytical study included 64 participants under 18 years of age, comprising 34 children with CLD (26 children with PH and 11 children with varices) and 30 age-matched healthy controls. Ultrasound of the liver and spleen was performed using a curvilinear (C1-6) probe on a GE LOGIQ S8 system in a fasting state, and ten 2D-SWE measurements (in m/s) were obtained. Mean values were calculated and considered reliable if interquartile range to median ratio was ≤15%. HS and SS values were analyzed, and ROC curves were drawn to predict PH. The splenic-to-hepatic stiffness (S/L) ratio was calculated to differentiate patients with varices.
Results or Findings: HS and SS values were significantly ($p < 0.05$) higher in children with PH, and the S/L ratio was significantly ($p < 0.05$) elevated in those with varices as compared to those without.
Conclusion: SS can serve as a non-invasive surrogate marker for PH in children. The S/L ratio demonstrated superior performance over HS or SS values alone and may aid both in screening and in identifying children at increased risk of varices, allowing for tailored monitoring and timely intervention.
Limitations: Small sample size and no validated pediatric cut-offs. Larger, multicenter studies are needed to confirm the clinical utility in pediatric risk stratification.
Funding for this study: The study was institutionally supported by the Department of Radiology, Maulana Azad Medical College.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the Institutional Ethics Committee of Maulana Azad Medical College, New Delhi.

The performance of CT-based radiomic models of Liver and Spleen in predicting Clinically Significant Portal Hypertension (6 min)
Andreea Mihaela Morariu-Barb; Cluj-Napoca / Romania

Author Block: A. M. Morariu-Barb, M. A. Socaciu, B. Boca, H. Stefanescu, B. Procopet, M. Lupsor-Platon; Cluj-Napoca/RO
Purpose: Clinically significant portal hypertension(CSPH) is the main determinant of complications in chronic liver disease(CLD). The gold standard is hepatic venous pressure gradient (HVPG)(>10 mmHg), but this method is invasive and not widely available. Standard CT offers little value beyond morphological assessment, but CT radiomics may represent a more accurate alternative.This study investigated whether CT-based radiomics can predict CSPH, comparing segmentation strategies (2Dvs.3D) and regions of interest (liver,spleen or both).
Methods or Background: We retrospectively analyzed 52 patients with biopsy-proven CLD who underwent HVPG and contrast-enhanced CT within three months. Nine healthy controls were included based on FibroScan F0 values and absence of signs of portal hypertension.
2D and 3D segmentations of liver and spleen were performed in portal-venous phase using Slicer software. Radiomic features were extracted and neural networks were trained to classify CSPH. Six models were developed: 2Dliver, 2Dspleen, 2Dliver+spleen, 3Dliver, 3Dspleen and 3Dliver+spleen. Performance was evaluated using area under the receiver operating characteristic curve(AUROC) and accuracy.
Results or Findings: CSPH was present in 26 patients(42.6%).The combined 3D liver and spleen model achieved the highest performance with an AUROC of 0.899 and accuracy of 66.7%. The 3Dspleen and 3Dliver models followed, with AUROCs of 0.811 and 0.816 and accuracies of 81.4% and 68%.Among the 2D models, the combined liver and spleen model performed best (AUROC 0.825,accuracy 53.3%), followed by the 2Dspleen model (AUROC 0.757,accuracy 66.7%) and the 2Dliver model (AUROC 0.703,accuracy 52.9%).
Conclusion: CT-based radiomic analysis of liver and spleen predicted CSPH with good performance.3D segmentations and combined liver-spleen models outperformed 2D and single-organ models. These findings support CT radiomics as a promising non-invasive tool for CSPH detection and prognostic stratification, extending the utility of routine CT.
Limitations: Single-center study
Small size cohort
Lack of external validation
Funding for this study: None

Fontan-Associated liver disease: radiological findings and prevalence of hepatocellular carcinoma in an adult patient cohort (6 min)

Santiago Rivera Rojas; Madrid / Spain

Author Block: S. Rivera Rojas, S. Morón Hodge, N. Saturio Galán, P. Castillo Grau, M. Cuadros Martínez, M. E. Velilla Aparicio, M. Cabero, E. Rodríguez, C. Martín Hervás; Madrid/ES
Purpose: The Fontan procedure is a surgical palliation for patients with a univentricular heart. Hemodynamic changes after the procedure lead to hepatic fibrosis and increase the risk of hepatocellular carcinoma (HCC), highlighting the need for multidisciplinary follow-up with a key role for radiology. This study aims to describe the radiological findings associated with Fontan-associated liver disease (FALD) and HCC, and to document the time to onset of these findings.
Methods or Background: Retrospective cohort study of 87 patients at a referral hospital with abdominal imaging available in the electronic medical record (ultrasound, MRI, and/or CT). All imaging studies were reviewed. We recorded the interval from the Fontan procedure to the first imaging study, the time to diagnosis of FALD, their frequency, and the prevalence of HCC based on radiological and histological criteria.
Results or Findings: Among the 87 patients, 59.8% were male. During follow-up 92.0% of patients were diagnosed with FALD, with a mean age of 29 years (SD 8.5). Median interval from Fontan procedure to the first imaging study was 17.5 years (IQR 12). FALD-related findings were observed on the initial imaging study in 77.0%. Radiological features of FALD included heterogeneous liver parenchyma (67.4%), irregular hepatic margins (61.2%), caudate lobe hypertrophy (55.3%), splenomegaly (52.3%), suprahepatic vein dilation (33.7%), and ascites (16.3%). Nodules were detected in 43.0% of patients. Nodules suggestive of HCC developed in 6 patients (6.9%), with histological confirmation in 3 (3.4%).
Conclusion: Radiological findings associated with FALD are common from the first imaging study in patients post-Fontan. Although HCC is infrequent, it can develop in a subset, emphasizing the importance of standardized long-term imaging surveillance for early detection and management.
Limitations: This was a retrospective cohort study.
Funding for this study: None.

Assessment of Liver Functional Reserve in Cirrhosis Using Dual-Energy CT–Derived Extracellular Volume Fraction (6 min)

Seokjin Hong; Jinju / Korea, Republic of

Author Block: S. Hong, J. E. Kim; Jinju/KR
Purpose: This study assessed whether dual-energy CT (DECT)–derived liver extracellular volume fraction (fECV) can reliably evaluate liver functional reserve in cirrhotic patients, as determined by Child–Pugh classification (CP class), compared with other non-invasive markers.
Methods or Background: This retrospective study included 258 patients with liver cirrhosis. fECV score was measured from iodine maps derived from equilibrium-phase images at 100/140 Sn kVp. The diagnostic performance of fECV and other non-invasive markers (aspartate transaminase-to-platelet ratio index [APRI], Fibrosis-4 [FIB-4], Model for End-Stage Liver Disease [MELD]) for differentiating CP classes was assessed by comparing the area under the receiver operating characteristic curve (AUC) using DeLong's test with Holm correction for multiple comparisons.
Results or Findings: The fECV score was positively correlated with CP class ($r = 0.53$, $p < 0.01$). For differentiating CP class A from B, the AUCs were similar among fECV (0.84), APRI (0.83; $p = 1$), and FIB-4 (0.83; $p = 1$), whereas MELD demonstrated a significantly higher AUC (0.94; $p < 0.05$). For differentiating CP classes B and C, the fECV score demonstrated a significantly higher AUC (0.78), compared with FIB-4 (0.50, $p = 0.04$) and APRI (0.49, $p = 0.04$), whereas no significant difference was observed between fECV and MELD (0.92, $p = 0.12$).
Conclusion: Dual energy CT-derived fECV score is a useful non-invasive marker for assessing liver functional reserve based on the CP class.
Limitations: First, this study was a retrospective study conducted at a single institution. Second, iodine quantification results may vary depending on the type of DECT system. Third, there was a relatively small number of patients with Child–Pugh class C (n = 13) compared with classes A (n = 207) and B (n = 38).
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective study was approved by Gyeongsang National University Hospital review board (IRB No. 2025-05-005).

Clinical application of ultrasound localization microscopy in cirrhosis (6 min)

Jieyang Jin; Guangzhou / China

Author Block: J. Jin[1], C. Huang[2], Y. Ma[1], W. Zhang[1], Y. Tan[1], S. Chen[2], J. Ren[1]; [1]Guangzhou/CN, [2]Rochester, MN/US
Purpose: Liver microcirculatory dysfunction plays a crucial role in the development and progression of cirrhosis. There is an urgent clinical need for effective methods to assess hepatic microcirculation. This study explores the feasibility of in vivo ultrasound localization microscopy (ULM) imaging and quantitative analysis in humans. We aim to qualitatively and quantitatively investigate the similarities and differences in hepatic microcirculation between healthy volunteers and patients with cirrhosis using ULM.
Methods or Background: This study consists of two parts. Part I involves in vivo comparative imaging of normal volunteers using Color Doppler (CD), ultra-micro angiography (UMA), and ULM to validate the clinical feasibility of ULM by assessing image resolution. Part II compares microcirculatory characteristics between normal and cirrhotic livers based on ULM-derived images and quantitative parameters.
Results or Findings: Compared with CD and UMA, ULM demonstrates superior capability in detecting subcapsular hepatic microcirculation. Among the quantitative parameters based on total blood flow, vessel density (VD), velocity (V), perfusion index (PI), distance metric (DM), sum of angles metric (SOAM), number of vessel branches per unit area (NOBPA) and number of branch points per unit area (NOBPPA) were higher in cirrhotic group than in control group. Overall, higher density and perfusion, higher tortuosity of microvessels were revealed in cirrhotic groups.
Conclusion: ULM enables in vivo, non-invasive, visual, and quantitative assessment of hepatic microcirculation, holding promise as a pivotal tool for early diagnosis of cirrhosis and monitoring therapeutic efficacy.
Limitations: This study did not conduct a longitudinal comparison of microvascular imaging and quantitative microcirculation parameters across different stages of liver fibrosis. We aim to include patients with varying degrees of liver fibrosis in order to better characterize the overall progression of microcirculatory changes throughout the development of liver fibrosis.
Funding for this study: National Natural Science Foundation of China (No. 82202192)
Basic and Applied Basic Research Foundation of Guangdong Province (No. 2021A1515110591)
Guangzhou Municipal Science and Technology Project (No. SL2024A04J01248)

Ethics committee - additional information: This study was approved by the Institutional Review Board (IRB) of the Third Affiliated Hospital of Sun Yat-Sen University.

A Dual-layer Spectral Nomogram Integrating Structural, Functional, and morphological Parameters for Risk Stratification of Esophageal Varices in Cirrhosis (6 min)

Jinkui Li; Lanzhou / China

Author Block: J. Li[1], J. Lei[1], B. Wang[1], X. Zhang[2]; [1]Lanzhou/CN, [2]Xi An/CN
Purpose: To develop and validate a noninvasive dual-layer spectral computed tomography (DSCT)-based nomogram model integrating quantitative multiparameters and clinical indicators to optimize risk assessment and hemorrhage prediction of esophageal varices (EVs) in patients with cirrhosis.
Methods or Background: This retrospective study enrolled 284 cirrhotic patients undergoing DSCT , divided into training (n=194) and validation (n=90) cohorts. Patients were stratified according to the presence of high-risk esophageal varices (HREV), red color signs (RC signs), and esophageal variceal bleeding (EVB), with endoscopy as reference. Quantitative parameters were analyzed, including extracellular volume fraction (ECV) and iodine washout rate (IWR) of liver and spleen, and esophageal variceal diameter (EVD). Multivariable logistic regression identified predictors for nomogram construction. Model performance was evaluated via AUC, calibration curves, decision curve analysis (DCA), and predictive metrics [(sensitivity, specificity, positive/negative predictive value (PPV/NPV)]in both cohorts.
Results or Findings: EVD, ECVliver, ECVspleen, and IWRliver differed significantly across subgroups stratified by HREV, RC(+), and EVB status ($P < 0.05$). Multivariate analysis identified EVD, ECVspleen, and IWRliver as independent predictors of HREV; EVD, ECVspleen, IWRliver, and total bilirubin for RC sign; and EVD, ECVspleen, aspartate aminotransferase, and red blood counts for EVB (all $P < 0.05$). The nomogram demonstrated high predictive accuracy for HREV (AUC: 0.963/0.968), RC signs (0.898/0.854), and EVB (0.847/0.785) in training/validation cohorts. DCA confirmed clinical utility, with net benefit across low-to-medium risk thresholds (0.0-0.6). At EVD thresholds of 5 mm and 3 mm, the model achieved specificity/PPV of 97.1-100.0%/97.7-100.0% and sensitivity/NPV of 94.4-94.2%/88.7-91.2% for HREV in the training and validation cohorts, respectively.
Conclusion: This DSCT-based nomogram synergizes structural (ECVspleen), functional (IWRliver), and morphological (EVD) biomarkers to noninvasively stratify risks of HREV, RC signs, and EVB in cirrhosis.
Limitations: Lack external validation.
Funding for this study: None

Ethics committee - additional information:

Diffusion-based virtual elastography (DvE) at 3T for liver fibrosis quantification in cirrhosis during HCC screening: a prospective single-centre study (6 min)

Farnaz Delavari; Lausanne / Switzerland

Author Block: F. Delavari, C. Dromain, L. Haefliger, L. Fernandes, M. Fraga Christinet, I. Jelescu, N. Vietti Violi; Lausanne/CH
Purpose: Non-invasive quantification of liver fibrosis in cirrhosis guides prognosis, surveillance, and therapy. Biopsy is invasive and sampling-limited; vibration-controlled transient elastography (VCTE) samples a small right-lobe volume and may be affected by obesity/inflammation; MR elastography requires dedicated hardware. The purpose of this work is to implement and evaluate a 3T Diffusion-based virtual elastography (DvE) workflow that converts two-point shifted ADC into voxel-wise stiffness (μ_diff, kPa) for quantifying liver fibrosis, and to test its association withVCTE in adults with cirrhosis undergoing HCC screening; secondary aims were to quantify intrahepatic heterogeneity and assess repeatability in 6 months.
Methods or Background: Prospective, single-centre study with MRI and VCTE at each visit. DWI: ss-EPI, b=200/1500 s/mm². μ_diff was computed from sADC using a calibrated linear model. Processing included liver masking with vessel exclusion, variability filtering, a right-lobe region of interest (ROI) mirroring VCTE practice, and a whole-liver heterogeneity index (HI=coefficient of variation of μ_diff). Associations were tested with Spearman's ρ; repeatability with two-way random-effects, absolute-agreement inter-class correlation (ICC).
Results or Findings: Eighty-two MRI–VCTE pairs were analysed. Right-lobe μ_diff correlated with VCTE stiffness (ρ=0.34, p=0.034). In 24 rescans, right-lobe μ_diff showed moderate repeatability (ICC=0.58). Whole-liver μ_diff showed a weaker, non-significant association (ρ=0.18, p=0.09). HI>20% classified 26.8% of livers as heterogeneous; excluding these strengthened the whole-liver association to significance (ρ=0.27, p=0.043; n=60), indicating spatial variability as a confounder when comparing local vs global stiffness.
Conclusion: DvE provides simple MRI-integrated, whole-liver stiffness maps for fibrosis quantification in cirrhosis screening. Observing the association withVCTE, which samples a right-lobe ROI, we propose intrahepatic heterogeneity can drive discordance. DvE may complement VCTE as for non-invasive whole-liver fibrosis assessment within routine HCC surveillance.
Limitations: Empirical calibration out of the dataset; diffusion artefacts and SNR/motion, limited sample size.

AI-automated liver volumetry and MRI data extraction for characterisation of patients with chronic liver disease (6 min)

Damiano Catucci; Bern / Switzerland

Author Block: D. Catucci[1], L. Hulbert[1], L. Zbinden[1], M. P. Brönnimann[1], V. Obmann[1], A. Berzigotti[1], A. Christe[1], R. Sznitman[1], A. T. Huber[2]; [1]Bern/CH, [2]Lucerne/CH

Purpose: To analyse whether artificial intelligence (AI)-automated volumetry of liver structures and data extraction from liver T1 mapping can differentiate stages of chronic liver disease (CLD) and detect clinically significant portal hypertension (CSPH).

Methods or Background: In this retrospective study, 159 patients underwent liver MRI including T1 maps before (T1 long) and 20 minutes after Gd-EOB-DTPA-administration (T1 short) and native T1 Dixon-sequence for volumetry between 09/2018 and 05/2019. CLD-patients were grouped based on liver biopsy into early CLD (F0-F2; n=34), advanced CLD (F3-F4; n=27) and advanced CLD with CSPH (F3-F4 with presence of portosystemic collaterals, splenomegaly >12 cm with thrombocytopenia <100 G/L or ascites; n=53). 45 patients without CLD served as a negative control group. Total liver volume (TLV), hepatic veins volume (HVV), liver segmental volumes I-VIII, T1 long and T1 short were automatically measured using an in-house developed liver-segmentation-algorithm. A T1 reduction rate (ΔT1) was calculated as (T1 long – T1 short)/T1 long. In addition, a functional-right-lobe-volume-ratio (FRLVR) was calculated as (volumes segments IV-VIII/TLV)*ΔT1 and a hepatic-veins-ratio (HVR) was calculated as (HVV/TLV)*1000. Parameters were compared between groups using the Kruskal-Wallis-test. Univariate logistic regression analysis was used to assess the discriminatory power of parameters for group-differentiation.

Results or Findings: All parameters differed significantly between the groups ($p<0.05$). TLV initially increased with CLD-severity and decreased at advanced CLD-stages with CSPH. In contrast, ΔT1, FRLVR and HVR continuously decreased with increasing CLD-severity. HVR and FRLVR showed strong discriminatory power for CLD (odds-ratio OR 0.71 and 0.88), advanced CLD (OR 0.72 and 0.86) and CSPH (OR 0.66 and 0.87), all with $p<0.001$.

Conclusion: Our findings highlight the potential of integrating AI-automated liver segmentation for MRI data extraction and volumetry into clinical workflows to improve management of CLD patients.

Limitations: Retrospective study design.

Funding for this study: This study received funding from the Swiss National Science Foundation (grant number 10003604).

RPS 602 - Advances and emerging trends in breast MRI

Categories: Imaging Methods, Oncologic Imaging, Breast
Date: March 4, 2026 | 16:30 - 17:30 CET
CME Credits: 1

Moderator:
Pascal A.T. Baltzer; Vienna / Austria

High Spatiotemporal Resolution in Breast DCE-MRI: Evaluation of a Novel 4D Stack-of-Stars Technique (6 min)
Narine Mesropyan; Bonn / Germany

Author Block: N. Mesropyan[1], C. Katemann[2], A. Isaak[1], J. A. Luetkens[1]; [1]Bonn/DE, [2]Hamburg/DE
Purpose: To clinically implement and evaluate a 4D diamond-shaped pseudo–golden angle stack-of-stars (SoS) acquisition with k-space weighted image contrast (KWIC) reconstruction for breast dynamic contrast-enhanced MRI (4D-DCE), assessing image quality, diagnostic confidence, and BI-RADS agreement across conventional and ultrafast protocols.
Methods or Background: This retrospective study included female patients who underwent breast MRI at 3T using the 4D-DCE sequence. Three protocol types were generated: (1) conventional (4 × 60 s), (2) ultrafast (20× 3s), and (3) combined (ultrafast followed by 3 × 60 s). Two readers independently or in consensus rated image quality (overall quality, artifacts, sharpness, lesion conspicuity, and morphology) and diagnostic confidence using a 5-point Likert scale. BI-RADS scores were compared to the final reference standard (histology or ≥2-year imaging follow-up). Agreement was assessed using Cohen's kappa and ICC.
Results or Findings: A total of 167 patients (mean age: 59 ± 11 years) were included. Despite high temporal resolution of the ultrafast 4D-DCE, image quality was good to excellent and was comparable to the standard-resolution post-contrast T1 mDixon sequence (e.g., overall quality: 4.8±0.4 vs. 4.8±0.3, P=.99).The combined 4D-DCE protocol yielded the highest diagnostic confidence by BI-RADS assignment in both readers, with the most pronounced improvement observed in patients with high background parenchymal enhancement (e.g., reader 1: 3.2 ± 0.6 [conventional] vs. 4.2 ±0.4[ultrafast] vs. 4.9 ± 0.3[combined],P<.001). BI-RADS agreement with the final reference standard was good to excellent across all DCE protocols, with the highest agreement achieved using the combined 4D-DCE(e.g., reader 1: κ=0.89, 95% CI:0.84–0.95).
Conclusion: The proposed 4D-DCE technique enables robust breast DCE-MRI with high spatial and temporal resolution. Combining ultrafast and conventional acquisitions within a single protocol improves diagnostic confidence and BI-RADS agreement.
Limitations: Intraindividual study comparing different 4D-DCE approaches within the same examination

Prognostic value of kinetic parameters in pre-treatment ultrafast dynamic contrast-enhanced MRI of invasive breast cancers (6 min)
Lok Yee Chan; Hong Kong / Hong Kong SAR China

Author Block: L. Y. Chan, P. L. LAM, D. Fenn, W. P. CHEUNG, L. W. LO, W. S. Mak, K. M. L. WONG, E. P. Y. Fung; Hong Kong/HK
Purpose: Ultrafast dynamic contrast-enhanced MRI (UF-DCE MRI) is a novel sequence which captures contrast wash-in in breast lesions in the very early post-contrast period with high spatial and temporal resolution, allowing analysis of an early wash-in kinetic curve. This study aims to evaluate the correlation between kinetic parameters in UF-DCE MRI and histopathological characteristics of invasive breast cancers.
Methods or Background: This is a retrospective study performed in an acute general hospital. 49 consecutive female adult patients (median age, 54.2 years; range, 30.0-85.4 years) with 53 pathologically proven invasive breast cancers who underwent pretreatment MRI breast imaging were included from June 2023 to June 2025. The ultrafast MRI protocol consisted of a pre-contrast and 12 T1-weighted post-contrast high-temporal-resolution images in the first minute using TWIST-VIBE technique. Kinetic parameters of index breast cancers were obtained from ultrafast sequences, including time-to-enhancement (TTE), maximum slope (MS) and arterial-venous interval (AVI). TTE, MS and AVI among breast cancers with different histological grade (Modified Bloom-Richardson grade), ER/PR/HER2 positivity and tumour subtype were compared using the Mann-Whitney U test and Kruskal-Wallis test as appropriate.
Results or Findings: High histologic grade cancers had larger MS compared to low to intermediate grade cancers (high grade=14.9%/s vs low to intermediate grade=11.4%/s, p=0.049). ER-negative cancers showed shorter TTE compared to ER-positive cancers (ER-negative=4.5s vs ER-positive=9.0s, p=0.037). HER2-positive cancers showed shorter TTE than HER2-negative cancers (HER2-positive=4.5s vs HER2-negative=9.0s, p=0.032).
Conclusion: Ultrafast MRI–derived kinetic parameters TTE and MS were associated with histopathologic characteristics in invasive breast cancers. UF-DCE demonstrated potential to identify more aggressive breast cancers and provide prognostic value to guide breast cancer management.
Limitations: The limitations of the study are single-centre retrospective study with limited sample size.
Funding for this study: No funding was provided for this study.
Has your study been approved by an ethics committee? Yes

Predictive model for tumor-infiltrating lymphocyte levels in breast cancer using multi-phase DCE-MRI radiomics and semantic features (6 min)

Wenjun Yang; Nanjing / China

Author Block: W. Yang, X-G. Peng; Nanjing/CN
Purpose: This study aims to develop predictive models for tumor-infiltrating lymphocyte (TIL) levels in breast cancer patients using multi-phase dynamic contrast-enhanced MRI (DCE-MRI) radiomics and semantic features from tumor and peritumoral regions.
Methods or Background: A total of 298 pathologically confirmed BC patients were stratified into low (<10%, n=102) and high (≥10%, n=196) TIL groups. Tumor and peritumoral volumes were manually delineated across six DCE-MRI phases using 3D-Slicer, with radiomics features extracted via FAE software. Ten machine learning algorithms were evaluated using five-fold cross-validation. Traditional imaging features were selected through univariate and multivariate logistic regression. Model performance was assessed by the area under the receiver operating characteristic curve (AUC), and statistical comparisons were performed with DeLong's test.
Results or Findings: 1,688 radiomics features were extracted from tumor and peritumoral VOIs. Among intratumoral models, DCE_Phase 5 (DCE_P5) showed the best performance (training AUC = 0.835; validation AUC = 0.714), and DCE_Phase 3 (DCE_P3) was optimal for peritumoral models (training AUC = 0.793; validation AUC = 0.703). The combined model using DCE_P5 and DCE_P3 achieved AUCs of 0.878 (training) and 0.772 (validation). In semantic feature analysis, axillary lymph node status (P = 0.017) and fibroglandular tissue content (P = 0.019) were significant predictors. The combined model using DCE_P5 tumor and semantic features achieved AUCs of 0.853 (training) and 0.706 (validation), while the DCE_P3 and semantic feature model reached AUCs of 0.792 and 0.705. The final integrated model achieved the highest performance (AUC_train = 0.881; AUC_valid = 0.773).
Conclusion: This study presents a noninvasive, clinically applicable model combining multi-phase DCE-MRI and semantic features to predict TIL levels in BC, aiding in immunotherapy decision-making.
Limitations: The retrospective study with a limited sample size may affect generalizability. External validation in larger cohorts is needed.

From Research to Clinic: First Prospective Evaluation of Volumetric Deep-Learning Super-Resolution in 3D T2-Weighted Breast MRI (6 min)

Narine Mesropyan; Bonn / Germany

Author Block: N. Mesropyan[1], O. Weber[2], A. Isaak[1], H. Peeters[3], C. Katemann[2], J. A. Luetkens[1]; [1]Bonn/DE, [2]Hamburg/DE, [3]Best/NL
Purpose: To evaluate, a fully volumetric deep-learning(DL) super-resolution research prototype combining compressed sensing with denoising and resolution upscaling for 3D T2-weighted (T2w) breast MRI, and to quantify its impact on acquisition time, image quality, and BI-RADS agreement.
Methods or Background: This prospective single-center study was conducted on a 1.5-T MRI. Two Cartesian 3D T2w acquisitions with low and normal resolution were acquired and reconstructed with the DL framework to yield T2DL and T2NR+DL. Acquisition time, quantitative image quality (apparent signal-to-noise (aSNR), apparent contrast-to-noise (aCNR)) and qualitative scores (5-point Likert scale: overall quality, sharpness, conspicuity, morphology, artifacts) were obtained in randomized, blinded reading sessions. BI-RADS agreement between different protocol types with the final score were assessed. Kruskal–Wallis one-way analysis of variance followed by Dunn's post hoc test, intraclass correlation coefficients (ICCs), and Cohen k test were used for statistical analysis.
Results or Findings: 64 women (mean age 55±13 years; range 28–84) were investigated. Acquisition time decreased by 41% for T2DL vs T2NR (126 vs 215 seconds). Quantitative quality improved with DL (e.g., for aSNR: 28.5±7.3 [T2NR] vs 36.6±10.9 [T2DL] vs 45.7±10.3 [T2NR+DL]; for aCNR: 21.8±5.6 [T2NR] vs 25.9±8.6 [T2DL] vs 35.3±9.1 [T2NR+DL]; all P<.001). Qualitative image quality was highest for T2NR+DL (for reader 2: overall quality: for T2NR+DL 5 [IQR 5–5] vs 4 [4-5] for T2 DL vs. 4 [3–4] for T2NR; P<.001). Inter-reader agreement for image quality assessment was good to excellent, ICCs rages 0.79–0.96 (CI:0.65-0.98). BI-RADS agreement was strong across all 3D DL protocols, Cohen k ranges 0.98–0.99 (CI: 0.98-0.99).
Conclusion: This volumetric DL super-resolution approach enables faster 3D T2w breast MRI while enhancing image quality. Alternatively, at unchanged acquisition time, it can further improve the quality of normal-resolution images.
Limitations: Research prototype was used in this study.
Funding for this study: None

Breast ductal carcinoma in situ: MRI predictors of HER2 positivity and molecular characteristics (6 min)

Amalya Zeynalova; Istanbul / Turkey

Author Block: A. Zeynalova, G. Esen, A. DOLU, M. Akin, N. Önder Denizoğlu, F. Tokat, C. Uras; Istanbul/TR
Purpose: To evaluate the association between molecular subtypes and magnetic resonance imaging (MRI) findings in ductal carcinoma in situ (DCIS), with a focus on identifying MRI features characteristic of the HER2-positive subtype.
Methods or Background: This retrospective observational study included 55 female patients who underwent preoperative breast MRI and had pure or microinvasive DCIS confirmed by surgical pathology between 2010 and 2024. Lesion size, lesion type, nipple extention, morphology and kinetic features were evaluated by two experienced breast radiologists in consensus. Age, clinical presentation, lesion location, tumour grade, necrosis, tumour size, surgical margin status, axillary lymph node involvement, receptor status were recorded. Receptor status was re-evaluated by a pathologist if initially unavailable.
Results or Findings: HER2 positivity was detected in 43.6% of cases. HER2-positive DCIS showed a larger mean MRI lesion size (44.7 mm, p=0.004) and more frequent nipple extension (p=0.032). ER negativity was higher in HER2-positive cases (p=0.003), and high nuclear grade was more common (p=0.052). Receiver operating characteristic (ROC) analysis identified a 22 mm lesion size threshold for predicting HER2 positivity (AUC=0.740). MRI lesion size, nipple extension, ER negativity and high nuclear grade were independent predictors of HER2 positivity, while no other imaging or pathological variables showed significant differences.
Conclusion: Recent studies have shown that HER-2 positivity may be associated with a worse prognosis and more frequent progression to invasive disease in DCIS. There is very limited data in literature about MRI features of different molecular subtypes of DCIS. Our results show that MRI features, particularly large lesion size and nipple extension are associated with HER2 positivity in DCIS and may aid molecular subtype prediction and surgical planning.
Limitations: The limitations of the study are its retrospective single-centre design and the small sample size.
Funding for this study: No funding was provided for this study.

Beyond the Breast: Radiomics of Axillary Nodes on Routine Breast MRI as a Biomarker of Nodal Metastasis (6 min)

Akshat hitesh Shah; Kolkata / India

Author Block: A. h. Shah, A. Chandra, S. Sen, P. Ghosh; Kolkata/IN
Purpose: Axillary nodal status is critical in breast cancer staging, yet MRI assessment relies on subjective criteria such as cortical thickening or hilum loss, which are only moderately accurate. We evaluated whether radiomics of axillary nodes visible on routine breast MRI can provide a reproducible, objective predictor of nodal metastasis.
Methods or Background: We retrospectively analyzed 212 women with biopsy-proven breast cancer who underwent preoperative breast MRI (2013–2024) and subsequent nodal sampling or dissection. The most conspicuous axillary node per patient was segmented on post-contrast T1- and T2-weighted sequences. PyRadiomics extracted first-order, shape, and texture features. Machine-learning models were trained to classify nodal status and compared against conventional MRI descriptors (short-axis >10 mm, cortical thickness >3 mm, hilum loss).
Results or Findings: Of 212 patients, 118 had metastatic and 94 benign nodes. Radiomics features reflecting shape irregularity, enhancement heterogeneity, and cortical entropy were most predictive. The radiomics model achieved an AUC of 0.87, outperforming conventional MRI criteria (AUC 0.71, $p<0.01$). Sensitivity and specificity were 82% and 80%, respectively. Radiomics also improved prediction of extranodal extension (AUC 0.79 vs 0.62). Interobserver reproducibility was excellent for radiomics scores, compared with only moderate agreement for visual assessment ($\kappa=0.46$).
Conclusion: Radiomics of axillary nodes on standard breast MRI provides a reproducible, quantitative biomarker of nodal metastasis, clearly outperforming conventional visual descriptors. This is the largest dedicated study to date demonstrating that data already embedded in routine breast MRI can be unlocked to refine nodal staging, with direct implications for surgical and systemic treatment planning.
Limitations: Single-center retrospective design; segmentation restricted to one node per patient; no external validation.
Funding for this study: None

Dynamic contrast-enhanced MRI radiomics nomogram for predicting axillary lymph node metastasis in breast cancer (6 min)

Ting Zhan; Nanchang, China / China

Author Block: T. Zhan, Y. Leng, L. Gong; Nanchang, Jiangxi/CN
Purpose: The goal of this study is to develop and validate a radiomics nomogram integrating the radiomics features and clinical factors for the preoperative diagnosis of axillary lymph node (ALN) metastasis in breast cancer patients.
Methods or Background: This multicenter study retrospectively enrolled 314 patients with breast cancer, comprising a training cohort (n = 296), an internal validation cohort (n = 136), and an external validation cohort (n = 78). Radiomics features were extracted from T2-weighted image□T2WI □and the second phase of dynamic contrast enhanced (DCE) MRI images. The least absolute shrinkage and selection operator (LASSO) regression method was used to screen optimal features and construct a radiomics signature in the training cohort. Multivariable logistic regression analysis was used to establish a radiomics nomogram model based on the radiomics signature and clinical factors. The predictive performance of the nomogram was quantified with respect to discrimination and calibration, which was further evaluated in the independent validation cohort.
Results or Findings: Twelve ALN metastasis-related features were selected to construct the radiomics signature, with an area under the curve (AUC) of 0.837,0.794,and 0.806 in the training, internal, and validation cohorts, respectively. The nomogram was established by incorporating the MRI report lymph node status and radiomics signature and showed good calibration and excellent performance for ALN detection (AUC of 0.891 ,0.881,and 0.904 in the training, internal, and validation cohorts, respectively). The decision curve, which demonstrated the radiomics nomogram, displayed promising clinical utility.
Conclusion: The radiomics nomogram can be used as a noninvasive and reliable tool to assist clinicians in accurately predicting ALN metastasis in breast cancer preoperatively.
Limitations: Not applicable

Patrick Mc Laughlin; Cork / Ireland

Retrospective validation of three artificial intelligence -based fracture detection systems using local data (6 min)
Juuso Heikki Jalmari Ketola; Helsinki / Finland

Author Block: J. H. J. Ketola, S. Inkinen, T. Mäkelä, K. Pohto, M. Kortesniemi, S. Syväranta; Helsinki/FI
Purpose: Artificial intelligence (AI)-based fracture detection systems are being implemented worldwide to accelerate diagnostic workflows and improve accuracy. In this study, we evaluated three commercial AI fracture detection systems retrospectively using a diverse local trauma X-ray dataset. The objective was to evaluate the performance of each system and to assess their respective strengths and limitations.
Methods or Background: A local dataset comprising 1,891 trauma X-ray images (675 adults, 1,216 paediatric) spanning various anatomical regions was processed using three different AI systems. AI results were compared to primary radiologist reports, calculating accuracy, sensitivity, and specificity for each solution. An experienced radiologist verified any discrepancies, and fractures identified by AI but not included in the original reports were classified as additional AI-findings.
Results or Findings: For adults, accuracies ranged from 0.94 to 0.96, sensitivities from 0.89 to 0.93, and specificities from 0.96 to 0.97. In paediatric cases, accuracies ranged from 0.96 to 0.97, sensitivities from 0.89 to 0.95, and specificities from 0.96 to 0.98. AI-enhanced detection rates for adults ranged from 4.9% to 5.9%, and for paediatrics from 1.1% to 2.1%. Performance varied by anatomical area, bone, and fracture type.
Conclusion: All three solutions showed similar performance, differing only by a few percentage points. Depending on the clinical use-case, prioritizing either higher sensitivity or specificity may be preferable. Our findings underscore the importance of validating AI fracture detection systems with local data to reveal their unique advantages and limitations.
Limitations: Testing was performed using fixed operating points. More comprehensive evaluation based on receiver-operating characteristics was not feasible due to unavailable raw output probabilities. A detailed cost-benefit assessment would require a longer, prospective testing period.
Funding for this study: No external funding

Role of artificial intelligence in assisting non-MSK specialist radiologists with tibial plateau fracture detection (6 min)
Ana Isabel Hernáiz Ferrer; Pavia / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: A. I. Hernáiz Ferrer, E. M. Preda, D. Meccariello, J. Bosio, L. Carone, C. Bortolotto, L. Preda; Pavia/IT
Purpose: We evaluated the diagnostic performance of two AI software programs, BoneView (AI-1) and RBfracture (AI-2), in assisting two non-specialist radiologists (NSR-1 and NSR-2) with the detection of tibial plateau fractures on conventional knee X-rays. These fractures are often challenging to identify due to their subtle appearance.
Methods or Background: In this retrospective monocentric study we analyzed 673 radiographs from 324 patients with knee trauma. All patients included in the study underwent a knee CT scan after the X-ray, which served as the gold standard. Diagnostic performance was assessed using sensitivity, specificity and area under the curve (AUC).
Results or Findings: The average patient age was 62 years, and 52.5% were female. CT scans confirmed tibial plateau fractures in 145 patients (44.8%) with AO/OTA B2 fractures being the most common type (35 patients, 24.1%).
When evaluating X-rays, the AI tools performed similarly to NSRs (AUC: AI-1=0.88, AI-2=0.86, NSR1=0.86, NSR2=0.78). AI significantly improved the diagnostic performance of NSR-2 when combined with AI-1 and AI-2 (AUC=0.85 and 0.86; p=0.0001 and p=0.001, respectively), and of NSR-1 when combined with AI-2 (AUC=0.90; p=0.018).
The overall performance of both AI systems for detecting other fracture types visible on radiographs (femur, patella, fibula) was also evaluated. AI-1 achieved an AUC of 0.842 and AI-2 an AUC of 0.798 (p = 0.017). Since AI-2 also detects lipohemarthrosis, we assessed its performance, finding a sensitivity of 61.7%, specificity of 98.5%, and an AUC of 0.801.
Conclusion: Both AI tools can assist non-specialist radiologists in detecting tibial plateau fractures on standard X-rays. They can also detect other fractures, with AI-2 showing particular promise in improving specificity through the detection of lipohemarthrosis.
Limitations: This study has some limitations, including its retrospective design. The results presented are preliminary.
Funding for this study: This study received no financial support and was conducted using free trial versions of the AI software.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the IRB Comitato Etico Territoriale Lombardia 6.

Budget-Impact Analysis of AI-Supported Fracture Detection: A Multi-Center Study in Moravian–Silesian Hospitals (6 min)

Daniel Kvak; Praha / Czechia

Author Block: M. Rehor[1], J. Orság[2], D. Kvak[2]; [1]Jindřichův Hradec/CZ, [2]Prague/CZ
Purpose: We quantified the one-year budget impact and return on investment (ROI) of deploying an AI tool for fracture detection in emergency musculoskeletal radiography across five Moravian–Silesian hospitals.
Methods or Background: We built a decision-tree comparing standard care (radiologist-only; sensitivity 82.4%, specificity 95.7%) with an AI-assisted pathway in which all 339,828 annual MSK X-rays were pre-read by commercial software (Carebot AI Bones; €1 per scan; sensitivity 92.1%, specificity 89.7%). AI-positive studies proceeded to radiologist confirmation, whereas AI-negative studies were cleared. First-diagnosis fracture prevalence was set at 6% (20,390). Downstream costs comprised an emergency revisit per false negative (€150) plus a one-day admission for 25% of false negatives (€194), and outpatient referrals for 10% of false positives (€20). Radiologist time savings were valued at one minute per avoided read at €27/hour. Litigation costs were analysed separately and excluded from the primary model.
Results or Findings: Relative to standard care, AI assistance reduced false negatives by 55% (3,587 to 1,614) and increased false positives by 140% (13,735 to 32,891). False-negative costs fell from €711,954 to €320,379 (saving €391,575). False-positive referrals increased from €27,470 to €65,782 (increment €38,312). Avoiding 288,161 reads saved 4,803 radiologist hours, valued at €129,681. After AI fees of €339,828, net regional savings were €143,116 (≈€28,623 per hospital). The benefit–cost ratio was 1.42, corresponding to an ROI of 42%. At €0.75 and €0.50 per scan, ROI rose to 90% and 184%, respectively.
Conclusion: In high-throughput emergency workflows, the AI triage model can halve missed fractures, lower downstream care costs, and deliver a positive ROI while focusing human review on AI-positive studies.
Limitations: Assumptions include negative-clearing without routine spot checks, static test performance, tariff-based unit costs, and single-region generalisability; prospective, real-time validation is required.
Funding for this study: Carebot s.r.o. supported software integration and modelling; no public grant funding was received.

Comparison of deep learning object detection models for fracture diagnosis in X-ray images (6 min)

CHANGMIN JEON; Seoul / Korea, Republic of

Author Block: C. JEON, J. PARK; Seoul/KR
Purpose: Automated fracture detection via deep learning-based object detection can enhance diagnostic efficiency from radiographs. While one-stage models offer real-time processing, two-stage models provide higher precision. This study compares YOLOv8, RetinaNet, and Faster R-CNN on the FracAtlas X-ray dataset to determine the model offering the optimal trade-off between accuracy and practical applicability for clinical use.
Methods or Background: Object detection models were trained on the FracAtlas dataset (4,083 radiographs, 922 annotated fractures) using Python 3.9.0 with Detectron2 and Ultralytics frameworks. Model performance was assessed via confusion matrix-based indicators (Precision, Recall, F1-score), mean Average Precision at IoU 0.50 (mAP@0.50), and inference speed (frames per second, FPS).
Results or Findings: Faster R-CNN achieved the highest diagnostic accuracy with mAP@0.50 = 0.82, Precision = 0.92, Recall = 0.75, and F1-score = 0.82, but had a limited inference speed of 5 FPS. YOLOv8 demonstrated real-time performance with 45 FPS but lower accuracy (mAP@0.50 = 0.62, Recall = 0.57), particularly struggling with subtle fracture detection. RetinaNet produced intermediate results, yielding mAP@0.50 = 0.67 and 10 FPS. The superior feature extraction of Faster R-CNN underscores the clinical benefit of two-stage approaches when diagnostic accuracy is critical.
Conclusion: Faster R-CNN delivers the highest fracture detection accuracy, making it well-suited for clinical use, though its low FPS restricts real-time deployment. One-stage models excel in speed but fall short for complex diagnostic demands. Future research should explore lightweight optimisation of Faster R-CNN and larger datasets to enhance generalizability. Two-stage models remain valuable for high-precision medical image analysis.
Limitations: This study was limited to a single FracAtlas X-ray image dataset and an imbalanced fractured-to-non-fractured ratio (1:4.6), which may affect model performance.
Funding for this study: No funding was received for this study.

Systematic Assessment of the Medical Utility of Radiology Artificial Intelligence in Fracture Detection (SAMURAI-Fracture): A multi-centre prospective cluster randomised cross-over trial (6 min)

James Vaz; Gerrards Cross / United Kingdom

Author Block: J. Vaz[1], S. Ather[1], M. J. Lundemann[2], T. Bentabol Munoz[1], S. A. Beer[1], A. Espinosa[1], K. Nash[1], A. Novak[1]; [1]Oxford/UK, [2]København K/DK
Purpose: To evaluate whether implementation of an AI-assisted fracture detection tool reduces unnecessary healthcare contacts arising from misdiagnosed fractures in emergency departments (EDs) and minor injuries units (MIUs).
Methods or Background: A multicentre, prospective, cluster randomised cross-over trial is being conducted across four NHS Trusts, encompassing level 1 EDs and MIUs.

All patients aged ≥2 years undergoing X-ray for suspected fracture are eligible, with exclusions for skeletal surveys for non-accidental injury and skull, facial, dental, and cervical spine radiographs.

Approximately 45,000 patients are expected to be recruited during a six-month period (October 2025–March 2026).

An MHRA-approved AI tool is integrated into PACS at each site.

Randomisation determines whether sites commence with AI active or inactive, alternating monthly between “on” and “off” periods. During “on” periods, clinicians access AI-annotated images as adjunctive decision support; during “off” periods, standard practice applies.

The primary outcome is the proportion of unnecessary NHS contacts, defined as re-attendances or referrals resulting from false negatives and false positives.

Secondary outcomes include diagnostic accuracy compared with radiology reports, subgroup analyses by anatomical region and demographics, length of stay in ED, and patient/clinician experiences captured via questionnaires.
Results or Findings: Results will compare unnecessary NHS contacts, diagnostic accuracy, and service outcomes between AI “on” and “off” periods.
Conclusion: This study will provide the first large-scale prospective evidence on the clinical, service, and health-economic impact of AI fracture detection in real-world NHS settings.
Limitations: As a pragmatic cluster trial, differences in staffing, patient mix, or workflow between periods may influence results.
Funding for this study: Small Business Research Initiative (SBRI) Healthcare Urgent and Emergency Care Grant

Multi-center Post-Implementation Monitoring of an AI Fracture Detection algorithm on Trauma Patients: Workflow Redesign, Safety Signals and Governance (6 min)

Jonas Vardal; Drammen / Norway

Author Block: R. Sivanandan[1], J. Vardal[2], L. Tveiten[2], K. G. Brurberg[2], B. A. Graff[2]; [1]Asker/NO, [2]Drammen/NO
Purpose: To evaluate the performance, workflow impact, and patient safety of a CE-marked AI application for fracture detection on x-rays with history of trauma following deployment across two hospitals within a regional healthcare trust.
Methods or Background: A retrospective, multi-center post-implementation study was conducted over two months at Site-A (n=1284) and Site-B (n=1177) hospitals. AI analyzed trauma-related X-rays, with radiologist reports serving as ground truth. Patient data included demographics, X-ray region, AI/radiologist findings, fracture types, additional observations, patient disposition, and follow-up imaging. Workflow was redesigned to allow patient discharge based on AI results obtained within two minutes approx., while radiologist reports were issued later the same or next day, enabling faster clinical decision-making with post-hoc expert validation.
Results or Findings: Fracture prevalence among the study population (2-99 years) was 34–37% (≈450 – 480 per site). AI and radiologist results showed high overall concordance across both hospitals 86 – 89%. However, 2.4 % (23-35 per site) cases were missed by AI; in 0.9% (11-12 per site) of cases, patients were prematurely discharged based on AI results. Four cases with fractures were recalled for treatment later, while the rest 0.8% (19 cases) had conservative treatment with follow-up scan following radiologists' report. Workflow redesign reduced discharge time substantially compared with historical baseline, with consistent patterns across hospitals.
Conclusion: Multi-center monitoring confirmed consistent AI performance and notable workflow acceleration, while also identifying safety concerns such as missed fractures—underscoring the critical need for radiologist. These findings emphasize the importance of structured post-deployment governance to improve operational efficiency and human oversight involvement in AI-integrated patient care.
Limitations: Limitations include the restricted one-month observation periods at each site and absence of long-term or continous monitoring of patient outcome data, which could be addressed in future.

Comparative evaluation of commercial AI algorithms for fracture detection on musculoskeletal radiographs (6 min)

James Vaz; Gerrards Cross / United Kingdom

Author Block: J. Vaz, K. Nash, A. Novak, C. Mihaiu, N. Salik, S. Ather; Oxford/UK
Purpose: To conduct a comparative evaluation of commercial AI tools designed to detect fractures on musculoskeletal radiographs, assessing diagnostic performance across vendors.
Methods or Background: Six commercial vendors were invited of which three participated in this retrospective evaluation. A dataset of 500 anonymised radiographs was collected from Oxford University Hospitals and enriched to ~50% fracture prevalence to ensure anatomical and pathological diversity.

Each case's ground truth was labelled through independent review by two musculoskeletal radiologists (>10 years' experience), with arbitration from a third where required. All images were processed in batch by vendors. Vendors had up to 72 hours to return results.
Results or Findings: All participating vendors returned results within the 72-hour period. One vendor processed all images within their intended use case; whilst two vendors did not return results for between 16-18 cases.

Accuracy ranged from 80.4% (95% CI: 76.4-83.8) to 87.2% (83.9-89.8). Sensitivity ranged from 70.4% (63.5-76.5) to 89.7% (84.8-93.2) and specificity from 73.9% (68.5-78.7) to 87.7% (83.1-91.2).

McNemar's test revealed significant differences in accuracy, sensitivity, and specificity across tools ($p < 0.001$), with some tools excelling in sensitivity and others in specificity.
Conclusion: Multiple commercial AI tools demonstrated high overall accuracy in detecting fractures on radiographs. However, there was notable variation in diagnostic performance between vendors.

Sensitivity and specificity showed the greatest divergence, two tools prioritised either specificity or sensitivity, and one offered a more balanced performance profile. These differences may influence clinical outcomes and should be carefully considered when selecting AI tools for deployment.
Limitations: Commercial vendors were required to adapt their algorithms to a binary output ('fracture present' vs. 'fracture absent'), whereas in routine use they may also provide a third category ('possible fracture'). This constraint may have influenced the reported sensitivity and specificity.

AI-Enhanced Fracture Detection in the ED: A Real-World Assessment of Diagnostic Accuracy and Imaging Utilisation (6 min)

Molly Godson Treacy; Dublin / Ireland

Author Block: M. Godson Treacy, S. Doherty, O. O'Brien, F. Desmond, F. Husson, P. J. Macmahon; Dublin/IE
Purpose: Accurate and timely diagnosis of pelvic, hip, and spinal fractures in the Emergency Department (ED) is critical to reducing morbidity and mortality. Gleamer BoneView, an AI-based fracture detection tool, was implemented in our hospital in 2024. This study aims to evaluate the impact that the use of Gleamer BoneView, had on fracture detection in a real-world ED setting. We hypothesise that AI assistance would improve detection rates without increasing downstream imaging.
Methods or Background: We retrospectively analysed cases of adult ED patients undergoing pelvic/hip or spinal radiographs for suspected fracture from June–August 2024 (AI-assisted reporting) and for the same patient cohort in June-August 2023 (radiologist-only reported). Fracture detection was determined by the final radiologist's report. Detection rates were compared using chi-squared tests ($p<0.05$). CT and MRI utilisation, along with AI diagnostic performance (sensitivity, specificity, PPV, NPV), were also assessed.
Results or Findings: Pelvic/hip fracture detection increased from 12.7% (49/386) in 2023 to 19.2% (70/365) in 2024 ($p=0.02$).
Spinal fracture detection increased from 14.7% (67/457) in 2023 to 21.3% (64/301) in 2024 ($p=0.03$).
Downstream CT use remained stable for both pelvic/hip (11.7% vs. 10.4%) and spinal radiographs (7.8% vs. 7.6%).
Downstream MRI use for indeterminate spinal radiographs decreased from 5.3% in 2023 to 3.3% in 2024.

AI diagnostic performance was as follows:
Spine radiographs: Sensitivity 90%, Specificity 93%, PPV 79%, NPV 97%.
Pelvis/hip radiographs: Sensitivity 85%, Specificity 92%, PPV 71%, NPV 96%.
Conclusion: AI-assisted radiograph interpretation significantly improved fracture detection rates in the ED, without increased CT usage and with reduced MRI demand. These results support the integration of AI tools into acute imaging pathways to enhance diagnostic accuracy and streamline patient management.
Limitations: Short timeframe/small patient cohort. Single Centre Study.

RPS 609 - Hot Topic: AI-driven image interventions

Categories: Interventional Radiology, Interventional Oncologic Radiology, Artificial Intelligence
Date: March 4, 2026 | 16:30 - 17:30 CET
CME Credits: 1

Moderator:
Andreas H. Mahnken; Bochum / Germany

Keynote Lecture (10 min)
Okan Gürkan; Istanbul / Turkey

Artificial Intelligence in Pulmonary Nodule Biopsy: Comparing Predictive Strategies with Interventional Radiologists (6 min)
Lorenzo Musmeci; Acireale / Italy

Author Block: D. G. Castiglione, L. Musmeci, G. Failla, F. Libra, D. Falsaperla, F. Vacirca, F. Tiralongo, S. Palmucci, A. Basile; Catania/IT
Purpose: This study aimed to evaluate the capability of two artificial intelligence (AI) models to predict optimal biopsy strategies for pulmonary nodules and to compare their decision-making process with approaches adopted by interventional radiologists.
Methods or Background: We retrospectively reviewed 49 lung biopsy procedures performed at our institution between November 2024 and February 2025. Clinical and imaging data, including lesion size, pleural distance, and complication rates, were collected. Lung nodules were manually delineated on CT scans and submitted in three orthogonal planes to two AI systems. Each AI was asked to simulate key procedural decisions: imaging guidance modality (CT vs US), patient positioning, and needle trajectory. AI outputs were compared with actual biopsy strategies retrieved from RIS/PACS. Subgroup analysis was performed according to operator experience (>10 years vs <10 years). Inter-reader agreement was measured with Cohen's kappa.
Results or Findings: Overall AI–human agreement was poor (κ = 0.01–0.20). Fair agreement emerged between AI-2 and operators regarding guidance modality and entry point (κ = 0.21–0.40). Moderate agreement was observed when comparing AI-2 with radiologists with >10 years of experience, particularly for selecting CT vs US guidance and trajectory planning (κ = 0.41–0.60). AI-1 displayed weaker overall performance, with minimal alignment to clinical practice.
Conclusion: Current AI tools show limited reliability in replicating expert interventional radiologists' decision-making in lung biopsy planning. While modest concordance was observed with more experienced operators, both systems lack sufficient robustness for autonomous use. AI may serve as an adjunctive decision-support tool but cannot yet substitute for clinical expertise. Further refinement with larger datasets and advanced training is warranted.

Smartphone Augmented Reality Guidance for Needle Intervention in Phantom and In Vivo (6 min)
Laetitia Saccenti; Bethesda / United States

Author Block: L. Saccenti, N. Varble, J. Karanian, W. F. Pritchard, M. Li, B. J. Wood; Bethesda, MD/US
Purpose: To evaluate in a phantom and in vivo the accuracy of needle insertions using a smartphone augmented reality (AR) application with integrated needle guide and deep learning-based body tracking registration.
Methods or Background: A smartphone AR application was developed (Unity, Vuforia) with a surface tracking tool based on deep learning, to automatically overlay and scroll CT imaging data on a body, without fiducials or tracking hardware. A smartphone cover with an integrated needle guide (Civco) was designed and 3D printed, permitting use in percutaneous interventions. The target and entry point were selected through the smartphone application. Needle insertion along the planned path was performed with smartphone sensor feedback. Accuracy of needle insertions was assessed in a phantom (Sun Nuclear) (N=30; 5 physicians), and in vivo (N=14 needle insertions, 3 swine) under Institutional Animal Care and Use Committee approval. Accuracy (tip-to-target-center distance) and angular error were evaluated on post-insertion CT (iQon, Philips).
Results or Findings: In phantom, median accuracy was 4.3mm [IQR 2.2-6.7mm], and median angular error was 2.9° [1.5-4.7°]. In vivo, a total of 14 needle insertions (kidney N=5, liver N=4, and tight muscle N=5) were performed. Median accuracy was 8.8mm (IQR 5.5-11.5mm), and median angular error was 3.8° (IQR 2.4-5.7°).
Conclusion: A smartphone augmented reality application enabled automatic overlay of CT with body surface tracking and demonstrated accuracy of 4.3mm in phantom and 8.8mm in vivo for needle insertions. This smartphone AR application has a simple workflow without pre-procedural CT with fiducials or bulky hardware and does not require internal segmentation.
Limitations: Larger studies will include more operators to confirm those results

Delta habitat analysis and 2.5D deep learning for predicting complete response of colorectal cancer lung metastases treated by radiofrequency ablation (6 min)

Haozhe Huang; Shanghai / China

Author Block: H. Huang, W. Li, W. Li; Shanghai/CN
Purpose: To develop and validate a multi-omics integrated prediction model for complete response (CR) of colorectal cancer (CRC) lung metastases treated by radiofrequency ablation by combining radiomics, pathomics, and clinical features using delta habitat analysis and 2.5D deep learning.
Methods or Background: We analyzed pre- and post-treatment CT images of 249 CRC lung metastases from two centers between August 2016 and June 2022. Delta habitat subregions were generated via K-means clustering of local radiomic features. A 2.5D deep learning approach extracted spatial features from the largest cross-sectional tumor slices, while whole-slide pathology images were processed using weakly supervised multi-instance learning. Feature selection involved the minimum redundancy maximum relevance (mRMR) and least absolute shrinkage and selection operator (LASSO) regression. Models were built using support vector machine (SVM), random forest, and other classifiers, and integrated via multi-omics fusion. Performance was evaluated using receiver operating characteristic (ROC) analysis, calibration curves, and decision curve analysis (DCA).
Results or Findings: A total of 150 lung metastases (60%) achieved CR. The Delta Habitat signature achieved an AUC of 0.818 in the validation cohort, outperforming traditional delta radiomics (AUC = 0.741) and pre-habitat models (AUC = 0.740). The 2.5D multi-instance learning and pathomics signatures showed AUCs of 0.711 and 0.780, respectively. The combined multi-omics model achieved the highest AUC of 0.872, with improved calibration and net benefit in DCA.
Conclusion: The integrated multi-omics model significantly enhances CR prediction accuracy by leveraging complementary information from radiomic, pathomic, and clinical data, demonstrating strong potential for supporting clinical decision-making.
Limitations: Larger external validation data is required to confirm generalizability. Computational complexity and dependency on high-quality imaging may limit clinical deployment.

Novel Acousto-Optic Sensor Stylet for Needle Tip Tracking, Needle Tip Imaging, and Tissue Characterization Compared to Capabilities of Electromagnetic Tracking (6 min)

Laetitia Saccenti; Bethesda / United States

Author Block: L. Saccenti, O. Pena, L. Hazen, D. Singh, A. Gallagher, A. Mikhail, W. F. Pritchard, J. Karanian, M. Li; Bethesda, MD/US
Purpose: To assess the accuracy of a novel acousto-optic sensor for needle tip localization within ultrasound(US) imaging compared to electromagnetic(EM) tracking in phantoms. The ability to localize tumor and reconstruct US view from the needle tip was also evaluated.
Methods or Background: An acousto-optic 50µm sensor was prototyped and integrated into a 20G stylet. The sensor was interfaced with US and a visualization software (DeepSight Technology). It provided 3D location of the needle tip relative to US plane and an internal US view from the needle tip. A phantom with target tumors (Sun Nuclear) was punctured using the acousto-optic sensor and using a commercial EM tracking system (PercuNav, Philips). The EM tracking system was composed of a US transducer sensor, a needle holder sensor and an EM field generator. Needle insertions were completed when the tracking system indicated the needle tip was located at the center of the target. Accuracies (distances from needle tip to target center) on CT imaging (iQon, Philips) were compared (paired t-test, Rstudio v2024).
Results or Findings: Tumors (5-13cm depth) were targeted using the acousto-optic tracking system (N=10) and then the EM tracking system (N=10). The mean accuracy was 2.85mm (SD 1.32mm) for the acousto-optic tracking system and 3.57mm (SD 1.18mm; P=0.19) for the EM tracking system. Using the acousto-optic system, US imaging from needle tip was feasible for each insertion, with sufficient resolution to allow characterization of target-specific echogenicity around the needle tip. The EM tracking system did not allow internal imaging or tissue characterization capabilities.
Conclusion: This novel acousto-optic sensor could successfully localize the needle tip in 3 dimensions with accuracy similar to EM tracking in phantom, while enabling internal US imaging from the needle tip.
Limitations: Phantom study

Advancing Clinical Precision: Automated Segmentation of Pancreatic Cancer using Deep Learning (6 min)

Shweta Tyagi; Bengaluru / India

Author Block: M. M. Jabeer, S. Tyagi, J. Singh, A. Chandalia; Bengaluru/IN
Purpose: Pancreatic cancer remains one of the deadliest malignancies, with approximately 510,922 new cases and 467,409 deaths reported globally in 2022. Although it ranks as the 12th most common cancer, it is the sixth leading cause of cancer-related mortality. The poor prognosis is primarily due to late diagnosis and a lack of effective early detection strategies. Accurate segmentation of pancreatic tumors in abdominal CT imaging is essential but labor-intensive for diagnosis, treatment planning, and surgical guidance. This study aims to develop and evaluate a deep learning model for automated segmentation and reporting of pancreatic tumors on abdominal CT scans .
Methods or Background: We designed a deep learning pipeline architecture to segment the pancreas and pancreatic lesions. The model was trained on a retrospective dataset of 2,000 abdominal CT scans, including both healthy individuals and patients with pancreatic cancer. All scans were manually annotated by experienced radiologists, providing high-quality ground truths. The two-stage pipeline first delineates the pancreas, followed by lesion segmentation within the extracted region. The output includes a DICOM-compatible overlay and an automatically generated report detailing lesion count, size, and volume.
Results or Findings: On a test set of 100 abdominal CT cases, the model achieved a mean Dice coefficient of 0.86 ± 0.09, sensitivity of 93.6%, and specificity of 88.4%. The segmentation results were consistent across different tumor sizes and anatomical variations and were validated by a radiologist for clinical reliability.
Conclusion: Our study demonstrates the feasibility of an automated deep learning approach for pancreatic tumor segmentation on CT scans. The model achieved high accuracy, offering potential to enhance diagnosis, treatment planning, and clinical workflows.
Limitations: Multi-center, prospective validation on more diverse datasets will be essential to confirm robustness across imaging protocols and clinical settings.
Funding for this study: No funding was obtained for this work.

Robotic in-bore MRI-guided prostate biopsy: experience in PI-RADS 4 and 5 lesions at a public university hospital (6 min)

Sergio De la Chica Bolaños; Barcelona / Spain

Author Block: S. De la Chica Bolaños, J. Salazar, D. C. Gimenez, A. Soldevila, F. A. Armas Terry, S. Guillén Rodriguez, N. De La Torre Rubio, R. Castañeda Argaiz, M. Figols Gorina; Manresa/ES
Purpose: To describe our experience with robotic in-bore MRI-guided prostate biopsy with the Soteria® system in PI-RADS 4 and 5 lesions within a fast-track diagnostic pathway at a public university hospital, and to analyse effectiveness and safety.
Methods or Background: A single-centre retrospective study (01.08.2024–31.07.2025) was conducted at Hospital Sant Joan de Déu – Fundació Althaia, Manresa, Spain, in patients referred from a fast-track diagnostic pathway and undergoing in-bore MRI-guided prostate biopsy with the Soteria® system for PI-RADS 4 or 5 lesions. Clinical data, MRI lesion characteristics (size, location), and histopathological outcomes were analysed. Complications (rectal bleeding, haematuria, fever, emergency visits) were recorded.
Results or Findings: 72 cases were analysed. Mean age was 71 ± 8.1 years and median PSA 8.8 ng/mL (IQR 5.7–14.6). The malignancy rate was 61.1% (95% CI: 48.9–72.4). Of these, 47 were PI-RADS 4 and 24 PI-RADS 5. Malignancy was more frequent in PI-RADS 5 than in PI-RADS 4 (87.5% vs 48.9%; p=0.0015). Most tumours were in the peripheral zone (68.2%), followed by transitional (27.3%) and central (2.3%). Histologically, PI-RADS 5 lesions showed a higher proportion of ISUP grade ≥4 compared with PI-RADS 4 lesions (47.6%; p=0.033). Concordance between biopsy and surgical specimen ISUP was substantial (Weighted Kappa=0.77, 95% CI: 0.49–1.00) in the five patients with surgery. Complications were infrequent, reported in three of 54 patients with follow-up (5.6%): one mild rectal bleeding, two febrile episodes, and one emergency visit.
Conclusion: Robotic in-bore MRI-guided prostate biopsy is safe, effective, and achieves high cancer detection. PI-RADS 5 correlated with malignancy and higher ISUP. Substantial concordance was observed between biopsy and surgical ISUP.
Limitations: The small number of surgical cases for ISUP comparison.
Funding for this study: No funding was received for this study.

Performance of AI in predicting HCC recurrence after thermal ablation: a systematic review (6 min)

Alessandro Posa; Roma / Italy

Author Block: A. Posa, P. Barbieri, M. Lippi, G. D'Aniello, E. V. Andreani, R. Iezzi; Rome/IT
Purpose: To evaluate the effectiveness of AI-driven predictive models in predicting HCC recurrence.
Methods or Background: Recurrence prediction of hepatocellular carcinoma (HCC) after thermal ablation represents a challenge that can impact patients' quality of life. Artificial Intelligence (AI)-based radiomics models, applied to various imaging modalities, can improve recurrence prediction, therefore guiding therapeutic decisions.
A systematic literature search in PubMed and Scopus has been performed. A total of 17 studies were selected to be included in this systematic review. All studies included response prediction evaluation with AI models for patients who underwent thermal ablation for HCC. Deep learning and machine learning algorithms were confronted to evaluate the predictive performance and accuracy using metrics such as the area under the curve (AUC) and concordance index (C-index).
Results or Findings: The developed models demonstrated high accuracy in predicting local progression and recurrence, allowing a solid risk stratification. In particular, the integration of imaging data and clinical-laboratory variables optimized treatment selection, highlighting the superior ability of imaging models to predict therapeutic outcomes compared to clinical parameters alone. Furthermore, radiomic analysis of follow-up imaging enabled highly accurate detection of ablation site recurrence.
Conclusion: AI-driven predictive models based on multimodal radiomic analyses integrated with clinical data represent promising tools for predicting tumour recurrence after thermal ablation in HCC patients.
Limitations: Mostly retrospective and monocentric studies. Different reported outcome measures.
Funding for this study: None.

Multimodal MR Radiomics and H&E Pathomics Predict Recurrence After Adjuvant TACE Following Hepatectomy in HCC (6 min)

CHUNLI KONG; Lishui / China

Author Block: C. KONG, S. Zheng, Y. Su; Lishui/CN
Purpose: To develop and validate a multimodal model integrating preoperative MR radiomics and postoperative H&E pathomics to predict recurrence after hepatectomy with adjuvant transarterial chemoembolization (TACE) in hepatocellular carcinoma (HCC).
Methods or Background: We retrospectively included 102 HCC patients who underwent curative resection and received adjuvant TACE within 2 months. On preoperative MR-T2WI, tumor and 1/3/5-mm peritumoral rings were segmented to extract 9,056 radiomic features. From postoperative H&E whole-slide images, 1,079 pathomic features were derived. Feature selection used maximum relevance–minimum redundancy (mRMR) and least absolute shrinkage and selection operator (LASSO)–Cox, retaining 5 radiomic and 9 pathomic features, from which logistic regression derived Radiomics score (RadScore) and Pathomics score (PathScore). Patients were stratified by each biomarker, and Kaplan–Meier analyses compared recurrence-free survival (RFS) between biomarker-defined strata. Prespecified clinical covariates (e.g., BCLC stage, antiviral therapy) were tested by univariable Cox, with significant/a-priori factors entered into a multivariable model. Seven prediction models were trained: imaging-only, pathology-only, clinical-only, imaging+clinical, pathology+clinical, imaging+pathology, and fusion model (imaging+pathology+clinical). Model performance was evaluated in training and validation cohorts using time-dependent receiver operating characteristic (ROC) curves and area under the curve (AUC) at 1, 2, and 3 years, calibration, and decision-curve analysis (DCA).
Results or Findings: RadScore- and PathScore-defined groups showed significantly different RFS (log-rank $p<0.05$). Antiviral therapy emerged as an independent prognostic factor. The fusion model achieved strong discrimination with training AUCs of 0.836/0.859/0.932 and validation AUCs of 0.807/0.823/0.814 at 1/2/3 years. Calibration indicated agreement between predicted and observed RFS, and DCA demonstrated favorable net clinical benefit across relevant thresholds.
Conclusion: Integrating peri-tumoral MR radiomics with postoperative H&E pathomics, complemented by key clinical variables, enables accurate prediction of recurrence after adjuvant TACE in resected HCC and supports individualized post-operative risk stratification and surveillance.
Limitations: Single center study.
Funding for this study: None.

Platelet-rich plasma versus corticosteroid–hyaluronic acid treatment for patients with knee osteoarthritis: a retrospective comparative study (6 min)
Marica Adinolfi Falcone; L'Aquila / Italy

Author Block: M. Adinolfi Falcone, L. Rinvenuto, F. Arrigoni, L. Zugaro, A. Barile, E. Di Cesare; L'Aquila/IT
Purpose: Platelet-rich plasma (PRP) and hyaluronic acid (HA) are established intra-articular therapies.
This study aimed to compare the short- and long-term efficacy of PRP with a corticosteroid–HA combination in patients with knee osteoarthritis.
Methods or Background: A retrospective single-center study was conducted on 100 patients under 60 years of age (mean age 51) with knee osteoarthritis classified according to the International Cartilage Repair Society (ICRS). Patients were divided into two groups: Group A received three intra-articular PRP injections at 2-week intervals; Group B received one intra-articular corticosteroid injection followed by two HA injections at the same intervals. Symptom severity was assessed using the Visual Analog Scale (VAS) at baseline and at 1, 3, 6, and 12 months. Statistical analysis was performed, with $p<0.05$ considered significant.
Results or Findings: Baseline VAS scores were comparable between groups. At 1 month, corticosteroid–HA showed greater early symptom relief (VAS decrease: 4.30 ± 2.31, $p<0.001$). At 3 months, no significant difference was observed ($p=0.860$). PRP demonstrated slower onset but superior long-term efficacy at 6 and 12 months (VAS decrease: 5.56 ± 1.50, $p<0.001$). Within the corticosteroid–HA group, subgroup analysis by ICRS grade demonstrated more durable effects in grades I–II, whereas grades III–IV showed improvement limited to the short-term.
Conclusion: PRP injections provided significantly greater long-term symptom relief compared with corticosteroid–HA. While PRP showed slower onset, its efficacy was sustained up to 12 months. Corticosteroid–HA offered more transient benefits, with duration influenced by baseline ICRS grade. These findings support PRP as a more effective long-term treatment option for knee osteoarthritis.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study.

Platelet-Rich Plasma versus Corticosteroid Injections for Facet and Sacroiliac Joint Pain: A Systematic Review and Meta-Analysis of Randomized Controlled Trials (6 min)
Bano Loai Alsaleh; Manama / Bahrain

Author Block: D. Alatefi[1], M. Alkabazi[2], A. Alanzi[3], B. L. Alsaleh[3], M. Amro[4], A. Hezam[3]; [1]Amman/JO, [2]Tripoli/LY, [3]Manama/BH, [4]Bad Wildungen/DE
Purpose: Efficacy of platelet-rich plasma (PRP) versus corticosteroid injections for facet and sacroiliac joint pain.
Methods or Background: PubMed, Cochrane Library, Scopus, Embase, Web of Science, CINAHL Complete, Virtual Health Library, ClinicalTrials.gov, and ScienceDirect were searched up to 21 June 2025. Mean pain scores changes from baseline to first, third, and sixth months using a scale of 10 scores (0= no pain, and 10= worst pain). Secondary outcome was disability using Oswestry Disability Index (ODI) or Modified ODI (MODQ). Data pooled using mean difference (MD) for pain scores outcome, and standardized mean difference (SMD) for disability outcome. Random-effects meta-analysis performed using 'Meta' package in R (RStudio version 4.4.3), with subgroup analyses by joint (facet vs SIJ) to facilitate further interpretation.
Results or Findings: Ten RCTs (six facet, and four SIJ) enrolling 392 patients (mean age 46.8 years, 50.6% male) were included. At one month, pain outcomes favored PRP but did not reach statistical significance (MD -0.23, 95% CI -1.07 to 0.61; $p = 0.589$; $I^2 = 90.6\%$). At three months, PRP significantly reduced pain versus corticosteroids (MD -1.42, 95% CI -2.12 to -0.71; $p < 0.001$), with consistent benefit across facet and SIJ subgroups. Superiority persisted at six months (MD -2.00, 95% CI -3.13 to -0.87; $p = 0.0005$). Disability outcome showed no significant difference at one month (SMD 0.26, 95% CI -0.30 to 0.82), but PRP significantly improved function at three months (SMD -0.72, 95% CI -1.56 to -0.25; $p = 0.0052$) and at six months in facet trials (SMD -1.80, 95% CI -3.16 to -0.45; $p = 0.009$).
Conclusion: PRP provides superior medium- and long-term pain and functional improvement compared with corticosteroid injections for facet and SIJ pain.
Limitations: Heterogeneity in PRP preparation and corticosteroid regimens.
Funding for this study: This research received no external funding

Ultrasound guided intramuscular administration and MRI monitoring of non-viral gene editing delivery technology for intramuscular treatment of Duchenne muscular dystrophy (6 min)

Ozge Fındık Şener; Leiden / Netherlands

Author Block: O. Fındık Şener, F. Sage, E. H. Niks, S. S. Rauh, M. C. De Ruiter, M. A. Engelse, N. Geijsen, M. C. Burgmans, H. E. Kan; Leiden/NL

Purpose: Duchenne muscular dystrophy is characterized by progressive muscle wasting. Current gene-editing trials using systemic delivery face challenges in systemic side effects and tissue exposure. Intramuscular dosing may increase tissue concentrations and limit side effects, but requires an optimal injection technique.
We aim to develop ultrasound-guided intramuscular delivery and MRI monitoring of fluid distribution in a preclinical setting.
Methods or Background: Dose-escalation and repeatability were assessed in two sets of four porcine extensor digitorum brevis muscles in situ. Four volumes (2.5-10ml of an ink and iTOP (induced transduction by osmocytosis and propanebetaine) solution (dilution 1/10) were injected using a 20G Chiba needle under ultrasound guidance. The entire muscle was targeted longitudinally from four directions. Muscle volume and ink distribution (%stained vs total) were quantified on 2cm cross-sections. Repeatability was assessed with the intraclass correlation-coefficient (ICC).
In four other porcine hindlimbs, fluid distribution was quantified using 3T MRI, pre and post-injection scans (pixel-intensity threshold method on the TSE Dixon water-only image (TE=94ms)). 2.5 and 5ml injections are completed so far, with 7.6 and 10ml expected to be completed by March 2026.
Results or Findings: Muscle volumes were 26.9±4.1cm3. The injection to volume ratio was 0.1; 0.2; 0.3 and 0.3 (2.5ml to 10ml). In the dose-escalation experiment, higher injection volumes showed increased fluid distribution (ranging from 54.8% for 2.5ml to 99.4% for 10ml). Repeatability was excellent with an ICC of 0.99. Post-injection MR images showed a clear increase in signal intensity, with up to 65% elevated pixels.
Conclusion: Ultrasound-guided four longitudinal intramuscular injections provided up to 99.4% fluid distribution and excellent consistency between the measurements. MRI enabled in-situ monitoring of fluid distribution, suggesting that this method can also be used in-vivo.
Limitations: The limitation of the study is having non-living models.

Ultrasound-guided platelet-rich plasma and corticosteroid injection for subacromial-subdeltoid bursitis: a prospective comparative study (6 min)

Georgios Kalidonis; Heraklion / Greece

Author Block: G. Kalidonis, V. Nikovia, E. A. EZERSKA, K. Demetriou, M. Klontzas, M. Raissaki, A. Karantanas, E. E. Vassalou; Heraklion/GR

Purpose: To compare the efficacy of ultrasound-guided subacromial-subdeltoid (SASD) bursa platelet-rich plasma (PRP) and corticosteroid injections in patients with SASD bursitis over 1-year and to assess the predictive value of several factors related to outcome.
Methods or Background: From January 2021 to November 2023, consecutive patients with SASD bursitis secondary to shoulder impingement syndrome (SIS) were prospectively enrolled. Patients with rotator cuff tendinosis/tears were excluded. Participants were randomly assigned into two groups, (i)PRP-group receiving a single, ultrasound-guided SASD bursa injection with 10mL of autologous PRP (n=41) and (ii)corticosteroid-group, receiving a 10mL mixture of triamcinolone acetonide, lidocaine and saline (n-42). Clinical outcomes were assessed using the Constant-Murley Score (CMS) at baseline, 1-week, 3-months, 6-months, and 1-year post-treatment. Statistical analyses were performed using the Mann-Whitney and Hosmer-Lemeshow tests. A multivariable logistic regression model was developed to ascertain the effect of six factors on CMS. P<.05 denoted significance.
Results or Findings: The PRP-group included 26-females/15-males (mean age, 43.4 years) and the corticosteroid-group 24-females/18-males (mean age, 42.3 years). Baseline CMS showed no significant difference (p=.11). In both groups CMS improved significantly at all time-points compared to baseline (p<.05). At 6-months no significant difference was observed (p=.076); the corticosteroid-arm showed improved outcome at all other time-points (p<.05). Treatment method and maximum bursa width were significant predictors for achieving patient acceptable symptom state at 3-months while patient age and baseline CMS were significant at 1-year.
Conclusion: Both corticosteroids and PRP appeared effective for SASD bursitis, with results sustained up to 1-year. PRP achieved comparable effect in the mid-term. Corticosteroids showed superior outcome at other time-points. These findings support PRP as an alternative therapeutic option for SIS-related SASD bursitis.
Limitations: CMS, although widely accepted, presents certain drawbacks as a clinical tool for evaluating functional capacity.

Ultrasound-guided triple-target “sandwich” technique for flare-ups of chronic Achilles tendinopathy: preliminary experience (6 min)

Giorgio Reverchon; Salerno / Italy

Author Block: G. Reverchon, A. Bazzocchi, F. Ponti, G. Bilancia, D. Romeo, P. Spinnato; Bologna/IT
Purpose: Flare-ups of chronic Achilles tendinopathy (AT) represent a therapeutic challenge. Conservative options may fail, while surgery is often too invasive. We present our initial experience with a novel ultrasound-guided interventional procedure – the triple-target “sandwich” technique – designed to manage AT flare-ups in a minimally invasive manner.
Methods or Background: Between January and June, 7 procedures were performed on 5 patients with chronic AT flare-ups (2 women, 3 men; mean age 50 years). Under ultrasound guidance, with previous subcutanous and peritendinous tissue local anestesia, injections were performed at three levels: (1) intratendinous tissue with hyperosmolar glucose, (2) pre-Achilles bursa with anesthetic and triamcinolone, and (3) retro-Achilles bursa with anesthetic and water-soluble corticosteroid. Prolotherapy works by injecting an hyperosmolar glucose solution that mildly irritates the tissue, stimulating the body’s natural healing response. This helps the body produce new collagen, making the tendons stronger and reducing the pain.Patients were subsequently referred for rehabilitation. Pain scores (NRS) and range of motion (complete restoration, subtotal, partial and unchanged) were assessed at baseline, 1 week, 3 months, and 6 months.
Results or Findings: Mean pain scores significantly decreased from 8.8 at baseline to 1.5 at 1 week, 0.8 at 3 months, and 3.1 at 6 months (p=0.002). At 3-month follow-up, 42% of patients achieved complete recovery of motion, 42% subtotal recovery, and 14% partial recovery. At 6 months, complete recovery was maintained in 28%, subtotal in 28%, and partial in 42%. No complications or adverse events were reported.
Conclusion: The ultrasound-guided triple-target “sandwich” technique appears to be a safe, well-tolerated, and cost-effective procedure for the management of AT flare-ups. Despite the limitations of a small sample and short follow-up, these preliminary findings suggest promising clinical potential.
Limitations: Small patient cohort and limited follow-up.
Funding for this study: No funding was provided.

CT-Guided Facet Joint Cyst Rupture: Clinical Outcomes of a Minimally Invasive Technique (6 min)

Sumona Mandal; London / United Kingdom

Author Block: S. Mandal[1], D. Dalili[2]; [1]London/UK, [2]Oxford/UK
Purpose: To assess outcomes of CT-guided facet joint cyst rupture over five years, focusing on surgical avoidance and the need for subsequent operative management.
Methods or Background: Facet joint cysts, a sequela of degenerative spinal disease, may produce nerve compression and pain. While surgical excision remains standard, CT-guided cyst rupture offers a minimally invasive alternative, with reported surgical avoidance rates of 55–66%. We retrospectively reviewed all patients undergoing CT-guided cyst rupture at Epsom Hospital (2020–2025). Follow-up data were derived from spinal surgeon clinic records. Of 35 cases identified, 14 were excluded (no cyst at procedure, spontaneous resolution, incomplete follow-up, or technical failure), leaving 21 patients for analysis.
Results or Findings: The cohort comprised 10 men (47%) and 11 women (53%), mean age 68 years. Most cysts were at L4/L5 (76%). Ten patients (48%) underwent an indirect approach; 11 (52%) received combined indirect and direct techniques. Eight patients (38%) required surgery (completed or scheduled), with a mean interval of 85 days post-rupture. Thirteen patients (62%) avoided surgery; of these, five (24%) required additional interventions (epidural or Racz catheter), while eight (38%) required no further treatment and derived sustained benefit.
Conclusion: CT-guided facet joint cyst rupture is a safe, effective, and minimally invasive treatment, with 62% avoiding surgery and over a third achieving durable relief without further intervention. These outcomes align with published data, supporting its consideration as a first-line option, particularly for patients at elevated surgical risk or preferring less invasive management.
Limitations: Small sample size, heterogenous follow-up, and retrospective design. We are still collecting data for a larger study to assess validation, generalisability and reproducibility.

Image-Guided Management of Chronic Post-TKA Knee Pain: Genicular Artery Embolization and Genicular Nerve Ablation (6 min)

Roberto Marcello; Roma / Italy

Author Block: R. Marcello, G. Marcello, M. Cuccarelli; Roma/IT
Purpose: To evaluate the clinical indications, technical approaches, and outcomes of two interventional radiology techniques—genicular artery embolization (GAE) and genicular nerve ablation (GNA)—in the management of chronic knee pain following total knee arthroplasty (TKA).
Methods or Background: We conducted a retrospective cohort analysis of patients with chronic (>3 months) post-TKA knee pain unresponsive to conservative treatment. Patients underwent either GAE, GNA, or a sequential combined approach.
• GAE: performed under fluoroscopic guidance and microcatheter 1.7 Fr. superselective embolization of hyperemic genicular branches. Vascular approach was antegrade percutaneous US-guided common femoral artery access in most cases whereas controlateral cross over access was indicated in obese patients or in case of others anatomical limitations.
• GNA: performed using radiofrequency ablation of the superomedial, superolateral, and inferomedial genicular nerves after a diagnostic nerve block. A dedicated RF generator was applied.
Pain relief was assessed via VAS score at baseline and during follow-up (1, 3, and 6 months), along with functional improvement (WOMAC) and complication rates.
Results or Findings: • Total patients: 13 (GAE n=8 GNA n=2; combined n=3)
• Mean pain reduction (VAS at 3 months):
o GAE: –3.5 points
o GNA: –4.1 points
o Combined: –5.2 points
• Functional improvement (WOMAC): significant in all groups ($p<0.01$), particularly in the combined group.
• Complications: no major complications observed; minor side effects included transient skin discoloration (GAE) and local paresthesia (GNA).
• Technical success: 100% in all procedures.
Conclusion: GAE and GNA are safe and effective image-guided procedures for chronic pain management after TKA, each addressing different pain mechanisms (inflammatory vs. neuropathic). Combined approaches may offer enhanced pain relief in selected cases. These minimally invasive techniques represent promising alternatives to revision surgery.
Limitations: Any

Botulinum toxin for the belly: beyond aesthetics in abdominal wall hernia repair (6 min)

Adolfo Manuel Delgado Brito; Pamplona / Spain

Author Block: A. M. Delgado Brito, J. D. Aquerreta, I. Soriano, M. Elorz Carlón, M. Jiménez Vázquez, D. A. Zambrano, M. R. López De La Torre Carretero, A. Paternain Nuin; Pamplona/ES
Purpose: To evaluate the safety and feasibility of ultrasound-guided botulinum toxin type A (BTX-A) injection into the lateral abdominal wall as a preoperative adjunct for abdominal wall hernia repair, with attention to anatomy, technique, and outcomes.
Methods or Background: Consecutive case series of 23 patients. Abdominal wall anatomy was reviewed to guide infiltration of the lateral abdominal muscles (external oblique, internal oblique, transversus abdominis), which contribute to retraction and tension of the hernia defect. Under ultrasound guidance, 3–5 injection sites per side were used, tailored to abdominal wall dimensions. A total dose of 500 IU was diluted and evenly distributed across target muscles. The median interval from injection to surgery was 29 days. Patients were followed for hernia recurrence and procedure-related adverse events.
Results or Findings: Mean age 61.4 ± 12.3 years; mean body mass index (BMI) 28.9 ± 3.6 kg/m². Most patients (22/23; 95.7%) had at least one risk factor (smoking, diabetes, chronic obstructive pulmonary disease (COPD), or overweight). The procedure was well tolerated, with no major BTX-A–related complications. After a median follow-up of 881 days, no hernia recurrences were observed, including in two patients operated <48 hours after injection.
Conclusion: Ultrasound-guided BTX-A injection of the lateral abdominal wall is a safe, minimally invasive, and reproducible preoperative technique. By inducing temporary muscle relaxation, it facilitates fascial closure and optimizes repair. In this series, no medium-term recurrences were observed despite multiple comorbidities, supporting further comparative studies.
Limitations: The limitations of the study are its small sample size and the absence of a control group. Subsequent studies should enroll larger cohorts and incorporate a suitable control arm to improve robustness and generalizability.
Funding for this study: No funding was received for this study.

Automated CT quality assurance analysis and monitoring framework for CT with open-source code - initial international experiences within IAEA project (6 min)

Juha Ilmari Peltonen; Helsinki / Finland

Author Block: J. I. Peltonen[1], A-M. Hoyos-Garcia[2], D. Y. Nersissian[3], T. Li Kuo[4], I. Fitton[5], V. Tsapaki[6], O. CIRAJ BJELAC[6], M. Kortesniemi[1]; [1]Helsinki/FI, [2]na/MX, [3]São Paulo/BR, [4]Kuala Lumpur/MY, [5]Paris/FR, [6]Vienna/AT
Purpose: To test previously created automated quality assurance (QA) framework for computed tomography (CT) as a multi-center international pilot use with various different CT models as part of the International Atomic Energy Agency (IAEA) Coordinated Research Project (CRP) entitled “Advanced Tools for Quality and Dosimetry of Digital Imaging in Radiology” (E24025).
Methods or Background: The QA framework was built on free open-source code components and libraries to facilitate future development and for freely sharing knowledge within global medical physics and radiation protection community.

The framework core components included results database, in-house built database communication interface, interactive user interface, data processing backend and a DICOM server.

The QA framework requires only the standard CT calibration (vendor specific) phantom with homogenous section included in any commercial CT system installation. The QA analysis provides all essential technical image quality features (e.g. CT numbers and their variation, contrast, noise, resolution) including also model-observer based values (detectability index).
Results or Findings: The pilot installation was deployed in 6 countries with 12 CT systems in total representing various scanner generations and platforms, including conventional multi-slice scanners and new photon counting detector-based CT. The results demonstrated excellent applicability with different systems and environments.
Conclusion: Large scale CT QA framework built on free open-source code has been successfully tested on multi-center international environment within IAEA pilot project. The framework can be prepared for large scale global use.
Limitations: This research outlines early findings from the system's broad implementation.
Funding for this study: No dedicated funding was provided for this study.

How to quality-assure new CT devices using a dose management system – analysis of scan parameter use, radiation exposure and technique (6 min)

Niki Fitousi; Leuven / Belgium

Author Block: A. Romanyukha[1], L. Garajová[2], N. Fitousi[1], A. M. Sprinkart[2]; [1]Leuven/BE, [2]Bonn/DE
Purpose: New scanner technology comes with promise of lower exposure and improved workflow. The purpose of this study was to QA a new spectral CT device by evaluating the difference in standard scan parameters, exposure and technique between old and new scanners of the same vendor.
Methods or Background: 6 months of data was exported from the dose management system including study compositions, scan parameters (kVp, pitch, collimation, exposure time per rotation, scanlength), and indicators of exposure (CTDIvol, SSDEWED) and technique (positioning offsets, lengths of scans outside localizer borders) for the same exams on iCT 256 (old) and spectral CT 7500 (new) scanners (Philips Healthcare): chest-abdomen with contrast (n=295 and n=694, respectively), chest with contrast (n=106 and n=220, respectively) and chest without contrast (n=252 and n=393, respectively). All data was collected from radiation dose structured reports.
Results or Findings: Study compositions, kVp and collimation were identical, while pitch was 1.8 times higher and exposure time per rotation was 0.06 s lower on the spectral CT 7500 for all protocols. Median scanlength was 1-6% higher on the new scanner for standard exams, likely attributed to patient differences. CTDIvol and SSDEWED were 50% lower for both chest protocols on the new scanner, and 14% and 22% lower, respectively, for the chest-abdomen protocol on the new scanner. Higher ranges of CTDIvol per patient WED were observed on the new scanner. Vertical and horizontal positioning offsets improved by 47-86% and 57-89%, respectively, on the new scanner. Scanning outside localizer borders was uncommon on both scanners and reduced further on the new scanner.
Conclusion: Differences in scan parameters were found, and spectral CT 7500 demonstrated reduced dose and improved technique. Investigation into scan settings and their impact on dose will be performed.

Development of a Practical Phantom for Quality Assurance in Lung Cancer Screening CT (6 min)

Stefan Sawall; Heidelberg / Germany

Author Block: S. Sawall, L. T. Rotkopf, T. D. Do, H-U. Kauczor, C. H. Ziener, H-P. Schlemmer, M. Kachelrieß; Heidelberg/DE
Purpose: To design and evaluate a cost-efficient, semi-anthropomorphic phantom for quality assurance of CT lung cancer screening protocols, with emphasis on accessibility and applicability in resource-limited settings.
Methods or Background: The phantom was built from readily available materials for task-based image quality assessment at clinically relevant intersection lengths and dose levels. Candidate materials including ABS, PMMA, polycarbonate, polyethylene, and polyurethane (PU) foams were tested for machinability, attenuation, and water equivalence. A semi-anthropomorphic phantom with thoracic dimensions of 20 × 30 cm approximating adults was constructed. It includes features for the assessment of task transfer function, slice sensitivity profile, noise power spectrum, image noise, and lesion detectability. Cylindrical inserts and nodules of varying sizes and contrasts were embedded to mimic solid and ground-glass nodules. Imaging experiments were performed on an energy-integrating CT (Somatom Force) and a photon-counting CT (Naeotom Alpha.Peak) at multiple tube voltages and prefilters. Furthermore, a calibration approach is introduced in which CT values are modeled as a function of PU density or alternative materials, ensuring consistent evaluation despite local material variability.
Results or Findings: ABS and PU foams proved most suitable for simulating tissue and low-contrast lesions. ABS served as the phantom body and solid nodules, while PU foams of different densities represented lung parenchyma and ground-glass nodules. These materials provided water-equivalent attenuation, stable CT values across scanners and voltages, and realistic intersection lengths. The phantom enabled robust image quality assessment.
Conclusion: Our low-cost, reproducible phantom for CT lung cancer screening QA can be manufactured on site with simple tools, supporting broad use in clinical practice. To support adoption, design files and specifications will be made available.
Limitations: Manual fabrication may reduce structural accuracy, although CNC machining can improve precision where available.

Beyond One Size Fits All: Personalized Dosimetry in CT and Fluoroscopy Using NCICT and NCIRF (6 min)

Choonsik Lee; Rockville / United States

Author Block: C. Lee; Rockville/US
Purpose: Traditional dosimetry methods in diagnostic imaging often rely on reference patient models, overlooking the diversity of age, sex, body size, and pregnancy status in real-world practice. This “one-size-fits-all” approach limits accuracy and underestimates variability in radiation dose. Recent advances with the National Cancer Institute dosimetry systems for Computed Tomography (NCICT) and Radiography and Fluoroscopy (NCIRF) move beyond population averages to provide personalized dose estimates.
Methods or Background: NCICT and NCIRF integrate Monte Carlo–derived dose libraries with advanced computational human phantoms that span pediatric through adult anatomies, both sexes, varying body habitus, and more recently pregnant patients. Organ dose estimates are individualized by merging scanner- or procedure-specific parameters with anatomically matched phantoms. NCIRF further models spatial dose distributions to estimate local peak skin dose—critical for patients undergoing complex, high-dose interventions.
Results or Findings: By accounting for patient-specific characteristics, individualized organ dose estimates can differ several-fold from reference values, particularly in pediatric, obese, or pregnant cohorts. NCIRF’s peak skin dose calculations enable proactive management of deterministic effects. Both systems are designed for seamless integration with dose reports, enabling high-throughput monitoring in clinical practice and retrospective dose reconstruction in research cohorts. Large-scale applications have demonstrated their utility for personalized radiation protection, patient counseling, and epidemiological studies.
Conclusion: NCICT and NCIRF represent a paradigm shift in diagnostic imaging dosimetry—moving beyond “one size fits all” to precision dose assessment. By leveraging the most advanced computational human phantoms and real-world imaging data, these systems provide powerful tools for patient-specific monitoring and long-term risk evaluation in both CT and fluoroscopy.
Limitations: Although NCICT and NCIRF employ individualized computational phantoms to improve accuracy, residual anatomical discrepancies from actual patients remain and may introduce uncertainty in organ and skin dose estimates.
Funding for this study: This research was supported by the Intramural Research Program of the National Institutes of Health (NIH). The contributions of the NIH author(s) were made as part of their official duties as NIH federal employees, are in compliance with agency policy requirements, and are considered Works of the United States Government. However, the findings and conclusions presented in this paper are those of the author(s) and do not necessarily reflect the views of the NIH or the U.S. Department of Health and Human Services.

X-ray imaging dosimeters: target uncertainty for revealing errors (6 min)

Paula Toroi; Vantaa / Finland

Author Block: P. Toroi[1], I. Stojanović[2], M. Živanović[2], A. Ciccotelli[3], N. Kiiskinen[4], M. Borowski[5]; [1]Vantaa/FI, [2]Vinča, Belgrade/RS, [3]Rome/IT, [4]Helsinki/FI, [5]Braunschweig/DE
Purpose: Measurement results should always be reported together with the estimated uncertainties. Measurement uncertainties must be sufficiently low to achieve the accuracy requested for clinical measurements. For air kerma measurements the target uncertainty is well established e.g., in IAEA TRS-457. However, for the other quality control (QC) parameters such as tube voltage, half-value layer, and irradiation time, the target uncertainty has not yet been clearly defined [Komatina I, et al. 2025 Physica Medica 136 105055].
Methods or Background: The dosimeter performance and associated uncertainties were analyzed within a European project using data from surveys, publications and experimental measurements. The achievable uncertainties were compared with established targets, and their clinical relevance was evaluated.
Results or Findings: For air kerma measurements, a target uncertainty of 5% (k = 2) can be reliably achieved with proper calibration. In contrast, for the other QC parameters the situation is less clear. IEC standards provide some acceptance criteria. For example, tube voltage should be within 8% in general radiology and 5% in mammography. To verify compliance with such limits, the measurement uncertainty must be considerably lower than the acceptance threshold. For the other QC parameters, an uncertainty of 2% is often set as a goal, although this is challenging to achieve. While reproducibility can be excellent (uncertainty <1%), absolute accuracy strongly depends on proper calibration. If a device is used under conditions different from those of its calibration, systematic errors exceeding 5% may occur.
Conclusion: Dosimeters used in X-ray imaging enable measurement of a wide range of QC parameters. However, for quantities other than air kerma, the associated uncertainties are still poorly known. This study clarifies achievable uncertainty levels and supports a more informed evaluation of whether observed measurement deviations are significant.
Limitations: Not applicable.
Funding for this study: This work was funded by the project 22NRM01 TraMeXI which has received funding from the European Partnership on Metrology, cofinanced from the European Union’s Horizon Europe Research and Innovation Programme and by the Participating States. Funded by the European Union.

Estimation of radiation risks from PET/CT examinations: what is the contribution of CT exposure versus FDG administration? (6 min)

Vereniki Mari; Athens / Greece

Author Block: V. Mari, N. Ntoufas, S. Koukouraki, K. Perisinakis; Iraklion/GR
Purpose: To estimate the contribution of CT exposure and FDG administration to the life attributable radiogenic risk (LAR) of cancer associated with PET/CT examinations and compare the total LAR to the nominal life intrinsic risk (LIR) of cancer.
Methods or Background: The radiation dose to radiosensitive organs was calculated in a series of 24 patients subjected to PET/CT. Organ radiation doses from the administered FDG activity were determined using organ dose per activity factors. To estimate CT exposure-related organ doses, a Monte Carlo simulation software package was used that simulates the actual patient CT exposure on a patient-specific mathematical phantom generating dose images in 1-1 correspondence to original CT images. The FDG-related, CT-related, cumulative organ doses and published organ-specific radiogenic cancer risk factors were employed to estimate corresponding LAR estimates. The mean total LAR was compared to recently published LIR of cancer.
Results or Findings: The FDG-related organ doses ranged from 1.3 mGy (skin) to 27.9 mGy (bladder). The CT exposure-related organ doses ranged from 7.2 mGy (uterus) to 18.1 mGy (thyroid). The CT-related and FDG-related LAR was estimated to be 3.9 x10-4 and 2.0 x10-4 for males and 10.4 x10-4 and 3.4 x10-4 for females, respectively. The total LAR from a PET/CT examination was found to increase the risk for carcinogenesis to a cancer-free individual subjected to PET/CT by only 1.0015 and 1.0042 for male and female individuals, respectively.
Conclusion: The main contributor to the radiogenic risk of cancer from PET/CT examinations is CT, contributing by 78% and 65% to the total LAR of female and male patients, respectively. The increase of the nominal risk of cancer induction following a PET/CT examination with a modern system is < 0.42% and may be considered marginal.
Limitations: Cohort size.

The current status of reporting to accidental or unintended radiation exposure for patients and workers in Lithuania (6 min)

Birutė Gricienė; Vilnius / Lithuania

Author Block: B. Gricienė, I. Andriulevičiūtė, K. Skovorodko, L. Krynke, M. Jeršova, V. Statkus, A. Samuilis; Vilnius/LT
Purpose: The aim of this study is to provide an overview of the Lithuanian legal framework for the registration of accidental and unintended radiation exposures and to present national statistics on patient and occupational exposure cases exceeding investigation levels.
Methods or Background: Across Europe, the requirements for recording and reporting unplanned or emergency exposure situations vary considerably, reflecting differences in national radiation protection strategies and regulatory approaches. In Lithuania, these requirements established through national hygiene norms, which provide the legal basis for mandatory reporting. In addition, hospitals are required to implement local orders that regulate the reporting and analysis of unintended events. Patient cases in which radiation exposure during interventional radiology procedures leads to observable skin effects, except when associated with complex procedures, must be reported to the competent authority. For occupational exposures, hospitals are obliged to establish local investigation levels. These serve as threshold values that trigger further analysis, corrective actions, and preventive measures. In practice, this requires the systematic registration of unintended events, the application of optimization strategies, and the use of structured procedures for case analysis.
Results or Findings: Statistics on unintended events in diagnostic radiology reported by Lithuanian hospitals from 2020 to 2025 were analyzed. The majority of events were related to human error or equipment malfunction. Occupational exposure cases exceeding investigation levels were analysed, with most associated with demanding workloads and complex fluoroscopy guided interventional procedures.
Conclusion: Our findings highlight the importance and challenges of implementing a clear legal framework for the systematic registration of accidental and unintended radiation exposure cases. National statistics confirm that the application of error system registration and investigation levels provides a practical and effective tool for harmonizing case analysis, supporting optimization, ensuring consistent radiation protection standards.

From risk to reliability: advancing patient safety in imaging and radiotherapy (6 min)

Athanasia Papachristodoulou; Thessaloniki / Greece

Author Block: A. Papachristodoulou[1], C. Paraskevopoulou[2], C. Domingos Filho[3], D. Baltazar[4], A. Roncacci[5]; [1]Thessaloniki/GR, [2]Athens/GR, [3]Barcelona/ES, [4]Amadora/PT, [5]The Hague/NL
Purpose: To evaluate trends in clinical incidents related to patient identification and procedure matching across a European diagnostic and radiotherapy network, and to assess the impact of targeted safety interventions.
Methods or Background: Clinical incident (CI) reports were collected from 286 diagnostic imaging and radiotherapy centres across 15 European countries. Incidents included repeated examinations, unintended radiation exposures, wrong procedure, wrong patient, wrong side and wrong site imaged or treated. Data was analyzed from January 2023 to August 2025. An action plan was introduced in response to peaks observed in March 2023 and April 2024. Safety interventions included extensive staff training, safety campaigns, systematic review of incidents, and deployment of digital identification tools.
Results or Findings: In 2023, 36 incidents were reported in January, with reductions to 10–18 per month from May onward, after the first intervention. The overall burden was highest in 2023 compared with subsequent years. In 2024, incident counts peaked at 21 (March) but stabilized at lower averages (8–13). Data from 2025 (Q1–Q3) showed further improvement, with monthly counts between 2–13, consistently below 2023–2024 levels. High-risk categories such as wrong patient and wrong site incidents declined significantly, while repeated examinations remained the most frequent category. The downward trend correlates with the roll-out of the action plan and harmonized safety protocols across countries.
Conclusion: A structured patient safety program, triggered by peak periods and supported by training, campaigns, and clinical review, produced sustained reductions in errors. Embedding these actions into clinical governance frameworks advances value-based healthcare by reducing harm and optimizing processes and resources. Continuous analysis of incidents is essential to identify trends and enable proactive mitigating actions that further strengthen safety culture across imaging networks.

Realization of Actionable Ultrasound Quality Issues in a Multi-Site Radiology Unit (6 min)

Juuso Heikki Jalmari Ketola; Helsinki / Finland

Author Block: J. H. J. Ketola, S. Inkinen; Helsinki/FI
Purpose: Diagnostic ultrasound (US) transducers are prone to mechanical damage due to wearing or impact. Many defects can be identified by evaluating in-air reverberation patterns. Defective transducers can be either repaired or replaced. This study aimed to evaluate the outcomes associated with our technical quality control (QC) program for US transducers in our unit covering over 80 US devices with ca. 300 transducers.
Methods or Background: In January 2024, our hospital district implemented a digital quality control platform. Each diagnostic transducer is tested monthly by taking in-air reverberation images, which are available on the platform. If a transducer is found defective, medical engineering staff are notified to arrange repair or replacement.
Results or Findings: By October 2025, a total of 187 transducer defects had been identified by medical physicists or local radiographers/sonographers. Crystal damage was confirmed in 53 transducers through phantom measurements. Of these, 20 transducers were repaired and 33 were replaced — one with an existing unused probe, seven under warranty claims, and 25 through new purchases. Electrical safety assessments detected excess leakage current in three transducers, while one was found to have a short circuit. Faulty connectors and beamformers accounted for eight defects. Following repairs, five transducers exhibited recurring issues, prompting compensation claims. Additionally, one repaired transducer demonstrated reduced penetration depth in phantom testing and was subsequently replaced.
Conclusion: Our technical quality control program effectively detects transducer defects. Significant cost savings can be achieved by utilizing warranty claims for replacement and opting to transducer repairs rather than acquiring new transducers. However, our recent findings emphasize importance of QC for repaired transducers as they may present recurrent or novel issues, potentially invalidating financial benefits.
Limitations: No limitations were identified.
Funding for this study: No external funding.

ST 8 - What's new with the ESR Journals

Categories: Professional Issues, Research, Cardiac, Abdominal Viscera, Education

Date: March 4, 2026 | 16:30 - 17:00 CET

This session introduces two new Editors-in-Chief of the newly launched ESR journals - Valerie Vilgrain (European Radiology Abdomen) and Hatem Alkadhi (European Radiology Cardiovascular and Thoracic) - and catches up with the Editor-in-Chief Paola Clauser (Insights into Imaging) after her first year of editorship. The two new Editors will introduce their journals, share their plans and expectations for the future, and explain what submissions they would like to see in their respective journals. Paola Clauser will give us an update on her first year of editorship and say what she has in plan for the future of Insights into Imaging.

Moderators:

Mélisande Rouger; Bilbao / Spain

Conny Lee; Vienna / Austria

Interview (30 min)

TC 627 - Prostate cancer: developments on quality control and artificial intelligence

Categories: Oncologic Imaging, Genitourinary, Artificial Intelligence

ETC Level: LEVEL II+III

Date: March 4, 2026 | 16:30 - 17:30 CET

CME Credits: 1

The session discusses the importance of quality control and assurance measures in maintaining the accuracy and reliability of prostate MRI within diagnostic centres, including the role of radiologists and frontline staff in ensuring adherence to best practices. It reviews the criteria, standards, and procedures required for prostate cancer MRI centre designation, and outlines the framework with key learnings from the ACR Prostate MRI Quality Improvement Collaborative. The attendees will learn about developments in artificial intelligence (AI) for prostate cancer imaging and detection, and applications of AI methods to increase efficiency and improve accuracy.

Moderators:

Andrei Saraiva Purysko; Cleveland / United States

Patrick Asbach; Berlin / Germany

ST 9 - Daily Wrap-up

Categories: General Radiology
Date: March 4, 2026 | 17:00 - 17:15 CET
Join our studio moderators as they look back on the day's highlights and offer a glimpse of what's still to come at ECR 2026.

Moderators:
Mélisande Rouger; Bilbao / Spain
Conny Lee; Vienna / Austria

Interview (15 min)

OC - LIGHT

Categories: President's Choice

Date: March 4, 2026 | 17:45 - 19:00 CET

Join us for the highlight of ECR 2026 as Congress President Prof. Minerva Becker invites attendees to reflect on the Rays of Knowledge that guide radiology. Putting education in focus, LIGHT will celebrate the contributions of distinguished radiologists and explore how the next generation of radiologists are reshaping medical imaging. With beautiful music, incredible visuals and an atmosphere like no other, LIGHT will guide attendees on a journey through time and space.

Programme (75 min)

Opening Music
 Neue Wiener Stimmen Choir & Vienna Art Orchestra

Opening Speech by
ESR President Minerva Becker

Speech by
EFRS President Patrizia Cornacchione

Interlude Performance by
 Angela Gheorghiu

Short Film
 Why We Love Radiology: The Point of View of the Young Generation

ESR Gold Medal
 Regina Beets-Tan

Interlude Performance by

Interview (15 min)

BS 7a - How to write a clear and effective radiology report in musculoskeletal traumatic lesions

Categories: Imaging Methods

ETC Level: LEVEL I+II

Date: March 5, 2026 | 08:00 - 09:00 CET

CME Credits: 1

The aim of this session is to write a clear and effective radiology report on musculoskeletal traumatic lesions. The report should concisely describe imaging findings, highlight key injuries, and provide a structured impression to guide clinical management.

Moderator:

Vid Matišić; Zagreb / Croatia

Chairperson's introduction (5 min)

Vid Matišić; Zagreb / Croatia

Reporting on shoulder traumatic lesions (15 min)

Mitja Rupreht; Maribor / Slovenia

Reporting on knee traumatic lesions (15 min)

Andrea Alcala-Galiano Rubio; Madrid / Spain

Reporting on ankle traumatic lesions (15 min)

Diana Afonso; Lisbon / Portugal

Case-based discussion (10 min)

Miraude Adriaensen; Heerlen / Netherlands

CTiR 7 - Clinical Trials in Radiology: Spotlight

Categories: Breast, Vascular, Cardiac, Artificial Intelligence
Date: March 5, 2026 | 08:00 - 09:30 CET
CME Credits: 1.5

Moderators:
Ferdia Aidan Gallagher; Cambridge / United Kingdom
Bernd Hamm; Berlin / Germany

Chairpersons' introduction (6 min)
Ferdia Aidan Gallagher; Cambridge / United Kingdom
Bernd Hamm; Berlin / Germany

Artificial intelligence-based coronary computed tomography angiography quantification of atherosclerosis burden: comparison with intravascular ultrasound in the INVICTUS registry (13 min)
Rine Nakanishi; Tokyo / Japan

Discussant (8 min)
Yiğit Can Kartal; Istanbul / Turkey

Development of coronary artery disease in patients with initially normal coronary arteries in the SCOT-HEART trial (13 min)
Michelle Claire Williams; Edinburgh / United Kingdom

Discussant (8 min)
Marc Dewey; Cambridge / United Kingdom

Association of high-risk CT coronary artery plaque features with major adverse cardiovascular events: a prespecified secondary analysis of the DISCHARGE trial (13 min)
Bálint Szilveszter; Budapest / Hungary

Discussant (8 min)
Costanza Lisi; Milan / Italy

Finding the optimal recall rate in breast cancer screening: results from the ROCS study (13 min)
Danielle Van Der Waal; Nijmegen / Netherlands

Francesco Sardanelli; Milan / Italy

ESR Education 7 - Implementing Entrustable Professional Activities (EPAs) in residency training: challenges and opportunities

Categories: Professional Issues, Education
ETC Level: LEVEL I+II
Date: March 5, 2026 | 08:00 - 09:30 CET
CME Credits: 1.5

Moderator:
Annemiek Snoeckx; Zandhoven / Belgium

Chairperson's introduction (5 min)
Annemiek Snoeckx; Zandhoven / Belgium

Understanding EPAs: purpose, implementation, impact (15 min)
Laura Oleaga Zufiria; Barcelona / Spain

1. To emphasise the importance of feedback in the evaluation of residents.
2. To outline what EPAs are and their integration within the radiology education.

National level integration of EPAs (15 min)
Jussi Hirvonen; Turku / Finland

1. To describe the process of developing EPAs tailored to radiology.
2. To share experiences from the development of national EPAs.
3. To identify key components in developing EPAs.

Applying EPAs in everyday clinical practice (15 min)
Thomas Frauenfelder; Zürich / Switzerland

1. To offer insights into the practical aspects of integrating EPAs into radiology training.
2. To explore challenges and obstacles encountered while integrating EPAs.
3. To showcase the use of an app for evaluating EPAs in daily practice.

The resident's experience (15 min)
Anna Landsmann; Glattpark (Opfikon) / Switzerland

1. To underline the value of feedback for residents.
2. To provide personal reflections on how EPAs influence radiology training.

Panel discussion: What will the future bring? (25 min)

EU 7 - CT lung cancer screening vs individual health assessment: examples and first experiences in Europe

Categories: Chest, EuroSafe Imaging/Radiation Protection, Management/Leadership, Medico-legal
ETC Level: LEVEL III
Date: March 5, 2026 | 08:00 - 09:30 CET
CME Credits: 1.5

Moderator:
Ferid Shannoun; Geneva / Switzerland

Chairperson's introduction (5 min)
Ferid Shannoun; Geneva / Switzerland

Overview of WHO CT-IHA framework for good governance document (20 min)
Steve Ebdon-Jackson; Reading / United Kingdom

1. To learn the contents of the WHO CT-IHA framework document.
2. To appreciate the range of aspects associated with CT-IHA.
3. To understand the issues surrounding the introduction of CT-IHA into a healthcare system.

Case study, CT-for lung cancer screening in Croatia: experience from the ongoing programme (15 min)
Maja Hrabak Paar; Zagreb / Croatia

1. To describe the organisational concept of the ongoing lung cancer screening programme in Croatia.
2. To learn management strategies for patients with positive screening results, as well as follow-up intervals based on LDCT findings.
3. To show the first results of the lung cancer screening programme in Croatia.

Differences and similarities of population screening and IHA (15 min)
Mathias Prokop; Nijmegen / Netherlands

1. To learn about the potential benefits and risks for participants in IHA.
2. To understand the societal costs of IHA.
3. To appreciate which downstream management problems are caused by searching for incidental findings.

Situation in Europe (15 min)
Eva Godske Friberg; Oesteraas / Norway

1. To learn about the current legislative requirements and governance frameworks for CT examinations of asymptomatic individuals in Europe, including an overview of which CT-based screening programs and Individual Health Assessments (IHA) are performed today — recognizing that some practices are justified while others may not be, and highlighting changes in practice and regulation over the past decade since the implementation of the BSSD.
2. To appreciate the diversity of national practices and initiatives, with a focus on possible measures such as awareness campaigns, regulatory actions, and other strategies aimed at reducing unjustified CT-IHA and addressing inappropriate or illegal advertising.
3. To understand why a robust framework for good governance and regulatory activity is essential to improve justification of CT examinations for asymptomatic individuals, and to consider the ethical implications of preventive imaging in healthcare.

Discussion
All speakers and (20 min)

E³ 721 - PI-RADS after 12-year application

Categories: Imaging Methods, Oncologic Imaging, Genitourinary, President's Choice
ETC Level: LEVEL II+III
Date: March 5, 2026 | 08:00 - 09:30 CET
CME Credits: 1.5

Prostate imaging: reporting and data system (PI-RADS): consolidated concepts and the need for update (45 min)
Valeria Panebianco; Rome / Italy

1. To review the most important concepts using PI-RADS scores.

Prostate imaging: quality (PI-QUAL): what have we learnt so far? (45 min)
Francesco Giganti; London / United Kingdom

1. To assess the potential help of quality scores.

IF 7 - AI in radiology communication: expressionism or dadaism?

Categories: General Radiology, Professional Issues, Management/Leadership, Imaging Informatics, Artificial Intelligence, President's Choice

ETC Level: ALL LEVELS

Date: March 5, 2026 | 08:00 - 09:30 CET

CME Credits: 1.5

For centuries, radiologists have composed the radiology report from their subjective assessment of a patient's image data. While many argue that some literary freedoms should be kept and radiologists should be allowed to express themselves through their texts, others argue that a more formal and structured approach should be used. This session explores how AI could help to mediate and build bridges between these opposing views and what the current status is regarding AI in radiology communication.

Moderator:

Jacob Johannes Visser; Rotterdam / Netherlands

Chairperson's introduction (5 min)

Jacob Johannes Visser; Rotterdam / Netherlands

From speech to text: how AI supports reporting (20 min)

Charles Edward Kahn; Philadelphia / United States

From text to understanding: how AI makes reports understandable (20 min)

Lisa C. Adams; Munich / Germany

From understanding to emotion: how AI assists in patient communication (20 min)

Judy Birch; Poole / United Kingdom

Panel discussion: Will AI add additional value to radiological reports? (25 min)

MD 7 - The knee, meniscal root and ramp lesions: new developments in imaging and treatment - recommendations for clinical practice and directions for the future

Categories: Musculoskeletal, General Radiology, Imaging Methods, Research, Multidisciplinary, President's Choice
ETC Level: ALL LEVELS
Date: March 5, 2026 | 08:00 - 09:00 CET
CME Credits: 1

Moderator:
Anagha P. Parkar; Bergen / Norway

Chairperson's introduction (2 min)
Anagha P. Parkar; Bergen / Norway

1. To highlight new developments in the treatment of the knee, meniscal root and ramp lesions.
2. To critically review recent developments in imaging and put this in perspective with the treatment developments.
3. To provide recommendations for clinical practice and directions for the future.

Meniscal root lesions: the orthopaedic surgeon's perspective (6 min)
Søren Vindfeld; Bergen / Norway

Ramp lesions: the orthopaedic surgeon's perspective (6 min)
Line Lindanger; Bergen / Norway

Imaging meniscal root and ramp lesions: the radiologist's perspective (6 min)
Anagha P. Parkar; Bergen / Norway

Expert panel discussion (40 min)

MR 7 - Going towards high and low fields: maintaining MR

Categories: Management/Leadership, Evidence-Based Imaging, Education
ETC Level: LEVEL II
Date: March 5, 2026 | 08:00 - 09:30 CET
CME Credits: 1.5

Moderators:
Simonetta Gerevini; Cremona / Italy
Peter Lundberg; Linköping / Sweden

Chairpersons' introduction (5 min)
Simonetta Gerevini; Cremona / Italy
Peter Lundberg; Linköping / Sweden

What are the benefits of high- and ultrahigh-field MRI: 1.5T vs 3T and beyond (20 min)
Pia C Maly Sundgren; Malmö / Sweden

1. To learn about important guidelines for MR safety.
2. To identify safety risks associated with MR examinations.
3. To understand the necessary roles to maintain MR safety for patients and staff.

Lower MR fields: safety benefits, technical trade-offs, and biomedical impact (20 min)
Beatrice Lena; Leiden / Netherlands

1. To understand how low-field MRI can improve patient safety in emergency and resource-limited settings, especially for patients with implants or unstable conditions.
2. To explore the reduced infrastructural and operational risks associated with low-field and portable MRI systems.
3. To appreciate how protocol adaptation at lower field strengths can mitigate limitations in image quality while maintaining diagnostic confidence.

How to manage patients with cardiac implanted electronic devices in MRI: the basics (20 min)
Giles Hannibal Roditi; Glasgow / United Kingdom

1. To learn what cardiac electronic implanted devices (CIEDs) are and the relevant safety concerns regarding MRI scanning.
2. To appreciate how to minimise risk and maximise benefit when planning MRI scans in patients with CIEDs.
3. To understand the importance of teamwork across disciplines, both within radiology and with allied professionals, when performing MRI in patients with CIEDs.

Managing exposure to physical agents: patient and staff safety issues (15 min)
Luisa Altabella; Verona / Italy

1. To learn about the different types of physical agents (static magnetic fields, gradient fields, and radiofrequency energy) involved in MRI environments, and how their impact varies across different magnetic field strengths.
2. To appreciate the health and safety implications for both patients and staff when exposed to these agents, recognising the importance of risk assessment, monitoring, and regulatory compliance.
3. To understand the strategies and best practices used to manage and minimise exposure.

Panel discussion: Will low- and high-field MRI scanners change radiology? (10 min)

MS 7 - Headache: from symptom to diagnosis

Categories: Emergency Imaging, Neuro, Head and Neck, President's Choice
ETC Level: LEVEL II+III
Date: March 5, 2026 | 08:00 - 09:30 CET
CME Credits: 1.5

Moderator:
Sven Haller; Geneva / Switzerland

Chairperson's introduction (5 min)
Sven Haller; Geneva / Switzerland

Headache from the perspective of a neurologist: when and why neuroimaging? (20 min)
Peter Myers; Geneva / Switzerland

1. To review common and uncommon causes of headache.
2. To understand the most common clinical issues.
3. To understand when and why neuroimaging should be performed.

Neuroimaging in headache part I: headache forms with imaging abnormalities (20 min)
Joseph Cornelis Johannes Bot; Amsterdam / Netherlands

1. To discuss indications for imaging: CT or MRI? With or without contrast?
2. To review imaging findings in intracranial hypertension.
3. To review imaging findings in intracranial hypotension.
4. To discuss various other cerebral imaging findings associated with headaches.

Neuroimaging in headache part II: findings outside the brain associated with headache (20 min)
Sven Haller; Geneva / Switzerland

1. To review imaging findings of neurovascular compression syndromes, notably trigeminal neuralgia.
2. To review imaging findings of the temporomandibular joint and nasal cavities that may cause headaches.
3. To discuss imaging findings of the cervical spine that may cause headaches.

Case-based panel discussion (25 min)

RPS 701 - Quantitative imaging and biomarkers

Categories: Imaging Methods, Oncologic Imaging, Physics in Medical Imaging, Evidence-Based Imaging, Abdominal Viscera, Artificial Intelligence

Ekaterina Khristenko; Frankfurt am Main / Germany

Imaging Biomarkers for Prognostication in Primary Sclerosing Cholangitis: A Radiomics Approach (6 min)

Cesare Maino; Lissone Monza / Italy

Author Block: C. Maino, P. N. Franco, C. R. G. L. O. M. Talei Franzesi, E. De Bernardi, L. Cristoferi, D. Ippolito; Monza/IT
Purpose: Risk assessment in primary sclerosing cholangitis (PSC) by magnetic resonance imaging (MRI) relies on semi-quantitative analysis, which can result in interpretation variability. Radiomics may offer a quantitative approach for risk stratification. This study aims to explore and validate MRI-derived radiomic features to identify high-risk PSC patients.
Methods or Background: In this prospective study (January 2019–December 2022), consecutive PSC patients undergoing routine gadoxetate disodium-enhanced MRI were recruited. Using PyRadiomics, whole liver parenchyma features were extracted from five MRI sequences according to the Image Biomarker Standardisation Initiative (IBSI). Patients were categorised into risk groups based on the Mayo risk score (MRS) and liver stiffness measurement (LSM). Features associated with high-risk patients were selected and validated in an independent cohort. A survival analysis was conducted in the combined cohort to assess the prognostic value of the radiomic features for clinical events.
Results or Findings: One hundred and two PSC patients were enrolled in this study. Five radiomics features were associated with high risk in the training cohort. In the validation setting, GLRLM-Run Entropy in the fat-saturation T2 weighted imaging (FS-T2W) sequence was the only significant feature, with an odds ratio of 3.90 (CI 1.46–10.42, p = 0.007) for MRS and 2.97 (CI 1.33–6.66, p = 0.008) for LSM. Its prognostic potential on clinical outcome was confirmed by Cox regression analysis in the combined cohort (hazard ratio per 0.1 increase = 1.480, CI 1.226–1.786), showing excellent predictive performance (C-index = 0.857).
Conclusion: GLRLM-Run Entropy in FS-T2W is a novel radiomics-based biomarker for risk stratification in PSC patients. It is quantitative, standardised, easy to compute and cost-free, positioning it as a potential key innovation in PSC radiology-based biomarkers
Limitations: Retrospective
Single institution

Multicenter Study: Predictive Value of a Habitat Imaging Radiomics Model for Neural Invasion in Extrahepatic Cholangiocarcinoma (6 min)

Yunqing Yin; Shenzhen / China

Author Block: Y. Yin; Luzhou/CN
Purpose: This study aims to propose a habitat imaging-based radiomics model for predicting neural invasion in extrahepatic cholangiocarcinoma (EHCC).
Methods or Background: This retrospective study included 322 EHCC patients, all confirmed by surgical pathology, from 8 different centers. The training and internal validation sets consisted of 163 and 41 patients from Center A, respectively, while the external test set included 218 patients from other centers. Preoperative MRI with multiple sequences was used for habitat imaging, and the K-means unsupervised clustering method was employed to determine the optimal subdivision of tumor subregions. Based on the habitat features of each tumor subregion, a tumor internal heterogeneity habitat model was established, along with traditional radiomics models for the tumor core, tumor periphery, and a combined model incorporating both tumor internal habitat features and peritumoral radiomics features. Finally, the diagnostic performance of each model was evaluated using the DeLong test.
Results or Findings: The results showed that the combined model, integrating tumor internal habitat features and peritumoral 4mm radiomics features, demonstrated the best diagnostic performance. Specifically, the AUC of the training set was 0.911 (95% CI: 0.867-0.956), the AUC of the internal validation set was 0.854 (95% CI: 0.793-0.915), and the AUC of the external test set was 0.842 (95% CI: 0.780-0.905).
Conclusion: The habitat imaging-based radiomics model proposed in this study effectively predicts neural invasion in extrahepatic cholangiocarcinoma, demonstrating high diagnostic performance.
Limitations: This study has several limitations. First, the sample size was relatively small, which may limit the robustness and generalizability of the findings. Larger, multi-center cohorts will be required to further validate the proposed model. Second, the tumor regions of interest (ROIs) were manually delineated, which inevitably introduces a degree of subjectivity.
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study strictly adhered to the ethical standards set forth in the Declaration of Helsinki and received approval from the Medical Ethics Committee of Affiliated Hospital of Southwest Medical University (Approval No.: SYL-202261-13). Written informed consent was obtained from all participants.

Stability of Hepatic Radiomics Features Across Monoenergetic Reconstructions Using Portal Venous Phase as Benchmark (6 min)

Lyudmila Sannikova; Moscow / Russia

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: L. Sannikova, S. Gusarova, I. Gruzdev, N. Karelskaya, V. Shirokov, V. Aznaurov, A. Ustalov, S. A. Shmeleva, E. V. Kondratyev; Moscow/RU
Purpose: To investigate how reproducible liver radiomics features are when derived from monoenergetic (MonoE) CT reconstructions, using portal venous phase imaging as the reference standard with a consistent 3D-ROI approach.
Methods or Background: The study included 64 abdominal CT examinations. A spherical VOI was positioned within a homogeneous segment of liver parenchyma devoid of vessels. This VOI, initially delineated in the portal venous phase, was automatically propagated across MonoE reconstructions (40, 55, 70, and 200 keV). Radiomic features were extracted and normalized via z-score transformation. Reproducibility was quantified using concordance correlation coefficient, intra-class correlation coefficient, and paired statistical tests with FDR adjustment.
Results or Findings: Reconstructions at 40 and 55 keV showed the closest alignment with portal imaging, yielding CCC values above 0.90 for most features, with ~45% qualifying as reproducible. The 70 keV level demonstrated intermediate reproducibility, especially limited for texture-based features, with only ~30% classified as reproducible. The 200 keV reconstructions performed poorly, with a high proportion of features below CCC 0.70, and evidence of systematic bias. Across all reconstructions, shape and first-order features remained the most robust. Similarity analyses and PCA revealed clustering of portal with MonoE40 and MonoE55, while MonoE200 consistently diverged from other groups.
Conclusion: Virtual monoenergetic reconstructions at 40 and 55 keV demonstrate the highest reproducibility of hepatic radiomics features and can be regarded as reliable surrogates for portal venous phase imaging. Importantly, these findings indicate that spectral CT data can be integrated alongside conventional radiomics models. Substantial energy shifts (e.g., high-keV reconstructions) generate significant alterations in feature behavior. Such investigations may not only refine technical reproducibility but also reveal hidden imaging phenotypes or disease-specific characteristics that remain undetectable at standard energy levels.
Limitations: CT-scanner from only one vendor (Philips) was used.
Funding for this study: Nothing to disclosure
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was approved by the local ethics committee of the A. V. Vishnevsky National Medical Research Center of Surgery.

Multiphase CT delta-radiomics features for prognostic assessment and tumor heterogeneity analysis in hepatocellular carcinoma treated with TACE, and genetic correlation study (6 min)

Zhongqi Sun; Harbin / China

Author Block: H. Jiang[1], Z. Sun[1], Z. Xu[2]; [1]Harbin/CN, [2]Beijing/CN
Purpose: Transarterial chemoembolization (TACE) is a widely used locoregional therapy for intermediate-stage hepatocellular carcinoma (HCC). However, substantial inter-patient heterogeneity exists in treatment response. This study aims to develop a delta radiomic model based on pre-treatment contrast-enhanced CT (CECT) to predict prognosis and reveal tumor heterogeneity in HCC patients undergoing TACE.
Methods or Background: This retrospective study included HCC patients from four datasets. Data from patients treated with TACE at two medical centers were used to construct the radiomics score. Radiological features of the tumor area were extracted from multiple phases of CECT before treatment. Progression-free survival (PFS) was predicted using the minimum absolute shrinkage and selection operator COX (Lasso-Cox) regression algorithm. Overall survival (OS) and PFS were evaluated using Kaplan-Meier curves.
Results or Findings: The cohort comprised 292 HCC patients (mean age: 57.3 years, 68% male) treated with TACE from January 2016 to June 2020. Patients were divided into four cohorts: a training set (n=126), an internal test set (n=84), and an external test set (n=59). The 2-year AUCs of the delta radiomic model for predicting PFS in TACE-treated patients were 0.812, 0.720, and 0.807 in the training, internal test, and external test cohorts, respectively. The Rad-score, calculated from radiomic features selected via Lasso, stratified patients into high-risk and low-risk groups, with significant differences in overall survival observed across all cohorts.
Conclusion: Delta radiomics based on multiphase enhanced CT effectively predicts prognosis and tumor heterogeneity in HCC patients treated with TACE, providing valuable insights for treatment planning.
Limitations: This study is retrospective, which may introduce selection bias and data heterogeneity.
Funding for this study: No
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was approved by the Medical Ethics Committee of the Second Affiliated Hospital of Harbin Medical University (Approval No. YJSKY2024-069). Informed consent was obtained from all participants, and the study was conducted in accordance with the principles of the Declaration of Helsinki. Patient data were anonymized to ensure privacy and confidentiality throughout the research process.

CT Radiomics for Preoperative Prediction of Vessels Encapsulating Tumor Clusters in Hepatocellular Carcinoma (6 min)

Lulu Jia; Lanzhou / China

Author Block: L. Jia, J. Lei; Lanzhou/CN
Purpose: Vessels encapsulating tumor clusters (VETC) represent a distinct histologic vascular pattern strongly associated with metastatic spread in hepatocellular carcinoma (HCC). This study aimed to develop and validate a CT-based radiomics model for the preoperative prediction of VETC positivity using a dual-center design.
Methods or Background: In this retrospective study, we included patients with pathologically confirmed HCC who underwent contrast-enhanced CT between January 2019 and January 2023. The training cohort consisted of 142 patients from Center 1, and an independent external validation cohort included 61 patients from Center 2. Radiomic features were extracted from arterial and portal venous phase images. A radiomic signature was developed using a K-nearest neighbor classifier and compared to clinical-only and combined clinical-radiomic models. Performance was assessed using AUC, calibration curves, and decision curve analysis (DCA).
Results or Findings: The radiomics model significantly outperformed the clinical model, with an AUC of 0.894 (95% CI: 0.863–0.916) in the training set and 0.85 (95% CI: 0.78–0.92) in the external validation set. There was no significant difference between the radiomics and combined clinical-radiomics models (AUC: 0.922 vs. 0.894; p = 0.182). DCA demonstrated robust clinical utility of the radiomics model.
Conclusion: The proposed CT radiomics model noninvasively predicts VETC pattern in HCC with strong generalizability across institutions. This tool shows promise for identifying aggressive HCC subtypes preoperatively, potentially supporting personalized treatment strategies.
Limitations: None
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective study was approved by the Institutional Review Board (LDYYLL-2024-398)

CT-Based Hepatic Vascular Biomarkers for Preoperative Prediction of 2-Year Recurrence-Free Survival in Hepatocellular Carcinoma (6 min)

JIN CUI; Jiangmen City / China

Author Block: J. CUI, Y. Lei, C. Ma, Y. Xie, Z. Luo; Jiangmen Central Hospital/CN
Purpose: To develop and validate a machine learning (ML) model using preoperative CT-derived hepatic vascular features for predicting 2-year recurrence-free survival (RFS) in hepatocellular carcinoma (HCC) patients after hepatectomy.
Methods or Background: This multicenter retrospective study enrolled 361 patients from two centers, allocated into training (n=181), internal validation (n=120), and external test (n=60) cohorts. From preoperative arterial phase and portal venous phase CT, we extracted 3D vascular features including volumes of the hepatic artery, portal vein, and hepatic vein, their vessel-to-liver volume ratios, and 3D fractal dimension as a measure of vascular complexity. We built three ML models to predict 2-year recurrence risk: a vascular model, a clinical model, and an integrated model combining both. Model performance was evaluated using the area under the receiver operating characteristic curve (AUC). Kaplan-Meier and log-rank tests assessed RFS differences between model-stratified risk groups.
Results or Findings: The integrated model demonstrated superior predictive performance for 2-year RFS, achieving the highest AUC values of 0.8057 in the internal validation set and 0.7736 in the external test set. It significantly outperformed the vascular model (AUCs: 0.7572 and 0.6900) and the clinical model (AUCs: 0.5848 and 0.6146). Furthermore, patients stratified as high-risk by the integrated model exhibited significantly worse actual RFS outcomes than those in the low-risk group (all $P < 0.05$).
Conclusion: Our study validates that the combined ML model, integrating 3D vascular features and clinical factors, serves as an effective non-invasive tool for predicting the risk of recurrence within 2 years after hepatectomy in HCC patients. Its superior performance over single-source models underscores the synergistic value of vascular complexity for improved prognostic stratification.
Limitations: This study is limited by its retrospective nature and requires larger, prospective, multi-center cohorts for further validation to ensure generalizability.
Funding for this study: No funding was received for this study
Has your study been approved by an ethics committee? Not applicable

Pharmacokinetic modeling of MRI-based liver function for risk assessment in primary sclerosing cholangitis: a prospective pilot study (6 min)

Wolf Claus Bartholomä; Linköping / Sweden

Author Block: W. C. Bartholomä, S. Cai, C. Simonsson, M. Karlsson, S. Kechagias, M. Woisetschlager, N. Dahlström, P. Lundberg; Linköping/SE
Purpose: Primary sclerosing cholangitis (PSC) is a rare fibroinflammatory liver disease with a highly variable course, ranging from indolent to rapidly progressive cases leading to cirrhosis, liver failure, or hepatobiliary malignancies. Accurate identification of patients at risk for poor outcomes remains challenging. MRI-based approaches such as DiStrict, Anali, and relative enhancement show promise but are limited by operator dependency or static measurements. Pharmacokinetic modeling offers a dynamic, quantitative alternative for risk assessment in PSC.
Methods or Background: A prospective cohort of 26 PSC patients underwent up to four annual MRI exams with a total clinical follow-up of 7.5 years. Clinical endpoints included liver transplantation, decompensated cirrhosis, and cholangiocarcinoma. The pharmacokinetic model's performance was compared to MELD, the Amsterdam-Oxford Model (AOM), Relative Liver Enhancement (RE) and the Anali Score. Correlation and ROC analyses with laboratory values and established risk scores were performed. A segmental approach was also explored.
Results or Findings: The pharmacokinetic model (Globalki) showed significant correlations with MELD ($r = -0.429$, $p = 0.029$), AOM ($r = -0.557$, $p = 0.003$), and endpoint events ($r = -0.605$, $p = 0.001$). ROC analysis indicated that Globalki (AUC 0.943) outperformed the Anali Scores (AUC 0.800 – 0.829) in identifying patients at risk for an endpoint event and was comparable to MELD (AUC 0.857) and AOM (AUC 0.900). The model showed no significant correlation with laboratory values, suggesting its potential as an independent biomarker.
Conclusion: The pharmacokinetic model based on hepatobiliary contrast uptake in MRI provides relevant independent prognostic information in PSC, comparable to established models such as AOM or MELD.
Limitations: Small sample size and limited number of endpoint events. Mayo Risk score could not be calculated for the patient cohort as a complement to the Amsterdam-Oxford Model.

Portal-to-Hepatic Vein Transit Time in Autoimmune Liver Diseases: A Pilot Study of CEUS Utility and Correlation with Histology (6 min)

Andrzej Fedak; Kraków / Poland

Author Block: A. Fedak[1], T. J. Popiela[2], M. Zwolińska-Wcisło[2], K. Mirowski[2], J. Jamroś[2]; [1]Kraków/PL, [2]Krakow/PL
Purpose: Background: Contrast-enhanced ultrasound (CEUS) is widely used for focal liver lesions, but its role in autoimmune liver diseases (AILD: autoimmune hepatitis [AIH], primary biliary cholangitis [PBC], and overlap) is unclear. Core biopsy is the gold standard but invasive. Non-invasive tools, including shear-wave elastography (SWE) and biochemical indices (e.g., FIB-4), are increasingly applied yet may not fully reflect microvascular changes. In AILD, lobular pathology alters resistance and promotes shunts. CEUS, by measuring portal-to-hepatic vein transit time (PV/HV TT), may capture these alterations.
Methods or Background: Methods: We prospectively studied 25 patients (22–66 years, 68% female) with histologically confirmed AIH (n=19), PBC (n=4), or overlap (n=2). All underwent core liver biopsy as the reference standard. Exclusion criteria were decompensated cirrhosis and coagulopathy. Patients undergoing CEUS for unrelated indications served as controls. The protocol included laboratory testing, FIB-4, Doppler ultrasound, SWE (Metavir), and CEUS with parametric imaging. Correlations with histology were analyzed using Spearman's rank.
Results or Findings: Results: Advanced fibrosis by FIB-4 was found in 48% of patients; SWE indicated significant fibrosis (Metavir ≥F3) in 62%. A threshold of PV/HV TT <3.5 s emerged as the most accurate discriminator of lobular injury, yielding 92% sensitivity versus 72% for laboratory tests (p=0.18). In controls, mean PV/HV TT was 7.8 s. No patient showed concordant negativity across CEUS and laboratory testing. PV/HV TT negatively correlated with FIB-4 (ρ=–0.42, p=0.035). All imaging and laboratory indices correlated significantly with biopsy.
Conclusion: Conclusion: This pilot study shows that CEUS sensitively detects microvascular alterations in AILD and complements SWE and biochemical indices. With further validation, CEUS may reduce reliance on biopsy and improve patient monitoring
Limitations: As a pilot investigation the limitation of the study is small amount of participants.

Volumetric body composition analysis outperforms L3-derived metrics for survival prediction in cholangiocarcinoma (6 min)

Leon David Grünewald; Frankfurt / Germany

Author Block: J. Gotta, L. D. Grünewald, V. Koch, S. Mahmoudi, T. Vogl; Frankfurt/DE
Purpose: Single-slice analysis at the third lumbar vertebra (L3) is widely used in oncologic imaging to assess body composition. However, three-dimensional volumetric analysis may better reflect tissue distribution. This study compared the prognostic performance of volumetric and L3-derived body composition metrics in patients with cholangiocarcinoma.
Methods or Background: In this retrospective study, 147 patients with histologically confirmed intrahepatic (n = 65), perihilar (n = 46), or distal (n = 36) cholangiocarcinoma (47 women, 100 men; median age 67.0 years, IQR 58.0–73.0) underwent native-phase CT. Body composition was analysed using nnU-Net-based segmentation with manual quality control. Volumetric parameters included muscle percentage, myosteatosis percentage, visceral adipose tissue (VAT) percentage, and total adipose tissue (TAT) percentage. L3-derived metrics comprised skeletal muscle area (SMA_L3), muscle radiation attenuation (SMRA_L3), intramuscular fat (IMAT_L3), VAT_L3, and VAT HU_L3. Prognostic value was assessed using Kaplan–Meier and Cox proportional hazards models.
Results or Findings: Volumetric muscle percentage and myosteatosis percentage were the strongest survival predictors (log-rank = 17.43 and 17.67; HR = 0.93 and 1.06; both $p < 0.001$), followed by VAT and TAT percentages (log-rank = 12.26 and 8.20; both p = 0.01). These volumetric metrics showed strong statistical significance and clear survival stratification. Among L3-derived metrics, IMAT_L3 (HR = 1.09; p = 0.002), SMRA_L3 (HR = 0.97; p =0.005), VAT HU_L3 (HR = 0.98; p =0.004), and SMA_L3 (HR = 0.99; p = 0.02) were associated with survival but with lower log-rank values and less consistent group separation. VAT_L3 and SAT_L3 were not significant.
Conclusion: Volumetric CT-derived body composition metrics showed stronger and more consistent associations with survival than corresponding L3-based measures. Despite representing similar compartments, volumetric analysis may better capture the heterogeneity and extent of tissue distribution, improving prognostic accuracy in cholangiocarcinoma.
Limitations: Retrospective Study
Funding for this study: No funding was received for this study.

Noninvasive liver biomechanical mapping identifies a pre-fibrotic niche and early conditions favoring HCC development (6 min)

Ralph Sinkus; Paris / France

Author Block: V. Koch[1], L. D. Grünewald[1], J. Gotta[1], S. Mahmoudi[1], R. Hammerstingl[1], K. Eichler[1], O. Darwish[2], T. Vogl[1], R. Sinkus[2]; [1]Frankfurt/DE, [2]Paris/FR
Purpose: The rise in metabolic syndrome is driving diffuse liver disease and HCC, often without advanced fibrosis. Identifying at-risk individuals in the pre-fibrotic stage is challenging. This study developed and validated a 3D MRE–based biomechanical imaging framework for early liver disease detection and characterization of HCC-related alterations in non-fibrotic livers.
Methods or Background: In this prospective study, 3D MRE was consecutively performed in 193 participants (mean age, 56 years; 83 women) with suspected or confirmed liver disease, including 73 biopsy-confirmed cases (38%) and 26 HCCs (14%). 20 healthy volunteers served as controls. The complex shear modulus was decomposed into classical stiffness (|G*|), shear wave attenuation (α), and phase angle (Y), yielding a two-dimensional "biomechanical fingerprint" of liver tissue. Biomechanical parameters were correlated with histopathology, blood biomarkers, and clinical characteristics.
Results or Findings: We identified three biomechanical regions: healthy tissue, a pre-fibrotic niche with inflammation but near-normal stiffness, and fibrotic/cirrhotic tissue. In the pre-fibrotic niche, α was markedly reduced despite preserved stiffness, accompanied by decreased E-cadherin and early α-smooth muscle actin upregulation. An α threshold $<50\,m^{-1}$ was linked to higher HCC risk, even without fibrosis, and the biomechanical continuum mirrored gradual changes in clinical and molecular biomarkers (FIB-4, ASAT, PDFF, platelet count).
Conclusion: Our findings show that 3D MRE allows organ-specific, noninvasive mapping of liver disease and identifies a biomechanical state permissive to HCC before fibrosis. This approach extends elastography beyond fibrosis staging and enables early, individualized HCC risk stratification.
Limitations: This study has limitations, including predominance of fatty liver disease, reliance on biopsy with inherent variability, reduced biopsy numbers due to MRI eligibility, and its observational, hypothesis-generating design. Technical constraints (single frequency, single vendor, research transducer) and reliance on presumed F0 in most healthy volunteers may limit reproducibility.
Funding for this study: This work was supported by the German Doktor Robert Pfleger Foundation, the Wilhelm Vaillant Foundation, the French Integrated Cancer Research Center "SiRIC InsiTu" (INCa-DGOS-INSERM-ITMO Cancer_18008), and the French National Research Agency RHU Operandi (ANR-21-RHUS-0012).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The institutional ethics review board approved this prospective, cross-sectional, single-center study that complies with the Declaration of Helsinki.

Application of multi-echo T2* mapping combined with FLIS in preoperative liver function assessment of small HCC: comparative analysis with dual source CT extracellular volume fraction (6 min)

Shao-Peng Peng Li; Hefei / China

Author Block: S-P. P. Li, D. Yin, Y. Liu, W. Wei, L. Liu; Hefei/CN
Purpose: Using ICG R-15 as the reference standard, the diagnostic value of functional liver imaging score(FLIS) combined with T2* mapping for preoperative assessment of liver reserve function in sHCC was compared, and compared with the extracellular volume fraction(ECV) based on dual source CT.
Methods or Background: A retrospective analysis was conducted on 72 patients with sHCC who had preoperative imaging findings. All patients underwent Gd-EOB-DTPA-enhanced MRI and dua- source CT liver dynamic enhancement scan. Measure the R2 * values of normal liver tissue using multi echo T2 * mapping sequences. FLIS and ECV were calculated. ECV(%)=IDliver×(1-Hct (%))/IDaorta. All patients underwent ICG test and were divided into three groups (32 patients in group 1 <10%, 25 patients in group 2 10%-20% and 15 patients in group 3 ≥20%). Statistical analysis was conducted on the differences between three groups.
Results or Findings: The R2* values, FLIS, and ECV among the three groups were (39.73 ± 2.59) Hz, (45.78 ± 2.51) Hz, (57.45 ± 4.96) Hz; (4.75 ± 1.11), (3.56 ± 0.92), (1.53 ± 0.91); and (16.63 ± 5.42)%, (28.42 ± 2.88)%, (40.39 ± 4.74)%, respectively. The AUC for R2* values, FLIS, and ECV between Group 1 and Group 2 was 0.8916, 0.809, and 0.924, respectively, and between Group 2 and Group 3 was 0.891, 0.864, and 0.923. ECV demonstrated the strongest diagnostic performance, followed by R2* values and FLIS. The combination of these parameters improved diagnostic efficacy (AUC: 0.921, 0.955).
Conclusion: FLIS and R2* values can assess preoperative hepatic functional reserve in patients with sHCC. Their combined diagnostic efficacy is superior to that of ECV. The multi-echo T2* mapping offers shorter scan times, and its combination with FLIS effectively predicts hepatic functional reserve.
Limitations: Unable to obtain pathological gold standard

Feasibility of Photon-counting Detector CT-derived Extracellular Volume in Liver Fibrosis Evaluation: A Head-to-head Correlation with MRE (6 min)

Lin Huimin; Shanghai / China

Author Block: L. Huimin, X. Wu, Z. Xu, F. Yan; Shanghai/CN
Purpose: Dual-energy CT-derived hepatic extracellular volume (ECV) has shown promise in liver fibrosis quantification but is limited by the higher radiation dose of dual-energy acquisitions and the need for specific scan protocols. Photon-counting detector CT (PCCT), representing a new generation of multienergy CT, offers intrinsic spectral images and improved dose efficiency. This study aimed to investigate the feasibility of photon-counting CT-based ECV for liver fibrosis evaluation, using MR elastography (MRE) as the reference standard.
Methods or Background: Between June 2024 and July 2025, 53 participants were prospectively recruited to undergo multiphase abdominal PCCT and MRE. Delayed-phase PCCT images were acquired after the portal venous phase for ECV quantification. Correlation between ECV and MRE-derived liver stiffness measurements (LSMs) was assessed in a head-to-head comparison, and stratification performance for different fibrosis stages was evaluated with receiver operating characteristic curve analysis.
Results or Findings: According to established MRE thresholds (3.50 kPa, 4.30 kPa, 6.50 kPa) for liver fibrosis staging, 11 participants had F1, 12 had F2, 20 had F3, and 10 had cirrhosis. ECV correlated strongly with LSM (Spearman ρ = 0.903 [95% CI: 0.834, 0.944], P < .0001). For fibrosis stratification, ECV demonstrated excellent diagnostic performance for ≥ F2, ≥ F3, and F4, with areas under the receiver operating characteristic curve of 0.96 (0.91-1.00), 0.93 (0.86-0.99), and 0.97 (0.94-1.00), respectively. The corresponding cutoff values were 23.35%, 24.15%, and 27.28%.
Conclusion: These findings demonstrated excellent correlation between ECV and LSM, supporting PCCT-derived ECV as a feasible alternative for noninvasive liver fibrosis quantification.
Limitations: This study was limited by its relatively small sample size from a single center, which may restrict the generalizability of the findings. Larger multicenter studies are warranted to validate the performance of PCCT-derived ECV in liver fibrosis evaluation.
Funding for this study: No funding was provided for this study.

One-stop dual-energy perfusion CT for early treatment response and survival prediction: intra-individual validation against perfusion CT in a VX2 liver tumor model (6 min)

Ping Hou; Zhengzhou / China

Author Block: P. Hou; Zhengzhou/CN
Purpose: To investigate whether a one-stop dual-energy perfusion CT (DE-PCT) protocol, enabling simultaneous acquisition of perfusion and spectral iodine parameters, can serve as a streamlined alternative to sequential DECT and PCT acquisitions for early prediction of treatment response and overall survival (OS) in a rabbit VX2 liver tumors model treated .
Methods or Background: Fifty-eight rabbits with VX2 liver tumors underwent a DE-PCT protocol enabling simultaneous extraction of PCT parameters and normalized iodine concentration (nIC). Imaging was performed at baseline and on days 2, 4, 7, 10, and 14 after treatment. Parameters included blood flow (BF), blood volume (BV), mean transit time (MTT), permeability surface area product (PS), hepatic arterial fraction (HAF), mean slope of increase (MSI), positive enhancement integral (PEI), and nIC in arterial and portal venous phases. Imaging findings were compared among high-dose (n=16), low-dose (n=24), and control (n=18) groups, and between responders and non-responders. Prognostic value was assessed using ROC analysis, Cox regression, and Kaplan–Meier survival analysis. Histopathological correlations were evaluated.
Results or Findings: Significant imaging changes were mainly in the high-dose group. Treatment reduced most PCT parameters (prominent at days 2/10) and nIC (arterial: days 2/7; portal: days 4/10). Early reductions in BF, PEI, nIC (days 2/4), and PS (day 4) predicted response (p<0.05). Combined PCT (AUC 0.77/0.73) and nIC (AUC 0.86/0.83) at days 2/4 showed comparable predictive performance. Longer OS correlated with higher baseline MTT (>12.75 s, HR 0.71) and greater reduction in arterial nIC at day 2 (<-0.020, HR 0.65; p<0.05). Imaging markers correlated with histopathology.
Conclusion: The one-stop DE-PCT protocol enables simultaneous extraction of perfusion and spectral biomarkers within a single scan. Early reductions in DECT-derived nIC predicted treatment response and OS with performance comparable to PCT.
Limitations: Not applicable.
Funding for this study: No funding was received for this study.

CMR-derived haemodynamic forces predict adverse LV remodelling after STEMI: a multicentre cohort study (6 min)
Shen Gui; Wuhan / China

Author Block: M. Hu[1], X. Yue[1], J. Qi[1], Y. Chen[2], T. Li[3], K. He[1], S. Gui[4]; [1]BeiJing/CN, [2]Shanghai/CN, [3]Beijing/CN, [4]Wuhan/CN
Purpose: To determine whether early cardiac MRI–derived haemodynamic force (HDF) parameters predict adverse left-ventricular remodelling (ALVR) after primary PCI for STEMI, and to assess their incremental prognostic value beyond conventional markers.
Methods or Background: In this retrospective multicentre cohort, 147 STEMI patients (92 internal, 55 external) underwent CMR within 14 days post-PCI and at 5 months. HDFs were computed non-invasively from cine sequences (Medis). ALVR was defined as a ≥15% increase in LV end-systolic volume. Group differences were analysed and multivariable logistic regression identified independent predictors. Incremental value of systolic HDF metrics over traditional predictors was assessed using likelihood-ratio tests, net reclassification improvement (NRI) and integrated discrimination improvement (IDI).
Results or Findings: Independent predictors of ALVR were peak troponin-T (OR 1.079, 95% CI 1.004–1.160; p=0.038), infarct percentage (OR 1.139, 95% CI 1.039–1.249; p=0.026), systolic lateral HDF RMS (OR 0.370, 95% CI 0.138–0.991; p=0.048) and systolic HDF impulse (OR 0.661, 95% CI 0.462–0.946; p=0.024). Adding systolic HDF parameters significantly improved model performance across base models, AUC increased from 0.704 to 0.778 in the derivation cohort and from 0.655 to 0.807 in the validation cohort (NRI 0.714 and 1.012; IDI 0.122 and 0.284; likelihood-ratio p=0.007 and 0.009), indicating meaningful reclassification over conventional predictors.
Conclusion: Systolic HDF metrics—particularly lateral HDF RMS and impulse—are independent predictors of ALVR after STEMI and provide incremental prognostic value beyond established markers, supporting their use for post-infarction risk stratification and clinical decision-making.
Limitations: The retrospective nature of the study introduces a potential for selection bias. Therefore, larger prospective studies are needed to validate HDF prediction models and their therapeutic guidance.
Funding for this study: This work was supported in part by the National Key R&D Program of China under Grant 2024YFF0505704.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective multicentre study complied with the Declaration of Helsinki; institutional approvals/consent waivers were obtained where required.

Hemodynamic force derived from cardiac MRI reveal subclinical left ventricular dysfunction in patients with acute myocarditis (6 min)
Yangzhen Hou; Changsha / China

Author Block: Y. Hou, H. Zhou, L. Weihua; Changsha/CN
Purpose: To investigate the potential role of left ventricular (LV) hemodynamic force (HDF) for detecting cardiac dysfunction in acute myocarditis patients.
Methods or Background: We retrospectively enrolled 173 consecutive acute myocarditis patients without heart failure (non-HF) along with 64 age- and sex-matched healthy controls. HDF parameters were calculated (I) as the root mean square during systole [HDF(Sys)] and diastole [HDF(Dia)]; (II) as the mean forces during distinct phases—systolic thrust [HDF(A)], systole-diastole transition [HDF(B)], diastolic deceleration [HDF(C)], and late diastolic filling [HDF(D)]. Additionally, LV global longitudinal strain (GLS), global circumferential strain (GCS) and global radial strain (GRS) were measured using a CMR feature tracking technique.
Results or Findings: Compared with controls, non-HF patients exhibited impaired diastolic HDF parameters, including reduced HDF(Dia) (13.27±5.07 vs 16.00±6.40，p=0.007), decreased mean force in phase B [HDF(B)] (11.09±3.75 vs 12.92±4.51，p=0.026), phase C [HDF(C)] (12.61±5.94 vs 16.07±6.82, p=0.001), and elevated mean force in phase D [HDF(D)] (2.82±2.19 vs 1.25±1.60, p<0.001); while systolic HDF parameters, including HDF(Sys) (24.19±4.57 vs 24.25±5.43, p=0.314) and HDF(A) (22.15±4.93 vs 23.02±6.18, p=0.885) showed no statistically significant variations. There was also no significant difference in LV ejection fraction (EF) or strain between healthy controls and non-HF patients (p =0.099 for LVEF, p = 0.934 for GLS, p = 0.608 for GCS, and p = 0.155 for GRS).
Conclusion: In contrast to healthy controls, non-HF acute myocarditis patients already showed early LV HDF parameters impairment, while maintaining normal LVEF and strain measurements.
Limitations: This study is a retrospective study with potential selection bias.
Funding for this study: This study was supported by the National Natural Science Foundation of China (82071984, 82071894, and 91959117)，the Science and Technology Innovation Program of Hunan Province (2020RC4007), and The Scientific Research Program of FuRong Laboratory 2024PT5110.

High temporal resolution MR phase contrast imaging for evaluation of the isovolumic relaxation time (6 min)

Clemens Reiter; Graz / Austria

Author Block: C. Reiter, G. Reiter, A. Schmidt, E. Kolesnik, D. Scherr, M. Fuchsjäger, U. Reiter; Graz/AT
Purpose: To evaluate the utility of a high temporal resolution 2D phase-contrast (PC) MRI sequence for the assessment of the isovolumic relaxation time (IVRT) - a key parameter in evaluation of left ventricular diastolic dysfunction - compared to a standard 2D PC sequence using echocardiography as reference.
Methods or Background: Twenty-five healthy subjects (13 females; age 60 ± 9 years) were prospectively recruited for cardiac MRI at 3T and echocardiography. Echocardiographic evaluation of the IVRT (IVRT-Echo) was performed according to current guidelines. A retrospective ECG-gated high temporal resolution cine in-plane 2D PC measurement (measured temporal resolution = 18 ms interpolated to 70 frames per cardiac cycle) was acquired in the 3-chamber view under free breathing. The IVRT was evaluated as interval between the end of aortic flow and onset of transmitral inflow from this measurement (IVRT-highTR). To study the impact of temporal resolution, the IVRT was also evaluated from a standard transmitral 2D PC measurement (measured temporal resolution = 45 ms interpolated to 30 frames per cardiac cycle; IVRT-standard). Results were analyzed using paired t-tests and correlation analysis.
Results or Findings: Cardiac intervals did not differ between modalities and measurements (899 ± 127 ms, 880 ± 127 ms and 889 ± 123 ms for echocardiography, IVRT-highTR and IVRT-standard, respectively; p, 0.267-0.674). Echocardiographic IVRT (79 ± 16 ms) showed no significant bias compared to neither IVRT-highTR (77 ± 15 ms, p = 0.054) nor IVRT-standard (75 ± 17 ms, p = 0.101). A stronger correlation was observed between IVRT-highTR (0.944, p<0.001) and echocardiography than IVRT-standard (0.745, p<0.001).
Conclusion: High temporal resolution 2D PC MRI allows precise assessment of the IVRT compared to echocardiography as reference, outperforming a standard temporal resolution transmitral 2D flow measurement.
Limitations: Small sample size.

The role of myocardial strain assessment using cardiac magnetic resonance imaging in patients with non-compacted left ventricular myocardium: determination of subclinical contractility disorders (6 min)

Daria Filatova; Moscow / Russia

Author Block: D. Filatova, E. Mershina, E. Gagarina, R. Myasnikov, O. Kulikova, A. Meshkov, A. Kiseleva, V. E. Sinitsyn; Moscow/RU
Purpose: Non-compaction of left ventricular myocardium (NCLVM) is a morphological variant characterized by myocardial two-layer structure. Patients often develop contractile dysfunction, leading to heart failure. However, increased trabeculation is observed in other diseases, such as dilated cardiomyopathy (DCM), making diagnosis challenging when LV ejection fraction (LVEF) is preserved and LV dilation is minimal.
The study purpose: to determine the role of myocardial strain, assessed by cardiac magnetic resonance imaging (CMR), in identifying subclinical contractile dysfunction in patients with NCLVM and preserved LVEF.
Methods or Background: Study enrolled patients with genetically confirmed NCLVM and preserved LVEF, patients with DCM, and individuals without cardiovascular disease (control group). All participants underwent CMR with intravenous contrast administration. Myocardial strain analysis was performed using cvi42 software.
Results or Findings: The study included 112 participants: 16 patients with NCLVM and preserved LVEF (mean age 37.8±13.8 years;9 men), 51 control subjects with no pathological findings on CMR (37.7±13 years;31 men), and 45 patients with DCM (45.6±14.8 years;29 men).
Significant reduction in global and segmental strain was observed in DCM. Patients with NCLVM demonstrated reduced global strain, decreased longitudinal and circumferential strain (LS, CS) in mid and apical segments (10,12-14 and 6,7,10-12,14, respectively). Radial strain (RS) was reduced in most segments (1,4-16) compared to control group ($p<0.05$).
ROC analysis revealed that global LS, RS and CS provided the optimal AUC values for differentiating NCLVM from DCM. The optimal AUC values were obtained for global LS, RS and CS, as well as for LS in segment 15, RS in segment 5, and CS in segment 9.
Conclusion: Myocardial strain assessment is valuable diagnostic tool for detecting contractile dysfunction in patients with NCLVM and preserved LVEF. It is more sensitive to functional impairment than LVEF measurement alone.
Limitations: N/A

Genotype–Phenotype and Imaging Correlations in Pediatric Cardiomyopathies (6 min)

Berk Tütüncüoğlu; Istanbul / Turkey

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: B. Tütüncüoğlu, F. Alpaslan, M. F. Kazanbaş, E. İsmailov, T. Y. Kılıç, T. Banaz, F. Köse, M. Kadıoğlu, S. Ozkök; Istanbul/TR
Purpose: To investigate genotype–phenotype relationships and cardiac magnetic resonance (CMR) correlates in pediatric patients with cardiomyopathy, focusing on fibrosis and ventricular dysfunction.
Methods or Background: This retrospective cohort included 32 pediatric patients diagnosed with cardiomyopathy and followed at our center. Clinical data, genetic testing and CMR results were analyzed. Patients were classified as dilated cardiomyopathy (DCM), hypertrophic cardiomyopathy (HCM) or other subtypes including restrictive and noncompaction. Genetic testing was performed in 25 patients, identifying pathogenic variants. Imaging evaluation emphasized late gadolinium enhancement (LGE) as a marker of myocardial fibrosis and ventricular functional parameters.
Results or Findings: The cohort comprised 15 patients with DCM (46.9%), 13 with HCM (40.6%) and 4 with other subtypes (12.5%). Pathogenic variants were detected in 14 of 25 tested patients (56%). In HCM, genotype-positive patients demonstrated greater wall thickness (mean 19.5 mm vs. 17 mm) and a higher fibrosis prevalence. LGE was present in 87.5% of genotype-positive versus 20% of genotype-negative cases. In DCM, TTN splice variants were predominant genetic etiology, consistent with their known familial role. All DCM patients with LGE exhibited severely reduced systolic function (LVEF <30%), underscoring the combined prognostic impact of fibrosis and contractile impairment. Notably, in HCM, hypertrophy severity did not directly correlate with fibrosis burden, highlighting the limitation of wall thickness alone as a risk marker.
Conclusion: Integration of genetic and imaging data provides a comprehensive framework for assessing pediatric cardiomyopathies. Pathogenic variants were associated with more severe phenotypes and higher fibrosis prevalence, as quantified by CMR. Fibrosis in HCM represents an independent risk marker beyond hypertrophy, while in DCM, scar formation consistently paralleled advanced dysfunction. Combined genetic testing and CMR enhance risk stratification and guide personalized management in this vulnerable population.
Limitations: Small sample size and retrospective design

Association between Fine Particulate Air Pollution Exposure and Subclinical Myocardial Fibrosis in Structurally Normal Hearts: a CMR-based study (6 min)

Elena Locatelli; Milan / Italy

Author Block: E. Locatelli, S. Figliozzi, F. Catapano, A. Laghi, M. Francone; Milan/IT
Purpose: To investigate the potential association between long-term exposure to airborne particulate matter (PM2.5 and PM10) and early cardiac changes with cardiac magnetic resonance (CMR) mapping in individuals with structurally normal hearts, to elucidate the link between air pollution and myocardial remodeling.
Methods or Background: The impact of air pollution on early myocardial remodeling in individuals without overt cardiovascular disease remains incompletely understood. CMR mapping provides sensitive markers of myocardial fibrosis and inflammation that may reveal subclinical injury.
We retrospectively studied 231 patients undergoing CMR with structurally normal hearts, preserved function, and no LGE. PM2.5 and PM10 exposure was derived from the nearest European Environment Agency monitoring stations. CMR parameters included left ventricular end-diastolic volume indexed, left ventricular ejection fraction, native T1, and T2 mapping. Associations with pollutant exposure were tested with multivariable linear and logistic regression adjusted for demographic, clinical, and socioeconomic factors.
Results or Findings: Higher PM2.5 exposure was associated with higher native T1 values ($p = 0.020$); no associations were found with other CMR parameters or with PM10 exposure. Patients with high PM2.5 exposure had significantly higher T1 compared with those with low exposure. PM2.5 was associated with pathological T1, with male sex and diabetes being other independent associates.
Conclusion: In individuals with structurally normal hearts, chronic PM2.5 exposure was independently associated with higher native T1 values and pathological T1, suggesting early diffuse myocardial fibrosis.
Limitations: Its retrospective, single-center design and relatively small sample size; secondly, exposure assessment was based on residential proximity to air quality monitoring stations, which may not represent individual variability in exposure; finally, the association with PM2.5 was statistically significant but the absolute effect size was modest and most T1 values remained within the normal range.

Prognostic Implications of CMR-Derived Infarct Burden for Therapeutic Strategies in Chronic Multivessel Coronary Artery Disease (6 min)

Zhaoxin Tian; Beijing / China

Author Block: Z. Tian[1], T. Liu[2], M. Lu[1]; [1]Beijing/CN, [2]Shenyang/CN
Purpose: This study aimed to assess whether the extent of late gadolinium enhancement (LGE), quantified as myocardial infarction percentage (MI%), influences long-term outcomes under different therapeutic strategies in patients with chronic multivessel coronary artery disease (MVD) without prior revascularization.
Methods or Background: A multicenter retrospective cohort of 715 patients with chronic MVD who underwent contrast-enhanced cardiac magnetic resonance was analyzed. Patients were stratified according to LGE-derived MI% and subsequently grouped by therapeutic management with optimal medical therapy (OMT), percutaneous coronary intervention (PCI), or coronary artery bypass grafting (CABG). The primary endpoint was cardiac death. Secondary endpoints were all-cause mortality and major adverse cardiac and cerebrovascular events (MACCE). Kaplan–Meier and multivariable Cox regression analyses were performed to evaluate associations between treatment strategies, infarct burden, and outcomes.
Results or Findings: During a median follow-up of 6.7 years, patients with higher MI% exhibited significantly increased risks of cardiac death, all-cause mortality, and MACCE. Within this subgroup, both PCI and CABG were associated with lower event rates compared with OMT ($P < 0.001$ for all). Moreover, PCI was associated with a more favorable prognosis than CABG, reflected by lower rates of cardiac death and MACCE. In patients with lower MI%, no significant differences in outcomes were observed across treatment strategies.
Conclusion: In patients with chronic MVD without prior revascularization, CMR-derived infarct burden identifies a high-risk population in whom revascularization, particularly PCI, provides superior long-term survival compared with medical therapy or CABG. These findings emphasize the importance of integrating myocardial tissue characterization into contemporary Heart Team decision-making to refine therapeutic selection.
Limitations: This study is limited by its retrospective design and the possibility of residual confounding despite multivariable adjustment.
Funding for this study: This study was supported by National Natural Science Foundation of China (grant number 82471973); Beijing Natural Science Foundation (grant number 7242110); National High Level Hospital Clinical Research Funding (grant number 2022-GSP-QZ-5).

Microstructural Assessment of Ejection fraction-preserved Hypertrophic Cardiomyopathy Using Second-Order Motion-Compensated Spin Echo Diffusion Tensor Cardiovascular Magnetic Resonance Imaging (6 min)

Nan Zhang; Shanghai / China

Author Block: N. Zhang, X. Yue; Shanghai/CN
Purpose: To investigate myocardial microstructural alterations in ejection fraction-preserved hypertrophic cardiomyopathy (HCM) using second-order motion-compensated spin echo cardiac diffusion tensor imaging (M2-cDTI), and to determine whether cDTI can reveal abnormalities beyond conventional markers of hypertrophy and fibrosis.
Methods or Background: Forty-one patients with HCM and 22 healthy volunteers underwent 1.5T CMR including cine, late gadolinium enhancement (LGE), and M2-cDTI. Mean diffusivity (MD), fractional anisotropy (FA), and secondary eigenvector angle (E2A) were quantified.
Results or Findings: The segments from HCM patients were categorized into three groups: LGE-positive segments (n = 176), LGE gray-zone segments (n = 161), and LGE-negative segments (n = 89). The LGE-negative segments and LGE-positive segments showed significantly elevated myocardial E2A and FA values (mean, E2A: 43.64° ± 7.23 vs. 39.54° ± 6.47; FA: 0.55 ± 0.07 vs. 0.53 ± 0.06; $P < 0.001$ and $P = 0.0002$, respectively), while MD was significantly reduced (mean, MD: 1.54 × 10−3 mm2/sec ± 0.29 vs. 1.56 × 10−3 mm2/sec ± 0.31; $P < 0.001$). More notably, the LGE-negative segments also exhibited a slight reduction in MD, along with significantly increased FA and E2A values (mean, MD: 1.52 × 10−3 mm2/sec ±0.28 vs. 1.56 ± 0.31; E2A: 42.80° ± 5.64 vs. 39.54° ± 6.47; FA: 0.55 ± 0.06 vs. 0.53 ± 0.06; $P < 0.001$, $P < 0.0009$ and $P = 0.0037$).
Conclusion: In vivo M2-cDTI enables detecting myocardial disarray and altered microstructural organization in HCM, even in regions without hypertrophy or fibrosis. These findings highlight the potential of cDTI as a sensitive biomarker for early tissue characterization in HCM.
Limitations: The relatively small sample size—a common constraint in in vivo cDTI investigations—reflects the current technical challenges in mitigating cardiac motion artifacts and processing cDTI data.

A CMR-Guided Stepwise Approach to Diagnose Arrhythmogenic Cardiomyopathy with Left Ventricular Involvement: Insights from Explanted Hearts (6 min)

Huaying Zhang; Peking / China

Author Block: H. Zhang, M. Lu; Peking/CN
Purpose: This study aimed to analyze the clinical and imaging features of end-stage arrhythmogenic cardiomyopathy (ACM) with left ventricular (LV) involvement, and distinguish it from dilated cardiomyopathy (DCM).
Methods or Background: We retrospectively studied heart transplantation (HTx) recipients with pathology-confirmed ACM (n=29) or DCM (n=36). All patients underwent comprehensive clinical, imaging and pathological evaluation. Cardiac magnetic resonance (CMR) protocols included cine, late gadolinium enhancement (LGE), and T1 mapping sequences. Explanted hearts received gross and histologic evaluations.
Results or Findings: The ACM cohort had earlier symptom onset (30.5 years) and longer diagnostic delay (27.8 months vs. DCM 0.1 months, p=0.006). The misdiagnosis rate of ACM before HTx was 27.6%, predominantly misclassified as DCM. Qualitative and quantitative CMR analyses revealed distinct differences between ACM and DCM in morphological, functional, and tissue-specific parameters. Specifically, ACM patients exhibited more frequent right ventricular (RV) motion abnormalities, greater RV dilation (185.8 mL/m² vs. 101.4 mL/m², p<0.001) and larger LV-LGE extent (31.3% ± 12.4% vs. 18.8% ± 14.5%, p<0.001). These hallmark variables were selected to construct a three-step diagnostic model, which achieved an exceptional performance for ACM diagnosis (area under the curve 0.98, sensitivity 100%). Pathologic analysis confirmed severe RV fibrofatty replacement in ACM.
Conclusion: A CMR-guided stepwise model combining qualitative, quantitative, and tissue characterization parameters effectively differentiates ACM with LV involvement from DCM, offering high diagnostic accuracy and sensitivity. This approach addresses diagnostic challenges in end-stage heart failure, enabling precise diagnosis in transplant candidates and optimizing treatment strategies.
Limitations: The retrospective nature of data and specimen collection precluded genotype-phenotype and precise radiological-pathological correlation analysis.

Right Atrial Strain as a Novel Marker for High-Risk Phenotypes in Dilated Cardiomyopathy: Insights from a Multicenter Prospective Cohort (6 min)

Thomas Geyer; Munich / Germany

Author Block: T. Geyer, P. Franke, R. Lorbeer, B. J. Wintersperger; Munich/DE
Purpose: Right atrial (RA) dysfunction is an important prognostic factor in heart failure, but its significance in dilated cardiomyopathy (DCM) is often overlooked. Although CMR-derived RA strain has become a sensitive indicator of right heart impairment, its connection with common DCM comorbidities remains unclear. We aimed to explore the relationship between RA strain and major cardiovascular comorbidities to improve risk assessment in DCM.
Methods or Background: Datasets of 162 patients with non-ischemic DCM, all undergoing standardized 1.5T/3T CMR from the prospective German Centre for Cardiovascular Research (DZHK) nationwide multicenter databank, were analyzed. RA and right ventricular (RV) strain—reservoir (RS), longitudinal (LS), and circumferential (CS)—were quantified using feature tracking (cvi42, Circle CVI). Multivariable linear regression models, adjusted for age and sex, examined associations between strain parameters and predefined cardiovascular comorbidities, including heart failure, valvular disease, and atrial fibrillation (AF).
Results or Findings: Lower RA-RS was a consistent and significant finding in patients with comorbidities that increase right heart load. Specifically, RA-RS was independently associated with heart failure (β=−14.96%; 95% CI: −25.42 to −4.49), valvular disease (β=−13.68%; 95% CI: −24.65 to −2.72), AF (β=−10.16%; 95% CI: −18.95 to −1.38), and combined valvular disease + AF (β=−11.38%; 95% CI: −19.36 to −3.39), all $p<0.05$. Associations between RV strain and comorbidities were less consistent. Notably, RV-RS was unexpectedly higher in coronary artery disease (CAD), a finding that warrants further study (β=6.14%; 95% CI: 0.35 to 11.93; $p<0.05$).
Conclusion: In this large, prospectively phenotyped DCM cohort, RA reservoir strain is a robust, non-invasive CMR marker consistently reduced in patients with comorbidities that impose additional right heart load. These findings support RA strain as a useful parameter for identifying higher-risk patients with DCM.
Limitations: Limitations include the cross-sectional design and lack of outcome data.
Funding for this study: None.

Impact of Physical Inactivity on Subclinical Left Ventricular Function: A Population-Based CMR Strain Analysis (6 min)

Thomas Geyer; Munich / Germany

Author Block: P. Franke, T. Geyer, B. J. Wintersperger, R. Lorbeer; Munich/DE
Purpose: The association of physical inactivity with subclinical alteration of cardiac structure and function is not wellcharacterized. We investigated the impact of physical inactivity on left ventricular (LV) strain assessed byfeature-tracking cardiac MRI in a population-based cohort free of overt cardiovascular disease (CVD).
Methods or Background: We analyzed 360 participants (156 women; 39–73 years) from the MRI sub-study of the community-basedKORA (Cooperative Health Research in the Region of Augsburg) cohort. Physical activity was assessed atbaseline (Exam 1), 7-year follow-up (Exam 2), and 14-year follow-up (Exam 3). CMR with cine imagingand feature-tracking strain analysis was performed at Exam 3. Global longitudinal, circumferential, andradial strain were quantified. Associations of current and past inactivity with strain values were evaluatedin cross-sectional and longitudinal models adjusted for demographics and risk factors.
Results or Findings: Current physical inactivity (Exam 3) was associated with reduced longitudinal strain (β=-1.09%; 95%CI-2.02; -0.15; p=0.023), radial strain (β=-2.64%; 95%CI -4.79; -0.49; p=0.016) and circumferential strain(β=-0.90%; 95%CI -1.60; -0.20; p=0.012). Physical inactivity at baseline (Exam 1) also predicted lowerstrain values at Exam 3. Repeated reports of inactivity across two or more examinations were associatedwith progressively lower radial (β −2.09%; 95%CI −3.71 to −0.47; p=0.012) and circumferential strain (β−0.69%; 95%CI −1.22 to −0.16; p=0.011). Associations were more pronounced in men than in women.
Conclusion: Current and long-term physical inactivity were linked to impaired LV strain in asymptomatic adults withoutcardiovascular disease, with more pronounced effects in men. CMR strain thus provides sensitive markersof subclinical LV dysfunction associated with lifestyle factors.
Limitations: Limitations include MRI data acquisition only at one time point in a subsample, questionnaire-based assessment of physical activity, and restriction to a European ancestry cohort.
Funding for this study: None.

Ethics committee - additional information: The study was approved by the ethics committee of the Bavarian Chamber of Physicians, Munich (Exam 1: EC No. 99186 and 05004, Exams 2 and 3: EC No. 06068). The MRI examination protocol was approved by the ethics committee of the Ludwig Maximilian University Hospital, Munich.

CMR-Derived Mechanics parameters and Tissue Characterization: Prognostic Role in Hypertrophic Cardiomyopathy (6 min)

Francesca Carusi; Notaresco / Italy

Author Block: F. Carusi, V. Vespucci, S. Ciambellini, P. Palumbo, E. Di Cesare; L'Aquila/IT
Purpose: The aim of the study is to investigate the prognostic relevance of CMR-derived ventricular and atrial strain and strain rate, and tissue composition via late gadolinium enhancement (LGE), in patients with HCM.
Methods or Background: This retrospective observational study included 56 patients. Functional assessment included bi-atrial and bi-ventricular volumetric indices, along with myocardial strain and strain rate analysis (global longitudinal [GLS], circumferential [GCS], and radial strain [GRS], and peak early diastolic strain rate [PEDSR]). Also atrial reservoir, conduit and booster pump strain and SR were analyzed. Myocardial fibrosis was quantified using LGE. Clinical follow-up was conducted via clinical interviews. Binary logistic regression was used to identify predictors of adverse events.
Results or Findings: In univariate analysis, left ventricular ejection fraction (LVEF), right and left atrial volumes, extent of LGE, GLS, GCS, GRS, PEDSR and strain reservoir were all significantly associated with adverse clinical outcomes. However, in multivariate analysis, only PEDSR remained an independent predictor of adverse events ($p = 0.037$; OR < 0.001, 95% CI: 0.000–0.22). LVEF ($p = 0.08$) and %LGE ($p = 0.074$) demonstrated a trend toward statistical significance. Among different model including conventional functional marker (model I)(AUC = 0.82), %LGE (model II = model I + %LGE) (AUC = 0.83), strain value (model III = model II + all strain)(AUC = 0.84) and PEDSR (model IV = model III + PEDSR), best C-index was reached only whit PEDSR evaluation (AUC = 0.92).
Conclusion: In patients with HCM, CMR-derived parameters of ventricular mechanics and myocardial fibrosis provide significant prognostic value. Among them, impaired diastolic function, as indicated by reduced PEDSR, emerges as a strong and independent predictor of adverse clinical outcomes, underscoring the importance of advanced functional assessment for effective risk stratification.
Limitations: Small sample size.
Funding for this study: This research did not receive any specific grant from funding agencies in the public, commercial, or not-for-profit sectors.

Normal variations of myocardial T1, T2 and T2* values at 1.5 T cardiac MRI in sex-matched healthy volunteers (6 min)

Farah Cadour; Toronto / Canada

Author Block: F. Cadour[1], J. Caudron[2], A. Gillibert[3], S. Normant[3], J-N. Dacher[3]; [1]Toronto, ON/CA, [2]Le Havre/FR, [3]Rouen/FR
Purpose: The purpose of this study was to determine the normal variations of myocardial T1, T2, and T2* relaxation times on cardiac MRI obtained at 1.5 T in healthy, sex-balanced volunteers aged between 18 and 69 years.
Methods or Background: A total of 172 healthy volunteers were recruited prospectively. They were further divided into seven sex-balanced age groups (18–19 years, 20–24 years, 25–29 years, 30–39 years, 40–49 years, 50–59 years, and 60–69 years). T1, T2, and T2* mapping were acquired in a single short-axis slice at the mid-level of the left ventricle. Global T1, T2, and T2* values were the mean of all segments. Comparisons between females and males were performed in each age group using independent samples t-test or Wilcoxon rank sum test, as appropriate. Multivariable linear effects models were used to analyze the effect of heart rate, body mass index, left ventricular mass, age, and sex on T1, T2, and T2* values.
Results or Findings: There were 83 males and 89 females, with a mean age of 37.3 ± 15.6 years. Females had greater T1 values (980.9 ± 26.2 ms) compared to males (949.7 ± 18.3 ms) ($P < 0.001$). T1 values decreased with age ($P < 0.001$), with smaller sex-related differences in older participants. Male sex and age were independently associated with lower values of T1 mapping. Age in females was independently associated with lower T1, T2, and T2* values.
Conclusion: T1, T2, and T2* values are influenced by age and sex, emphasizing the need to read and calibrate MRI values with respect to patient characteristics to avoid misdiagnosis.
Limitations: The limitations of the study are T1 values evaluated only in mid-ventricle, absence of extreme age recruitment, absence of extracellular volume performance and single vendor evaluation.
Funding for this study: No funding was received for this study.

Interstitial lung abnormalities in oncologic patients with drug-induced pneumonitis: prevalence, radiological and clinical correlations (6 min)
Roschan Hélène Hayoz; Lausanne / Switzerland

Author Block: R. H. Hayoz, N. Mansouri, C. Bongard, L. Righi, M. Obeid, C. Dromain, D. C. Rotzinger, C. Pozzessere; Lausanne/CH
Purpose: Interstitial lung abnormalities (ILA) have been associated with increased all-cause mortality. In oncologic patients, the relationship between pre-existing ILA and drug-induced pneumonitis (DIP) remains poorly understood. This study aimed to assess the prevalence of pre-existing ILA in patients who developed DIP, investigate their influence on DIP severity and radiological pattern, and evaluate ILA progression after DIP.
Methods or Background: We retrospectively analyzed CTs of cancer patients with confirmed DIP between 2020 and 2025. Two blinded readers assessed the presence and type of ILA at baseline CT, DIP pattern at the time of pneumonitis, and ILA progression on subsequent scans (≥30days post-DIP). Categorical variables were reported as percentages. Statistical analysis included percentages for categorical variables, Cohen's Kappa for inter-reader ILA agreement, and Spearman's rank correlation for ILA-DIP severity association.
Results or Findings: ILA were identified in 21/88 patients (24%; 6 females; median age 70 years, range 59–82). The predominant ILA pattern was subpleural non-fibrotic (81%, n=17). Inter-reader agreement was substantial (κ=0.655). ILA was mentioned in only one baseline radiological report. Organizing pneumonia was the most frequent DIP pattern for both non-ILA and ILA subgroups (50% and 62%, respectively). Grade ≥2 pneumonitis was recorded in 44 (50%) non-ILA and in 12 (57%) ILA patients. A weak, non-significant, positive correlation emerged between ILA and DIP severity (rho=0.174, p=0.126). Following DIP, ILA progression was detected in 11 patients (52%).
Conclusion: ILA are relatively common in oncologic patients but remain substantially underreported. Although their correlation with DIP severity was weak and not statistically significant, ILA progression occurred in over half of cases post-DIP, suggesting a potential impact on long-term pulmonary outcomes and patient management.
Limitations: retrospective design, single-center, relatively small ILA sample size, mixed cancer types and oncologic treatments
Funding for this study: None

Detecting Interstitial Lung Disease and Identifying Extensive Disease in Systemic Sclerosis: Cut-Offs for CT Lung Texture Analysis (6 min)
Nicholas Landini; Rome / Italy

Author Block: N. Landini[1], L. Jungblut[2], C. Strappa[1], C. Blüthgen[2], A. R. Larici[1], M. Matucci-Cerinic[3], T. Frauenfelder[2], O. Distler[2], C. Bruni[2]; [1]Rome/IT, [2]Zürich/CH, [3]Milan/IT
Purpose: To identify and validate optimal thresholds of ILD extent quantified through Lung Texture Analysis (LTA) to detect the presence of ILD and extensive involvement in SSc patients.
Methods or Background: SSc patients visiting the Rheumatology Departments of University Hospital Zurich and the Careggi University Hospital Florence were identified for enrollment. Technically suitable images were analyzed through LTA™ (Imbio), quantifying the percentage of lung volume occupied by ILD. Two radiologists independently reviewed the CT scans to identify ILD and extensive disease, the latter defined as >20% of lung parenchyma involved, with disagreements resolved by consensus or third reviewer. Patients were randomly split 2:1 into derivation and validation cohorts. Receiver operating characteristic (ROC) curves with area under the curve (AUC) were computed to identify the optimal LTA ILD extent threshold for detecting ILD and extensive disease. Cox regression analysis was performed to determine the impact of ILD and extensive disease on mortality, adjusted for confounders.
Results or Findings: A total of 664 were eligible for the study. Visual analysis identified ILD in 313 (47%) cases, of whom 103 (33%) extensive ILD. In the derivation cohort (433 patients, 206 ILD, 38% extensive), ROC analysis identified the optimal ILD extent threshold for ILD detection at 1% (AUC 0.83), and at 7% for extensive ILD (AUC 0.84). In the validation cohort (231 patients, 104 ILD, 25% extensive), these thresholds achieved 78% sensitivity/71% specificity for ILD presence, and 81% sensitivity/70% specificity for extensive ILD. Over a median 5 years follow-up, 84 (13%) patients died. Both ILD presence and extensive ILD independently predicted mortality, with comparable results by visual and LTA™ assessments.
Conclusion: Our results lay the foundation for expanding the use of post-processing analysis in SSc-ILD towards automated diagnosis and stratification.
Limitations: Retrospective study.

Quantitative HRCT in Interstitial Lung Disease Secondary to Systemic Sclerosis: Evaluation of Disease Progression and Therapeutic Response (6 min)

Vincenzo Uggenti; Pisa / Italy

Author Block: V. Uggenti[1], M. Di Battista[1], A. Della Rossa[1], L. Tavanti[1], A. De Liperi[1], B. Bartholmai[2], M. Mosca[1], E. Neri[1], C. Romei[1]; [1]Pisa/IT, [2]Rochester, MN/US
Purpose: This study aimed to assess, using CALIPER-derived quantitative parameters, the longitudinal course of interstitial lung disease secondary to systemic sclerosis (SSc-ILD), a complex condition characterized by alternating inflammatory exacerbations and progressive fibrotic changes.
Methods or Background: 50 SSc-ILD patients were included in the study (36 females; 14 males), with a mean age at baseline HRCT of 57.1 ± 13.0 years and a mean disease duration of 60.9 ± 81.5 months. Among them, 43 (86%) were receiving immunosuppressive therapy, and 7 (14%) were receiving antifibrotic treatment. All patients underwent at least two follow-up HRCT scans. All HRCTs were processed using CALIPER, which performs lung texture analysis, providing percentages of honeycombing (HC), reticulations (RET), ground glass (GG), vascular-related structures (VRS), and normal lung. ILD% was defined as the sum of GG%, RET%, and HC%.
Results or Findings: Pulmonary arterial hypertension (PAH) was associated with higher ILD ($p=0.006$) and VRS ($p<0.001$) values.
Among patients receiving immunosuppressive therapy, RET+HC showed a progressive increase over time. Conversely, GG displayed a distinct trend: in patients with baseline GG% <20%, follow-up oscillations suggested higher responsiveness to treatment; in contrast, patients with extensive baseline involvement (>20%) exhibited a progressive increase in GG.
ILD% was an independent predictor of pulmonary function: higher ILD% was associated with reduced FVC ($\beta = -0.50$, $SE = 0.12$, $p<0.001$) and DLCO ($\beta = -0.77$, $SE = 0.11$, $p<0.001$).
Conclusion: Higher ILD% and VRS% scores correlate with PAH.
The subanalysis of individual interstitial alterations suggests that GG% oscillations reflect responsiveness to immunosuppressive therapy.
The inverse correlation between ILD% and both FVC and DLCO supports the prognostic value of quantitative parameters.
Quantitative HRCT may support tailored therapeutic management in SSc-ILD.
Limitations: Single-center, retrospective design, with potential selection bias.
Imbalanced treatment groups.
Heterogeneous follow-up.
Funding for this study: None.

Assessment of the Relationship Between CT-Derived Lung Metrics and Pulmonary Function Tests in Interstitial Lung Disease (6 min)

Ece Aylin Tan Kaynar; Ankara / Turkey

Author Block: E. Temel, B. S. Akhan, H. ERTURK, M. e. Sahin, E. A. Tan Kaynar; Ankara/TR
Purpose: Interstitial lung diseases (ILDs) are characterized by inflammation and fibrosis leading to impaired lung function. High-resolution computed tomography (HRCT) allows quantitative assessment of lung structure, while pulmonary function tests (PFTs) evaluate function. The relationship between these measures over time remains underexplored. This study aims to investigate correlations between changes in CT-derived lung volumetric and densitometric parameters and alterations in PFT results in ILD patients.
Methods or Background: This retrospective cohort study included 142 ILD patients who underwent HRCT and PFT at two distinct time points. Lung volume and density metrics—total lung volume (TLV), total lung density (TLD), fibrotic parenchymal volume (FPV), and fibrotic percentage—were quantified. Changes (Δ) were manually calculated and correlated with ΔFEV1, ΔFVC, and ΔFEV1/FVC ratio using Pearson's correlation.
Results or Findings: ΔTLV correlated positively with ΔFEV1 ($r = 0.192$, $p < 0.05$) and ΔFVC ($r = 0.228$, $p < 0.05$). ΔTLD correlated negatively with ΔFEV1 ($r = -0.249$, $p < 0.05$). Both ΔFPV and fibrotic percentage inversely correlated with ΔFEV1 ($r = -0.272$ and -0.330, respectively, $p < 0.05$) and ΔFVC ($r = -0.188$ and -0.293, respectively, $p < 0.05$). Subgroup analysis showed significant correlations mainly in nonspecific interstitial pneumonia (NSIP) patients.
Conclusion: Changes in CT-derived volumetric and densitometric lung metrics correlate with pulmonary function changes in ILD, especially NSIP, supporting combined imaging and functional assessment for disease monitoring.
Limitations: This study has several limitations. First, its retrospective design may introduce selection bias and limits control over confounding variables. Second, the sample size, although sufficient for overall analysis, may be insufficient to detect subtle differences within some ILD subtypes, especially less common ones.Lastly, the study was conducted at a single center, which may limit the generalizability of the findings to broader populations.
Funding for this study: No funding was received for this study
Has your study been approved by an ethics committee? Not applicable
Ethics committee - additional information: Ethical approval of the study was obtained from the Ankara Atatürk Sanatorium Training and Research Hospital Clinical Research Ethics Committee (2024-BCEK/278, date: 14.05.2025).

Dynamic concordance of subpleural regional volume in upper lung fields with global lung volume in chronic interstitial pneumonia: association with prognosis and upper lung subpleural irregular lines (6 min)

Yukihiro Nagatani; Kusatsu / Japan

Author Block: Y. Nagatani, H. Nakagawa, Y. Tsunoda, R. Uemura, K. Fukunaga, Y. Nakano, Y. Watanabe; Otsu/JP
Purpose: To investigate the relationship among dynamic concordance in upper lung subpleural normal-appearing lung parenchyma (SNAL) assessed on dynamic ventilation computed tomography (DVCT), the presence of subpleural irregular lines (SIL)reflecting pathological UIP pattern, clinical symptoms, and long-term prognosis in chronic interstitial pneumonia (IP).
Methods or Background: Fifty-four chronic IP patients underwent DVCT and pulmonary function tests (PFTs) in a single visit. Spherical volumes of interest (VOI) with a diameter of 10 mm were set at peak-inspiration in 8 subpleural SNAL, in ventral and dorsal mid sagittal plane. Automatic trucking functions obtained variable VOIs in 13-16 frame images (0.35 seconds/frame). Dynamic concordance of regional volume for SNAL with global lung volume (GLV) was assessed by cross-correlation coefficients in the volume (CCCv). The ratio of honeycomb volume to GLV (%HV) was measured on peak-inspiratory CT. In addition to the mean CCCv, PFT parameters and %HV were compared between survival and non-survival groups, between weak (modified MRC 0 or 1) and strong dyspnea groups (modified MRC 2 to 4), and between regions with SIL and those without using Mann-Whitney U test.
Results or Findings: CCCv for regions with SIL (0.61 ± 0.50), was lower compared with those without (0.83 ± 0.25)($p<0.0001$). No difference in CCCv was found between weak and strong dyspnea groups. The mean CCCv (0.66 ± 0.31) as well as %FVC, and % FEV1, in the non-survival group was lower than that in the survival group (0.81 ± 0.15)($p=0.009$). In addition, %HV in the non-survival groups (3.68 ± 2.52) was higher compared with the survival group (2.17 ± 2.15) ($p=0.005$).
Conclusion: DVCT demonstrated that dynamic discordance of the upper lung SNAL with global lung field was associated with subpleural irregular lines and long-term poor prognosis for chronic IP patients.
Limitations: The number of included patients was not so large.

Quantitative CT Analysis in Interstitial Pneumonia with Autoimmune Features: Diagnostic and Prognostic Insights from a Retrospective Cohort Study (6 min)

Marijan Puseljic; Graz / Austria

Author Block: M. Puseljic, A. J. Schlemmer, I. Vlasicek, A-K. Kaufmann-Bühler, F. Moazedi-Fürst, M. Fuchsjäger, E. Talakic; Graz/AT
Purpose: The position of interstitial pneumonia with autoimmune features (IPAF) within the interstitial lung disease (ILD) spectrum remains unclear, with limited data on the role of quantitative CT (QCT). This study aims to evaluate threshold-based QCT for distinguishing IPAF from other ILD subtypes and to assess the prognostic value of specific QCT features.
Methods or Background: In this retrospective single-center study, 227 patients (mean age, 63.6 ± 12.8 years) with CTD-ILD (n = 123), IPAF (n = 54), or IPF (n = 50) diagnosed between January 2005 and October 2024 were included. QCT assessed ground-glass opacity (GGO), consolidation, emphysema, affected lung, and the GGO-to-consolidation ratio. A general linear model was used for group comparison of QCT features; progression-free survival (PFS) was analysed with Kaplan–Meier and Cox regression to identify QCT-based risk factors for the whole study sample and for each subgroup.
Results or Findings: Lung consolidation was significantly higher in IPAF than in CTD-ILD ($p = 0.046$), while CTD-ILD showed higher GGO-to-consolidation ratios than IPAF ($p < 0.001$) and IPF ($p = 0.009$). IPAF had shorter PFS than CTD-ILD but longer than IPF. Higher GGO-to-consolidation ratios (HR, 0.87; 95% CI: 0.79–0.97; $p = 0.011$) and higher emphysema percentage (HR, 0.96; 95% CI: 0.93–0.99; $p = 0.011$) were associated with reduced risk of progression, whereas the usual interstitial pneumonia pattern was linked to higher risk (HR, 1.70; 95% CI: 1.07–2.71; $p = 0.024$). The GGO-to-consolidation ratio was associated with lower PFS only in the CTD-ILD group.
Conclusion: QCT demonstrated significant differences in imaging features and prognostic implications when comparing IPAF with other ILD subtypes.
Limitations: CT scans were performed on different scanners, and there was an imbalance between subgroup sample sizes.
Funding for this study: No fundings recieved.

Respiratory discordance of global bronchial volume against global lung volume measured on dynamic ventilation computed tomography: association with prognosis of chronic interstitial pneumonia patients (6 min)

Yukihiro Nagatani; Kusatsu / Japan

Author Block: Y. Nagatani, H. Nakagawa, R. Uemura, Y. Tsunoda, K. Fukunaga, Y. Nakano, Y. Watanabe; Otsu/JP
Purpose: To investigate the association of dynamic concordance between global lung volume (GLV) and global bronchial volume (GBV) measured on dynamic ventilation computed tomography (DVCT) with prognosis
Methods or Background: Sixty-seven chronic interstitial pneumonia patients, including 22 idiopathic pulmonary fibrosis (IPF), underwent DVCT. GLV and GBV were measured in each of 13 to 17 frame images (0.35 seconds/frame), and their change ratio (GLVcr and GBVcr) were calculated. Cross-correlation coefficients between GLV and GBV (CCCv), and between GLVcr and GBVcr (CCCvcr) were assessed. Percentage of honeycomb volume to GLV (%HV) was measured as pulmonary fibrosis extent on peak-inspiratory CT. Mortality and the latest survival data were recorded. Following two analyses were performed in IPF, non-IPF as well as the total population: 1) CCCv, CCCvcr and %HV were compared between alive and non-alive groups. 2) Using cutoff values determined based on the area under the receiver operating characteristic curve, mortality difference for the 3 parameters were assessed by log-rank test under Kaplan-Meier curve.
Results or Findings: In addition to value difference between the 2 groups, patients with %HV of 2.05 or more had lower survival rates compared to those without (median survival time, 1756 vs 1933 days; p=0.002) for non-IPF as well as total. In contrast, CCCvcr for non-alive group (0.584±0.254) was lower than alive group (0.814±0.092) for IPF as well as total (p=0.008). Moreover, patients with CCCvcr of 0.795 or less had lower survival rates compared to those without (median survival time, 932 vs 1701 days; p=0.034) for IPF as well as non-IPF and total.
Conclusion: Respiratory discordance of GBVcr with GLVcr assessed on DVCT as well as %HV could be a useful indicator of prognosis especially for IPF.
Limitations: The number of included patients was not so large.

Three CT Visual Scores versus Two Lung Texture Analyses in Systemic Sclerosis-Related Interstitial Lung Disease: Associations with Pulmonary Function Tests (6 min)

Marco Emanuele Diana; Erice (TP) / Italy

Author Block: M. E. Diana[1], G. Pellegrino[2], D. Mohammad Reza Beigi[1], M. Orlandi[3], C. Bruni[4], V. Riccieri[1], M. Matucci-Cerinic[2], V. Panebianco[1], N. Landini[1]; [1]Rome/IT, [2]Milan/IT, [3]Modena/IT, [4]Florence/IT
Purpose: To compare the relationships of three CT Visual Scores (VSs) of lung alterations and two Lung Texture Analyses (LTAs) with pulmonary function tests in Systemic Sclerosis-Interstitial Lung Disease (SSc-ILD), identifying which method best reflects functional decline.
Methods or Background: Patients followed by two Rheumatology Units were evaluated. Chest CTs with Forced Vital Capacity (FVC%) and Lung Carbon Monoxide Diffusing Capacity (DLCO%) assessed within one month were included. Two radiologists performed three visual scores in consensus: Visual1 (involvement assessed at five levels), Visual2 (six levels), and Visual3 (six zones, whole lung evaluation). LTAs were performed with two software (Aview and IMBIO). A linear regression including clinical covariates (age, sex, smoking habits, antibody subset, pulmonary hypertension) was applied. The model fit was assessed using adjusted R2 ($p<0.05$). The agreement between the best VS and LTA was also evaluated using Bland–Altman analyses.
Results or Findings: 55 patients were included (44 women, median age 59 years). The median ILD extent ranged 17.0%-20% with VSs, and 6%-9.7% with LTAs. Linear regression with FVC% yielded R^2 values ranging from 0.267 to 0.371 for VSs, and from 0.223 to 0.478 for LTAs ($p<0.01$). Aview provided the best fit, followed by Visual3. Linear regression with DLCO% produced R^2 values ranging from 0.143 to 0.283 for VSs and from 0.223 to 0.230 for LTAs ($p<0.05$). Visual3 provided the best fit, followed by Aview. As ILD extent increased, the difference between Aview and Visual3 tended to increase (mean difference -13%, slope -0.213).
Conclusion: Aview and Visual3 assessments provided the best relationship with FVC% and DLCO%, respectively. The difference in ILD extent between the two methods may not be negligible at higher extents, where Aview tends to underestimate ILD compared to Visual3.
Limitations: Retrospective study, patients number

Interstitial Lung Abnormalities (ILA) in the Post-COVID19 Era: A call for radiologists awarness (6 min)

Zakaria Chahbi; Agadir / Morocco

Author Block: Z. Chahbi, S. Wakrim; Agadir/MA
Purpose: Interstitial lung abnormalities (ILA) are incidental radiological findings involving at least 5% of the lung parenchyma in asymptomatic individuals. The COVID-19 pandemic has raised concerns about post-viral lung damage contributing to ILA and its progression to pulmonary fibrosis. This study aims to assess the prevalence and characteristics of ILA in a post-COVID-19 population and explore potential associations with fibrotic changes.
Methods or Background: A retrospective analysis was conducted on 343 chest CT scans of patients over 40 years old with no prior diagnosis of interstitial lung disease (ILD) from January 2023 to January 2024. ILAs were classified into three subtypes based on Fleischner Society criteria: non-subpleural ILA, subpleural non-fibrosing ILA, and subpleural fibrosing ILA. CT scans were evaluated for key radiological features, including ground-glass opacities, reticulations, septal thickening, traction bronchiectasis, cysts, honeycombing, and architectural distortion. Statistical analysis was performed using IBM SPSS Statistics.
Results or Findings: The overall prevalence of ILA was 18%, with subpleural fibrosing ILA and subpleural non-fibrosing ILA each accounting for 8%, and non-subpleural ILA for 2%. A female predominance (58%) was observed, with a mean patient age of 59 years. Compared to pre-pandemic literature, which reported a 7% prevalence in general populations, our findings suggest an increase in ILA prevalence, particularly in fibrosing subtypes.
Conclusion: The study highlights a potentially higher detection rate of fibrosing ILAs in the post-COVID era, raising concerns about long-term lung remodeling and progression to ILD. The increased proportion of fibrosing ILA warrants further longitudinal research to assess its evolution and the need for modified follow-up strategies. Radiologists play a crucial role in early identification and risk stratification to prevent irreversible lung damage.

Frequency of Interstitial Lung Disease in Patients with Psoriasis und Psoriatic Arthritis in a Retrospective Observational Cohort (6 min)

Anne Bettina Beeskow; Leipzig / Germany

Author Block: A. B. Beeskow, A. Frille, T. Denecke, U. Wagner, M. Krasselt; Leipzig/DE
Purpose: Lung involvement in psoriatic arthritis (PsA) is rare and underrecognized, with interstitial lung disease (ILD) not currently listed as a comorbidity in European PsA treatment guidelines. However, a Scandinavian registry suggests PsA patients are 4.4 times more likely to develop ILD. This study retrospectively assessed ILD frequency in PsA patients at Leipzig University Medical Center.
Methods or Background: Retrospective data from 2010 to 2025 were analyzed, including demographics, diagnoses, medications, and thoracic imaging (chest X-rays [CXR] and CT scans).
Results or Findings: A total of 157 PsA patients (mean age 54.2 ±15.6 years; 45.9% female) underwent thoracic imaging. All had CXRs; 21 patients (13.4%) also had chest CT scans. ILD was diagnosed in 10 patients via CT, corresponding to 5.6% of the total cohort and 47.6% of those scanned by CT. Among ILD cases, patterns included usual interstitial pneumonia (UIP, n=2), non-specific interstitial pneumonia (NSIP, n=3), and fibrotic changes without a definitive pattern in the remaining patients (e.g., reticular changes ± traction bronchiectasis).
Conclusion: ILD was present in 5.6% of PsA patients and 6.4% of psoriasis patients without PsA. No predominant ILD pattern emerged. ILD was more frequently identified in patients with shorter PsA duration, suggesting early lung involvement. Given that ILD is not currently considered a PsA-related comorbidity, it may be underdiagnosed. These findings highlight the need for greater awareness and further research into pulmonary manifestations of PsA.
Limitations: Due to the retrospective design, only 13.4% of patients underwent CT imaging, with native high-resolution CT performed in 15 cases.
Funding for this study: No funding was received.

Deep Learning-Based Airway Segmentation in Systemic Lupus Erythematosus Patients with Interstitial Lung Disease (SLE-ILD): A High-Resolution CT Analysis (6 min)

Sirong Piao; Beijing / China

Author Block: S. Piao, B. LI, L. Zhao, R. Zhao, J. Wang, R. Xiao, Y. Ming, W. Song; Beijing/CN
Purpose: To characterize lobar and segmental airway volume differences between systemic lupus erythematosus (SLE) patients with interstitial lung disease (ILD) and those without ILD (non-ILD) using a deep learning-based approach on non-contrast chest high-resolution CT (HRCT).
Methods or Background: A retrospective analysis was conducted on 106 SLE patients (27 SLE-ILD, 79 SLE-non-ILD) who underwent HRCT. A customized deep learning framework based on the U-Net architecture was developed to automatically segment airway structures at the lobar and segmental levels via HRCT. Volumetric measurements of lung lobes and segments derived from the segmentations were statistically compared between the two groups using two-sample t-tests (significance threshold: $p < 0.05$).
Results or Findings: At lobar level, significant airway volume enlargement in SLE-ILD patients was observed in the right upper lobe ($p=0.009$) and left upper lobe ($p=0.039$) compared to SLE-non-ILD. At the segmental level, significant differences were found in segments including R1 ($p=0.016$), R3 ($p<0.001$), and L3 ($p=0.038$), with the most marked changes in the upper lung zones, while lower zones showed non-significant trends.
Conclusion: Our study demonstrates that an automated deep learning-based approach can effectively quantify airway volumes on HRCT scans and reveal significant, region-specific airway dilation in patients with SLE-ILD compared to those without ILD. The pattern of involvement, predominantly affecting the upper lobes and specific segments, highlights a distinct topographic phenotype of SLE-ILD and implicates airway structural alterations as a potential biomarker for disease presence. This AI-powered quantitative imaging biomarker holds promise for enhancing the early detection and monitoring of ILD in the SLE population, ultimately contributing to more personalized patient management.
Limitations: It was a retrospective and single-center study, and the generalizability of our findings needs validation in larger, multi-ethnic and longitudinal cohorts.

Longitudinal CT Progression, Quantitative CT Parameters, and Prognostic Implications in Anti-synthetase Antibody Syndrome Associated Interstitial Lung Disease (6 min)

Jiaru Wang; Beijing / China

Author Block: J. Wang, R. Zhao, R. Xiao, S. Piao, R. Zhao, Y. Ming, X. Sui, W. Song; Beijing/CN
Purpose: To characterize longitudinal chest CT changes in patients with antisynthetase antibody syndrome–associated interstitial lung disease (ASS-ILD), evaluate their relationship with pulmonary function, and assess the prognostic value of quantitative CT parameters.
Methods or Background: This retrospective study included 60 newly diagnosed ASS-ILD patients (April 2014–December 2022) with positive anti-synthetase antibodies and ≥2 chest CT scans. Clinical, serological, pulmonary function test, and CT data were analyzed. CT abnormalities and patterns were assessed visually and quantified using semi-quantitative CT scores and automated quantitative CT software. Patients were stratified by clinical outcomes (regression, stability, deterioration) and baseline disease severity.
Results or Findings: Median follow-up was 25 months with 404 CT scans reviewed. Ground-glass opacities, linear opacities, and consolidations predominated at baseline. Over time, traction bronchiectasis significantly progressed ($p<0.001$), while consolidation, pleural thickening, and OP patterns declined. Fibrotic patterns increased, particularly in anti-PL-12 (100%), anti-Jo-1 (77.4%), and anti-EJ (77.8%) subgroups. Baseline traction bronchiectasis was more frequent in stability/deterioration groups, whereas OP pattern and consolidation favored regression. CT scores and quantitative CT parameters (MLD, HAV%) correlated strongly with FVC%, FEV_1%, TLC, and VC, and moderately with DLco%. The more advanced group exhibited higher CT scores, MLD values and HAV% and lower LAV%.
Conclusion: Longitudinal CT assessment in ASS-ILD reveals progression to fibrotic patterns, with strong correlations between quantitative CT parameters and pulmonary function test. Both CT scores and quantitative CT parameters provide prognostic insights and may guide individualized management.
Limitations: First, it was a single-center, retrospective study with relatively small subgroup sizes, which may limit the generalizability of our findings. Second, the follow-up period was relatively short, preventing evaluation of the association between imaging scores and patient survival outcomes.

Deep Learning-Based Segmentation of Pulmonary Vasculature in Systemic Lupus Erythematosus Patients with Interstitial Lung Disease (SLE-ILD): A High-Resolution CT Analysis (6 min)

Sirong Piao; Beijing / China

Author Block: S. Piao, B. LI, L. Zhao, Y. Ming, R. Zhao, J. Wang, R. Xiao, R. Zhao, W. Song; Beijing/CN
Purpose: To investigate the structural differences in pulmonary arteries and veins at lobar and segmental levels between systemic lupus erythematosus (SLE) patients with interstitial lung disease (ILD) and those without ILD (non-ILD) using deep learning-driven chest high-resolution CT (HRCT) analysis.
Methods or Background: A retrospective cohort of 106 SLE patients (27 SLE-ILD, 79 SLE-non-ILD) underwent chest HRCT. A deep learning algorithm (U-Net
architecture) was trained to segment pulmonary arteries and veins at lobar and segmental levels via non-contrast chest HRCT, and vascular volumes were calculated. Group-wise comparisons were performed using two sample t-test, with significance set at $p<0.05$.
Results or Findings: Significant differences in pulmonary vasculature were observed between SLE-ILD and SLE-non-ILD groups. At lobar Level, SLE-ILD patients demonstrated significantly larger arterial volumes in the right upper lobe ($p<0.001$) and left upper lobe ($p=0.002$) compared to SLE-non-ILD. SLE-ILD patients exhibited increased venous volumes in the right upper lobe ($p=0.001$) and reduced volumes in the left lower lobe ($p=0.030$). At segmental Level, SLE-ILD patients showed higher arterial volumes in segments R1 ($p=0.010$), R3 ($p<0.001$), R7 ($p=0.010$), and L3 ($p=0.001$), but lower volumes in L9 ($p=0.005$) and L10 ($p=0.019$). SLE-ILD patients had elevated venous volumes in segments R1 ($p=0.001$), R2 ($p=0.003$), R3 ($p=0.002$), L1-2 ($p=0.017$), and L3 ($p=0.019$), but reduced volumes in L9 ($p=0.003$) and L10 ($p=0.004$).
Conclusion: Our study demonstrates a characteristic pattern of upper lobe arterial and venous enlargement coupled with lower lobe venous reduction in SLE-ILD, suggesting a complex interplay between SLE-associated vasculopathy and interstitial changes. AI-derived vascular metrics hold promise for improving the early diagnosis, risk stratification, and monitoring of SLE-ILD.
Limitations: It was a retrospective and single-center study, and the generalizability of our findings needs validation in larger, multi-ethnic and longitudinal cohorts.

Assessment of CT Quantitative Characteristics derived from CT in connective tissue disease-associated interstitial lung disease (6 min)

Yuxin Cheng; Shanghai / China

Author Block: Y. Cheng, Y. Guan, Y. Xiao; Shanghai/CN
Purpose: To quantitatively compare pulmonary structural alterations between CTD patients with and without ILD and to identify independent CT-derived discriminators for ILD diagnosis by means of quantitative CT.
Methods or Background: This study prospectively enrolled 51 patients with CTD-ILDand 33 CTD patients without ILD. All participants underwent paired inspiratory-expiratory chest CT scans and pulmonary function tests. Quantitative CT parameters including lung density, functional small airway metrics, and pulmonary vascular measurements were analyzed using specialized software. Group differences were compared using Mann–Whitney U tests. Univariate and multivariate logistic regression analyses were employed to develop nomograms identifying independent predictors of ILD in CTD patients. Predictive accuracy was assessed via calibration curves, and clinical utility was evaluated using DCA.
Results or Findings: The CTD-ILD group exhibited significantly higher HAA%-IN and HAA%-EXP (both $P < 0.001$), and lower LAA%-EXP, fAT volume, fSAD volume, and fSAD volume ratio (all $P < 0.001$). Vascular parameters, including the number of vessels and vessels with CSA < 5 mm^2 at 6 mm, 12 mm, and 24 mm from the pleural surface, as well as BV1, BV5, BV10, and TBV, were also significantly reduced in the CTD-ILD group (all $P < 0.001$). Multivariate analysis identified FEV1%, HAA%-IN, HAA%-EXP, and vessel counts at 6 mm, 12 mm, and 24 mm as independent predictors of ILD in CTD patients. The nomogram demonstrated high predictive accuracy, with calibration curves showing strong agreement between predicted and observed outcomes.
Conclusion: Quantitative CT can serve as a crucial and highly promising imaging biomarker for the diagnosis and assessment of CTD-ILD.
Limitations: The inclusion of non-age-matched CTD patients reflects the clinical reality that CTD-ILD patients are typically older, likely due to longer disease duration.

Monitoring Black-Box AI Tools for Radiology with a Local Foundation Model (6 min)
Camila Gonzalez; Vienna / Austria

Author Block: C. Gonzalez, Z. Fang, H. S. Na, D. Larson, A. Chaudhari; Palo Alto, CA/US
Purpose: The offering of AI tools for radiology is expanding rapidly, yet their performance on local data is often unclear. Manually annotating site-specific studies or training local models for each use case is unfeasible. We show how a single vision-language model trained on routinely collected scans and radiology reports can estimate the confidence of commercial AI tools.
Methods or Background: We trained a vision–language model on 4,648 in-house non-contrast head CT studies (median patient age 69.4 years, 43.7% female) and associated radiology reports. We extracted zero-shot predictions for intracranial hemorrhage, midline shift, mass effect, and ischemic stroke by formulating textual prompts and calculating the cosine similarity between positive and negative prompts in the latent space. We utilized those predictions and density-based uncertainty quantification to calibrate three black-box AI models, including an FDA-cleared tool.
Results or Findings: The vendor model reached a sensitivity of 0.64 and specificity of 0.83 on the in-house test set. Distance distributions between false negative and true negative black-box predictions differed significantly across all splits ($p < 0.001$; Mann-Whitney U), showing that misclassifications can be identified from image embeddings. Selecting different confidence thresholds on validation data increased sensitivity to 0.75 and 0.81, with only moderate rises in false positives.
Conclusion: A single vision-language model trained on routinely collected data can help evaluate the usability of black-box AI tools both before and after deployment. By providing scalable oversight across multiple products and clinical tasks with minimal overhead, the proposed framework supports safer integration of AI into radiology practice.
Limitations: Our current results are limited to data from a single hospital. We plan to make the proposed framework openly available and extend validation to additional clinics in the future.

Enhancing Ultrasound Image Analysis: Domain Adaptation of Vision-Language Models with Adapters (6 min)
Jingguo Qu; Hong Kong / China

Author Block: J. Qu, X. Han, T. Xiao, J. Qin, A. D. King, W. C. W. Chu, J. Cai, M. Ying; Hong Kong/HK
Purpose: To develop and evaluate domain adaptation methods for vision-language foundation models (VLMs) to enhance medical ultrasound (US) image analysis. This study addresses the performance limitations of existing VLMs caused by the domain shift from natural to medical images, aiming to improve automated segmentation and classification of lesions in US scans.
Methods or Background: We adapted a pre-trained CLIP model using parameter-efficient fine-tuning. Specifically, we integrated a novel multi-cognitive visual adapter (Mona) into the vision transformer backbone of a frozen CLIP model. For downstream tasks, we designed lightweight segmentation and classification heads incorporating feature map up-sampling and adaptive average pooling to handle variations in lesion size and reduce computational overhead. The framework was evaluated on six public and in-house US datasets (including one external testing set) for lymph nodes, breast, thyroid, and prostate.
Results or Findings: For segmentation, our adapted CLIP model with the Mona adapter without fine-tuning, outperformed all available models and achieved 0.831 in Dice score on the interal lymph node dataset. For classification, supervised fine-tuning was necessary, as zero-shot accuracy was near random chance. The fine-tuned model achieved up to 0.738 accuracy and 0.850 AUC on an external lymph node test set. Fine-tuning on small datasets led to performance degradation in segmentation, indicating catastrophic forgetting.
Conclusion: Our study demonstrated that adapting large-scale VLMs pre-trained on natural images is a highly effective strategy for ultrasound image segmentation. Our proposed method demonstrates superior segmentation capabilities. However, robust classification and overcoming the negative effects of fine-tuning on small datasets remain key challenges for future work.
Limitations: Key limitations include poor zero-shot classification, requiring supervised data for diagnosis, and catastrophic forgetting, where fine-tuning on small datasets degrades robust pre-trained features, especially for segmentation.
Funding for this study: This work was supported by General Research Funds of the Research Grant Council of Hong Kong (Reference no. 15102222 and 15102524).

ThighSeg: Foundation Model Adaptation for Thigh Composition Analysis in Multi-Sequence MRI (6 min)

Shengqian Huang; Beijing / China

Author Block: S. Huang, G. Hu, Q. Wang, D. Zhang, Z. Jin, H. Xue; Beijing/CN
Purpose: To develop and validate a universal deep learning framework, based on the adaptation of a large-scale medical vision foundation model, for automated thigh composition analysis across diverse MRI sequences.
Methods or Background: Multisequence MRI data (e.g., T1, T2, STIR, and Dixon sequences) from five public datasets and two local datasets were annotated for sartorius, quadriceps, adductor muscles, gracilis, hamstrings, femur, and subcutaneous tissue. Training set included 498 sequences (222 participants) from TotalSegmentatorMRI, UFATS, HuashanMyo, and local cohort 1; internal testing used 109 sequences (55 participants); two external test sets comprised 54 sequences (27 participants, Folkhälsan) and 154 sequences (19 participants, MyoSegmenTUM) respectively. A 2D nnUNet model fine-tuned from MedDINOv3 for 100 epochs was applied to segment thigh components. Segmentation and measurements were evaluated using Dice similarity coefficient (DSC) and intraclass correlation coefficient (ICC). Six-week resistance-training effects were evaluated in 12 participants from local cohort 1 using paired t-tests; age-related changes were assessed in 1017 participants from local cohort 2 using Pearson correlation.
Results or Findings: The model demonstrated robust segmentation performance on internal (DSC: 0.889-0.956) and external test sets (DSC: 0.806-0.938 for Folkhälsan, 0.834-0.900 for MyoSegmenTUM). Automated measurements of muscle volume and muscle fat fraction showed strong agreement with reference values in both healthy volunteers (ICC: 0.931-0.995) and patients with neuromuscular diseases (ICC: 0.905-0.988). The model detected significant resistance-exercise-induced increases in the volume of the sartorius, quadriceps, and hamstrings ($P < 0.01$). Muscle volumes correlated negatively with age in the local population cohort, especially for the quadriceps femoris ($r = -0.546$ in females, -0.450 in males).
Conclusion: ThighSeg is an automated and robust tool for thigh composition analysis.
Limitations: The limitations of the study include the retrospective design and the insufficient assessment of generalization ability to unseen sequences.

Distinguishing ILA from Atelectasis on Radiographs Using a Foundation Model with Multi-Institutional Validation (6 min)

Tician Schnitzler; Aarau / Switzerland

Author Block: T. Schnitzler[1], A. P. Gehret[1], H. Zaytoun[1], A. Nowroozi[2], M. Bondarenko[2], J. H. Sohn[2]; [1]Aarau/CH, [2]San Francisco, CA/US
Purpose: To evaluate the performance of a radiology vision foundation model (RAD-DINO) combined with a lightweight multi-layer perceptron (MLP) classifier for distinguishing interstitial lung abnormalities (ILA) from atelectasis on chest radiographs, validated externally across institutional datasets.
Methods or Background: A classification pipeline was developed using RAD-DINO as a frozen feature extractor with an appended MLP classifier. Training utilized a curated dataset comprising posteroanterior (PA) chest radiographs of confirmed ILA and atelectasis cases, verified through same-day CT imaging. The internal dataset included 542 ILA and 1,167 atelectasis cases. The external validation cohort consisted of 85 ILA and 100 atelectasis cases. Data were split into training, validation, and internal test sets using an 80:10:10 ratio. Given the limited number of ILA cases, the RAD-DINO backbone remained frozen to mitigate overfitting. Random sampling ensured balanced representation of atelectasis cases during training epochs. The model was trained for 10 epochs using cross-entropy loss and the Adam optimizer. Performance metrics included accuracy, precision, recall, F1 score, and ROC-AUC, assessed on internal and external test datasets.
Results or Findings: The final model demonstrated robust performance with an accuracy of 79.8% on internal validation and 81.1% externally. ROC-AUC scores were 0.865 (internal validation) and 0.890 (external test). The frozen RAD-DINO effectively provided generalizable features, while random sampling enhanced training stability and performance consistency across diverse datasets.
Conclusion: Radiological vision foundation models, combined with a lightweight MLP classifier, effectively distinguish ILA from atelectasis on chest radiographs. Freezing the RAD-DINO backbone facilitated robust transfer learning with limited labeled data, maintaining high generalizability and diagnostic accuracy across multiple institutions.
Limitations: No Limitations.

How Many Samples to Label for an Application given a Chest X-Ray Foundation Model? (6 min)

Anton Khardin; Moscow / Russia

Author Block: N. Nechaev, D. Umerenkov, V. Gombolevskiy, E. Przhezdzetskaya, A. Khardin, D. Dylov; Moscow/RU
Purpose: Estimating how many labeled cases are needed to meet a clinical performance target is essential for planning cost-effective model development. We investigate whether power-law fits to early learning curves can predict the training size required to reach an ROC-AUC threshold for chest X-ray (CXR) pathology classifiers built on top of foundation models.
Methods or Background: We constructed pathology-specific binary CXR datasets from MIMIC-CXR using RadGraph-derived labels normalized into 20 distinct classes. For each pathology, we formed train/val/test splits and sampled training subsets, adding negatives at a 1:5 ratio. We evaluated feature-based transfer learning with four encoders: RadDINO-MAIRA-2, XrayCLIP, XraySigLIP, and a ResNet-50 baseline. We then fit a power-law to the observed learning curves and estimated the number of positive cases needed to reach ROC-AUC 0.90—using fits built from limited early points.
Results or Findings: Foundation models substantially reduced labeled data needs versus ResNet-50. Across several pathologies, XraySigLIP/XrayCLIP achieved strong ROC-AUC with n@90 in the tens to low hundreds, while ResNet-50 often required orders of magnitude more data. For example, n@90 dropped from thousands or millions with ResNet-50 to double-digit counts with XraySigLIP. Crucially, fits using ≤50 positive cases provided reliable extrapolations of the eventual plateau. Early-slope magnitude correlated with final ROC-AUC across model–pathology pairs, supporting its use as a planning signal.
Conclusion: A simple protocol—train on small, incremented subsets; fit a power law; extrapolate to a target ROC-AUC—enables practical sample-size estimation for CXR pathologies with foundation-model features. In many cases, ~50–100 positive cases suffice to predict (and often achieve) clinically competitive performance, guiding annotation budgets and deployment timelines.
Limitations: Results are derived from one public dataset with RadGraph-based labels and frozen encoders; prospective, multi-center validation, end-to-end finetuning, and alternative targets (e.g., F1, sensitivity at fixed specificity) warrant study.
Funding for this study: No external funding was received; the work was conducted as part of the authors' institutional duties.

Automated monitoring framework for foundation model-generated draft reporting: Example use case in chest radiography (6 min)

Laura Brink; Reston / United States

Author Block: L. Brink[1], A. Burade[2], N. Bhatia[2], K. Schmidt[1], M. K. Kalra[2], S. Mercaldo[2], L. Coombs[1], B. C. Bizzo[2]; [1]Reston, VA, VA/US, [2]Boston, MA/US
Purpose: To develop and test a framework for automated performance monitoring of draft reports from foundation models using chest radiographs (CXR) as a use case example.
Methods or Background: Our retrospective, single-site study used 147 adult patients' CXR reports with radiologist-annotated findings (625 positive findings in total) to evaluate large language models (LLMs) for automated extraction of 233 predefined findings (regardless of criticality, significance, and severity) from each report. The best prompting strategy was then applied to AI draft reports generated with a commercial visual language model (VLM, Harrison.ai) from additional 121 CXRs. Radiologist reports served as the reference. Performance metrics with 95% confidence intervals (CIs) were calculated per finding and summarized at the case level and by finding criticality.
Results or Findings: Both one-shot and zero-shot prompting with Claude-3.5 achieved high accuracy (99.2%, CI:99.1–99.3) and specificity (99.6%, CI:99.6–99.7) for extracting reported findings, with minor sensitivity differences (one-shot: 77.8%, CI:74.4–80.9; zero-shot: 74.9%, CI:71.4–78.2). Using the selected extraction approach, the VLM achieved high accuracy (98.2%, CI:98.0–98.3) but substantially lower sensitivity (39.2%, CI:34.6–44.0) and F1 score (0.38, CI:0.34–0.43), indicating lower performance in finding-positive reports and high performance in normal reports.
Conclusion: Our framework can help automate monitoring of VLM-derived radiology report drafts. Since the findings extraction methods were highly accurate, the framework exposed the VLM's limited ability to capture true findings despite the high overall accuracy. We expect to scale the framework for additional LLMs and VLMs with temporal performance monitoring.
Limitations: Small sample size, single-site data, single-country LLMs, and the lack of stratified PA/portable CXR analyses limit the generalizability evaluation of our approach.
Funding for this study: No funding was received for this study.

Diagnostic Accuracy of Pretrained Medical Foundation Models on Knee X-Rays (6 min)

Hanbin Ko; Gwangmyeongsi / Korea, Republic of

Author Block: H. Moon, H. Ko, Y. Kim, D. Lee, H. D. Chae, C. M. Park; Seoul/KR
Purpose: To investigate whether general medical foundation models can effectively adapt to downstream imaging tasks beyond their original training domains. Specifically, we evaluate their diagnostic accuracy in knee radiograph analysis—including Kellgren–Lawrence grading, effusion detection, and fracture identification—and compare them with a knee-specialised expert model trained on domain-specific data to assess the added value of task-focused adaptation.
Methods or Background: We retrospectively analysed 110,734 knee radiographic studies (2003–2023) from a tertiary hospital, reserving the most recent two years (10,248 studies) as a temporally separated test set. Labels for Kellgren–Lawrence grade (0–4), effusion, and fractures (acute and periprosthetic) were extracted from structured radiology reports using a rule-based approach. Three models with identical architectures were evaluated: MedSigLIP, a general medical foundation model pretrained via Google Med-Gemma; a knee-specialised model further trained with our images and reports; and a randomly initialised baseline. Performance was assessed using accuracy, F1-score, and AUC on both frontal views and multi-view inputs (frontal, lateral, skyline).
Results or Findings: The knee-specialised model consistently outperformed both MedSigLIP and the randomly initialised baseline. For effusion (all views), accuracy/F1/AUC were 87.7/87.3/93.4 for the knee-specialised model versus 82.2/82.2/91.8 for MedSigLIP and 80.7/79.8/89.1 for random ($p<.001$ for knee-specialised vs both). For fracture, values were 77.1/78.1/83.2 (knee-specialised) vs 68.9/67.3/72.8 (MedSigLIP) and 70.9/68.6/76.4 (random) ($p<.001$). For KL grading, accuracies were 56.5%, 54.1%, and 51.1%, respectively, with the knee-specialised model showing modest but significant gain over MedSigLIP ($p<.05$). Multi-view inputs improved effusion and fracture detection, while frontal views remained superior for KL grading.
Conclusion: General medical foundation models improved performance over models without pretraining, supporting their role in enhancing downstream imaging tasks. Additional task-specific adaptation further boosted diagnostic accuracy, underscoring the complementary value of both general pretraining and domain-specialised refinement.
Limitations: Findings are restricted to internal validation.
Funding for this study: This study was supported by a grant from the Korea Health Industry Development Institute (KHIDI)

A Foundation Model Framework for Multi-View MRI Classification of Extramural Vascular Invasion and Mesorectal Fascia Invasion in Rectal Cancer (6 min)

Yumeng Zhang; Maastricht / Netherlands

Author Block: Y. Zhang[1], S. A. Mali[1], H. C. Woodruff[1], S. Amirrajab[1], E. I. Crespo[2], A. Jimenez-Pastor[2], L. Marti-Bonmati[2], Z. Salahuddin[1], P. Lambin[1]; [1]Maastricht/NL, [2]Valencia/ES
Purpose: Accurate MRI-based identification of extramural vascular invasion (EVI) and mesorectal fascia invasion (MFI) is crucial for risk-stratified rectal cancer treatment. However, subjective visual assessment and inter-institutional variability limit diagnostic consistency. Therefore, this study aims to develop and externally evaluate a multi-center, foundation-model-driven framework that automatically classifies EVI and MFI on axial and sagittal T2-weighted MRI.
Methods or Background: 331 pre-treatment rectal-cancer MRI scans from three European hospitals (La Fe University and Polytechnic Hospital, Unidade Local de Saúde Hospital, and Centre Hospitalier Universitaire d'Angers) were retrospectively analyzed. A self-supervised frequency-domain harmonization pipeline was used to reduce scanner variability. Three classifiers—SeResNet, the universal biomedical pretrained transformer (UMedPT) with a multilayer perceptron (MLP) head, and a logistic-regression variant using frozen UMedPT features (UMedPT_LR)—were trained (n=265) and tested (n=66). Gradient-weighted class activation mapping (Grad-CAM) visualized model predictions.
Results or Findings: UMedPT_LR achieved superior EVI classification using fused axial and sagittal features (area under the receiver operating characteristic curve, AUC = 0.82). Optimal MFI detection occurred with UMedPT using axial harmonized images (AUC = 0.77); these results outperform the challenge winners. Frequency-domain harmonization enhanced MFI performance, with variable effects on EVI. Multi-view fusion, which combined axial and sagittal features, consistently improved EVI classification. Conventional convolutional neural networks (CNNs) underperformed, especially in F1 score and balanced accuracy. Grad-CAM demonstrated appropriate model attention on peritumoral regions (EVI) and mesorectal fascia margins (MFI).
Conclusion: The proposed foundation-model-driven framework leveraging frequency-domain harmonization and multi-view feature fusion achieves state-of-the-art performance in automated MRI classification of EVI and MFI, demonstrating excellent generalizability across multiple centers.
Limitations: Limitations include modest sample size, no center-specific analyses, and limited validation. Larger multi-institutional cohorts, advanced imaging, and in silico trials are needed to improve generalizability and clinical translation.

Best Practices for CT Foundation Model Embeddings: Ablation Studies and Cancer Immunotherapy Outcome Prediction (6 min)

Cristina Mendoza-Moreno; Barcelona / Spain

Author Block: C. Mendoza-Moreno, D. Navarro-Garcia, C. Zatse, A. Marcos Morales, O. Llorian-Salvador, R. Perez Lopez; Barcelona/ES
Purpose: Foundation models (FMs) offer powerful representations of medical imaging data, with the potential to improve performance in downstream tasks. Yet, it is unclear how their performance is affected by common machine learning (ML) pipeline choices. This study evaluates how design choices in data handling and model construction influence the predictive power of FM-derived features, benchmarked against hand-crafted radiomics.
Methods or Background: We analyzed the pre-treatment CT scans from 593 immunotherapy-treated cancer patients. Using a 10-iteration, 5-fold nested cross-validation framework, we conducted ablation studies to compare FM embeddings with hand-crafted radiomics across three endpoints: (a) clinical benefit, (b) lesion growth, and (c) lesion location. We examined the influence of five critical ML pipeline variables on predictive performance (AUROC): (1) class imbalance correction, (2) sample size variation, (3) feature normalization, (4) feature selection optimization, and (5) classifier–feature selector combinations.
Results or Findings: FMs consistently outperformed radiomics, particularly FMCIB embeddings (AUROC up to 0.66 vs. 0.59 for radiomics) for clinical benefit prediction . Standard preprocessing, such as feature normalization, improved performance when using hand-crafted radiomics but had no impact for FM embeddings. Performance did not uniformly degrade with reduced sample size, suggesting robustness to limited data in some tasks. Optimal feature number and classifier–selector combinations varied by endpoint. No universal “best” pipeline existed, and performance was highly context-dependent.
Conclusion: FM embeddings demonstrate superior performance compared to hand-crafted radiomics but require tailored pipelines. Moreover, both the prediction endpoint and the choice of FM embeddings significantly influence performance, underscoring the need for FM-specific workflows rather than one-size-fits-all solutions.
Limitations: This was a single-center study with limited external validation. Binary outcome definitions (e.g., clinical benefit, tumor growth) may oversimplify treatment response, and FM-specific architectural differences were not fully disentangled.
Funding for this study: Not applicable
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective study was approved by the institutional review board (PR(AG)70/2018). Informed consent was obtained from all patients participating in the clinical trials. The requirement for additional consent for computational image analysis was waived.

Non-invasive Prediction of MGMT Promoter Methylation in Glioblastoma from Routine MRI Using Foundation Models (6 min)

Zohaib Salahuddin; Maastricht / Netherlands

Author Block: Z. Salahuddin, C. Cortenraede, S. Amirrajab, H. C. Woodruff, P. Lambin; Maastricht/NL
Purpose: MGMT promoter methylation informs prognosis and treatment response in glioblastoma (GBM), but it is typically assessed invasively. We evaluated whether open-source foundation models can non-invasively predict MGMT methylation status from preoperative MRI, and explored model interpretability and fairness.
Methods or Background: We used multi-sequence MRI (T1, cT1, T2, FLAIR) from the UCSF PDGM and UPenn GBM datasets, restricted to WHO grade 4 GBM. After standardized tumor-centric preprocessing, we obtained 637 patients (70% training, 10% validation, 20% testing) for MGMT methylation status prediction. We benchmarked supervised, self-supervised, and multi-task foundation models (FMCIB, UMedPT, BrainIAC, Models Genesis, Med3D) under three training regimes: (1) frozen extractor + logistic regression, (2) frozen extractor + MLP, (3) full fine-tuning. Input fusion strategies (early/late) and augmentation ablations were tested. The primary metric was ROC-AUC.
Results or Findings: For MGMT status prediction, Models Genesis fine-tuned on FLAIR achieved a ROC-AUC of 0.73, exceeding previously reported MRI-only benchmarks (AUC 0.63). Logistic regression trained on UMedPT embeddings achieved an AUC of 0.69. Kaplan–Meier curves stratified by predicted MGMT labels showed separation comparable to curves stratified by true MGMT labels on the held-out test set. Counterfactual explanations indicated that the model primarily attends to peritumoral tissue rather than the enhancing core. MGMT prediction performance varied by age: AUCs were 0.74 (Q1: 17–54), 0.79 (Q2: 54–63), 0.61 (Q3: 63–71), and 0.48 (Q4: 71–94). Gender performance was balanced (Male: 0.675, Female: 0.658).
Conclusion: Foundation models enable improved, non-invasive MGMT methylation prediction from routine MRI in a clinically meaningful way, with interpretability indicating reliance on peritumoral context. While gender fairness is well maintained, age-related performance disparities warrant mitigation.
Limitations: Further work is needed to explore semantic and clinical feature fusion. Prospective validation and domain adaptation on unseen external datasets are required.

A Vision Language Foundation Model for MRI Harmonization Achieves High Accuracy in Modality and Anatomy Classification (6 min)

Greg Zaharchuk; Stanford / United States

Author Block: D. Wang[1], T. C. Arnold[2], A. Shankaranarayanan[1], G. Zaharchuk[1]; [1]Menlo Park/US, [2]Philadelphia, PA/US
Purpose: Magnetic Resonance Imaging (MRI) is widely used in both clinical and research settings. However, there is no standard system for naming or categorizing MRI sequences. As a result, MRI sequences often vary in appearance due to differences in imaging protocols, scanner vendors, and institutional practices. The goal of this study is to create an efficient streamlined method to standarize the MRI sequences.
Methods or Background: A vision-language model was designed with BERT and 3D ResNet-18 for text/image feature extraction (36 meta tags and 32 slices). Six transformer layers with two classification heads were then applied for modality and anatomy classification. An expert rule-based method performs final verification by checking metadata fields for sequence types better identified by rules, including MRA, SSFP, and ADC/DWI. We minimize reliance on the original Series Description tag, which is often inconsistent and potentially misleading.
Results or Findings: Anatomies include Neuro (Brain, Neck, CSPINE, TSPINE, LSPINE) and MSK (Wrist, Hip, Elbow, Knee). Modalities include T1, T1c, T2, T2-FLAIR, DWI, MRA, T2*, SWI, SSFP, ASL, ADC, CAL, and LOC, covering nearly all common MRI sequence types. Neuro achieved 97.38% modality and 92.02% anatomy accuracy, while MSK achieved 96.7% modality and 99.5% anatomy accuracy on a comprehensive test dataset comprising 1,501 cases. Our next step is to improve Neuro anatomy accuracy.
Conclusion: The proposed method enables MRI metadata standardization, with high accuracy in MRI sequence classification. This improves the reliability and efficiency of MRI data organization, retrieval, and downstream analysis.
Limitations: Model inference is 8–10 s per series on the app side; future work will also aim to improve inference speed.
Funding for this study: None

Explainable Anatomy-Guided AI for Prostate MRI: Foundation Models and In Silico Clinical Trials for Virtual Biopsy-based Risk Assessment (6 min)

Zohaib Salahuddin; Maastricht / Netherlands

Author Block: Z. Salahuddin[1], D. Khan[1], Y. Zhang[1], S. Kuang[1], S. A. Mali[1], H. C. Woodruff[1], S. Amirrajab[1], R. Cavill[1], E. I. Crespo[2], A. Jimenez-Pastor[2], A. Galiana-Bordera[2], P. Jimenez[2], L. Marti-Bonmati[2], P. Lambin[1]; [1]Maastricht/NL, [2]Valencia/ES
Purpose: To develop and validate a fully automated, anatomically guided deep-learning pipeline that combines foundation models with counterfactual explainability for prostate-cancer (PCa) risk stratification on routine magnetic-resonance imaging (MRI).
Methods or Background: The pipeline includes an nnU-Net module that segments the prostate and its zones on axial T2-weighted MRI, a classification module that fine-tunes the UMedPT Swin-Transformer on 3D patches with optional gland or zonal priors and clinical variables, and a VAE-GAN framework that generates counterfactuals to highlight image regions driving model decisions. Development used 1,500 PI-CAI cases for segmentation and 617 multicentre biparametric MRI exams with clinical data from the CHAIMELEON challenge for classification (70% training, 10% validation, 20% testing). Clinical utility was tested in a paired multicentre in-silico trial where 20 clinicians interpreted a 125-case test set with and without AI support after a 60-day washout.
Results or Findings: The incorporation of gland priors boosted the foundation model's Area Under the Curve (AUC) from 0.69 to 0.72, and a three-scale ensemble (patch sizes 160–224) obtained the best test performance (AUC = 0.79), surpassing the 2024 CHAIMELEON challenge winners. Counterfactual heat-maps consistently highlighted lesion-containing regions within the segmented gland, providing intuitive, voxel-level explanations of risk predictions. In the prospective in silico trial, AI assistance increased mean diagnostic accuracy from 0.72 to 0.77 and Cohen's κ from 0.43 to 0.53, while cutting average review time per case from 5.3 min to 3.1 min (≈ 40 % gain).
Conclusion: Anatomy-aware foundation models enriched with gland priors and counterfactual explanations deliver accurate, transparent and time-saving PCa risk stratification on standard MRI, supporting their integration as virtual biopsies in clinical workflows.
Limitations: Domain adaptation and prospective trials are needed to confirm robustness in real-world settings.

Are the foundation models the answer for radiology AI: Evaluating deep learning and foundation model embeddings for binary classification of pediatric foreign body aspiration on chest radiographs (6 min)

Ilker Özgür Koska; Izmir / Turkey

Author Block: I. Ö. Koska, I. Genişol; Izmir/TR
Purpose: Foreign body aspiration (FBA) in children is a common emergency, yet its early detection on chest radiographs is challenging. We aimed to develop a binary classifier to distinguish FBA from chronic cough patients using chest X-rays and to evaluate the performance of both conventional transfer learning and foundation model embeddings in this context
Methods or Background: A dataset of 251 pediatric chest X-rays was used, including 51 FBA cases and 200 chronic cough cases. A MobileNetV2 model was trained using transfer learning with weighted binary cross-entropy and focal loss to handle class imbalance. Additionally, embeddings were extracted from DINOv2 and TorchXRay foundation models and used to train classical machine learning classifiers: XGBoost, LightGBM, and Support Vector Machine (SVM). Models were evaluated using accuracy, F1-score, and area under the ROC curve (AUC).
Results or Findings: The best-performing model was the MobileNetV2 transfer learning approach, which utilized class-weighted binary cross-entropy loss and the ADAM optimizer, achieving an accuracy of 0.82, a weighted average F1-score of 0.84, and an AUC of 0.91. Among foundation models, the best performance was achieved by DinoV2 embeddings, achieving 0.79 accuracy, 0.79 F1-score, and AUC 0.80
Models built on foundation model embeddings demonstrated inferior performance, highlighting the limitation of directly applying large self-supervised models to radiology tasks with limited datasets.
Conclusion: In this small, imbalanced pediatric chest X-ray dataset, transfer learning with a lightweight CNN (MobileNetV2) outperformed models built on foundation model embeddings. This suggests that foundation models, while promising, may not yet provide a universal solution for radiology AI, particularly in specialized or small-scale clinical datasets.
Limitations: A small dataset and single-center design were the main limitations of this study.
Funding for this study: None

Building a Multicenter Radiology Foundation Model with Privacy-Preserving Swarm Learning: The ODELIA Consortium Initiative (6 min)

JieFu Zhu; Heidelberg / Germany

Author Block: J. Zhu, O. Lester Saldanha; Heidelberg/DE
Purpose: To develop a multicenter radiology foundation model for breast MRI screening using privacy-preserving swarm learning (SL) within the ODELIA consortium, demonstrating feasibility, performance, and clinical relevance across European institutions.
Methods or Background: Swarm learning enables decentralized training of AI models without centralizing sensitive data, addressing privacy and regulatory barriers. The ODELIA consortium connects >8 academic hospitals and research institutes across Europe, pooling an estimated >20,000 breast MRI examinations from heterogeneous scanners and protocols. We implemented an open-source SL framework (Mediswarm) built with Python, NVFlare, Docker, and cross-platform-based coordination. Foundation model pretraining was performed on public imaging datasets, followed by weakly supervised fine-tuning with case-level diagnostic labels. Data never leaves local sites; secure aggregation, differential privacy, and active learning loops ensure robustness and efficiency.
Results or Findings: The swarm-trained foundation model achieved robust performance across institutions. For breast cancer detection, sensitivity reached 94% and specificity 92%, surpassing locally trained models (average sensitivity 88%, specificity 85%). Cross-institutional validation confirmed superior generalizability, with consistent AUROC >0.93 across diverse MRI protocols. Communication overhead was reduced by ~30% and computational load by ~25% compared with centralized training. Training remained stable under simulated node failures, and active learning improved minority-class performance, yielding a 7% gain in detecting small (<15 mm) tumors.
Conclusion: This work represents the first multinational SL implementation in radiology, delivering a scalable, open-source framework for collaborative foundation model training. ODELIA demonstrates that radiology foundation models can achieve robust, generalizable, and privacy-preserving performance in breast MRI, with potential for direct clinical translation and future expansion to additional oncologic imaging modalities.
Limitations: Preliminary results are based on ongoing training; full evaluation on all partner datasets and prospective clinical validation are pending.
Funding for this study: Funded by the European Union Horizon programme (Grant HORIZON-HLTH-2021-CARE-05-02, ODELIA project)
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study has been approved by the local ethics committees of all participating ODELIA consortium institutions. Imaging data are anonymised and processed in compliance with GDPR and national regulations. No raw patient data are exchanged between sites; all model training is performed via privacy-preserving swarm learning.

Quantitative contrast-enhanced ultrasound parameters correlation in the acute phase of paediatric inflammatory bowel disease: a comparative analysis with magnetic resonance imaging and colonoscopy (6 min)
Daniel Pelaez Sanchez; Madrid / Spain

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: D. Pelaez Sanchez, L. Vara de Andres, A. M. Lancharro Zapata, C. Marin Rodriguez, M. Sánchez Pérez, A. Aguado Del Hoyo, M. d. M. Tolin Hernandi, C. Miranda Cid, C. Sanchez Sanchez; Madrid/ES
Purpose: Contrast-enhanced intestinal ultrasound (CEUS) is a less invasive and more cost-effective imaging modality compared to magnetic resonance enterography (MRE) and colonoscopy for assessing the lower gastrointestinal tract and related complications in Crohn's disease. Its use in paediatric settings is gaining interest due to its safety profile and real-time functional imaging capabilities.
Methods or Background: This study included 48 CEUS measurements performed in paediatric patients during the acute phase of inflammatory bowel disease. Quantitative CEUS parameters - including area under the curve (AUC), time to peak (TTP), and peak intensity (PI) - were correlated with findings from MRE and colonoscopy, as well as with faecal calprotectin levels, to evaluate their diagnostic utility against parameters in subacute and chronic phases - with no active inflamation - in order to establish a clincally useful threshold.
Results or Findings: The CEUS parameters showed a strong correlation with faecal calprotectin levels and with imaging and endoscopic findings consistent with active inflammation. Increases in AUC, TTP, and PI were directly proportional to the degree of inflammatory activity identified through MRE and colonoscopy.
Conclusion: Quantitative parameters obtained from CEUS appear to reliably reflect the presence and severity of active inflammation in paediatric Crohn's disease. These findings support the potential role of CEUS as a non-invasive, reproducible, and effective tool for diagnosis and follow-up in this patient population.
Limitations: The limitations of the study are the small sample size which may limit the statistical power and generalisability of the findings, the retrospective and observational analysis, which may introduce potential biases and limit causal inferences and the single-hospital focus, which may restrict the applicability of the results to broader or more diverse paediatric populations..

Ultrasound and MRI Fusion for Non-Invasive Diagnosis of Placental Invasion" (6 min)
Rathinamoorthy Praveenkumar; Chengalpattu / India

Author Block: D. Velan, F. Abubacker Sulaiman, R. Praveenkumar, M. Nivitha, J. Lydia; Chennai/IN
Purpose: To assess diagnostic efficacy of an integrated ultrasound–MRI fusion protocol in the non-invasive detection and grading of placenta accreta spectrum (PAS) disorders. The objective was to determine whether combining real-time sonographic vascular evaluation with high-resolution MR tissue characterization enhances diagnostic precision, surgical planning, and maternal safety.
Methods or Background: A prospective cohort of antenatal women at high risk for PAS underwent comprehensive grayscale and color Doppler ultrasonography, followed within 48 hours by 3-Tesla MRI.

The MR protocol incorporated T2-weighted single-shot fast spin echo (SSFSE), balanced steady-state free precession (b-SSFP), diffusion-weighted imaging (DWI; b-values 0 and 800 s/mm²), and 3D T1-weighted spoiled gradient-echo sequences for detecting hemorrhagic or fibrotic changes.

A DICOM-based co-registration platform enabled seamless fusion of sonographic vascular maps with MRI morphology, generating hybrid images for multiplanar analysis. Diagnostic findings were correlated with intraoperative and histopathological outcomes to validate accuracy.
Results or Findings: Fusion imaging demonstrated remarkable diagnostic performance, with sensitivity of 97% and specificity of 95% in defining invasion depth and lateral extension.

Characteristic fusion signatures included turbulent intraplacental lacunae with bridging vessels, disruption of the myometrial T2 hypointense interface, and parametrial vascular encasement seen distinctly on b-SSFP sequences. This hybrid modality substantially enhanced reader confidence, improved surgical preparedness, and correlated strongly with intraoperative findings.
Conclusion: Ultrasound–MRI fusion imaging provides an innovative, non-invasive paradigm for prenatal detection of PAS. By uniting the vascular functional data from Doppler with anatomical and textural detail of MRI, it enables unparalleled visualization, supporting safer obstetric interventions and redefining the imaging standard for high-risk pregnancies
Limitations: The principal limitations include limited sample size, dependence on operator expertise for accurate spatial registration, and restricted availability of advanced fusion workstations. Larger multicentric validation studies are warranted to establish reproducibility and universal diagnostic thresholds.

Ultrasound-derived fat fraction for identifying pediatric metabolic dysfunction-associated steatotic liver disease: a prospective study (6 min)

Yi Dong; Shanghai / China

Author Block: Y. Dong, Y. Huang, Y. Qiu, Y. Wang, J. Chen, L. Wei, R. Cheng; Shanghai/CN
Purpose: To evaluate the diagnostic performance of ultrasound-derived fat fraction (UDFF) in diagnosing hepatic steatosis in pediatric patients with metabolic dysfunction-associated steatotic liver disease (MASLD).
Methods or Background: In this prospective study, pediatric patients diagnosed with MASLD were enrolled. All patients underwent UDFF measurements (six acquisitions) in V/VIII hepatic segments, using the Acuson Sequoia ultrasound system (Siemens Healthineers, USA) with a DAX probe (1.0 – 3.5 MHz) before magnetic resonance imaging proton density fat fraction (MRI-PDFF) measurement within one week. Bland-Altman analysis and Spearman correlation coefficient were performed. Area under the receiver operating characteristic curves (AUCs) was performed to assess the diagnostic performance of UDFF measurements in hepatic steatosis. Intraclass correlation coefficients (ICCs) were calculated to estimate the consistency of UDFF measurements.
Results or Findings: From May 2024 to December 2024, 27 patients (median age, 12 years; median body mass index, 28.4 kg/m2) were included. The median UDFF value was 13.0 % (IQR: 6.0 – 21.5). UDFF and MRI-PDFF had a mean bias of 3.4 %, with a 95 % LOA ranging from -17.3 % to 24.0 %. UDFF values showed a positive correlation with MRI-PDFF (r = 0.69). Taking MRI-PDFF ≥ 5 %, ≥ 15 %, and ≥ 25 % as the reference standard for diagnosing hepatic steatosis grade ≥ S1, ≥ S2, and S3, the AUCs of UDFF were 0.80, 0.84, and 0.82, with the cutoff values of 9.5 %, 10.5 %, and 12.8 %, respectively. The ICC of UDFF measurements was 0.92 (95 % CI: 0.86 – 0.96).
Conclusion: UDFF measurement demonstrates good diagnostic performance in diagnosing and grading hepatic steatosis in pediatric MASLD patients.
Limitations: The sample size is limited because it includes pediatric patients with metabolic dysfunction-associated steatotic liver disease from one center.
Funding for this study: This project was supported by the Sino-German Mobility Program of NSFC and DFG (Grant No. M-0504) and the National Natural Science Foundation of China (Grant No. 82071942).

Normal values for shear wave elastography, shear wave dispersion and attenuation imaging in healthy paediatric livers (6 min)

Michael Zellner; Zurich / Switzerland

Author Block: M. Zellner, M. S. Schmidt, F. Huber, C. Paverd, A. Martin, S. Micic, V. Spyropoulou, C. J. J. Kellenberger; Zürich/CH
Purpose: The burden of liver disorders in children, including metabolic dysfunction-associated steatotic liver disease, underscores the need for non-invasive diagnostic tools. Ultrasound modalities namely Shear wave elastography (SWE), shear wave dispersion (SWD), and attenuation imaging (ATI) are potential alternatives to invasive methods. However, robust paediatric reference data for these techniques remain scarce.
Methods or Background: This retrospective study aimed to define normative values for SWE, SWD, and ATI in a healthy paediatric population and explore how these parameters are influenced by age, sex, body mass index (BMI), and fasting state. From a larger cohort of 734 children, 264 (135 girls; median age 11.5 years) with no evidence of liver pathology were included. All participants underwent liver ultrasound with a standardized protocol, acquiring five ATI and ten SWE/SWD measurements per child. Only high-quality acquisitions were analyzed.
Results or Findings: Median values were: ATI 0.54 dB/cm/MHz (IQR: 0.50–0.58), SWE 1.24 m/s (IQR: 1.14–1.33), and SWD 11.70 (m/s)/kHz (IQR: 10.84–12.13). ATI and SWD were inversely associated with age ($p = 0.0003$ and $p = 0.0048$), and SWD showed a significant negative correlation with BMI z-score ($p < 0.0001$) and was lower in females ($p = 0.0013$). SWE demonstrated a weak positive relationship with depth of measurement ($p = 0.0261$). Fasting duration did not significantly affect any parameter.
Conclusion: These findings establish paediatric reference ranges for SWE, SWD, and ATI, highlighting the influence of age and sex—especially on SWD and ATI and emphasizing the importance of contextual interpretation in clinical practice.
Limitations: This study has several limitations. Its retrospective design introduces potential for selection and information bias. Despite careful screening, undetected minor illnesses may have subtly affected liver viscoelasticity. Finally, the predominantly white study population may limit generalizability to more diverse ethnic groups.
Funding for this study: The authors disclose that the retrospective data analysis was supported by funding from Canon Medical Systems, received by the first author

Ethics committee - additional information: Documentation of written informed consent from parents or legal guardians was reviewed retrospectively prior to data analysis. Clinical data and laboratory data were extracted from digital patient records. The study was approved by the local ethics committee

Diagnostic yield of post-mortem Micro-CT for abdominal and pelvic anomalies (6 min)

Ian C. Simcock; St Albans / United Kingdom

Author Block: I. C. Simcock[1], A. Lamouroux[2], S. C. Shelmerdine[1], C. Hutchinson[1], N. Sebire[1], O. Arthurs[1]; [1]London/UK, [2]Montpellier/FR
Purpose: To demonstrate the yield of abdominal and pelvic diagnoses at less-invasive autopsy following a post-mortem fetal micro-CT investigation for early gestation pregnancy loss.
Methods or Background: Micro-CT provides high-resolution imaging for early gestation fetuses (usually below 20 weeks, or <300 g bodyweight), typically following a miscarriage or termination of pregnancy, allowing parents a less invasive autopsy investigation. We retrospectively analysed micro-CT diagnoses made on an unselected population of over 1200 early gestation fetuses between 2017 and 2024.
Results or Findings: We made 277 individual abdominal/pelvic diagnoses on Micro-CT, in 196/1200 patients (16.3%). 100/277 (36.1%) were solely abdominal, 61/277 (22.0%) solely pelvic, 27/277 (9.7%) were both, and 96/277 (34.7%) were external anomalies. We demonstrate the spectrum of disorders detected using Micro-CT: the commonest were abdominal-pelvic wall defects 84/277 (30.3%) and renal anomalies 77/277 (27.8%). The commonest renal anomalies were horseshoe kidneys 16/77 (20.8%), and cystic kidneys 13/77 (16.9%).
Imaging was diagnostic in almost all cases except for 17/1200 (1.4%) non-diagnostic scans due to severe maceration.
Conclusion: We present the spectrum of abdominal/pelvic anomalies identified using post-mortem fetal Micro-CT. This information provides less-invasive autopsy for parents and clinical audit. The findings may be used to inform the likelihood of fetal abnormalities in subsequent pregnancies.
Limitations: Single centre data from a large specialist centre. Not all parents consented to invasive autopsy, so not all diagnoses could be histologically confirmed.

Ultra Micro Angiography for Evaluating Activity of Crohn’s Disease in Pediatric Patients: A Prospective Study (6 min)

Ying Wang; Shanghai / China

Author Block: Y. Wang, Y. Dong, H. Feng, L. Wei, R. Cheng, Y. Huang, Y. Wang; Shanghai/CN
Purpose: To investigate the value of Ultra Micro Angiography (UMA) imaging in evaluating the inflammation activity of pediatric Crohn's disease (CD) patients.
Methods or Background: The Pediatric Crohn's Disease Activity Index (PCDAI) was regarded as the reference standard to evaluate the activity of CD. Before treatment, pediatric CD patients underwent B mode ultrasound (BMUS) and recorded the parameters. Color Doppler Flow Imaging (CDFI) and UMA were used to evaluate the blood flow in the most thickened diseased bowel wall using Limberg scores. The diagnostic performance of UMA and CDFI in assessing the inflammatory activity of pediatric CD was compared.
Results or Findings: A total of 54 pediatric CD patients were included and divided into three groups: inactive, mild and moderate-to-severe CD. When assessing bowel wall blood flow using CDFI, there was no statistically significant difference in bowel wall blood flow signals between the mild CD and the inactive CD ($P > 0.05$). There was statistically significant difference in blood flow signals between the mild and moderate-to-severe CD groups ($P < 0.05$). When assessing bowel wall blood flow using UMA, there were statistically significant differences in blood flow signals among all three groups (all $P < 0.05$). ROC analysis revealed that diagnostic performance of the UMA-BMUS model was significantly better than that of the CDFI-BMUS model (AUC 0.911 vs. 0.819; sensitivity 86.9 % vs. 72.2 %; specificity 94.5 % vs. 91.7 %; $P < 0.05$).
Conclusion: By sensitively depicting the low-velocity and tiny blood flow signals of the inflamed bowel wall, UMA is an effective noninvasive imaging method to make semi-quantitative evaluation of the activity of pediatric CD.
Limitations: The assessment of pediatric CD activity was based on semi-quantitative evaluation. Further multi-center studies are still necessary to verify our results.

Optimizing MRI-PDFF prediction in pediatric based on AC and BSC considering respiratory effect (6 min)

Seunghyun Song; Seoul / Korea, Republic of

Author Block: S. Song, J. Kim, M-J. Lee, K. H. Han, Y. Kwon, H. Koh, Y. W. Kim, E. J. Lee, H. Yoon; Seoul/KR
Purpose: To evaluate correlation between MR-proton density fat fraction (PDFF) and ultrasound-based parameters (attenuation coefficient [AC] and backscatter coefficient [BSC]) in pediatric patients, assess respiratory influence, and derive the optimal predictive model under various breathing conditions.
Methods or Background: This prospective study included consecutive pediatric patients with suspected fatty liver disease who underwent abdominal ultrasound and MRI with PDFF at baseline. AC and BSC were each acquired ten times during free breathing (FB) and breath holding (BH). Pearson correlation and linear regression assessed associations of AC and BSC with MR-PDFF. Multiple regression incorporating AC and BSC evaluated respiratory interactions. Additionally, 12 novel predictive models were constructed under FB and BH, with performance compared using adjusted R^2 and root mean square error (RMSE).
Results or Findings: Finally 44 patients (mean age 14.1 years) were included. AC and BSC showed significant correlations with MR-PDFF regardless of breathing condition (all $p < 0.001$). Multiple regression models during BH demonstrated better performance compared with FB (adjusted R^2, 0.64 vs 0.58; RMSE, 7.5 vs 8.0). There was no significant interaction effects of AC and BSC on MR-PDFF with breathing condition. Among 12 predictive models, the ordinary least squares (OLS) model performed best under BH (RMSE 7.14), while the support vector machine (SVM) model performed best under FB (RMSE 7.66).
Conclusion: In conclusion, AC and BSC are significantly correlated with MR-PDFF in pediatric patients under both breathing conditions. Predictive performance is slightly higher with BH, but the difference is minimal. The SVM model under FB still provided clinically acceptable accuracy, may be helpful for children with limited respiratory cooperation.
Limitations: Limitations in our study include small sample size, single-center design, relatively older cohort, and lack of external validation.
Funding for this study: None.

Seeing beyond the loopogram : preoperative magnetic resonance imaging in anorectal malformation (6 min)

Prachi Maheshwari; Ajmer / India

Author Block: P. Maheshwari[1], A. Bhandari[2], A. Gupta[2]; [1]Ajmer/IN, [2]Jaipur/IN
Purpose: To evaluate the diagnostic accuracy and clinical utility of preoperative magnetic resonance imaging (MRI) in anorectal malformations (ARM) using surgical findings as the gold standard. Secondary objectives included comparison of MRI with distal loopogram (DLO) for fistula detection and assessment of associated spinal and genitourinary anomalies to guide surgical planning.
Methods or Background: ARM are complex congenital anomalies requiring detailed preoperative anatomical delineation for optimal surgical outcomes. Conventional imaging modalities, such as distal loopogram and voiding cystourethrogram, are invasive, involve ionising radiation, and offer limited soft tissue detail. In this prospective observational study (January–July 2025), 15 children aged 3 months–5 years with ARM underwent preoperative pelvic MRI on a 3T system. Standardised protocols were used without contrast instillation. Findings were compared with surgical outcomes, and diagnostic metrics (sensitivity, specificity, and accuracy) were calculated.
Results or Findings: MRI demonstrated high diagnostic accuracy (86.7%) and superior sensitivity (87.5%) compared with DLO (62.5%) for fistula detection. Specificity was slightly lower (85.7% vs 100%). MRI identified associated anomalies in 66.7% of patients, including spinal (46.7%) and genitourinary (40%) abnormalities, in a single comprehensive examination.
Conclusion: Preoperative MRI offers superior sensitivity and comprehensive anatomical evaluation in ARM, facilitating precise surgical planning while avoiding ionising radiation. It should be strongly considered in complex cases, particularly when associated anomalies are suspected.
Limitations: The small sample size (n=15) limited statistical power and subgroup analysis. The single-centre design and single-observer interpretation may affect generalisability. Larger, multicentre studies are required for validation.
Funding for this study: Funding for this study was not provided by any external agency.

Development of an algorithm for objective characterisation of spleen echotexture among peadiatrics with sickle cell disease (6 min)

Auwal Abubakar; Maiduguri / Nigeria

Author Block: A. Abubakar; Maiduguri/NG
Purpose: To develop an Algorithm for objective characterization of parenchymal echotexture and establish a nomogram for spleen echogenicity among pediatrics.
Methods or Background: A novel mathematical algorithm was developed using MATLAB (MathWorks Inc., Natick, MA), which enables the computation of tissue echogenicity values on USS DICOM images based on pixel intensity. The Algorithm was used to measure spleen echotexture among 80 pediatric subjects (40 normal and 40 SCD patients). The data were analysed using MATLAB software version 2024A. Student's t-test was used to compare the spleen echogenicity between normal subjects and SCD patients. The mean, 2.5, and 97.5 percentiles of spleen echogenicity values were computed for normal subjects to establish a nomogram.
Results or Findings: The patients' age ranges between 2 and 15 years, with a mean of 7.3±3.3 years. There is an increase in spleen echogenicity among SCD patients compared to normal subjects, and the difference is statistically significant ($p<0.05$). The spleen parenchymal echotexture in normal subjects ranged from 7.4 to 59.6, with a mean of 30.9 ± 12.9. In contrast, the echotexture of the SCD subjects ranged from 30.7 to 95.1, with a mean of 63.47 ± 14.67. The nomogram echogenicity range, defined by the 2.5th to 97.5th percentiles, is 40.6-81.2.
Conclusion: This study developed a novel mathematical Algorithm for the objective evaluation and characterization of parenchymal echogenicity on ultrasound images. The approach is simple and convenient, with great potential to curtail observer variability and improve accuracy in tissue characterisation on USS. A nomogram of spleen echogenicity among pediatric patients was also developed in the study.
Limitations: The echonecity was not compared with any goal standard, as this is perhaps the pioneer study on this subject.
Funding for this study: None

Up-to-date paediatric sonographic reference values and percentile curves for abdominal organ dimensions in a large European cohort (6 min)

Elena Höhne; Frankfurt / Germany

Author Block: E. Höhne, S. Fischer, T. Vogl, V. Koch, S. Mahmoudi, I. Yel, K. Eichler, L. D. Grünewald; Frankfurt/DE
Purpose: Accurate assessment of liver, spleen, and kidney size is essential in pediatric diagnostics, where ultrasound provides a safe, accessible, and non-invasive tool. This study aimed to establish contemporary, population-based reference values for abdominal organ dimensions in children and adolescents in order to reflect current growth patterns and support reliable clinical decision-making.
Methods or Background: A total of 27,696 abdominal ultrasound examinations performed in children and adolescents (0–18 years) between 2000 and 2025 at a large tertiary referral center in Germany were retrospectively evaluated. Organ dimensions were measured by experienced pediatric radiologists using standardized protocols. Age-related percentile curves (P3–P97) were established with Generalized Additive Models for Location, Scale, and Shape (GAMLSS) to account for non-linear growth dynamics.
Results or Findings: Organ-specific datasets included 12,254 livers, 12,703 spleens, 16,254 right kidneys, and 16,516 left kidneys. All organs exhibited characteristic non-linear growth trajectories. No significant sex-related differences were identified for spleen ($p = 0.195$), liver ($p = 0.517$), right kidney ($p = 0.712$), or left kidney ($p = 0.797$), supporting the use of unified reference values. The left kidney consistently exceeded the right in size ($p < 0.0001$), with a mean difference of 2–5 mm.
Conclusion: This study provides updated, population-specific percentile curves for liver, spleen, and kidney dimensions, derived from one of the largest pediatric ultrasound datasets in Central Europe. These normative values offer a robust reference framework to support the differentiation between physiological growth variation and pathological organ enlargement in children and adolescents.
Limitations: The retrospective, single-center design and the absence of anthropometric parameters such as height or weight may limit the generalizability of the presented age-based reference values.
Funding for this study: No funding was obtained for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This retrospective cohort study was approved by the institutional review board (approval #2024-1854_1) with waiver of informed consent.

Portal vein stenosis after paediatric liver transplantation: ultrasound criteria predictive of stenosis and risk factors for recurrence after balloon angioplasty (6 min)

Antoine Martin-Champetier; Marseille / France

Author Block: A. Martin-Champetier, B. Binselim, E. Dammann, B. Roquelaure, A. Fabre, O. Boillot, A. Dabadie, P. Petit; Marseille/FR
Purpose: Portal vein stenosis is a common complication after paediatric liver transplantation. The value of ultrasound compared with portal angiography in detecting stenosis and its recurrence after balloon angioplasty has been little studied.
Methods or Background: Children who underwent liver transplantation and subsequently received portal angioplasty in our centre were retrospectively included. Demographic, clinical, biological, and ultrasound data were collected and correlated with the presence of angiographic portal vein stenosis. In cases of recurrence after balloon dilatation, the previously collected data as well as angiographic findings were analysed.
Results or Findings: Twenty-one children (median age 42 months) underwent 43 portographies. Angiographic stenosis was confirmed in 37 procedures (86.0%), and recurrence occurred after 22 procedures (56.4%). In multivariate analysis, no criterion was associated with the presence of stenosis or recurrence. ROC curves suggested thresholds associated with angiographically proven stenosis (AUC > 0.5) for the following criteria: “B-mode measurement of stenosis”, “increase in trans-anastomotic velocity compared with postoperative ultrasound”, and “trans-anastomotic pressure gradient”. The ROC curve also suggested that the criterion “balloon size” was associated with recurrence (AUC > 0.5).
Conclusion: Our study did not identify predictive criteria for stenosis or recurrence in multivariate analysis. Further studies are required to reduce the number of portal angiographies and improve the management of these stenoses.
Limitations: This retrospective design resulted in missing data for certain variables, such as splenic elastography. Although this represents the largest cohort reported in the paediatric literature, the relatively small sample size may have limited the statistical power of the analysis.
Funding for this study: No external funding was received for the conduct of this study.
Has your study been approved by an ethics committee? Yes

Construction and validation of a scoring system for the diagnosis of biliary atresia based on multiparametric MRI and blood biochemical indicators (6 min)

Bo Liu; Chongqing / China

Author Block: B. Liu; Chongqing/CN
Purpose: This study aims to construct a non-invasive scoring system based on multiparametric MRI and blood biochemical parameters, and to evaluate its effectiveness in the diagnosis of biliary atresia (BA).
Methods or Background: This study included 79 infants confirmed with BA or non-BA, whom underwent MRI and blood biochemical tests. Abnormal development of the extrahepatic bile ducts and gallbladder displayed by three-dimensional magnetic resonance cholangiopancreatography, along with the mean apparent diffusion coefficient values of the right and caudate hepatic lobes measured by diffusion tensor imaging and the average serum gamma-glutamyl transpeptidase level, were used as parameters to construct the diagnostic model for BA using a binary logistic regression classifier. The model parameters were weighted and fused to generate a single diagnostic index for predicting whether an individual patient has BA. When this index was greater than 0.5, it indicated the possibility of BA. Intraoperative cholangiography, liver biopsy, and clinical treatment outcomes were used as the gold standards to assess the diagnostic performance of the fused diagnostic index, including accuracy, sensitivity, specificity and the area under the receiver operating characteristic curve (AUC).
Results or Findings: The performance of the scoring system in predicting BA was as follows: accuracy was 86.08%, sensitivity was 90.57%, specificity was 76.92%, and AUC was 0.9 ($P<0.001$).
Conclusion: This scoring system demonstrated good diagnostic performance and has the potential to serve as an effective means to distinguish whether infants have BA.
Limitations: First, the sample size was relatively small. Second, the data in our study were obtained from a single center. In the future, multicenter studies including external validation are needed. Finally, since our scoring system was based solely on routine blood biochemistry tests and hepatic DTI parameters, other potentially useful biomarkers were not assessed.
Funding for this study: This research was funded by the Chongqing Science and Technology Bureau (No. CSTB2024NSCQ-MSX0303).

Updated sonographic reference values and percentile curves for thyroid volume in children and adolescents (0–18 years) from a large European cohort (6 min)

Elena Höhne; Frankfurt / Germany

Author Block: E. Höhne, S. Fischer, T. Vogl, S. Mahmoudi, P. Reschke, J. Gotta, V. Koch, L. D. Grünewald; Frankfurt/DE
Purpose: Reference values for thyroid volume are essential for diagnosing goiter and interpreting pediatric thyroid imaging, yet comprehensive data across the full pediatric age range remain scarce. This study aimed to establish updated sonographic reference values and percentile curves in children and adolescents (0–18 years) from a large European cohort.
Methods or Background: This retrospective single-centre cohort study included pediatric thyroid ultrasound examinations performed between 2000 and 2025 at a tertiary referral hospital. Thyroid lobe volumes were calculated from standardized measurements using the formula length × width × depth × 0.5, excluding the isthmus. In total, 4,965 left and 4,948 right lobes fulfilled quality criteria and were included in the analysis. Age-dependent percentile curves (P3–P97) were modeled using GAMLSS.
Results or Findings: Thyroid volume (Tvol) increased steadily from birth to late adolescence in both sexes. In boys, mean Tvol rose from 0.71 ml at birth to 8.09 ml at 18 years, and in girls mean Tvol increased from 0.53 ml to 7.46 ml. Peak annual growth occurred earlier in girls (11–12 years, +0.99 ml) than in boys (13–14 years, +0.73 ml), but overall mean Tvol did not differ significantly between sexes ($p = 0.28$). Across all ages, the right lobe was consistently larger than the left ($p < 0.0001$).
Conclusion: This large single-centre study provides updated sonographic reference values and percentile curves for thyroid volume across the entire pediatric age range. The results confirm established growth patterns, demonstrate consistent right–left asymmetry, and highlight population-specific deviations from WHO standards, supporting accurate clinical assessment in children and adolescents.
Limitations: Limitations include the retrospective single-centre design; validation in independent cohorts is warranted.
Funding for this study: No external funding received.

Ethics committee - additional information: This retrospective cohort study received approval from the institutional review board (approval number 2024-1854_1), with informed consent waived.

Quantitative Analysis of Placental Perfusion in Twin Pregnancies Using Arterial Spin Labeling: A New Imaging Tool for Assessing Asymmetry and Hypoperfusion (6 min)

Xuan Zhang; Nanjing, Jiangsu Province, China. / China

Author Block: X. Zhang[1], L. Ji[1], R. Tang[2], M. Zhao[1]; [1]Nanjing/CN, [2]Shanghai/CN
Purpose: To evaluate the feasibility of using arterial spin labeling (ASL) to quantitatively assess placental perfusion in twin pregnancies and compare the results with singleton pregnancies.
Methods or Background: ASL imaging was performed on twin and singleton pregnancies to measure placental blood flow (BF). Gaussian mixture modeling was applied to partition twin placentas into regions corresponding to each fetus. Asymmetry index (AI) and hypoperfusion fraction (HF) were calculated for each fetus and compared between groups.
Results or Findings: Singleton placentas exhibited a mean AI close to 0%, with HF around 10% and BF_mean ranging from 150–400 ml/100g/min. Twin pregnancies showed a wider AI distribution (median -30%, range -120% to +90%) and higher HF in Twin A (11%) compared to Twin B (7%). The automated partitioning algorithm demonstrated stability in identifying perfusion regions.
Conclusion: ASL provides a non-invasive method to quantitatively assess placental perfusion in twin pregnancies, revealing significant perfusion asymmetry. This technique offers potential for early identification of at-risk fetuses and may complement existing imaging modalities in clinical practice.
Limitations: This study is a small-sample exploratory attempt, which may limit the generalizability of the findings. ASL acquisition was restricted to a few thick slices, potentially missing parts of the placenta. In twin pregnancies, placental vascular anastomoses make perfusion partitioning challenging, and our clustering-based segmentation may not fully match anatomical territories.

Tissue discrimination in brain metastases using neurite orientation dispersion and density imaging MRI (6 min)
Melanie Bauer; Innsbruck / Austria

Author Block: M. Bauer, S. Mangesius, M. Wagner, J. Kerschbaumer, D. Pinggera, J. Mangesius, A. E. Grams, E. R. Gizewski, C. Birkl; Innsbruck/AT
Purpose: Brain metastases exhibit complex microstructural heterogeneity, challenging accurate tissue characterisation. This study aimed to investigate whether the MRI model Neurite Orientation Dispersion and Density Imaging (NODDI) can differentiate tissue types across entire regions in brain metastases patients.
Methods or Background: This single-centre, prospective study included nine patients with 39 confirmed brain metastases, restricted to lesions of sufficient size for clinically relevant differential diagnosis. Head MRI scans were performed at 3 T using a multi-shell diffusion protocol. NODDI parameter maps were calculated for Orientation Dispersion Index (ODI), Neurite Density Index (NDI) and Free Water Fraction (FWF) using the Watson model. Whole-tissue regions representing oedema, necrosis, neoplasm, white matter, deep grey matter and cortical grey matter were segmented automatically in 3D Slicer using the MONAI deep learning pipeline on standard sequences. Univariate analyses of pairwise tissue differences employed the Wilcoxon signed-rank and paired Student's t-test. Multivariate analyses used Hotelling's T2, combining all three NODDI parameters to evaluate their joint discrimination power.
Results or Findings: Univariate analyses revealed multiple statistically significant differences in NODDI parameters, with the single non-significant result for all parameters when comparing neoplasm and cortex (ODI: $p = .55$; NDI: $p = .41$; FWF: $p = .17$). FWF and ODI showed significant differences between pathological and normal appearing regions ($p < .02$), suggesting their value as markers of microstructural alteration. Multivariate analyses demonstrated significant discriminations across all tissue comparisons ($p < .04$), except between cortex and necrosis ($p = .06$).
Conclusion: NODDI parameters differentiate necrosis, oedema and neoplasm in patients with clinically relevant brain metastases. Incorporating multivariate analyses offers the combined evaluation of NODDI parameters, providing complementary information.
Limitations: The used NODDI model may underestimate complex fibre dispersions in tumours. Automatic segmentation was not validated by experts.

Differential effects of IDH genotypes on corticospinal tract integrity and neurological functions in glioma patients: a study using neurite orientation dispersion and density imaging (6 min)
Kaiji Deng; Fuzhou / China

Author Block: K. Deng, Y. Xue, R. Jiang; Fuzhou/CN
Purpose: To explore the relationship among isocitrate dehydrogenase (IDH) genotypes of glioma,the diffusion MRI features of corticospinal tract (CST) and the neurologic assessment in neuro-oncology (NANO) score.
Methods or Background: 65 patients with gliomas adjacent to CST and 32 healthy controls underwent structural and diffusion MRI.Diffusion metrics, including DTI and NODDI, were calculated along the CST.Neurologic function was assessed using NANO scale.NANO score and subscores were compared between IDH wild-type and IDH mutant.The CST features were analysed between affected and healthy side for glioma patients and between left and right side for healthy controls.The relative CST features were evaluated among the three groups.Spearman rank correlation analysis was used to evaluate the correlation between the relative CST features and NANO score.
Results or Findings: Results showed significantly higher NANO scores, indicating worse function, in IDH wild-type patients compared to IDH mutant patients. Significant differences were found in motor subscores (gait, strength, ataxia, facial strength).CST microstructure on the affected side was significantly altered in both groups, with more extensive changes in IDH wild-type gliomas.Significant differences in relative CST metrics (ICVF, MD, RD) were found between IDH genotypes.There were differences in the relative CST features between the control group and different IDH genotypes.Furthermore, AD and MD correlated positively with NANO score, while ICVF and ODI correlated negatively.
Conclusion: Neurological impairment, particularly motor function,is more severe in IDH wild-type gliomas,likely due to greater CST microstructural injury. NODDI provides sensitive microstructural detection, confirming that CST integrity is better preserved in IDH mutant gliomas.
Limitations: There was no direct correlation between diffusion-sampled data and surgical findings. Therefore, it could not be ascertained whether the glioma truly infiltrated the CST. However, the decrease in motor function may indirectly reflect the injury of CST.

Enhancing brain metastasis detection in CT imaging: the impact of Maximum Intensity Projection (MIP) among radiologists with different levels of expertise (6 min)

Giovanni Pentassuglia; Martina Franca (TA) / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: G. Pentassuglia[1], M. Martucci[2], M. L. Angeli[2], F. Lisi[1], L. Ruscelli[3], A. Infante[2], S. Gaudino[1]; [1]Rome/IT, [2]Roma/IT, [3]Bergamo/IT
Purpose: Brain metastases are the most common intracranial tumors in adults and are critical for oncologic staging and treatment. Although MRI is the gold standard, contrast-enhanced head CT is frequently performed during whole-body oncologic follow-up and often interpreted by general radiologists, risking underdiagnosis. Maximum Intensity Projection (MIP) is a CT post-processing technique widely used in thoracic and vascular imaging but underutilized in neuroimaging. This study evaluated whether MIP can improve CT detection of brain metastases, particularly for less-experienced readers.
Methods or Background: This retrospective single-center study included 100 oncologic patients who underwent brain MRI within 30 days of contrast-enhanced whole-body CT. MRI served as the reference standard. Two radiologists—a general radiologist (R1) and a neuroradiologist (R2)—reviewed CT scans in two sessions: standard axial CT and CT with MIP reconstructions. The number of detected lesions, lesion size, and reporting time were recorded.
Results or Findings: MRI identified significantly more metastases than CT (mean ± SD: MRI = 12.4 ± 33.6; CT without MIP: R1 = 3.5 ± 5.9, R2 = 4.9 ± 10.0; CT with MIP: R1 = 3.8 ± 6.0, R2 = 4.9 ± 9.6; $p < 0.001$). MIP modestly improved detection for R1, while R2's results remained stable. R1's performance with MIP approximated R2's with standard CT, reducing inter-reader variability. MIP also shortened report times (−1 min for R1; −2 min for R2). In oligometastatic patients (<5 lesions), CT_MIP aligned more closely with MRI, improving reliability of findings relevant for treatment planning.
Conclusion: Although MRI remains superior, MIP-enhanced CT increases lesion detection and reduces report times, particularly for general radiologists. Incorporating MIP into routine CT protocols may improve diagnostic accuracy and efficiency in oncologic follow-up, especially in non-specialist or resource-limited settings.
Limitations: No limitations were identified.

Decoding Glioma Phenotypes: Quantitative Paramagnetic and Diamagnetic Susceptibility Mapping Using APART-QSM (6 min)

Liwei Mazu; GuangZhou / China

Author Block: L. Mazu[1], S. Zeng[1], W. Zhou[2], S. He[1], N. Zhu[1], J. Wu[1], Z. Yang[1], H. Wei[2], J. Chu[1]; [1]GuangZhou/CN, [2]Shanghai/CN
Purpose: This study aimed to (1) assess the value of quantitative paramagnetic(χpara) and diamagnetic(χdia) susceptibility in predicting glioma grading, IDH status, and prognosis; and (2)verify their correlations with intratumoral iron and tumor-associated macrophages (TAMs).
Methods or Background: We retrospectively enrolled 81 patients with diffuse gliomas (44 men, mean age 50 years) who underwent MRI including QSM. χpara and χdia were derived using a novel APART-QSM technique. Histological analysis included iron quantification (Perls stain) and multiplex immunofluorescence for TAM markers (CD68, CD86, CD163). Diagnostic models for tumor grade and IDH status were developed. Survival analysis and Spearman correlation with pathological indicators were performed.
Results or Findings: The diagnostic models for IDH status and tumor grade achieved AUCs of 0.81 (95%CI 0.71-0.90) and 0.87 (95% CI 0.78-0.97), respectively. The results showed that χdia was an independent predictor for IDH-mutant status (p=0.016.OR=0.12), while χpara was significantly associated with high-grade glioma (p=0.01.OR=8.16).Calibration curves and decision curve analyses confirmed good predictive performance and clinical utility. Kaplan-Meier analysis showed significant overall survival differences stratified by χpara/χdia. Both χpara and χdia positively correlated with iron concentration (r=0.32, r=0.29; p<0.05). Negative correlations were observed between χpara/QSM and $CD163^{+}$ macrophage infiltration (r=-0.27, r=-0.25; p<0.05). Additionally, there was no significant correlation among the other variables.
Conclusion: χpara and χdia serve as valuable imaging biomarkers for predicting molecular subtype, grading, and prognosis in gliomas. Their correlations with iron deposition were confirmed, supporting their biological relevance. These findings may aid in non-invasive glioma characterization and personalized treatment planning.
Limitations: Not applicable.

Diagnosis and Management of Radiation-Induced Gliomas in Children: An Interdisciplinary Perspective (6 min)

Nadezhda Plakhotina; Saint Petersburg / Russia

Author Block: N. Plakhotina, D. Drozdovskaya, A. V. Smirnova, D. I. Kuplevatskaya, K. Boiko, A. Brusser; Saint Petersburg/RU
Purpose: To define the imaging features and outcomes of pediatric radiation-induced brain tumors (RIBT) using a multicenter cohort. The study aimed to apply diagnostic criteria, ensure lesion-field concordance, utilize advanced imaging (MRI, amino-acid PET), and establish realistic follow-up expectations.
Methods or Background: We reviewed 14 young patients treated between 2019 and 2025 (average age, 5.4 years). To confirm these were radiation-induced tumors, we checked: did the tumor appear where radiation was given before, was it at least 4 years after radiation, was it a different tumor type than the original disease, and was there no family cancer history. Image analysis assessed field geometry, contrast enhancement, diffusion-weighted imaging, and radiopharmaceutical uptake on amino acid PET.
Results or Findings: All tumors were high-grade gliomas located within the previous radiation fields, emerging after a median latency of 7 years. MRI showed infiltrative tumors with heterogeneous contrast enhancement. Tumors were located in the cerebral hemispheres (54%), cerebellum (33%), and brainstem (13%). Differential diagnoses included neuroleukemia relapse and other encephalopathies. Amino acid PET confirmed high radiopharmaceutical uptake in the tumor foci, aiding visualization. Outcomes were poor: 7 patients died, median overall survival was 13.8 months, and progression-free survival was 8 months. Progression was predominantly local (~90%); extraneural spread was rare (0,5%). In a separate sub-cohort receiving repeat proton irradiation (n=8), median overall survival was 19 months.
Conclusion: In children, RIBT typically manifest as high-grade gliomas within irradiated areas after a long latency. Diagnosis relies on correlating radiation therapy history with modified criteria, supported by multiparametric MRI and amino acid PET. Despite modern treatments, the prognosis remains uncertain, necessitating careful, lifelong neuro-oncological monitoring for survivors of cranial irradiation. Imaging is critical for guiding biopsy timing and therapy selection.
Limitations: N/A

MR Imaging correlation of survival in patients with high-grade gliomas (6 min)

Sharavjamts Namkhainyam; Ulaanbaatar / Mongolia

Author Block: S. Namkhainyam, D. Khashbat, T. Dashjamts, A. Bat-Arildii, E. Ochirjav; Ulaanbaatar/MN
Purpose: To evaluate the survival of patients diagnosed with malignant gliomas and to identify MRI imaging features associated with prognosis.
Methods or Background: The study was conducted between 2018 and 2022 by sampling 125 clients who were diagnosed with malignant glioma brain tumor by undergoing MRI scan. Retrospective cohort analysis was done selecting 34 cases according to the inclusion and exclusion criteria.
Results or Findings: Total of 34 cases, 28 (60.5%) were male and 6 (29.5%) were female, with a median age of 50.67 ± 19.43 years. The median survival time after diagnosis was 15.7 months. For patients diagnosed with WHO Grade III malignant gliomas, the median survival time was 35.9 ± 10.1 months, while for those with Grade IV malignant gliomas, it was 12.2 ± 8.2 months. The overall survival rates among the study participants were 92% at 1month, 82% at 3months, 67% at 6months, 61% at 9months, 60% at 1 year, 12% at 3 years, and 0% at 5 years.
According to the comparison of survival rate with MRI imaging features were significantly associated with prognosis: high tumor square (P=0.011), multiple hemorrhagic components (P=0.047), high edema index (P=0.007), necrosis (P=0.0001), thickness of contrast enhancement (P=0.003) and midline shift (P=0.019).
Conclusion: The average survival time following diagnosis of high grade glioma was 15.7 months. For patients with WHO grade III gliomas, the mean survival time was 35.9 ± 10.1 months, whereas for grade IV gliomas 12.2 ± 8.2 months.
Patients with WHO grade IV gliomas had significantly shorter survival than those with grade III gliomas. MRI features such as tumor volume, peritumoral edema index, necrosis, hemorrhagic content, and mass effect were found to be negative prognostic factors for survival.
Limitations: Our study was conducted onrelatively small number ofcases.

QSM-derived histogram and intratumoral susceptibility features for noninvasive Glioma tumor grading (6 min)

Forough Sodaei; Tehran / Iran

Author Block: V. Shahmaei[1], F. Sodaei[2]; [1]Tehran/IR, [2]Odense/DK
Purpose: Accurate preoperative grading of gliomas is crucial for treatment planning and prognosis. Conventional MRI lacks specificity, whereas quantitative susceptibility mapping (QSM) sensitively detects magnetic susceptibility changes from iron, calcification, and microhemorrhage. Intratumoral susceptibility signals (ITSS), reflecting microvascular proliferation and hemorrhage, are closely associated with tumor angiogenesis and aggressiveness, offering a promising noninvasive biomarker for glioma grading.
Methods or Background: A retrospective analysis was conducted on 40 pediatric patients with histopathologically confirmed gliomas, categorized into low-grade (WHO grade II) and high-grade (WHO grade III–IV) groups. Multi-echo T2* gradient-echo MRI data were processed using the Morphology Enabled Dipole Inversion (MEDI) QSM pipeline. Tumor regions were delineated, and both histogram-derived susceptibility metrics (mean, percentiles, skewness, kurtosis) and ITSS counts were quantified. Statistical comparisons between groups were performed using independent-samples t-tests, and diagnostic performance was assessed with receiver operating characteristic (ROC) analysis.
Results or Findings: High-grade gliomas exhibited significantly higher mean susceptibility values and greater histogram heterogeneity (90th percentile, kurtosis; $p < 0.05$), as well as markedly increased ITSS counts, compared with low-grade tumors. ITSS alone achieved an area under the ROC curve (AUC) of 0.87 (sensitivity 82%, specificity 83%), while histogram-derived susceptibility metrics yielded an AUC of 0.88 (sensitivity 85%, specificity 80%). The combined model, integrating both histogram features and ITSS, demonstrated the highest performance, with an AUC of 0.92, sensitivity of 90%, and specificity of 85%.
Conclusion: Histogram features derived from QSM, together with ITSS quantification, provide robust, noninvasive biomarkers for glioma grading. In this study, incorporating ITSS improved the differentiation of glioma grades, highlighting the potential of QSM as a valuable adjunct to conventional MRI for preoperative tumor evaluation.
Limitations: The limitations of the study are the retrospective design and small sample size, which may limit generalizability.
Funding for this study: No funding was received for this study.

Comparative Analysis of 5.0T versus 3.0T Susceptibility-Weighted Imaging in Glioma: A Pair-Matched Study (6 min)

Yajing Zhao; Shanghai / China

Author Block: Y. Zhao, N. Mei, Z. Ruan, T. Xu, Y. Lu, B. Yin; Shanghai/CN
Purpose: To evaluate the feasibility of 5T SWI imaging in the diagnosis of gliomas, we conducted a comparative analysis with 3T imaging to assess image quality and determine the clinical value of 5T SWI in the preoperative evaluation of gliomas.
Methods or Background: Between 2024 and 2025, the glioma patients underwent 5T MRI scans. Each patient was individually matched with a control subject selected from the 3T MRI cohort. Radiologist scoring of image quality using a Likert scale, SNR, CNR, contrast ratio, and ITSS assessment were obtained. Paired Wilcoxon signed rank tests were used to compare characteristics derived at 3 T and 5T . The correlation between ITSS scores and molecular pathology was analyzed.
Results or Findings: A total of 27 participants were included undergoing 5T MRI. Each case was individually matched with one control subject selected from the 3.0T MRI cohort. Median image quality scores were 4.0 at 3 T and5.0 at 5T . SNR and CNR at 5 T was higher than at 3T. The degree of ITSS in 5.0 T cohort was significantly higher than that in 3T cohort . In the 5T cohort, a statistically significant association was observed between ITSS and WHO grades . The ROC curve analysis indicated that 1.5 was the best cutoff value to predict pathological grade. It shows that gliomas with a Ki-67 ≥ 10% exhibit a significantly higher ITSS than those with a Ki-67 < 10% .
Conclusion: SWI at 5T was found to be feasible and provided visualization of distal small vessel branches. And the image quality of 5T enables more precise ITSS delineation and demonstrating correlation with tumor proliferative activity
Limitations: The limitations of this study include its single-center design and small sample size, requiring future validation

Tertiary Lymphoid Structures in Glioblastoma: Association with Multiparametric MRI Imaging Phenotypic Features and Patient Survival (6 min)

Qing Zhou; Lanzhou / China

Author Block: Q. Zhou, J. Zhou; Lanzhou/CN
Purpose: Tertiary lymphoid structures (TLSs) are associated with improved survival in patients with various malignancies. However, their prognostic value and correlation with imaging features in glioblastoma (GBM) remain unclear. This study aimed to examine the relationship between TLSs and survival outcomes, and their association with imaging characteristics in patients with GBM.
Methods or Background: A retrospective analysis was conducted on 190 newly diagnosed patients with GBM. TLS-positive (TLSs+) and TLS-negative (TLSs-) groups were classified via hematoxylin-eosin staining to identify lymphocyte aggregates. Multiplex immunofluorescence staining (for CD20, CD3, CD21, and CD23) assessed TLS maturity, categorizing them into mature (mTLSs) and immature (imTLSs) subgroups. Survival was analyzed using the Kaplan-Meier method, while logistic regression developed TLS predictive models. Clinicopathological and Visually Accessible Rembrandt Images (VASARI) imaging features were compared between groups.
Results or Findings: Among 190 cases, 85 (44.73% positivity rate) were TLSs+, including 47 imTLSs and 38 mTLSs. Significant differences in overall survival were observed between TLSs+TLSs- groups and mTLSs/imTLSs groups (all $p < 0.05$). For VASARI features, the TLSs+/TLSs- groups differed significantly in F2, F8, F17, F22 ($p < 0.05$), while the mTLSs/imTLSs groups differed in F6, F16, F18 ($p < 0.05$); these features were independent predictors of TLS presence and maturity.
Conclusion: Conclusion: TLSs exist at different maturation stages in GBM and serve as favorable prognostic biomarkers. TLS presence and maturity are significantly correlated with patients' overall survival and specific VASARI features. Preoperative prediction of TLSs via imaging may support risk stratification and individualized treatment for patients with GBM.
Limitations: First, this was a single-center, retrospective investigation. Second, the patient cohort size was relatively small, which may have limited the robustness of the findings.
Funding for this study: This study is supported by grants from the National Natural Science Foundation of China (grant number: 82371914), the Cuiying Science and Technology Innovation Program of Lanzhou University Second Hospital (grant number:CY2023-YB-A03),the Science and Technology Program of Lanzhou City(grant number:2024-9-122), and the Science and Technology Program of Gansu Province(grant number: 24JRRA376).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was approved by the Medical Ethics Committee of our institution (Ethics Approval No. 2025A-364), and the research protocol adhered to the principles of the Declaration of Helsinki.

Contribution of Advanced MRI Biomarkers in the Characterization of Brain Lesions After Stereotactic Radiotherapy: Radionecrosis Versus Progression (6 min)

Joya Hadchiti; Villejuif / France

Author Block: J. Hadchiti[1], S. HAFFIANE[1], S. Ganjoo[2], M. El-AICHI[1], H. J. Howell[2], G. Garcia[1], N. Lassau[1], C. S. Balleyguier[1], S. Ammari[1]; [1]Villejuif/FR, [2]New York, NY/US
Purpose: Evaluate the predictive performance of a new set of imaging biomarkers related to microvasculature, blood flow, and tumor oxygen use in distinguishing tumor recurrence from radiation necrosis compared to the commonly used cerebral blood volume (CBV) biomarker
Methods or Background: 119 symptomatic patients with metastatic brain lesions post-radiotherapy were enrolled . 205 total lesions were analyzed across this sample. The diagnosis was tumor recurrence (n= 71 in test cohort and n = 7 in validation cohort) and radiation necrosis (n = 111 in test cohort and n = 16 in validation cohort) using expert-consensus derived from pathology and long-term follow-up as a reference standard. We studied 9 radiologist-reported imaging biomarkers (corrected CBV, non-corrected CBV, Delay, CTH, CTH Max, OEF, rLeakage, rCMRO2, COV). We performed univariate analyses to compare the area under the receiver operating characteristic curve (AUC) for the ratio values across all biomarkers in the test and validation cohorts. We additionally used a Random Forest model to identify the optimal combination of biomarkers with the highest predictive performance.
Results or Findings: In the test cohort, Delay_ratio, CTH_ratio, CTH Max_ratio , OEF_ratio , rCMRO2_ratio , and COV_ratio all significantly outperformed the predictive performance of CBV_corrected_ratio and CBV_noncorrected_ratio. The Random Forest algorithm demonstrated that the optimal model for differentiating between TR and RN was comprised of five biomarkers: CBV_corrected_ratio, CBV_noncorrected_ratio, Delay_ratio, OEF_ratio, and COV_ratio
with Delay_ratio having the highest feature importance and CBV_noncorrected_ratio having the lowest.
Conclusion: The novel imaging biomarkers investigated in this study demonstrate promising predictive performance in distinguishing between tumor recurrence and radionecrosis that warrants prospective validation
Limitations: Variation in patient numbers across different primary tumor types
Single institution study

A Study on the Predictive Value of a Multi-Parameter Model Combining Diffusion and Perfusion MRI Based on Histogram Analysis for MGMT Status and Prognosis in Glioblastoma (6 min)

Fengwei Yu; Chongqing, China / China

Author Block: F. Yu, W. Chen, P. Chen, J. f. Chen; Chongqing, China/CN
Purpose: Methylation of the O⁶-methylguanine-DNA methyltransferase (MGMT) promoter is a key molecular marker for guiding treatment strategies and predicting prognosis in glioblastoma. This study investigated the value of diffusion tensor imaging (DTI) and arterial spin labeling (ASL) histogram parameters for non-invasively predicting MGMT status, and explored the mediating role in how MGMT status influences patient survival outcomes.
Methods or Background: We retrospectively analyzed DTI and ASL data from 349 glioblastoma patients, extracting histogram parameters including fractional anisotropy (FA), mean diffusivity (MD), and cerebral blood flow (CBF). Intergroup comparisons were performed based on MGMT status. Predictive performance for MGMT status was evaluated using ROC curves, calibration curves and the Hosmer-Lemeshow goodness-of-fit test. For survival assessment, Kaplan-Meier and Cox regression analyses evaluated associations between imaging features, molecular markers, and overall survival (OS). Bootstrap mediation analysis assessed whether imaging parameters mediated the relationship between MGMT status and survival.
Results or Findings: The DTI model (AUC = 0.842) was significantly superior to the ASL model (AUC = 0.619) in predicting MGMT status. Kaplan-Meier analysis confirmed that MGMT promoter methylation was a significant protective prognostic factor (Log-rank P = 0.041). However, Cox proportional hazards regression analysis showed that while imaging parameters were not independent OS prognostic factors, mediation analysis identified FA 10th and MD skewness as complete mediators in the association between MGMT status and OS.
Conclusion: DTI histogram parameters are effective non-invasive biomarkers for predicting MGMT status. Specifically, FA 10th and MD skewness serve as complete mediators, clarifying the key mechanism by which unmethylated MGMT drives poor prognosis through inducing microstructural disruption and increased tissue heterogeneity in tumors. This provides important imaging insights for understanding glioblastoma biology and may suggest new targets for future targeted treatment strategies.

Mapping the MRI Patterns of Spinal Metastases: Compartment Distribution and Primary Tumor Insights from 12405 Patients (6 min)

Aruba Nawaz Khattak; Peshawar / Pakistan

Author Block: A. K. Nawaz, S. Ahmed, A. Iqbal, K. Siddique; Lahore/PK
Purpose: Spinal metastasis are the most common malignant lesions of spine and major cause of neurological morbidity. Large-scale data on lesion distribution across spinal compartments and their primary tumor origins are limited. This study analyzes MRI patterns of spinal metastasis and summarizes primary tumor types in a large cohort.
Methods or Background: We retrospectively reviewed MRI reports of 12,405 patients with biopsy-proven or clinically confirmed spinal metastasis from 2020-2025. Lesions were categorized into vertebral body, paravertebral soft tissues, epidural, intradural–extramedullary and intramedullary compartments. Primary tumor types and presence of cord compression were recorded. Counts and percentages were calculated.
Results or Findings: Compartment distribution: Epidural 10,918 [88%], vertebral body 5262 [42%], paravertebral 397 [3%], intradural–extramedullary 124 [1%], intramedullary 50 [less than 1%].
Primary tumors: Lung 4962 [40%], breast 3722 [30%], prostate 1737 [14%], renal 744 [6%], thyroid 248 [2%], gastrointestinal [496 [4%], melanoma 124 [1%], sarcoma to 48 [2%], lymphoma 124 [1%].
Epidural lesions were most frequent. Rare intradural and extramedullary metastasis were observed, particularly among melanoma, renal and lung cancers.
Compartment based evaluation improved distinction from mimics and provided a structured framework for reporting in multidisciplinary planning.
Conclusion: In this large cohort, spinal metastasis demonstrate distinct MRI patterns across anatomical compartments. Systemic compartment based assessment enhances diagnostic accuracy, facilitates early detection of cord compression and informs multidisciplinary management. Rarer intramedullary lesions, though uncommon, required high vigilance.
Key points:
1. MRI is essential for comprehensive assessment of spinal metastasis.
2. Compartment analysis improves differentiation from mimics.
3. Primary tumor data provides context without implying strict compartment correlations.
4. Rarer intramedullary lesions demand careful attention.
Limitations: None

Combined Diagnosis of Histogram Analysis of Magnetic Resonance Imaging for Differentiating Sellar/Suprasellar Germinomas and Craniopharyngiomas: A Support Vector Machine-Based Study (6 min)

Junhong Liu; Henan Province / China

Author Block: J. Liu; Henan Province/CN
Purpose: Purpose: This study was aimed to determine whether a combined diagnosis of histogram analysis of magnetic resonance imaging (MRI) based on support vector machine (SVM) can distinguish sellar/suprasellar germinomas from solid and cystic solid craniopharyngiomas.
Methods or Background: Methods: We retrospectively appraised a pathology database for 5 years and obtained 68 histopathologically proven sellar/suprasellar germinomas (n=20) or craniopharyngiomas (n=48) with magnetic resonance images. The T1-weighted imaging (T1WI), T2-weighted imaging (T2WI), apparent diffusion coefficient (ADC) map and contrast-enhanced T1WI (CE-T1WI) of each patient were analyzed with the Mazda software. Nine parameters were selected as indicators of comparison and they were variance, skewness, kurtosis, mean, 1st percentile, 10th percentile, 50th percentile, 90th percentile and 99th percentile. The parameters with differential-diagnosis significance were used to establish the combined diagnostic model of SVM.
Results or Findings: Results: Among the nine parameters extracted using histogram analysis, the kurtosis of T1WI and the skewness, 1st percentile of T2WI and the mean, skewness, 50th percentile of CE-T1WI and almost all parameters of ADC map except variance, kurtosis and 1st percentile showed statistical significance between groups. Among the above parameters, the area under the curve (AUC) of 50th percentile of ADC map was the largest with the value of 0.916 (83.3% sensitivity and 85.0% specificity). After the analysis of combined diagnosis was performed, the AUC of SVM model in testing set showed the value of 0.969 (90.0% accuracy).
Conclusion: Conclusions: The histogram analysis of MRI may help differentiate sellar/suprasellar germinomas from solid and cystic solid craniopharyngiomas. Furthermore, the combined diagnosis of MRI histogram based on SVM was more effective than each individual histogram parameters.
Limitations: The sample size of this study is limited and needs to be expanded in future studies
Funding for this study: None

Ethics committee - additional information: Our research received an approval from the Ethics Review Committee in Zhengzhou University, the Affiliated Tumor Hospital. Due to this research protocol requiring only a retrospective analysis of data, informed consents were waived.

Microstructure mapping with time-dependent diffusion MRI differentiates primary central nervous system lymphoma from glioblastoma (6 min)

Shen Gui; Wuhan / China

Author Block: W. Jun, L. Jue, S. Gui, J. Wang; Wuhan/CN
Purpose: This study aimed to evaluate the diagnostic utility of time-dependent diffusion MRI (td-dMRI)-derived microstructural parameters in differentiating PCNSL from GBM, and to correlate these parameters with histopathologic findings.
Methods or Background: This retrospective study included 32 GBM and 19 PCNSL patients who underwent 3.0-T MRI with oscillating gradient spin-echo (OGSE) and pulsed gradient spin-echo (PGSE) sequences. Microstructural parameters (intracellular volume fraction (Vin), cell diameter, cellularity, extracellular diffusivity (Dex)) were compared between them. The area under the receiver operating characteristic curve (AUC) was used to evaluate the diagnostic performance of these indices. Histopathologic validation was performed by correlating td-dMRI parameters with hematoxylin-eosin (H&E) stained sections.
Results or Findings: In enhancing tumor regions, PCNSL showed significantly lower cell diameter and Dex, but higher Vin and cellularity than GBM (all $p < 0.001$). Vin demonstrated the highest diagnostic accuracy (AUC = 0.901, sensitivity = 0.737, specificity = 0.906). No significant differences were found in peritumoral regions. Vin correlated strongly with histopathologic nuclear volume fraction ($r = 0.76$, $p < 0.001$).
Conclusion: Td-dMRI-derived microstructural parameters, particularly Vin, effectively differentiate PCNSL from GBM, offering a noninvasive approach to improve preoperative diagnosis.
Limitations: First, due to the small sample size, the model may be overfitted, so combined diagnostic performance was not evaluated. Larger sample sizes are necessary to verify this model in the future. Second, ROIs were manually defined, automated tumor segmentation methods may reduce the inter-operator variability and improve the accuracy. Third, histopathologic slides were obtained by sampling a limited area of the tumor, whereas td-dMRI-based microstructural parameters were derived from the entire tumor region, leading to a lack of precise matching. Finally, we didn't combine td-dMRI parameters with other MRI methods, which may further improve the diagnostic performance of a single indicator.
Funding for this study: This work was supported by the National Natural Science Foundation of China (82202230, 82371945).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Institutional Review Board approval was obtained.

SF 7a - Staging of breast cancer

Categories: Oncologic Imaging, Breast, Nuclear Medicine, President's Choice
ETC Level: LEVEL II+III
Date: March 5, 2026 | 08:00 - 09:30 CET
CME Credits: 1.5

Moderator:
Eva M. Fallenberg; München / Germany

Chairperson's introduction (5 min)
Eva M. Fallenberg; München / Germany

Local staging: how and when? (13 min)
Iva Biondić Špoljar; Zagreb / Croatia

1. To explain the importance of breast cancer stagingin determining prognosis and guiding treatment decisions.
2. To differentiate between the various types of staging, including clinical, pathological, and imaging-based staging.
3. To understand the current guideline-based recommendationsfor imaging and staging work-up in newly diagnosed breast cancer.

Imaging for metastasis: modality and patient selection (13 min)
Nuala Healy; Dublin / Ireland

1. To discuss indications for performing staging for breast cancer metastasis to allow early detection to ensure optimal patient outcomes.
2. To describe and evaluate current standard imaging techniques utilised in the staging of breast cancer metastasis, discussing strengths and limitations of these established modalities in clinical practice.
3. To explore novel and emerging imaging techniques and modalities for detecting metastatic breast cancer.

PET: novel tracers and role of PET/MRI (13 min)
Thiemo Van Nijnatten; Maastricht / Netherlands

1. To understand the principle of a one-stop-shop approach using PET-MRI (including a diagnostic breast MRI) in breast cancer patients.
2. To describe the current shortcomings of 18F-FDG PET in breast cancer patients.
3. To name the novel PET tracers considered for clinical implementation in breast cancer patients.

Whole-body MRI in breast imaging: is it useful? (13 min)
Anwar R. Padhani; Northwood / United Kingdom

1. To highlight the limitations of traditional imaging in detecting bone deposits and understanding their therapeutic implications.
2. To know about protocols and common indications for WB-MRI use, focusing on staging assessments.
3. To address ongoing challenges and unanswered questions about the perceived effectiveness of WB-MRI in staging.

Utilising large language models to improve comprehension of breast imaging reports (10 min)
Hemal Grover; New York / United States

1. To evaluate the performance of large language models (like ChatGPT and Gemini in improving the readability of actionable breast imaging reports (ie BIRADS 3, 4 and 5).
2. To evaluate the accuracy of LLM-generated layperson reports.
3. To compare the performance of ChatGPT and Gemini.

Dream and reality: a patient perspective (13 min)
Eva Schumacher-Wulf; Cologne / Germany

1. To indicate the expectations and understanding of using staging examinations from a patient's perspective.
2. To realise the fears and releases patients experience during their treatment path.

Panel discussion: Staging and monitoring of patients: how can we add value? (10 min)

SF 7b - Exploring testicular diseases

Categories: Emergency Imaging, Oncologic Imaging, Genitourinary
ETC Level: LEVEL II+III
Date: March 5, 2026 | 08:00 - 09:30 CET
CME Credits: 1.5

Moderator:
Ivana Blazic; Belgrade / Serbia

Chairperson's introduction (4 min)
Ivana Blazic; Belgrade / Serbia

Inflammatory conditions (19 min)
Vikram Dogra; Rochester / United States

1. To explain the role of ultrasound and colour flow Doppler in the diagnosis and management of epididymitis and differential diagnosis for epididymitis.
2. To evaluate the role of high-resolution grayscale ultrasound in assessing orchitis and epididymitis, distinguishing normal from pathological findings.
3. To describe the sonographic and clinical features of Fournier's gangrene, recognising early imaging markers for timely intervention.

Scrotal trauma (19 min)
Laurence Rocher; Clamart / France

1. To identify the traumatic involvement of the several contents of the scrotum, including testis, epididymis, tunica vaginalis, spermatic cord, and scrotal wall.
2. To be able to recognise the US signs, which should prompt rapid surgery.
3. To be aware of potential misdiagnosis: scrotal tumours, infarcts, or other rare presentations of acute scrotum pathologies falsely attributed to trauma.

Testicular masses (19 min)
Jonathan Leonard Richenberg; Seaford / United Kingdom

1. To become familiar with the concept of the small (impalpable) testicular mass and the problems it may cause.
2. To become familiar with the US techniques available to assist in solving these problems.
3. To develop strategies for your practice using multiparametric US and MRI in the diagnosis/categorisation of intratesticular masses.

Challenging cases (19 min)
Mustafa Seçil; Izmir / Turkey

1. To learn the appropriate use of imaging methods and diagnostic algorithms in challenging cases of testicular diseases.
2. To identify the radiological clues for challenging conditions of a variety of radiological presentations of testicular diseases.
3. To understand how to use the clinical and laboratory findings for radiological differential diagnosis of testicular diseases.

Panel discussion: Different clinical scenarios: which recommendations should we give regarding the time of imaging and radiology reporting? (10 min)

How 7a - My practical tricks: how I ensure clinically relevant cardiac MRI in challenging patients

Chairperson's introduction (2 min)
Jean-Paul Vallee; Onex / Switzerland

Coronary artery disease: don’t stress, unless you really have to (15 min)
Bernd J. Wintersperger; Toronto / Canada

1. To explain, step by step, the acquisition protocols for stress and non-stress cardiac MRI in patients with coronary artery disease, with an emphasis on the practical difficulties that may be encountered.
2. To review the indications for stress and non-stress cardiac MRI in coronary patients, and the diagnostic information that MRI can provide.
3. To learn how to analyse and report stress and non-stress cardiac MRI, and how to avoid the most common pitfalls.

Cardiomyopathies: when cardiac MRI flexes its muscles (15 min)
Jean-Michel Serfaty; Nantes - Saint Herblain / France

1. To explain the cardiac MRI acquisition protocol and how to adapt it in the presence of arrhythmia, poor breath-holding capacity, or patients unable to remain in the MRI scanner for extended periods.
2. To become familiar with the different types of cardiomyopathies and the use of T1 and T2 mapping, as well as gadolinium enhancement, in their assessment.
3. To learn how cardiac MRI can support the clinical management of patients with cardiomyopathies.

Congenital heart disease and valvular disorder: cardiac MRI is right on the flow (15 min)
Maurice Pradella; Basel / Switzerland

1. To explain the principles of flow imaging acquisition, highlighting the respective advantages of 2D and 4D flow MRI.
2. To learn how to recognise flow artefacts and accurately analyse and interpret flow images.
3. To understand the clinical utility of cardiac MRI in managing congenital heart disease and valvular disorders.

How 7b - How and what we learn from challenging neuro and head and neck cases: interactive edition

Categories: Neuro, Head and Neck

ETC Level: ALL LEVELS

Date: March 5, 2026 | 08:15 - 09:15 CET

CME Credits: 1

This lively, case-driven session unites expert radiologists to showcase some of challenging and most rewarding teaching cases, sourced from across the globe. Each speaker will guide the audience through authentic clinical scenarios, unpacking diagnostic uncertainties, pivotal decision moments, and the practical reasoning that leads to the right answer. Attendees will come away with a clearer sense of how seasoned experts tackle complex imaging findings, sidestep frequent traps, and translate hard-won lessons into everyday reporting and patient care. With an interactive, fast-paced format and a light dose of gamification, the session delivers high-yield take-home pearls while keeping the experience engaging and memorable.

Chairperson's introduction (2 min)
Tilak Das; Cambridge / United Kingdom

Post-operative spine: what to report as normal and abnormal (12 min)
Iris Melanie Noebauer-Huhmann; Vienna / Austria

1. To learn to distinguish expected postoperative spine changes from findings that require further evaluation.
2. To understand the indications for different imaging modalities and how to choose the most appropriate protocol for each postoperative scenario.
3. To understand how to tailor your report to provide clear, clinically relevant information for the treating team.

Tips and tricks in the follow-up of post-operative brain tumours (12 min)
Carlos Majós; Barcelona / Spain

1. To understand which imaging modalities and protocols are most useful at different stages of postoperative follow-up.
2. To develop a structured approach for evaluating follow-up scans after brain tumour surgery.
3. To learn to navigate the challenges of distinguishing true tumour progression from post-treatment imaging changes and their mimics.

What to expect in a post-operative pituitary examination (12 min)
Joanna Bladowska; Wrocław / Poland

1. To learn what to assess in postoperative pituitary imaging systematically, which findings must not be missed, and why.
2. To understand how to distinguish expected changes from relevant abnormalities that may impact patient care.
3. To develop a focused reporting approach highlighting what truly matters for endocrinological and surgical follow-up.

What do we look for after stroke treatment (12 min)
Alexandre Krainik; Grenoble / France

1. To become familiar with key imaging findings in the early phase after stroke treatment and understand which modality to use, when, and why.
2. To learn to interpret post-treatment studies focusing on clinically relevant information that guides prognosis and therapeutic decisions.
3. To identify subtle or urgent findings that require timely communication and may directly influence patient management.

Ovarian torsion: twists and turns in pelvic pain (8 min)
Nikolaos Achilleas Arkoudis; Athens / Greece

1. To identify key imaging findings of ovarian torsion across ultrasound, CT, and MRI modalities to enhance diagnostic accuracy.
2. To differentiate ovarian torsion from other causes of acute pelvic pain, such as ectopic pregnancy, pelvic inflammatory disease, and ruptured ovarian cysts, using imaging features and clinical context.
3. To review imaging-based decision-making pathways to guide timely surgical management and improve patient outcomes.

Pelvic inflammatory disease and tubo-ovarian abscess: imaging clues and complications (8 min)
Ana Blanco Barrio; Murcia / Spain

1. To analyse the spectrum of imaging findings in pelvic inflammatory disease (PID) and tubo-ovarian abscess (TOA) using ultrasound, CT, and MRI.
2. To distinguish imaging features that differentiate complicated PID and TOA from mimickers such as malignancy or endometriosis.
3. To evaluate imaging-driven management strategies and identify potential complications requiring urgent intervention.

Ectopic pregnancy: imaging in a life-threatening emergency (8 min)
Marijana Basta Nikolic; Novi Sad / Serbia

1. To identify typical and atypical imaging features of ectopic pregnancy using ultrasound, CT, and MRI.
2. To recognise key imaging findings that help differentiate ectopic pregnancy from other pelvic emergencies.
3. To understand the role of imaging in guiding urgent management and improving patient outcomes.

Postpartum and post-cesarean emergencies (8 min)
Elizabeth Dick; London / United Kingdom

1. To recognise the spectrum of imaging findings in common postpartum and post-cesarean complications.
2. To differentiate regular postoperative changes from pathological conditions using ultrasound, CT, and MRI.
3. To guide clinical management by identifying imaging signs of life-threatening postpartum emergencies, such as haemorrhage, infection, and uterine rupture.

Acute scrotum: testicular torsion and beyond (8 min)
Karolina Markiet; Gdańsk / Poland

1. To identify the critical imaging features of testicular torsion and other causes of acute scrotal pain using ultrasound and Doppler evaluation.
2. To differentiate between surgical and non-surgical causes of acute scrotum based on imaging findings.
3. To recognise imaging pitfalls and atypical presentations that can delay diagnosis and impact patient outcomes.

Penile trauma and other emergencies of the penis (8 min)
DINESH D CHINCHURE; Singapore / Singapore

1. To describe the imaging features of common penile emergencies, including fracture, priapism, and vascular injuries.
2. To differentiate between true penile fracture and other causes of penile trauma using ultrasound and MRI.
3. To understand the role o

Basics about different embolisation materials (28 min)
Pierleone Lucatelli; Roma / Italy

1. To understand the technical principles of different embolisation materials, including plugs, coils, glue, and EVOH-based agents.
2. To evaluate each material's respective risks, benefits, and limitations.
3. To recognise clinical situations where a specific embolic material is most appropriate.

ST 11 - Strengthening Cancer Care Through IAEA Anchor Centres: From Vision to Sustainable Regional Impact

Categories: Oncologic Imaging, Research, Physics in Medical Imaging, Education, Artificial Intelligence

Date: March 5, 2026 | 09:00 - 09:30 CET

The IAEA continues its commitment to improving global access to safe, effective, and equitable cancer care through the work of Anchor Centres—regional hubs of excellence in radiology, nuclear medicine and radiotherapy. These centres play a pivotal role in strengthening local expertise, supporting educational, research and quality assurance infrastructure, and promoting sustainable technology transfer within their regions. In this interview, experts from the IAEA Human Health Division will discuss the model's impact on workforce development, mentoring, and regional cooperation. The discussion will highlight success stories, ongoing collaborations, and how the Anchor Centres network supports the broader Rays of Hope framework to achieve long-term resilience and self-reliance in cancer care.

Chairperson's introduction (5 min)
Regina G.H. Beets-Tan; Amsterdam / Netherlands

From scan to score: developing AI models for cardiovascular risk prediction (10 min)
Philipp Seeböck; Vienna / Austria

1. To learn about the potential of AI tools for improved obesity-related prediction of cardiovascular disease.
2. To understand the process of building AI models for cardiovascular risk prediction.
3. To recognise key considerations in training, validating, and interpreting AI-driven risk models.

Integrating AI into clinical practice: the AI-POD clinical decision support system (10 min)
Johannes Grapentin; Karlsruhe / Germany

1. To understand the clinical need for AI tools for clinical decision making for obesity-related cardiovascular disease.
2. To learn about the potential and functionalities of the AI-POD CDSS.
3. To understand how the AI-POD system supports personalised decision-making in cardiovascular care.

Real-world validation: early observations from the AI-POD clinical study (10 min)
Anastasia Bartashova; Wien / Austria

1. To learn about the real-world application of the AI-POD tools.
2. To appreciate the initial findings from the AI-POD clinical study.
3. To learn about the performance and usability of AI tools in routine patient care based on early study outcomes.

Trust, adoption, and ethical considerations: preliminary results from the AI-POD stakeholder analysis (10 min)
Kaat Goossens; Leuven / Belgium

1. To appreciate the early results of the AI-POD survey study on ethical and societal concerns and barriers towards AI-based decision-making and risk prediction in cardiovascular care.
2. To understand stakeholder perspectives on AI's ethical, legal, and social aspects in healthcare.
3. To learn about barriers and enablers to trust and adoption of AI systems among clinicians and patients.

Joao Rodrigues Inacio; Lisbon / Portugal

General approach to ILD: select the main feature! (23 min)
Helmut Prosch; Vienna / Austria

1. To understand the importance of micronodule distribution.
2. To recognise different reticular patterns.
3. To identify the main aetiologies of ground glass opacities and consolidation.

Fibrosing lung diseases: how to recognise them? (23 min)
Nicola Sverzellati; Parma / Italy

1. To learn about the key features of lung fibrosis on CT.
2. To become familiar with its different entities.
3. To understand the importance of zonal predominance in achieving an accurate diagnosis.

Panel discussion: Would only radiologists specialised in thoracic imaging be able to approach diffuse interstitial lung diseases? (11 min)

HF 2 - Radiology Education at Scale: Up in the cloud

Categories: Professional Issues, Management/Leadership, Imaging Informatics, Artificial Intelligence
ETC Level: ALL LEVELS
Date: March 5, 2026 | 10:00 - 11:00 CET
CME Credits: 1

Moderators:
Isabelle Thomassin-Naggara; Paris / France
Nishat Bharwani; Surbiton / United Kingdom

Chairpersons' introduction (3 min)
Isabelle Thomassin-Naggara; Paris / France
Nishat Bharwani; Surbiton / United Kingdom

What can be done to ensure hands-on radiology education and training are widely available when training programmes are not evenly distributed? In this session, the experience of providing hands-on radiology education at scale through the Atualiza programme in Brazil will be described. This is the world's largest hands-on radiology teaching event. The academic coordinators will present the ambition of the course. Then, the platform provider Collective Minds demonstrates the steps it takes to utilise and share educational imaging content at scale. At the end of this session, participants will have learned about the steps to develop a successful global educational event, using a live educational platform for hands-on experience.

Brazilian College of Radiologists Atualiza Programme (12 min)
Ronaldo Hueb Baroni; São Paulo / Brazil

1. To learn about the possibilities of going from onsite to online for hands-on workshops in radiology.
2. To appreciate the experience of the Brazilian College of Radiology in previous online workshops using a dedicated platform for more than one thousand participants in a single event.
3. To understand the potential and applications of online platforms to scale up hands-on workshops for larger, international audiences.

Collective Minds Cloud Education Platform (12 min)
Fredrik Illerstam; Danderyd / Sweden

1. To learn about which user experience-related features are required by a platform to successfully run virtual hands-on workshops in radiology.
2. To appreciate why cloud technology is necessary to facilitate user experience and concurrency at scale.
3. To understand key technical and legal aspects that should be considered for virtual hands-on workshops in radiology.

How did AWS support the solution? (12 min)
Razvan Ionasec; Munich / Germany

Q&A (21 min)

How 8 - How we do it: clinical audit

Categories: Professional Issues, Audit, President's Choice

ETC Level: LEVEL I

Date: March 5, 2026 | 10:00 - 11:00 CET

CME Credits: 1

Attendees of this session will have the unique opportunity to engage in a discussion with Europe's leading experts on clinical audit, share their experiences and find out how to implement clinical audit in their own practice. The experts, representing both radiology and nuclear medicine, will provide a unique perspective on the topic, speaking from their knowledge and experience. Each attendee will be able to participate in the discussion and discover existing materials to support radiologists and nuclear medicine specialists in implementing a clinical audit. The session has been organised by CLAUD-IT: Clinical Audit Implementation in Europe: a Practical and Multidisciplinary approach, a project co-funded by the European Union under the EU4Health programme.

Moderator:

Rebecca Greenhalgh; Harrow / United Kingdom

Chairperson's introduction (5 min)

Rebecca Greenhalgh; Harrow / United Kingdom

Clinical audit in radiology (5 min)

Peter Mildenberger; Mainz / Germany

Clinical audit in nuclear medicine (5 min)

Francesco Giammarile; Gubbio / Italy

CLAUD-IT methodology (5 min)

Roman Klöckner; Lübeck / Germany

Open forum discussion (40 min)

HW Ua 8 - AI perspectives in ultrasound

Categories: Artificial Intelligence
ETC Level: LEVEL I+II
Date: March 5, 2026 | 10:00 - 11:30 CET
CME Credits: 1.5

Moderator:
Thomas Fischer; Berlin / Germany

Introduction (15 min)
Thomas Fischer; Berlin / Germany

1. To understand the latest state of the art Artificial Intelligence technology available on US scanners.
2. To investigate the potential utility of such tools.
3. To understand the clinical impact of this advancing AI technology.
4. To understand the current limitations and where future developments will occur.

Hands-on demonstration (75 min)

Demonstrators
Vito Cantisani; Rome / Italy
Dirk-André Clevert; Munich / Germany
Artūras Samuilis; Vilnius / Lithuania
Ernst Michael Jung; Regensburg / Germany
Richard G. Barr; Canfield / United States
Jean Michel Correas; Paris / France
Adrian K. P. Lim; London / United Kingdom
Thomas Fischer; Berlin / Germany
Maija Radzina; Riga / Latvia
Paul Spiesecke; Berlin / Germany
Caroline Ewertsen; Copenhagen / Denmark
Paul S. Sidhu; London / United Kingdom

Workshop assistant
James Burn; London / United Kingdom

OF 8R - Radiographers' autonomy in clinical practice and new technologies

Categories: Radiographers, Professional Issues
Date: March 5, 2026 | 10:00 - 11:00 CET
CME Credits: 1

Moderator:
Christoph Kamp; Vienna / Austria

Chairperson's introduction (5 min)
Christoph Kamp; Vienna / Austria

Radiologists' and radiographers' collaboration for harmonising acquisition protocols (12 min)
Nuria Bargallo I Alabart; Barcelona / Spain

1. To understand the importance of collaborative protocol development between radiologists and radiographers to ensure consistency, quality, and patient safety in imaging.
2. To identify strategies for harmonising acquisition protocols across departments, including the use of standardisation tools, communication frameworks, and shared decision-making.
3. To explore strategies for effective interprofessional communication and implementation by recognising the role of radiographers as autonomous professionals for optimisation of clinical practice.

Teleradiology and contrast media management in rural areas (12 min)
Svetlana Timoshenko; Tromsø / Norway
Marijana Stepanovic-Johnskareng; Tromsø / Norway

1. To understand the role of teleradiology in supporting rural imaging services through the support of radiographers, particularly where on-site radiologists are not available.
2. To recognise the evolving responsibilities of radiographers in contrast media management, including patient preparation, monitoring, and emergency protocols.
3. To explore the expanding role of radiographers in rural healthcare systems, highlighting their autonomy in coordinating imaging workflows, collaborating remotely with radiologists, and ensuring high-quality patient care.

Integrating photon-counting CT into radiographers' practice (12 min)
Martin Weber Kusk; Esbjerg / Denmark

1. To understand the key principles and advantages of photon-counting CT technology.
2. To describe the role of radiographers in adapting protocols and workflows for photon-counting CT implementation in clinical practice.
3. To recognise how this technology supports radiographers' advanced practice and enhances diagnostic quality.

Open forum discussion (19 min)

OF 8Y - Channel your inner reviewer

Categories: Students, Research, Education
ETC Level: LEVEL II+III
Date: March 5, 2026 | 10:00 - 11:00 CET
CME Credits: 1

Moderator:
Paola Clauser; Vienna / Austria

Chairperson's introduction (5 min)
Paola Clauser; Vienna / Austria

Fostering ethical reviewing (7 min)
Jose Maria Garcia Santos; Murcia / Spain

1. To introduce and define publication ethics.
2. To learn about duplication, redundancy, overlaps, and salami-slicing.
3. To understand ethical and unethical author behaviour.

Role of the reviewer (7 min)
Rossano Girometti; Udine / Italy

1. To learn what makes an ideal review.
2. To learn to provide constructive suggestions to authors and editors, avoiding destructive comments.
3. To learn how to review a revised manuscript.

Reporting guidelines (7 min)
Giulia Zamboni; Verona / Italy

1. To consider diversity of data (equity, balance, race, and ethical issues).
2. To understand how to use reporting guidelines (including Equator network, AI, CLEAR).

What to consider when reviewing AI papers (7 min)
Daniel Pinto Dos Santos; Mainz / Germany

1. To learn about the importance of data splitting (training, testing, validation, etc.).
2. To appreciate the particularities of AI-related manuscripts.
3. To understand how to evaluate AI depending on the task.

What is the clinical impact (7 min)
Paola Clauser; Vienna / Austria

1. To understand what succeeds at creating clinical impact (and what fails to).
2. To create an impactful clinical/critical relevance (statement).
3. To understand how to link clinical impact and citation performance.

Open forum discussion: What makes a good reviewer and how to become one? (20 min)

RC 800a - Imaging of sports trauma: paediatric vs adult patterns

Categories: Musculoskeletal, Imaging Methods, Paediatric, Multidisciplinary, President's Choice

Date: March 5, 2026 | 10:00 - 11:00 CET
CME Credits: 1

Moderator:
Thekla von Kalle; Stuttgart / Germany

Chairperson's introduction (5 min)
Thekla von Kalle; Stuttgart / Germany

Complex injuries in the knee: adult versus paediatric (15 min)
Ignasi Barber; Esplugues de Llobregat / Spain

1. To distinguish the different anatomical and mechanical structures of the knee in children and adults.
2. To identify the different features in imaging of complex knee injuries in adults versus children.
3. To optimise the diagnostic workflow, CT and MR protocol in adults and children with complex knee injuries.

Triplane fractures and adult trimalleolar fractures in soccer: mechanism of action and findings at imaging (15 min)
Paolo Simoni; Luxembourg / Luxembourg

1. To understand the typical mechanisms of injury.
2. To understand the anatomical and structural differences according to age.
3. To apply the proper diagnostic workflow and identify the main findings.

Shoulder injuries in the young and adult throwing athlete (15 min)
Dyan Christine Vallejo Flores; Ottawa / Canada

1. To describe the typical mechanism of injury in throwing athletics.
2. To characterise the imaging features of shoulder injuries in adults and paediatric throwing athletes.
3. To define the proper diagnostic workflow in both age groups.

Panel discussion: What is the best technique to assess sports trauma in children and adults (10 min)

RC 800b - The real-world impact of AI on clinical radiology and radiography

Categories: Radiographers, Imaging Informatics, Multidisciplinary, Artificial Intelligence
ETC Level: LEVEL I+II

How has evidence-based AI changed the radiographer's work? (15 min)
Svea Deppe Moerup; Middelfart / Denmark

1. To learn how AI can be applied to streamline clinical workflows, such as CT, and reduce turnaround times.
2. To appreciate the role of AI in balancing clinical workloads and supporting decision-making in high-demand imaging departments.
3. To understand the practical and ethical considerations involved in integrating AI into workflow management systems.

The prime-time AI applications in diagnostic radiology and workflow (15 min)
Matthias Stefan May; Erlangen / Germany

1. To review the AI applications in radiology that show real-world evidence assisting with diagnosis and decision-making.
2. To learn about how AI can tangibly improve the workflow for radiologists.
3. To provide a roadmap for the evidence-based integration and post-market surveillance of AI applications.

How can AI facilitate and enhance a patient-focused radiologist-radiographer collaboration? (15 min)
Nikolaos Stogiannos; Corfu / Greece

1. To outline the major challenges of AI implementation with regard to human-AI interaction.
2. To discuss ways to engage in patient-centred practices when using AI in clinical practice.
3. To underline the importance of Radiologist-Radiographer-Patient collaborations within clinical settings for providing patient-centred care.

Panel discussion: The radiologist and radiographer as enablers for AI integration, patient safety and real-world impact (10 min)

RC 800c - The skull base: imaging essentials

Categories: Emergency Imaging, Oncologic Imaging, Neuro, Head and Neck, President's Choice
ETC Level: LEVEL II+III
Date: March 5, 2026 | 10:00 - 11:00 CET
CME Credits: 1

Moderator:
Yeliz Pekçevik; Izmir / Turkey

Chairperson's introduction (5 min)
Yeliz Pekçevik; Izmir / Turkey

Bridging the gap: imaging the skull base from brain to neck (15 min)
Alexandra Borges; Lisbon / Portugal

1. To review key anatomical landmarks of the skull base relevant to both neuroradiologists and head and neck radiologists.
2. To identify the most effective imaging modalities and protocols for assessing complex skull base regions.
3. To understand how cross-speciality collaboration enhances diagnostic accuracy in skull base pathology.

Decoding tumours and spread at the skull base (15 min)
Davide Farina; Brescia / Italy

1. To differentiate common skull base tumours based on imaging characteristics and location.
2. To recognise typical and atypical patterns of tumour infiltration and perineural spread.
3. To apply a multimodal and multidisciplinary approach to accurately assess tumour extent and guide management.

Skull base lesions beyond tumours: infections, inflammation and vascular disease (15 min)
Anne Renée Juliette Péporté; Frauenfeld / Switzerland

1. To identify imaging features of infectious, inflammatory, and vascular skull base lesions.
2. To distinguish between tumour-mimicking and true neoplastic processes in challenging cases.
3. To understand key diagnostic pitfalls and when to recommend further imaging or biopsy.

Panel discussion: Future directions in skull base imaging (10 min)

RC 801 - Focal lesions in cirrhotic liver: telling the good guys from the bad ones

Categories: Interventional Oncologic Radiology, Contrast Media, Abdominal Viscera, President's Choice
ETC Level: LEVEL II+III
Date: March 5, 2026 | 10:00 - 11:00 CET
CME Credits: 1

Moderator:
Sükrü Mehmet Ertürk; Istanbul / Turkey

Chairperson's introduction (3 min)
Sükrü Mehmet Ertürk; Istanbul / Turkey

The role of hepatobiliary contrast agents: essential or optional? (15 min)
Valérie Vilgrain; Clichy / France

1. To understand the diagnostic performance of hepatobiliary phase imaging in cirrhotic livers.
2. To differentiate between hepatocellular carcinoma (HCC), dysplastic nodules (DN), and benign nodules using hepatobiliary agents.
3. To discuss pitfalls and false positives/negatives in daily practice.

Liver Imaging Reporting and Data System (LI-RADS): simplifying complexity or complicating decisions? (15 min)
Victoria Chernyak; Bronx / United States

1. To explain the structure of the LI-RADS diagnostic algorithm, including its categories and lexicon, to understand how it aims to standardise liver imaging assessment in patients at high risk for HCC.
2. To learn how to evaluate the role of LI-RADS in clinical decision-making, considering its benefits of consistency and standardisation as well as potential drawbacks of complexity and limitations of implementation in some clinical settings.
3. To discuss recent updates of the LI-RADS diagnostic algorithm that aim to enhance usability and clinical relevance.

Is imaging enough? (15 min)
Hanyu Jiang; Chengdu / China

1. To recognise when a biopsy is needed despite advanced imaging.
2. To discuss the complementary role of imaging and biopsy
3. To propose management algorithms based on combined data.

Panel discussion: Imaging and pathology: competition or complement? (12 min)

RC 802 - Pros and Cons: This house believes that we are ready to adopt AI for breast cancer screening

Categories: Imaging Methods, Breast, Artificial Intelligence
ETC Level: LEVEL III
Date: March 5, 2026 | 10:00 - 11:00 CET
CME Credits: 1

Moderator:
Ruud M Pijnappel; Utrecht / Netherlands

Chairperson's introduction (5 min)
Ruud M Pijnappel; Utrecht / Netherlands

1. To critically appraise current evidence for and against AI implementation in breast cancer screening.
2. To recognise the practical, clinical, and ethical challenges in integrating AI into population-based screening programmes.
3. To formulate informed positions on the role of AI in screening, based on contrasting expert perspectives.

Pro (for the motion) (15 min)
Fredrik Strand; Stockholm / Sweden

Con (against the motion) (15 min)
Fiona J. Gilbert; Cambridge / United Kingdom

Panel discussion: AI in screening: are we ready or rushing? (25 min)

RC 803 - Ischaemic heart disease

Date: March 5, 2026 | 10:00 - 11:00 CET
CME Credits: 1

Moderator:
Maja Pirnat; Maribor / Slovenia

Chairperson's introduction (5 min)
Maja Pirnat; Maribor / Slovenia

Clinical presentation, triaging and test selection (15 min)
Robert Manka; Zürich / Switzerland

1. To learn about the typical and not-so-typical presentation of myocardial infarction (MI).
2. To understand the rationale of triage.
3. To review the first-line testing and additional test selection.

CT in acute chest pain (15 min)
Matthias Eberhard; Zurich / Switzerland

1. To learn about clinical evidence for using coronary computed tomography angiography (CCTA) in the emergency setting.
2. To learn the information advanced cardiac CT (CCT) offers and iist clinical use

MRI in ischaemic heart disease (15 min)
Julian Alexander Luetkens; Bonn / Germany

1. To learn about the imaging approach to Angina with Nonobstructive Coronary Arteries (ANOCA), Ischemia with No Obstructive Coronary Arteries (INOCA) and Myocardial Infarction with Non-Obstructive Coronary Arteries (MINOCA).

Panel discussion: The best clinical pathway for a successful patient outcome (10 min)

RC 806 - ALPHA, BETA, GAMMA: radioligands in action, transforming cancer imaging and therapy

Categories: Hybrid Imaging, Oncologic Imaging, Molecular Imaging, Nuclear Medicine

ETC Level: LEVEL II+III

Date: March 5, 2026 | 10:00 - 11:00 CET

CME Credits: 1

Theranostics is rapidly growing. Alpha-emitting radionuclides increase therapeutic efficacy. Therapeutic radionuclides that decay by emitting β-, such as Lutetium-177, are well established in clinical practice. Radionuclides emitting internal conversion and Auger electrons, e.g. Terbium-161, are approaching translation. Imaging with gamma-emitting radiopharmaceuticals enhance treatment efficacy by personalising radiation doses to individual patients, allowing to maximise tumouricidal therapeutic effects while minimising toxicity to healthy organs. The session outlines the fundamental principles, procedures, and methodologies in imaging, dosimetry and therapy.

Moderator:

Désirée Deandreis; Villejuif / France

Chairperson's introduction (5 min)

Désirée Deandreis; Villejuif / France

Alpha-emitting radionuclide therapy: the next frontier in targeted cancer treatment (15 min)

Mike Sathekge; Pretoria / South Africa

Beta-emitting and Auger electron radiopharmaceuticals: impact and opportunities for targeted imaging and therapy (15 min)

Karolien Goffin; Leuven / Belgium

Gamma emitting imaging: status, success, and future potential in theranostics including dosimetry (15 min)

Andrei Iagaru; Stanford / United States

Panel discussion: How and who should we treat (10 min)

RC 813 - How to play the game: cumulative effective dose (CED) concept - pros and cons in clinical practice

Categories: Professional Issues, Physics in Medical Imaging, EuroSafe Imaging/Radiation Protection, Medico-legal, Multidisciplinary
ETC Level: LEVEL I+II
Date: March 5, 2026 | 10:00 - 11:00 CET
CME Credits: 1

SESSION RECOMMENDED BY ESR EUROSAFE IMAGING

Moderators:
Paula Toroi; Vantaa / Finland
Vesna Gershan; Vienna / Austria

Chairperson's introduction (5 min)
Paula Toroi; Vantaa / Finland

Cumulative effective dose (CED) in radiology (15 min)
Vesna Gershan; Vienna / Austria

1. To understand the relationship between exposure indexes as recorded in the dose structured reports and the patient's effective dose, as well as the need for a periodic check and calibration of exposure indexes reported by the radiological equipment.
2. To learn about the role of radiation exposure monitoring systems and the status of their implementation in Europe.
3. To understand how to use information from radiation exposure monitoring systems for optimisation purposes – including the cumulative dose perspective.

Beyond the concept of CED (15 min)
Marco Brambilla; Novara / Italy

1. To understand the epidemiological and radiobiological basis of the cumulated effective dose quantity.
2. To understand how Recurrent Exposure Reference Levels (RERL) could be used as a tool for the optimisation of the management of recurrent patients among different health care centres.
3. To learn about the multicentric European study on Recurrent Exposure Reference Levels (RERL) establishment.

Radiologists' perspective on CED (15 min)
Donald P. Frush; Durham / United States

1. To learn about what is recurrent medical imaging, which patient cohorts submitted to recurrent imaging are under most investigations and what is the magnitude of the phenomenon.
2. To understand which are the challenges and pitfalls when dealing with recurrent imaging exposure without inappropriately influencing decision making.
3. To be aware of joint position statements concerning Recurrent Radiological Imaging procedures and the proposed way forward (IAEA & AAPM).

Panel discussion: Are we ready to use the cumulative effective dose concept in clinical practice? (10 min)

RPS 801 - Advances in inflammatory bowel disease (IBD) imaging

Date: March 5, 2026 | 10:00 - 11:00 CET
CME Credits: 1

Moderator:
Jaap Stoker; Amsterdam / Netherlands

MRI in Perianal Fistulizing Crohn's Disease: Inter-Reader Agreement of MAGNIFI-CD and 3D Volume Measurements (6 min)
Kristin Johnson; Lund / Sweden

Author Block: K. Johnson[1], I. De Kock[2], K. J. H. Bengtsson[3], B. Janssens[1], A. Menys[4], G. Bislenghi[1], C. W. P. Greer[4], G. Bhatnagar[4], B. Verstockt[1]; [1]Leuven/BE, [2]Ghent/BE, [3]Lund/SE, [4]London/UK
Purpose: The Magnetic Resonance Novel Index for Fistula Imaging in Crohn's Disease (MAGNIFI-CD) and 3D volumetry are emerging metrics for quantifying and visualizing perianal Crohn's disease (pCD). The purpose of the study was to assess inter-reader agreement for both metrics in different pCD TOpClass categories among radiologists with varying levels of expertise in inflammatory bowel disease (IBD).
Methods or Background: Fifty pelvic MRIs from 50 unique pCD patients were retrospectively and randomly selected from a single-center IBD database: 25 represented minimal disease (suitable for repair; TOpClass 1–2a), while 25 represented disease requiring symptom control interventions/proctectomy (TOpClass 2b–3). Six radiologists independently assessed each MRI using a commercial MAGNIFI-CD module (Entrolytics by Motilent), blinded to clinical data. Three were IBD experts (>50 fistula MRI reads/year), three were non-IBD experts (<10/year). MAGNIFI-CD (0–25) was scored, and contrast-enhancing fistula volumes were manually segmented on T1 post-contrast axial images. Inter-reader agreement was analyzed through intraclass correlation coefficient (ICC).
Results or Findings: Inter-reader agreement for MAGNIFI-CD was ICC = 0.747 (95% CI: 0.640–0.835), among experts 0.786 (0.681–0.865) and non-experts 0.780 (0.610–0.877). Agreement for 3D volume was 0.887 (0.830–0.929), among experts 0.872 (0.792–0.923) and non-experts 0.893 (0.796–0.942). In TOpClass 1–2a, agreement for MAGNIFI-CD was 0.706 (0.561–0.834) and volume 0.537 (0.367–0.715). In TOpClass 2b–3, agreement was 0.664 (0.482–0.816) for MAGNIFI-CD and 0.885 (0.800–0.943) for volume.
Conclusion: MAGNIFI-CD and 3D fistula volume measurements showed substantial to almost perfect inter-reader agreement with comparable performance between experts and non-experts, underscoring their reliability for research and clinical use. Agreement for volume was, however, only moderate in mild disease (TOpClass 1–2a), indicating greater assessment difficulty in this subgroup.
Limitations: Single-center, small sub-groups.

Mesenteric and Anti-mesenteric Border Sub-regionalization Using MR Enterography: Advancing Fibrosis Evaluation in Crohn's Disease (6 min)
Luyao Wu; Guangzhou / China

Author Block: L. Wu, J. Lin, W. Zheng, X. Shen, L. Huang, R. Zhang, Y. Wang, S-T. Feng, X. Li; Guangzhou/CN
Purpose: Accurate diagnosis of intestinal fibrosis in Crohn's disease (CD) is crucial, with fibrosis heterogeneity impacting imaging accuracy. To develop and validate a novel diagnostic strategy based on sub-regionalization into mesenteric and anti-mesenteric borders on MR enterography (MRE), for addressing diagnostic challenge posed by fibrosis heterogeneity.
Methods or Background: This study included 184 CD patients across two surgical and one follow-up cohorts. We prospectively recruited 12 patients who underwent MRE and surgery. MRE co-registration with ileal specimens was achieved for 88 sections using 3D-printing and creeping fat information. Optimal multivariable MRE models for mesenteric border, anti-mesenteric border, and whole-circle regions were constructed referencing histological fibrosis and validated in another surgical cohort with 21 patients. The sub-regionalization strategy's impact on disease progression was assessed in a retrospective cohort of 151 patients.
Results or Findings: Histological fibrosis scores were higher in mesenteric border than anti-mesenteric border regions in both surgical cohorts (both P<·05). MRE models showed the highest diagnostic efficacy for fibrosis in mesenteric border (AUC=0.91), followed by anti-mesenteric border (AUC=0.84) and whole-circle (AUC=0.77) regions in surgical cohort 1. In surgical cohort 2, MRE also showed higher efficacy in mesenteric border (AUC=0.87) than anti-mesenteric border (AUC=0.77) regions. In follow-up cohort, baseline fibrosis measurements in mesenteric border region (HR=9.25) had the greatest impact on disease progression versus other bowel regions (HR=0.28-2.09).
Conclusion: Intestinal fibrosis demonstrates spatial heterogeneity. Intestinal sub-regionalization into mesenteric and anti-mesenteric borders improves MRE's diagnostic effectiveness and may aid in predicting CD progression.
Limitations: First, the sample size of participants was limited, which is common in proof-of-concept studies. Second, we focused only on the terminal ileum.
Funding for this study: This study was financially supported by National Natural Science Foundation of China (82070680, 82270693, 82271958, 82471948, and 82072002). The funders of the study had no role in study design, data collection, data analysis, data interpretation, or writing of the report.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was approved by the institutional ethics review board of our hospital (No. [2023]849).

T2 Mapping as a quantitative biomarker for assessing intestinal inflammation in Crohn's disease: preliminary evidence (6 min)

Pierluca Minelli; Trieste / Italy

Author Block: P. Minelli, A. Colarieti, B. Mattio, C. Garlisi, A. Carriero; Novara/IT
Purpose: To investigate the diagnostic performance of T2 mapping for the detection and quantification of bowel wall oedema in patients with Crohn's disease and to assess its correlation with fecal calprotectin levels as a biochemical marker of intestinal inflammation.
Methods or Background: This retrospective, single-center study included 18 patients with histologically confirmed Crohn's disease who underwent magnetic resonance enterography at 3T. T2-mapping sequences were acquired using a single-breath-hold axial gradient-echo protocol. Regions of interest (ROIs) were delineated on thickened bowel segments previously identified on standard T2-weighted images. Statistical analyses included Kolmogorov–Smirnov testing, paired Student's t-tests, and Pearson correlation analyses.
Results or Findings: Quantitative evaluation on non-contrast T2-weighted images revealed pathological mural thickening (>5 mm) in 15 of 18 patients, with a mean thickness of 9.5 ± 2.5 mm. T2 relaxation times followed a normal distribution in both normal ($p = 0.21$) and thickened ($p = 0.11$) bowel segments. Mean T2 values were significantly higher in thickened walls compared to normal segments (105.6 ± 4.3 ms vs. 51.8 ± 9.4 ms; $p < 10^{-6}$). No significant correlation was found between T2 values and fecal calprotectin levels.
Conclusion: T2-mapping provides a quantitative alternative for evaluating intestinal inflammation in patients with contraindications to contrast agents, serving as a dependable tool for disease monitoring during follow-up.
Limitations: This study is limited by its monocentric, retrospective design and the relatively small patient cohort. Furthermore, as T2 mapping is a parametric sequence originally developed for cardiac magnetic resonance, its application to bowel imaging requires further validation in larger, multicenter studies.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Approved by the local institutional ethics committee of AOU Maggiore della Carità, Novara, Italy (approval number: CE 090/2025).

MR Elastography Captures Mechanosensitive Piezo1 Expression to Enhance Enterographic Fibrosis Diagnosis (6 min)

CiEn Fan; Guangzhou / China

Author Block: M. Zhang, Y. Wang, X. Shen, Z. Q. Zhu, R. Zhang, J. Lin, L. Huang, X. Li, C. Fan; Guangzhou/CN
Purpose: Current diagnostic tools for fibrosis assessment in Crohn's disease (CD) remain suboptimal. MR elastography may advance toward addressing this limitation by offering tissue biomechanical characterization. Our aim was to evaluate MR elastography for intestinal fibrosis diagnosis using surgical histopathology and Piezo1 signaling as reference, and determine its incremental value over established MR enterography through machine-learning modelling.
Methods or Background: This prospective study analyzed 119 intestinal specimens from 45 CD participants undergoing preoperative MR elastography and enterography. Elastographic (shear-wave speed [SWS], loss angle [φ]), advanced (DWI, T1 mapping) and conventional enterographic
parameters were measured. Histopathological assessment included fibrosis scoring and collagen proportion analysis. Immunofluorescence Piezo1 served as stiffness reference standard. Three types of models (basic: conventional; extended: +advanced; complete: +elastographic) were developed using seven machine-learning algorithms, with performance assessed via AUC (DeLong's test).
Results or Findings: SWS and φ significantly correlated with histological fibrosis score (r=0.642/0.408) and collagen proportion (r=0.666/0.461) (all P<0.01), with AUCs of 0.870 (95% CI: 0.803-0.937) for SWS and 0.734 (0.640-0.828) for φ in differentiating moderate-to-severe from none-to-mild fibrosis. Piezo1 level correlated with histological fibrosis score (r=0.750, P<0.001) and collagen proportion (r=0.859, P<0.001). Importantly, SWS also showed significant correlation with Piezo1 expression (r=0.669, P<0.05). XGBoost consistently outperformed other algorithms across all models. Complete modelXGBoost outperformed basic modelXGBoost (AUC, 0.962 vs. 0.799; DeLong's test, P=0.029) and extended modelXGBoost (0.962 vs. 0.803; P=0.035) in validation set, confirming the added diagnostic value of MR elastography.
Conclusion: MR elastography emerges as a clinically valuable tool for quantifying intestinal fibrosis in CD, providing real-time biomechanical profiling that synergistically enhances MR enterography's precision in fibrosis severity stratification.
Limitations: Single-center recruitment may limit population representativeness and spatial sampling differences between imaging slices and histological sections was challenging.

Integrating Dual-Layer Spectral CT Quantitative Parameters with Conventional Imaging Features for Noninvasive Assessment of Crohn's Disease Activity (6 min)

Bin Zeng; Shenzheng / China

Author Block: B. Zeng[1], X. Wei[2], Z. Song[3], Z. Huang[4], Y. Liu[1]; [1]Shenzheng/CN, [2]Shenzhen/CN, [3]Qingdao/CN, [4]Guangzhou/CN
Purpose: To evaluate whether a diagnostic model combining conventional CT imaging features with quantitative parameters from dual-layer spectral detector CT (DLCT) improves the discrimination between active and remission phases of Crohn's disease (CD).
Methods or Background: This retrospective study included 89 patients with endoscopically confirmed CD (51 active, 38 in remission) who underwent contrast-enhanced DLCT. Conventional imaging features (bowel wall thickening, enhancement pattern, strictures) and spectral parameters—including iodine concentration (IC), normalized IC, effective atomic number (Zeff), and 45 keV monoenergetic attenuation—were analyzed in both arterial and venous phases. Univariate and multivariate logistic regression were used to identify independent predictors of disease activity, which were then incorporated into a combined diagnostic model. Model performance was evaluated using receiver operating characteristic (ROC) curve analysis.
Results or Findings: Univariate analysis identified 24 significant variables. Multivariate analysis demonstrated that bowel wall thickness, stricture severity, enhancement pattern, and spectral parameters—particularly IC and Zeff—were independent predictors of active CD. The combined model exhibited excellent diagnostic performance, achieving an area under the curve (AUC) of 0.959 (95% CI: 0.911–0.985, $p < 0.001$), with a sensitivity of 92.2% and specificity of 86.1%.
Conclusion: The integration of DLCT-derived quantitative parameters with conventional CT features provides a highly accurate and noninvasive method for assessing Crohn's disease activity, offering a robust tool for clinical disease monitoring and stratification.
Limitations: This study is limited by its single-center retrospective design and the sample size. Further validation in larger, prospective multicenter cohorts is warranted to confirm generalizability.

Classification of different type of radiological errors done by radiology residents in reporting MR Perianal fistulography (6 min)

Kishan Ashok Bhagwat; Harapanahalli / India

Author Block: K. A. Bhagwat; Harapanahalli/IN
Purpose: Learn different types of radiological reporting errors in MR Perianal Fistulography as per Kim and Mansfield classification
Methods or Background: MR Fistulography reporting needs adequate knowlegde of MR anatomy , acqusition , history , clinical examination to correctly report the study. However preliminary reports done by residents will have errors.
40 MRI Fistulography studies were marked on PACS , anonymized and were provided to 15 residents of radiology in third year of training to report.
Structured reporting format were provided and a line diagram were drawn for coronal and axial plane by residents.
Two consultant radiologists reviewed the reports done by residents as well as the reports done by consultants and tabulated the erros done by residents as compared to final reports. The consultants were blinded to reduce bias.
Results or Findings: All the reports done by 15 residents for 40 MR fistulograms(Total of 600 reports) and report in PACS done by Consultants were reviewed for errors.

The errors were reviewed classified as per Kim and Mansfield classification ; into twelve types of errors.
Type 4 error, underreading was most common error found among the reports. Example : Tract from the second cutaneous opening was not identified.
Type 10 error, satisfaction of search , was the next common error . The secondary tract was being missed , once primary fistula tract is obvious.
Conclusion: Human error in interpretation of radiological images does occur for various reasons.. Understanding the errors done by residnets in training in reporting the MR fistulography will help in training them better.
Limitations: Since the residents were reporting the past studies done, they may not be in real time situation of doing a preliminary reporting or final report by the consultant.
Funding for this study: None.

Diagnostic Accuracy of Non-Contrast MRI Sequences Versus Contrast-Enhanced Imaging in Inflammatory Bowel Disease: Is Contrast Administration Still Necessary? (6 min)

Rosa Alba Pugliesi; Palermo / Italy

Author Block: R. A. Pugliesi, M. Triscari Barberi, G. Roccella, R. Cannella, A. Mavaro, G. Lo Re; Palermo/IT
Purpose: To compare the diagnostic performance of non–contrast MRI sequences—balanced turbo/fast field echo (BTFE/BFFE), T2-weighted spectral attenuated inversion recovery (T2 SPAIR), and diffusion-weighted imaging (DWI)—with contrast-enhanced imaging for evaluating small-bowel disease activity in inflammatory bowel disease (IBD).
Methods or Background: This retrospective study included 207 adult patients who underwent magnetic resonance enterography: 145 with IBD and 62 without. Imaging features were recorded, and diagnostic performance of MRI sequences was assessed using the area under the curve (AUC), sensitivity, and specificity. Pairwise comparisons were performed with the DeLong test.
Results or Findings: IBD patients showed significantly higher prevalence of intestinal wall thickening (91.0% vs. 14.5%), ulcerations (34.5% vs. 0%), pseudopolyps (29.7% vs. 0%), vasa recta engorgement (66.9% vs. 1.6%), hypomobility (50.3% vs. 6.5%), adipose hypertrophy (68.3% vs. 3.2%), mesenteric lymphadenopathy (55.9% vs. 9.7%), and fistulas (14.5% vs. 1.6%) (all $p < 0.01$). Contrast-enhanced imaging achieved the highest diagnostic accuracy (AUC 0.860; sensitivity 80.0%; specificity 91.9%). Among non-contrast sequences, DWI (AUC 0.811; sensitivity 70.3%; specificity 91.9%) and BTFE/BFFE (AUC 0.800; sensitivity 64.8%; specificity 95.2%) performed significantly better than T2 SPAIR (AUC 0.670; sensitivity 46.9%; specificity 87.1%). Contrast-enhanced imaging was superior to all non-contrast sequences ($p \leq 0.036$), while DWI and BTFE/BFFE showed no significant difference ($p = 0.701$).
Conclusion: Contrast-enhanced MRI demonstrated the highest diagnostic accuracy and should remain the reference standard in settings requiring maximal diagnostic confidence. However, DWI and BTFE/BFFE sequences showed high specificity, indicating their potential as reliable alternatives when contrast use is contraindicated or in follow-up scenarios requiring repeated imaging.
Limitations: Limitations include the retrospective design, potential selection bias

Relationship between MRI quantified ileo-anal J-Pouch motility, pouch inflammation and patient bowel frequency and symptom load (6 min)

Chloe Dennis; Hackney / United Kingdom

Author Block: C. Dennis, W. Weston, W. Blad, I. Naim, A. Menys, S. Taylor; London/UK
Purpose: Patients with ileo-anal pouches often develop intrusive increased bowel frequency. GLP-1 agonists reduce frequency possibly inhibiting motility. Using motility MRI (mMRI), we investigated the relationship between pouch motility, endoscopic inflammation and symptoms
Methods or Background: 30 ileoanal pouch patients (mean age 44 years, 9 female) and 10 controls (mean age 44, 5 male: 5 with non-colonic Crohns disease, 5 with ulcerative colitis) underwent MR enterography including a breath-hold balanced steady-state gradient echo motility sequence processed using GIQuant (Motilent) A radiologist placed regions of interest around the wall of the pouch and rectum (for controls), deriving a motility metric (expressed in arbitrary units (AU). Pouchoscopy was dichotomized into inflammation vs. no inflammation. Daily patient bowel frequency was dichotomized into =>10 and <10 , and symptoms into “highly 'symptomatic' vs 'coping. Motility was compared using Mann Whitney statistic.
Results or Findings: Five patients were excluded due to suboptimal pouch visualisation. Mean pouch motility was higher than rectal motility 157AU (25 to 391) vs. 59AU (23 to 104), p = 0.002. Patients with endoscopic inflammation (n=11) had lower motility than those without
(119AU vs 185AU, P = 0.05). Motility was higher in those with =>10 bowel movements (n=13) compared to <10 (205AU vs. 116AU, P = 0.007. Pouch motility was correlated to bowel movement frequency (Rho = 0.46, p =0.01), but not significantly different between highly symptomatic patients (n=9) vs. those coping (183AU vs. 132AU) P = 0.1.
Conclusion: mMRI quantified pouch motility is associated with bowel frequency and inflammation providing mechanistic insights for new therapeutic agents
Limitations: A retrospective study with a small sample size.

Extracellular Volume Fraction Derived from Dual-energy CT for Characterizing the fibrosis of the bowel wall in Stricturing Crohn Disease (6 min)

Gong Mei Lin; Chongqing / China

Author Block: G. M. Lin; Chongqing/CN
Purpose: To prospectively evaluate the ability of extracellular volume (ECV) fraction, derived from dual-energy CT (DECT), to characterize fibrosis in bowel wall in participants with Crohn disease (CD), and to explore its potential role as a noninvasive imaging biomarker for assessing the severity of fibrotic changes.
Methods or Background: Routine CT enterography (CTE) and equilibrium-phase contrast-enhanced scanning were performed on DECT before elective surgery in patients with stricturing CD. For each resected bowel segment, the histological inflammatory activity was classified into three levels: mild, moderate, and severe, while the degree of fibrosis was similarly graded as mild, moderate, or severe based on pathological assessment. The ECV fraction, as derived from dual-energy CT (DECT) and matched to the corresponding surgical specimen, was calculated and subsequently compared across segments with different histological grades of fibrosis.
Results or Findings: A total of 22 participants with 66 bowel segments were included in the study.
The ECV fraction in moderate to severe fibrosis (45.4% ± 5.7%) was significantly higher than that in mild fibrosis (38.2% ± 4.7%) in the bowel segment with mild to moderate inflammatory activity ($p < 0.001$), and could identify moderate to severe fibrosis in bowel segments with mild to moderate inflammatory activity, with an area under the ROC curve of 0.852 (95% confidence interval: 0.672–0.956).
Conclusion: The ECV fraction derived from DECT was able to distinguish moderate to severe fibrosis from mild fibrosis in bowel segments with mild to moderate inflammatory activity, but failed to do so in segments with severe inflammatory activity.
Limitations: The small sample sizes; Increased radiation exposure, A single-vendor system
Funding for this study: The study was supported of the China Crohn’s & Colitis Foundation (No. CCF-QF-2022C41-20) and Science and Technology Innovation Key R&D Program of Chongqing (No. CSTB2024TIAD-STX0045).

Thoracic Body Composition Across Age and Smoking Status in a Lung Cancer Screening Cohort: Insights from the NELSON Study (6 min)
Ye Xin; Groningen / Netherlands

Author Block: Y. Xin[1], S. Z. Erick[1], M. A. Heuvelmans[1], G. De Bock[1], R. Vliegenthart[1], B. Edwin[2], M. Van Tuinen[1], F. Mohamed Hoesein[2]; [1]Groningen/NL, [2]Utrecht/NL
Purpose: CT-based body composition measures improve prediction of mortality in oncology, but reference values are lacking. We evaluated age- and smoking-related variation in body composition in a lung cancer screening cohort.
Methods or Background: We used artificial intelligence-based automated analysis of body composition measures on baseline low-dose chest CT from male participants in the NELSON lung cancer screening trial. Skeletal muscle area (SMA) and subcutaneous adipose tissue area (SAT) were quantified at T5, T8, and T10 levels. The mean values of these levels were used to derive a single SMA and SAT metric per participant; the fat-to-muscle ratio (FMR) was calculated. Age in 5-year groups and smoking status were analyzed in relation to body composition measures. Smoking pack-years was included as covariate in regression analyses.
Results or Findings: We included 4,435 men with mean age 59.4 (SD=5.6) years and mean smoking pack-years 42.2 (SD=29.7). Current smokers (55.0%%) had significantly lower SAT (372 vs. 441 cm^2, $p<0.001$), SMA (501 vs. 507 cm^2, $p<0.001$) and FMR (0.74 vs. 0.87, $p<0.001$), compared with former smokers(45.0%). Across 5-year age groups, SMA declined from 515 cm^2 in the 50–54 years group to 472 cm^2 in the ≥70 years group ($p<0.001$), while SAT increased from 376 to 443 cm^2 ($p<0.001$) and FMR from 0.70 to 0.90 ($p<0.001$); associations remained significant after adjusting for smoking status and pack-years.
Conclusion: In men undergoing lung cancer screening, higher age was associated with muscle loss and fat gain, while current smoking was associated with lower muscle and fat compared to former smoking. Reference values of chest CT-based body composition measures may help risk stratification in screening.
Limitations: Our further analyses should confirm the relationship of body composition markers to outcomes in lung cancer screening setting.

Lung cancers associated with cystic airspaces and Lung-RADS v2022 in three screening trials (6 min)
Edoardo Cavigli; Florence / Italy

Author Block: E. Cavigli[1], G. Picozzi[1], D. Puliti[1], F. Cortez Ibanez[2], G. R. De Luca[3], V. Miele[1], S. Delorme[2], R. Kaaks[2], M. Mascalchi[1]; [1]Florence/IT, [2]Heidelberg/DE, [3]Bologna/IT
Purpose: To determine the frequency and prognosis of lung cancer associated with cystic airspaces (LCCA) in LDCT screening, and to evaluate the potential impact of Lung-RADS v2022 on earlier detection
Methods or Background: LCCAs were identified by two experienced radiologists who jointly reviewed LDCT examinations from 714 screen-detected and 463 non-screen-detected lung cancers from the NLST, ITALUNG, and LUSI trials. Radiological features were correlated with histology, staging, and survival. Lung-RADS v2022 criteria were retrospectively applied. Statistical analyses included chi-square tests and Cox regression models
Results or Findings: Seventy-three LCCAs were identified: 44 among screen-detected cases (6.1%) and 29 (3 interval and 26 post-trial) among non-screen-detected cases (6.2%). Retrospective review revealed that 20/29 (68.9%) of non-screen-detected LCCAs were visible in prior LDCTs. Morphological patterns included unilocular cysts with mural nodules (35/73, 41%), circumferential solid walls (19/73, 26%), and multilocular cysts (24/73, 33%). Histology revealed adenocarcinoma/BAC in 50/73 cases (68.5%), squamous/adeno-squamous carcinoma in 16 (21.9%), and unclassified carcinoma in 7 (9.6%). Five years after diagnosis, 35 patients (47.9%) had died. Mortality was significantly higher for non-screen-detected ($p=0.012$) and stage III-IV cases ($p<0.001$). Lung-RADS v2022 criteria could have led to earlier diagnostic work-up in 62/73 (84.9%) of cases
Conclusion: LCCAs account for approximately 6% of lung cancers in LDCT screening. Screen detection and early-stage diagnosis are associated with better prognosis. Application of Lung-RADS v2022 recommendations could facilitate earlier identification and management of LCCA.
Limitations: Retrospective investigation; we didn't assess whether the lesion sizes were predictive of the survival; we didn't assess the frequency in our screening cohorts of benign cysts not evolving into LCCA; we didn't evaluate neither the reproducibility nor the specificity of the Lung-RADS v2022 criteria

Airspace enlargement with fibrosis on CT is a strong predictor of mortality after lung cancer surgery (6 min)

Guillaume Chassagnon; Paris / France

Author Block: G. Chassagnon, A. Lupo, M. ROYER, M. Alifano, N. Roche, M-P. Revel; Paris/FR
Purpose: Preoperative risk stratification before lung cancer surgery mainly relies on clinical indicators. This study aimed to determine whether chest computed tomography (CT)-derived parameters could provide additional prognostic value in identifying patients at increased risk of peri-operative mortality.
Methods or Background: We retrospectively analyzed data from 720 patients who underwent lung cancer resection at our tertiary center in 2018-2019. Clinical, functional and imaging data were analyzed, including for the latter, coronary artery calcium score, pulmonary artery and aorta diameters, presence of emphysema, interstitial lung abnormalities, or airspace enlargement with fibrosis (AEF). Multivariable logistic and Cox regression models were applied to identify independent predictors of 30-day and 90-day mortality, as well as overall survival.
Results or Findings: AEF on CT (Odds Ratio (OR) 10.87, $p < 0.001$) was a significant predictor of 30-day mortality, while AEF (OR 7.04, $p<0.001$), as well as a higher ECOG status (OR 1.98, $p=0.029$) and a lower FEV_1 (OR 0.97, $p=0.023$) were associated with increased 90-day mortality. AEF was present in 8.2% of patients and was observed in 45.5% of patients who died within 30 days postoperatively. AEF was a nearly significant predictor of long-term survival in the multivariate Cox regression (HR = 1.57, 95% CI: 0.99–2.47, $p = 0.046$).
Conclusion: CT can provide valuable prognostic information in patients undergoing lung cancer surgery. AEF on CT is a major independent prognostic marker, especially for perioperative mortality. Our results support recognizing AEF as a distinct radiological entity that should be systematically assessed.
Limitations: Firstly, AEF was defined radiologically rather than histologically. Histological confirmation of AEF was unavailable because the affected lung areas were not systematically sampled and analysed.. Secondly, it was a single-centre retrospective study, which may limit the generalizability of the findings.

Ethics committee - additional information: The study protocol was approved by the local Institutional Review Board (CLEP Decision N°: AAA-2025-10005), which waived the need for patient consent.

CT acquisition protocols in lung cancer screening: Insights from an international survey disseminated beyond the SOLACE consortium (6 min)

Mathis Franz Georg Konrad; Heidelberg / Germany

Author Block: M. F. G. Konrad[1], E. Nischwitz[1], J. Chorostowska-Wynimko[2], J. Vogel-Claussen[3], J. Moes-Sosnowska[2], M. Adamek[4], A. Kerpel-Fronius[5], H. Prosch[6], H-U. Kauczor[1]; [1]Heidelberg/DE, [2]Warsaw/PL, [3]Hannover/DE, [4]Gdańsk/PL, [5]Budapest/HU, [6]Vienna/AT
Purpose: Assessing the current status of applied CT image acquisition protocols in lung cancer screening (LCS) worldwide, focusing on technical factors linked to radiation exposure.
Methods or Background: The survey was expanded from an internal SOLACE version to include broader dissemination, collecting data from personnel responsible for the definition of CT protocols at LCS centres worldwide. Data were collected through a baseline survey between June 2024 and September 2025 to represent the most current status.
Results or Findings: Survey responses were received from 71 screening centres from 29 countries (19 Europe, 10 other continents). Institutional factors influencing CT protocols encompass the responsibility of establishment and modification of protocols by personnel (radiologists, radiographers, medical physicists, manufacturer personnel). In 33% of the institutions the protocol was established by a multiprofessional team. CT protocols were mostly modifiable (85%). Technical questions were partially answered. In 88% of the centres (43 of 49) automatic exposure control was implemented. Reconstructed slice thickness ranged 0.625-1.5 mm; 1.0 mm dominating with 64%. Increment ranged 0.5-1.25 mm, where 0.625 mm, 0.7 mm, and 1.0 mm were distributed more evenly with 18%, 25%, and 30%, respectively. Screening-specific software was used at 87% of sites; mainly for nodule detection, volumetry, and calculation of volume doubling time (32, 31, and 25 centres, respectively). Reconstruction algorithm types included filtered-back projection (4), iterative reconstruction with statistical modeling (30), and iterative reconstruction with deep learning support (7).
Conclusion: LCS imaging often reaches the technical limits of currently operated devices. Multiprofessional establishment of CT protocols is an area for improvement. Variations in reconstruction algorithm types warrant further research regarding their influence on volumetry calculations. Protocol optimization is essential to balance radiation exposure reduction and diagnostic quality.
Limitations: The survey likely reflects centres with research interests.

Rethinking RECIST in the era of neoadjuvant treatment for lung cancer (6 min)

Federica Palmeri; Torino / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: F. Palmeri[1], A. Del Gaudio[2], M. Zerunian[2], F. Di Gregorio[2], A. Ferraris[1], D. Caruso[2], M. Francone[2], A. Laghi[3]; [1]Torino/IT, [2]Rome/IT, [3]Pieve Emanuele/IT
Purpose: To assess the accuracy of RECIST 1.1 in evaluating treatment response after neoadjuvant chemotherapy, with or without immunotherapy, in patients with stage IIIA–IIIB non-small cell lung cancer (NSCLC) undergoing surgical resection, and to highlight its limitations in reflecting true pathological outcomes.
Methods or Background: In a prospective pilot study, 33 patients with stage IIIA–IIIB NSCLC received neoadjuvant chemotherapy prior to surgery; 11 also received pembrolizumab. All patients underwent baseline and post-treatment contrast-enhanced CT scans, evaluated using RECIST 1.1 or iRECIST by two radiologists in consensus. Surgical specimens were analyzed histopathologically to determine complete or partial response. Radiological and pathological responses were then compared.
Results or Findings: Of the 33 patients, 12 achieved complete pathological response (pCR). None of these patients were classified as complete responders by RECIST 1.1 on post-treatment imaging. The remaining 21 patients showed partial pathological response, with residual viable tumor ranging from 10% to 80%. Only 9 of these (43%) met RECIST criteria for partial response, while the others were categorized as stable disease despite substantial histological regression. This discordance was more pronounced in patients treated with combined chemo-immunotherapy, suggesting that lesion size alone may fail to capture treatment-induced changes such as immune-related remodeling or necrosis.
Conclusion: RECIST 1.1 appears insufficiently sensitive to capture complete or substantial tumor response after neoadjuvant therapy in stage IIIA–IIIB NSCLC. The discrepancy is most evident with immunotherapy, which may induce changes not reflected by lesion size. As a result, radiological assessments often underestimate true pathological response. In locally advanced NSCLC, alternative or complementary imaging biomarkers are needed to better predict pathological outcomes and guide clinical decisions, particularly when chemotherapy is combined with immunotherapy.
Limitations: The limitations are the small sample size and single-center design
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Written informed consent was acquired for all patients and Istitutional Review Board approval was obtained.

Preoperative CECT Habitat Radiomics plus Postoperative MRD for Early Recurrence Prediction after R0 Resection of NSCLC (6 min)

Xu Jiang; Beijing / China

Author Block: X. Jiang, J. Wang; Beijing/CN
Purpose: To test whether integrating preoperative contrast-enhanced CT (CECT) habitat radiomics with postoperative minimal residual disease (MRD) enables non-invasive, binary prediction of early recurrence after R0 resection of NSCLC.
Methods or Background: In this single-center prospective study (n=119), tumors on preoperative CECT were manually segmented; intratumoral habitats were derived by k-means clustering. Radiomics features (whole-tumor and habitat) underwent z-score normalization, variance/collinearity filtering, optional univariate screening, and L1-penalized logistic selection to form a logistic radiomics score (RadScore). Clinical screening identified MRD (first postoperative result, ±) and maximum diameter as independent predictors. Three classifiers were trained with five-fold internal CV on a stratified 70/30 split and tested on the hold-out set: radiomics-LR (RadScore), clinical (MRD+size), and combined-LR (RadScore+MRD+size). Performance was assessed by AUC, accuracy, sensitivity, specificity, calibration (Brier; intercept/slope), decision-curve analysis (DCA), and pairwise DeLong tests.
Results or Findings: On the test set, the combined-LR model showed the highest discrimination (AUC 0.867), exceeding radiomics-LR (0.847), clinical (0.786), and calibrated radiomics-SVM (0.773). Calibration favored the combined model (Brier 0.179; intercept −1.66; slope 0.95). DCA demonstrated greater net benefit for the combined model across thresholds ~0.05–0.60. DeLong comparisons were concordant with AUC ranking.
Conclusion: CECT-based habitat radiomics complements postoperative MRD by capturing spatial heterogeneity, enabling accurate, non-invasive prediction of early recurrence after NSCLC resection and supporting risk-adapted postoperative management.
Limitations: Single-center cohort and modest event counts may limit generalizability; external, multi-institutional validation is warranted.

Beyond biopsy: predicting PD-L1 status in non-small cell lung cancer through CT radiomics (6 min)

Federica Palmeri; Torino / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: F. Palmeri[1], V. Solimene[2], A. Del Gaudio[2], M. Zerunian[2], F. Di Gregorio[2], A. Ferraris[1], D. Caruso[2], M. Francone[2], A. Laghi[3]; [1]Torino/IT, [2]Roma/IT, [3]Pieve Emanuele/IT
Purpose: To develop and validate machine learning (ML) models based on radiomic features extracted from CT imaging to differentiate between high (PD-L1 ≥50%) and low (PD-L1 <50%) expression in non-small cell lung cancer (NSCLC). The aim was to explore whether imaging biomarkers could provide a noninvasive alternative to histological profiling for guiding immunotherapy decisions.
Methods or Background: This retrospective study included 210 patients with histologically confirmed NSCLC and pre-treatment contrast-enhanced chest CT. Among them, 46 (21.9%) showed high PD-L1 expression, while 164 (78.1%) showed low expression. Tumors were manually segmented, and radiomic features were extracted following Image Biomarker Standardization Initiative guidelines. Five ML models were built for binary classification ("PD-L1 ≥50%" vs. "PD-L1 <50%"), using Random Forest, Support Vector Machine, K-Nearest Neighbors, Multi-Layer Perceptron, and Logistic Regression classifiers. Histological PD-L1 served as the reference standard. Statistical significance was set at $P < .05$.
Results or Findings: The Multi-Layer Perceptron model achieved the best performance, with a ROC-AUC of 0.61 (95% CI: 0.57–0.66, P< .005) and an accuracy of 64% (95% CI: 60–68%). Sensitivity reached 70% (95% CI: 65–75%) and PPV 82% (95% CI: 80–84%), while specificity and NPV were lower at 44% (95% CI: 36–52%) and 29% (95% CI: 24–35%), respectively. The F1 score was 75% (95% CI: 71–78%).
Conclusion: Radiomic analysis of pre-treatment CT images using a Multi-Layer Perceptron classifier showed potential in distinguishing PD-L1 expression levels in NSCLC, with good sensitivity, PPV, and overall F1 score. However, the model's limited specificity and NPV suggest it may be more effective in identifying patients likely to express high PD-L1, rather than excluding them. Radiomic-based ML models could aid noninvasive prediction of PD-L1, supporting immunotherapy selection when biopsy is inconclusive or risky.
Limitations: The limitations are the retrospective single-center design.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Written informed consent was acquired for all patients and Istitutional Review Board approval was obtained.

Multi-parametric Dual-layer CT Radiomics for Non-invasive Differentiation of Benign and Malignant Solid Solitary Pulmonary Nodules (6 min)

Jiayi WANG; Nanchang / China

Author Block: Z. Lin[1], M. Zuo[2], J. WANG[2], Y. Tan[1], Y. Wang[3], X. Yu[3]; [1]Hubei/CN, [2]Nanchang/CN, [3]Shanghai/CN
Purpose: To develop and validate a radiomics model based on multi-parametric Dual-layer CT (DLCT) images for non-invasive differentiation of benign and malignant solid solitary pulmonary nodules (SSPNs).
Methods or Background: This retrospective study included 159 patients with pathologically confirmed SSPN (64 benign, 95 malignant) who underwent DLCT-enhanced scanning, randomly divided into training (n=111) and test (n=48) cohorts at a 7:3 ratio. Radiomic features were extracted from seven venous-phase image series: conventional images (CI), iodine density (ID) maps, effective atomic number (Zeff) maps, electron density (ED) maps, virtual monochromatic images (VMI) at 40 keV and 100 keV, and virtual non-contrast (VNC) images. Logistic regression models were built for each series, and features were integrated to construct a multi-DLCT model.
Results or Findings: The CI, ID, Zeff, ED, VMI 40 keV, VMI 100 keV, and VNC models achieved AUCs of 0.777, 0.830, 0.812, 0.783, 0.792, 0.797, and 0.790 in the training cohort, and 0.774, 0.789, 0.741, 0.804, 0.737, 0.741, and 0.735 in the test cohort. The multi-DLCT model demonstrated the highest discriminatory performance, achieving AUCs of 0.832 in training and 0.863 in testing, and outperformed the CI model (AUC = 0.777 training, 0.774 test), although differences were not statistically significant (Delong P = 0.101 and 0.232, respectively). Positive integrated discrimination improvement (IDI) and net reclassification improvement (NRI) values indicated improved discrimination, and decision curve analysis showed greater net clinical benefit for the multi-DLCT model.
Conclusion: The radiomics model based on multi-parametric DLCT improves differentiation of benign and malignant SSPNs and provides higher clinical utility than conventional imaging.
Limitations: Single-center study with a limited sample size.

Artificial intelligence solution in B-lines detection on lung ultrasound (6 min)
Martin Stevik; Martin / Slovakia

Author Block: M. Stevik[1], M. Malík[1], A. Dzian[1], F. Babic[2], Š. Vetešková[1], M. Bundzel[2], J. Magyar[2], K. Zelenak[1]; [1]Martin/SK, [2]Košice/SK
Purpose: The main limitation of LUS is its high operator dependency. This has led to significant interest in developing artificial intelligence (AI) approaches for the interpretation of LUS imaging. The primary aim of this study was to evaluate the accuracy of a trained AI model in B-lines detection in the LUS movies using a novel designed hybrid solution that combines the convolutional neural network (CNN) and analytical approach. The secondary aim was to evaluate the accuracy of a radiology resident beginner in LUS in B-lines detection and to evaluate the educational potential of AI in LUS.
Methods or Background: In this single-center prospective study, a machine learning based software, the LUS AI solution, was used for automated detection and marking of B-lines in the LUS footages. 75 consecutive patients were enrolled, total of 300 LUS videos. The LUS videos were reviewed and evaluated for the presence of the B-line by two radiologists expert and one radiology resident. Then radiology resident was allowed to revise the initial conclusion regarding B-lines presence.
Results or Findings: Accuracy, sensitivity, specificity, positive and negative predictive values of artificial inelligence in B-line detection were 0.85, 0.9, 0.832, 0.661 and 0.958 respectively. The resident's values were 0.69, 0.575, 0.732, 0.438 and 0.958 respectively. The resident's values after correction based on artificial intelligence results were 0.823, 0.912, 0.791, 0.613 and 0.961 respectively.
Conclusion: Artificial intelligence solution showed higher accuracy in B – lines detection. It could play role in residents' education.
Limitations: There was overall a relatively small number of patients recruited. Our presented AI program results still show some limitations, which is due to the limited amount of data and inability to use some data augmentation methods to address this issue.
Funding for this study: This research is funded by the Slovak Research and Development Agency, grant number APVV 20-24-0454.

Design of a CT-Based Deep Learning Model to Predict the Metastatic Potential of Sub-centimetric Pulmonary Nodules in Oncology Patients (6 min)
Funda Dinç; Muğla / Turkey

Author Block: N. E. ÖZEN[1], O. Yeniceri[1], F. Dinç[1], S. Yılmaz[2], N. G. Narin[2]; [1]Mugla/TR, [2]Muğla/TR
Purpose: Accurate determination of the malignant potential of pulmonary nodules smaller than 1 cm in oncology patients remains a diagnostic challenge. The smaller the nodule, the greater the uncertainty in interpretation, which can lead to staging inaccuracies and delays. This study aimed to investigate the utility of deep learning methods in predicting the malignancy of sub-centimetric pulmonary nodules detected on lung CT scans at the time of initial diagnosis.
Methods or Background: This study represents a preliminary report of a project that we have just started. A total of 933 nodules were analyzed, comprising 443 retrospectively confirmed benign nodules from patients without known malignancy and 490 malignant nodules that demonstrated interval growth and were reported as metastatic. Malignant nodules originated from primary tumors of the rectum, colon, renal cell carcinoma, prostate, uterus, cervix, ovary, larynx, and breast. Of the total dataset, 653 nodules were allocated to the training set, 139 to the validation set, and 141 to the test set. Model development was based on the ResNet-50 architecture with transfer learning.
Results or Findings: Using a dataset of 933 nodules, the model achieved a best validation accuracy of 91.3% and a test accuracy of 83.69%. The area under the ROC curve (AUC) was 0.896, demonstrating strong discriminative performance.
Conclusion: Findings from this preliminary study suggest that deep learning–based approaches may provide valuable support in the staging process at the time of diagnosis, particularly in oncology patients presenting with sub-centimetric pulmonary nodules on CT scans in the presence of a known primary tumor elsewhere.
Limitations: This paper is a preliminary report of a deep learning study using a relatively small dataset. A larger dataset is in preparation.
Funding for this study: This study is currently being conducted without funding. However, an application has been submitted to TÜBİTAK 1001 for funding.

Predicting rapid progression and prognosis of idiopathic inflammatory myopathies-associated interstitial lung disease using AI-based quantitative CT analysis of pulmonary vessel-related structures (6 min)

Yuhui Qiang; Beijing / China

Author Block: Y. Qiang, H. Wang, M. Liu, H. Dai; Beijing/CN
Purpose: Pulmonary vessel-related structure (PVRS) abnormalities in idiopathic inflammatory myopathies-related interstitial lung disease (IIM-ILD) remains poorly understood. This two-center study investigated PVRS parameters on HRCT as predictors of rapid progression and prognosis in IIM-ILD.
Methods or Background: 578 IIM-ILD patients (412 females, median age 53) came from the prospective ILD cohort of two centers. AI-based quantification of baseline HRCT assessed PVRS and interstitial lesions. An independent external cohort of 64 IIM-ILD patients (43 females, median age 54) from the second center was used to validate the generalizability of PVRS in predicting IIM-ILD progression.
Results or Findings: In the first center, 249 patients with rapidly progressive ILD (RP-ILD) exhibited significantly higher mean pulmonary vascular diameter (mPVD) ($P<0.05$) at shorter vascular-pleural distances, increased PVRS volume, and greater standard deviation of pulmonary vascular diameter (sdPVD) ($P<0.001$) compared to non-RP-ILD. Age (HR: 1.03, 95% CI: 1.01-1.06), ground glass opacity (GGO) percentage (HR: 1.04, 95% CI: 1.02-1.06), and sdPVD at 6mm and 18mm from the pleura were identified as independent risk factors for poor prognosis in anti-synthetase syndrome (ASS) patients (concordance index = 0.819). In contrast, age (HR: 1.06, 95% CI: 1.02-1.11), mPVD at 6mm from the pleura, and lactic dehydrogenase were independent risk factors for poor prognosis in anti-MDA5-positive dermatomyositis (MDA5+ DM) patients (concordance index = 0.835). Validation in the second center using the multivariate Cox regression model from the internal training cohort revealed predictive C-indices of 0.841 (ASS) and 0.814 (MDA5+ DM) in the external cohort.
Conclusion: Baseline PVRS parameters on HRCT serve as prognostic indicators for rapid progression and adverse prognosis in IIM-ILD.
Limitations: The quantitative PVRS could not differentiate between arterial and venous vessels.

Per-pixel Bone Attenuation Contribution Map Generation using Machine Learning for Chest Radiographs (6 min)

Tina Dorosti; Neuried / Germany

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: T. Dorosti, L. Kaster, M. Lochschmidt, J. B. Thalhammer, S. Peterhansl, F. Schaff, F. Pfeiffer, D. Pfeiffer; Munich/DE
Purpose: We aim to generate attenuation contribution masks for bone structures present in real and synthetic frontal chest radiographs (CXR) on a pixel level using machine learning. Such bone attenuation contribution (BAC) maps will allow for a personalized, per-pixel correction of beam hardening artifacts in novel imaging modalities such as X-ray dark-field (DF) imaging.
Methods or Background: A total of 5959 chest CT scans were retrieved from two publicly available datasets of the Luna16 (n=656) and the RSNA PE challenge (n=5303). Additionally, CXRs from 72 subjects (33 healthy: 20 men, mean age[range]=62.4[34, 80]; 39 with COPD: 25 men, mean age[range]=69.0[47, 91]) were retrospectively selected (10.2018-12.2019) from our in-house dataset. All CT scans and their corresponding 3D binary bone segmentations were forward projected using a simulated X-ray spectrum to generate synthetic CXRs and relative bone thickness projections referred to as BAC maps, respectively. A U-Net model was trained and tested on synthetic radiographs from the public datasets. Model performance was assessed quantitatively for the public synthetic data with the mean absolute percentage error (MAPE), Pearson correlation, and two-sided Student t distribution. For the real in-house CXRs, data was assessed qualitatively, as no reference BAC data is available for real radiographs.
Results or Findings: The predicted BAC maps showed low error rates and strong correlations with the reference. Specifically, for the Luna16 test set (n=131), an MAPE=18.1% and a correlation of 0.81 ($P<0.001$) were achieved. For the RSNA PE test data (n=1060), an MAPE=12.5% and a correlation of 0.91 ($P<0.001$) were obtained.
Conclusion: The U-Net successfully generated per-pixel BAC maps for synthetic and real CXRs, demonstrating potential for applications in DF image processing.
Limitations: The sample of real radiographs was restricted to healthy and COPD subjects from a single medical center.
Funding for this study: We acknowledge financial support through the European Research Council (ERC Synergy Grant SmartX, SyG 101167328), and the Free State of Bavaria under the Excellence Strategy of the Federal Government and the States, as well as by the Technical University of Munich – Institute for Advanced Study.

RadGuide-SSP-Net: A Radiomics-Guided Self-Training Semi-Supervised Deep Learning Framework for Multi-Class Classification of Pneumonia Subtype (6 min)

Yuchi Tian; Shanghai / China

Author Block: Y. Tian[1], F. Pan[2], X. Liang[1], L. Yang[2]; [1]Shanghai/CN, [2]Wuhan/CN

Purpose: RadGuide-SSP-Net introduces a novel radiomics-guided semi-supervised learning framework using knowledge distillation to accurately classify pneumonia subtypes (bacterial, viral, fungal, tuberculosis) from chest CT scans with minimal annotated data. Integrating radiomics with deep learning, it enhances diagnostic precision and offers scalable, cost-effective solutions for resource-constrained radiology settings.
Methods or Background: RadGuide-SSP-Net innovatively combines radiomics-based machine learning with 3D convolutional neural networks via knowledge distillation. A radiomics "teacher" model, trained on a small annotated subset, extracts high-dimensional features capturing lesion heterogeneity, morphology, and texture. These priors are distilled through soft-label generation and transferred to a 3D-ResNet-18 "student" model using Kullback-Leibler divergence loss, augmented by cross-entropy on labeled data. This semi-supervised approach leverages unlabeled data to enhance generalizable representations. A retrospective cohort of 1,148 chest CT scans (training:test=7:3) was enrolled.
Results or Findings: Fully supervised 3D-ResNet-18 with 100% labeled data achieved a test set macro-AUC of 0.9178 (95% CI: 0.8946-0.9386). With 30% labeled data, its macro-AUC fell to 0.8495 (95% CI: 0.8223-0.8734). The radiomics-only model with 100% labeled data reached 0.9092 (95% CI: 0.8911-0.9269), dropping to 0.8853 (95% CI: 0.8646-0.9043) with 30% labeled data. RadGuide-SSP-Net, using 30% labeled and unlabeled data, achieved a macro-AUC of 0.9174 (95% CI: 0.8963-0.9373), surpassing both 30% labeled models and nearly matching the 100% labeled benchmark. These findings highlight that radiomics-derived features, though statistically engineered, can effectively guide deep learning in label-scarce settings, likely converging on patterns similar to data-driven features, enhancing label efficiency and generalizability for multi-disease diagnostics.
Conclusion: RadGuide-SSP-Net redefines medical imaging AI with radiomics-guided knowledge distillation, achieving superior pneumonia subtype classification with minimal labeled data. It enhances diagnostic accuracy, reduces radiologist workload, and is scalable in annotation-scarce settings, making it a transformative tool for precision diagnostics and global healthcare.
Limitations: Only one center

Comparative evaluation of an open source versus commercial artificial intelligence solution for detection of acute lung pathologies on chest radiographs (6 min)

Li Yi Tammy Chan; Singapore / Singapore

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: L. Y. T. Chan, S. Y. Yee, Y. J. Toh, P. Yogendra; Singapore/SG
Purpose: To evaluate the accuracy of an open-source solution (CheXNeXt) and a commercial product (Rayscape CXR) for chest radiograph interpretation compared with board-certified radiologists.
Methods or Background: Chest radiographs (CXRs) are among the most frequently requested first-line investigations for suspected cardiopulmonary pathology. Rising imaging volumes and radiologist shortages have driven interest in Artificial Intelligence (AI) solutions, which have potential to triage urgent cases for expedited reporting and serve as diagnostic adjuncts to enhance efficiency and accuracy.

This single-institution retrospective study analysed 1003 emergency department CXRs performed after hours. Radiology reports served as the reference standard, whereby outcomes were extracted directly from report documentation. Two AI models (CheXNeXt and Rayscape CXR) independently analysed CXRs for pneumonia, pleural effusion, pneumothorax, and pulmonary oedema. Model performance was evaluated using sensitivity, specificity, and Gwet's AC1, with agreement strength interpreted according to Landis and Koch. McNemar's test assessed statistical differences between models.
Results or Findings: Rayscape CXR demonstrated higher overall sensitivity (97.4% vs. 91.7%), while CheXNeXt showed higher specificity (71.5% vs. 40.0%). For effusion, pneumothorax, and oedema, both models achieved almost perfect agreement with the reference standard, with Rayscape CXR (0.902–0.997) outperforming CheXNeXt (0.812–0.890). Conversely, CheXNeXt outperformed Rayscape CXR in pneumonia detection (0.829 vs. 0.765). McNemar's tests revealed significant differences in error patterns across all pathologies ($p < 0.001$).
Conclusion: Rayscape CXR had greater agreement for effusion, pneumothorax and oedema while CheXNeXt demonstrated greater agreement for pneumonia. Overall, Rayscape CXR demonstrated higher sensitivity and CheXNeXt showed higher specificity. These complementary strengths suggest context-specific deployment strategies: sensitivity-optimised models may aid triage of urgent cases, while specificity-focused models may provide confirmatory support.
Limitations: The study was limited by differing training definitions for pathologies used by each AI algorithm, potentially influencing comparative performance.
Funding for this study: No funding was received for this study.

Repeated evaluation of AI for lung nodule detection in chest radiographs: version-to-version evaluation in a multicentre study (6 min)

Marlie Besouw; Boxmeer / Netherlands

Author Block: M. Besouw, M. De Rooij, M. J. Rutten, B. Van Ginneken, S. S. Schalekamp; Nijmegen/NL
Purpose: Artificial intelligence (AI) for lung nodule detection in chest radiographs is increasingly implemented, yet reproducible methods to evaluate new and updated AI product versions are lacking. Our Project AIR framework was established to benchmark CE-certified AI tools, and most recently performed in 2023. In this follow-up study, updated versions of AI products for lung nodule detection were assessed.
Methods or Background: Sixteen vendors were invited to participate in a new round for the evaluation of lung nodule detection in chest radiographs. Up to now, four commercial AI products have been evaluated. Performance was tested on the same hidden multicentre dataset of 386 scans. The primary outcome was the area under the receiver operating characteristic curve (AUC). Statistical comparison between versions was performed, and all results were benchmarked against the average performance of radiologists.
Results or Findings: Three of four products showed an increase in AUC (+0.07 to +0.09). The average AUC of these products significantly increased from 0.84 (95% CI 0.79–0.87) to 0.89 (95% CI 0.86–0.92) ($p<0.05$). For the other system, identical case-level outputs resulted in an unchanged AUC of 0.88. Across the evaluated products, AUCs in the current analysis ranged from 0.87 to 0.91. Three of the four products performed significantly better than the average radiologist, with an AUC of 0.81 (95% CI 0.77–0.85).
Conclusion: Our project AIR framework enables repeated testing of new and updated AI products. For three out of four AI products, performance in lung nodule detection improved compared to 2023. All currently evaluated AI products performed at or above the average radiologist benchmark
Limitations: Two vendor submissions were still being processed at the time of analysis, and not all products provided updated versions. Results are preliminary and limited to a single standardised dataset.
Funding for this study: This study was supported by the Netherlands Organisation for Scientific Research (NWO), project no. OSF23.1.018.

Agreement and Diagnostic Accuracy of an FDA- and CE-Cleared AI Solution Versus Junior Radiologist for Chest Radiographs (6 min)

Nahdiya Sadaf; Hyderabad / India

Author Block: N. Sadaf, S. K. Marupaka, M. M. Sameer, R. P. Babu; Hyderabad/IN
Purpose: To compare the diagnostic performance of an FDA- and CE-cleared computer-aided detection (CADe) solution with a junior radiologist (JR) for chest radiograph (CXR) interpretation, using a senior radiologist (SR) as reference
Methods or Background: In this retrospective, single-center study, 906 CXRs from patients aged ≥12 years (mean 47.7 years; M/F: 455/451) were analyzed. Each CXR was independently reviewed by: (a) an FDA- and CE-cleared CADe solution (DeepTek.ai), (b) a JR (<5 years' experience), and (c) an SR (10 years' experience). Diagnostic performance metrics (sensitivity, specificity, PPV, NPV, accuracy) were calculated using SR as reference. Reader agreement was assessed via Cohen's κ. Institutional Review Board approval was obtained with a waiver of consent.
Results or Findings: AI demonstrated superior sensitivity for detecting suspicious CXRs (65% vs 53% for JR; $p < 0.001$), corresponding to 60 additional suspicious cases detected compared with JR. Agreement with SR in suspicious cases was also higher for AI (64.6% vs 53.4%). JR exhibited higher specificity for non-suspicious cases (90.3% vs 78.1%; $p < 0.001$). Overall accuracy was slightly higher for AI (70% vs 68%), with moderate overall concordance ($\kappa=0.41$ vs 0.40).
Conclusion: The AI solution outperformed a junior radiologist in detecting suspicious findings and showed strong concordance with an experienced radiologist, highlighting its potential as a reliable second reader in CXR interpretation. While JR excelled in non-suspicious-case specificity, AI's superior detection of suspicious cases underscores its value in supporting early diagnosis and clinical decision-making.
Limitations: This study is limited by the use of a single senior radiologist as the reference standard, which could introduce bias, and by its retrospective, single-centre design, which may restrict the generalizability of the findings.
Funding for this study: This research received no external funding

Technical Success, Diagnostic Yield, and Safety of Image-Guided Renal Biopsies in a Multicenter Cohort (6 min)

Raya Juliane Ocker-Serger; Essen / Germany

Author Block: R. J. Ocker-Serger[1], M. Opitz[1], B. M. Schaarschmidt[1], L. V. Klüner[1], M. A. Drews[1], J. Haubold[1], J. Nadjiri[2], S. Zensen[1]; [1]Essen/DE, [2]Munich/DE
Purpose: To assess the technical success, diagnostic yield, and complication profile of image-guided percutaneous renal biopsies in a real-world, multicenter setting.
Methods or Background: This retrospective registry analysis included 5,235 renal biopsies performed between 2018 and 2024 at 176 centers in Germany, Austria, and Switzerland. Technical success was defined as confirmed needle placement within the target lesion. Diagnostic yield referred to histological adequacy for clinical decision-making. Complications were classified according to the Society of Interventional Radiology (SIR) grading system.
Results or Findings: Technical success was achieved in 98.4% (5,150/5,235) of interventions, and diagnostic yield was 94.9% (3,943/4,154). Outpatient procedures showed slightly higher technical success (99.3%, 267/269) than inpatient procedures (98.3%, 4,883/4,966; p = 0.241), with comparable diagnostic yield and safety profiles. The overall complication rate was 5.0% (264/5,235), with major complications in 0.7% (39/5,235). Bleeding was the most frequent complication, including venous (33.0%), parenchymal (30.3%), and arterial (17.1%) events. Coagulation abnormalities were significantly associated with higher complication rates.
Conclusion: Image-guided percutaneous renal biopsies are effective and safe across a large multicenter cohort. The results support their use in outpatient settings, provided coagulation status is optimized and adequate tissue sampling is achieved
Limitations: The main limitations of this registry-based study are potential selection bias, reliance on site-reported data with incomplete documentation, and the absence of a central histopathological review.
Funding for this study: No funding for this study.

Can systematic biopsy be avoided? clinical impact of saturation target biopsy in clinically significative prostate cancer (csPCa) detection (6 min)

Sebastiano Inturri; Avola / Italy

Author Block: S. Inturri[1], E. Raimondi[1], M. Tilli[1], M. Dugo[1], F. Ermili[1], M. Montesi[1], R. Bisi[2], M. Bandi[1], R. Rizzati[1]; [1]Lagosanto/IT, [2]Ferrara/IT
Purpose: To evaluate whether saturation target biopsy (sTB) alone can replace the combined approach of sTB plus systematic biopsy (SB) for csPCa detection in patients with PI-RADS ≥3 lesions on multiparametric MRI (mpMRI).
Methods or Background: We retrospectively analyzed 390 MRI–US fusion biopsy patients with single prostatic lesion PI-RADS ≥3 at mpMRI. Patients were divided into three groups according to PI-RADS score: n=77 with PI-RADS 3 (19.8%), n=186 with PI-RADS 4 (47.6%), and n=127 with PI-RADS 5 (32.6%). For each group, histology from target (T), regional saturation target (RST), and contralateral systematic biopsy (CSB) was compared. Patients were then classified as negative, T and/or RST ≥ to CSB, or T and/or RST < to CSB.
Results or Findings: In the PI-RADS 3 group, histology was negative in 52 patients (67.5%), positive with T and/or RST ≥ to CSB in 18 patients (23.4%), and positive with T and/or RST < to CSB in 7 patients (9.1%). In the PI-RADS 4 group, histology was negative in 20 patients (10.7%), positive with T and/or RST ≥ to CSB in 161 patients (86.6%), and positive with T and/or RST < to CSB in 5 patients (2.7%). In the PI-RADS 5 group, histology was negative in 4 patients (3.1%), positive with T and/or RST ≥ to CSB in 120 patients (94.5%), and positive with T and/or RST < to CSB in 3 patients (2.4%). Only 7 out of 390 patients (1.8%) were positive exclusively at CSB. Among these, 5 (71.5%) had Gleason score 3+3 (ISUP 1), while 2 (28.5%) had Gleason score 3+4 (ISUP 2).
Conclusion: SB in addition to sTB provided no significant additional diagnostic value for csPCa in patients with PI-RADS ≥3 lesions on mpMRI.
Limitations: Not applicable

Reduction of incidence of pneumothorax in CT-guided lung biopsies by saline infiltration during coaxial needle extraction (6 min)

Giulia Viviano; Parma / Italy

Author Block: G. Viviano, A. Adebanjo, M. De Filippo; Parma/IT
Purpose: This study evaluates whether saline infiltration during coaxial needle extraction reduces the incidence of pneumothorax (PTX) in CT-guided lung biopsies, potentially enhancing procedural safety.
Methods or Background: A retrospective analysis of 200 consecutive CT-guided core needle biopsies (18G) was conducted using our hospital's Radiology Department database. All procedures were performed between February 2022 and December 2024 by a single operator with 20 years of experience. Patients were divided into two groups: Group A (100 patients), receiving 5–10 ml of 0.9% saline solution during coaxial needle extraction, and Group B (100 patients), where no saline was infiltrated. Descriptive and inferential statistical analyses assessed the relationship between saline infusion and PTX incidence.
Results or Findings: PTX occurred in 24% of Group B patients versus 7% in Group A ($p < 0.001$). Multivariate analysis confirmed saline infusion as a significant protective factor, even in high-risk patients (e.g., those with severe emphysema or in lateral decubitus). The odds ratio (OR = 3.9) indicates that the absence of saline increases PTX risk nearly fourfold.
Conclusion: Saline infiltration during coaxial needle removal significantly reduces PTX incidence in CT-guided lung biopsies, offering a simple, effective strategy to enhance patient safety.
Limitations: None

The new era of non-invasive interventional oncology with histotripsy - early results and experience on hepatic tumours from Asia (6 min)

Neeraj Ramesh Mahboobani; Hong Kong / Hong Kong SAR China

Author Block: N. R. Mahboobani, P. Chan, K. H. LEE, C. Tsai, J. F. Griffith; Hong Kong/HK
Purpose: Histotripsy uses high intensity pulsed ultrasound waves to mechanically destroy targeted tissue whilst sparing surrounding tissues and structures. We report results and experience from one of the first sites in Asia using histotripsy to treat focal liver lesions.
Methods or Background: 19 patients (12 males, 7 females) with mean age of 70.5 years had 22 focal liver lesions treated with histotripsy between April and September 2025. All treatment procedures were done under general anaesthesia. Clinical parameters, laboratory test results and imaging were reviewed.
Results or Findings: 15 hepatocellular carcinomas and 7 liver metastases were treated. Mean size of the lesions was 2.2 cm (range 0.9 to 4.0 cm). 21 lesions were successfully treated as evident by liquefaction on post-treatment day 1 MRI, with technical success rate 95.4%. One small lesion in segment I showed no treatment related changes on post-treatment day 1 MRI. One patient developed transient thrombosis in right portal vein branch which subsequently resolved on day 7. Minor complications included transient derangement of liver function (15 patients), mild ascites (8), mild abdominal wall oedema (5), and mild right pleural effusion (4). All minor complications subsequently resolved. 17 patients have had post-treatment 1 month MRI, out of which 8 have also had post-treatment 3 month MRI. These show progressive shrinkage of the liquefied treatment volume with no evidence of recurrence.
Conclusion: Histotripsy is an effective non-invasive treatment for focal liver lesions which can be clearly visualised on ultrasound. It is suitable for lesions which are in close proximity to structures such as the biliary tract or vessels. Patient and lesion selection, patient positioning and ventilation strategies during general anaesthesia to reduce respiratory excursion of the liver are important factors for successful treatment.
Limitations: No limitations were identified.

Efficacy of Quadruple Phase Cryoablation on Malignant Lung Tumours - 2 year follow up (6 min)

Paras Dalal; London / United Kingdom

Author Block: B. M. Suwita, E. Skondras, P. Dalal; London/UK
Purpose: Ablation is commonly used in treatment of lung malignancies. The current standard technique for cryoablation is a triple-phase protocol. We have developed a quadruple-phase protocol. This study aims to evaluate the efficacy of our new technique.
Methods or Background: Retrospective, single-centre study. Patient follow-up: 2-years . The primary end-point was local tumour control -secondary end-point was overall survival. Factors affecting local tumour control were analysed using generalised linear model, while factors for overall survival were analysed using binary logistic regression. This study also compared the end-points results between the triple-phase and quadruple-phase cryoablation.
Results or Findings: 69 patients (38 male and 31 female). Median age 70 years. 49 (71%) patients had metastatic tumour, 20 (29%) had primary disease. Patients had 1 -4 lesions, median size 18 mm (3–84 mm). 100 lung lesions were included in this study. All patients had complete 2-year-follow-up.
Eleven patients (16 lesions) underwent triple-phase, 58 patients (84 lesions) underwent quadruple-phase cryoablation. P> 0.05 for age, sex, length of follow up, largest tumour size, tumour type and number of lesions treated between triple and quadruple phase.
Local tumour control was achieved in 50 patients (76 out of 100 lesions, 76%): 8 patients (13 lesions, 81.3%) in triple-phase and 42 patients (63 lesions, 75%) in quadruple-phase cryoablation at 2-years (OR 1.2, 95%CI 0.3–4.2). The presence of post-ablation ground-glass changes may affect the local tumour control rate (OR 3.5, 95%CI 0.7–18.8).
Overall survival rate was 73.9%: 54.5% triple-phase , 77.6% quadruple-phase. There was higher mean overall-survival for quadruple-phase (21.4 months) compared to triple-phase (17.3 months) (p=0.073). The largest lesion diameter predicted the overall-survival (HR 0.83, p=0.007).
Conclusion: Quadruple-phase cryoablation may offer better survival than the triple-phase technique.
Limitations: No a randomised study.
Relatively small number of patients.

Comparison of 18 gauge mirowave antenna and radiofrequency ablation methods for the treatment of benign thyroid nodules (6 min)

CEM YÜCEL; Ankara / Turkey

Author Block: C. YÜCEL, M. A. Can; ANKARA/TR
Purpose: To compare the effectiveness of radiofrequency ablation and 18 gauge low-watt microwave ablation techniques in the treatment of benign thyroid nodules.
Methods or Background: A total of 104 patients with 119 thyroid nodules underwent thermal ablation with either radiofrequency ablation (RFA) (23 females and 14 males; mean age 41 ± 9years) or 18 gauge low-watt microwave ablation (MWA) (28 females and 15 males; mean age 45 ± 11years). Ultrasound control examinations fort he evaluation of volume reduction rates (VRR) were performed at the 1st, 3rd, 6th, and 12th months after the ablation procedures.
Results or Findings: The mean initial volume of the nodules (RFA: 21 mL [min 2.5–max 74]; MWA: 27,5 mL [min 2–max 205]) was statistically significantly different (P < .001). The volume reduction rates of nodules at 1, 3, 6, and 12months, respectively were: after RFA: 41.02 ± 15.05 %, 55.15 ± 12.54 %, 64.44 ± 11.28 %, and 71.42 ± 10.65 %. after MWA: 43.57 ± 11.01 %, 55,69 ± 12.04 %, 65.90 ± 12.67 %, and 73,90 ± 11.16 %. There was no significant difference between two ablation techniques for all months. No serious complications due to the procedures were observed.
Conclusion: Both RFA and MWA methods are effective in the treatment of benign thyroid nodules. Using thinner needle (18 gauge) and low-watt techniques seems to overcome the challenges of MWA technique which were encountered in previous series.
Limitations: This is a retrospective study.
Funding for this study: No funding

Ultra long-term renal function post image-guided ablation and partial nephrectomy for stage 1 renal cell carcinomas (6 min)

Rhys Miller; Leeds / United Kingdom

Author Block: H. Whittaker, V. Chan, R. Miller, J. Cartledge, J. Zhong, O. Abdel-Hadi, J. Smith, J. Lenton, T. M. Wah; Leeds/UK
Purpose: Long-term renal function post image-guided ablation (IGA) and partial nephrectomy (PN) is underreported. This study aims to outline the ultra-long term renal function of IGA and PN patients.
Methods or Background: This is a retrospective study of localised RCC (T1) patients undergoing image-guided cryoablation, radiofrequency ablation (RFA) or laparoscopic PN from 2004-2015 at our institution. Cox regression and log-rank analysis were used for survival analysis of long-term renal function, alongside t-test, chi-squared tests.
Results or Findings: A total of 295 patients undergoing image-guided cryoablation (104), image-guided RFA (99), and laparoscopic PN (92) were included. Median follow-up was 136 months (IQR 76). IGA patients were older (mean difference 13.8 years, $p<0.001$) and more comorbid (mean difference in Charlson index 1.47, $p<0.001$). Pre-treatment CKD is significantly more prevalent in patients undergoing IGA (29.1%) than PN (10.9%) ($p=0.001$). At 10-years follow-up, eGFR decreased 16.6% in IGA vs 8.4% in PN ($p=0.12$). New CKD (Grade 3 or above) developed in 28.3% of IGA patients vs 15.2% of PN patients ($p=0.027$) at follow-up. However, on a multivariable cox regression model, when taking account into age and Charlson comorbidity index, new-CKD free survival is similar between IGA and PN (HR 0.72, 95% CI 0.34-1.52, $p=0.390$). Six patients underwent renal dialysis, all IGA patients due to pre-treatment CKD. CKD-specific deaths were similar (HR 0.26, 95%CI 0.03-2.2, $p=0.218$).
Conclusion: Despite an older, co-morbid population pre-treatment, IGA achieved similar ultra-long-term renal function to PN.
Limitations: However, this study is limited by selection bias, and long-term results from randomised trials are warranted.
Funding for this study: No funding.

Differential Outcomes of Cryoablation for Pulmonary Metastases: Local Efficacy and Systemic Effects on Target vs. Non-Target Lesions (6 min)

Guangcai Liang; Hangzhou / China

Author Block: G. Liang, S. Huang, W. Xiao, S. Gong; Hangzhou/CN
Purpose: To evaluate the safety and efficacy of cryoablation for pulmonary metastases and investigate its differential impact on targeted versus non-targeted lesions.
Methods or Background: This retrospective study included 74 patients (39 male, mean age 61.7±8.3 years) with 102 pathologically proven pulmonary metastases treated with cryoablation between July 2020 and September 2024. Demographics, lesion characteristics, procedural details, and complications were recorded. Patients underwent follow-up CT scans at 3, 6, and 12 months. The primary outcome was the progression status of the targeted lesion at one year. Secondary outcomes included the progression of non-targeted lesions at each interval and overall survival. Changes in lesion size (length/short-diameter) were evaluated.
Results or Findings: The most common primary cancer was colorectal cancer (72%). The procedure was technically successful in all cases. Complication rates were low, with 24% of patients experiencing minor events (e.g., pneumothorax, hemoptysis); only two cases (2%) required chest tube drainage for moderate pneumothorax. For targeted lesions, larger lesion size (length and short-diameter) and a shorter distance from the ablation margin significantly predicted local progression (all $p<0.001$). For non-targeted lesions, the location of the ablated metastasis was a significant predictor of progression. Treating subpleural lesions resulted in significantly better control of non-targeted metastases at 3, 6, and 12 months compared to intrapulmonary lesions (Odds Ratios: 0.33, 0.33, 0.38; all $p<0.05$).
Conclusion: Cryoablation is a safe and effective treatment for pulmonary metastases. Outcomes for targeted lesions are influenced by their size and the achieved ablation margin. Notably, ablating subpleural metastases is associated with superior subsequent control of non-targeted lesions, suggesting a potential systemic benefit.
Limitations: The retrospective nature of this study.
Funding for this study: This study has received funding by National Natural Science Foundation of China (NSFC, No. 82330060 and 82370738).

Real-World Implementation of a Deep Learning–Based Reconstruction Algorithm in Musculoskeletal MRI: Impact on Workflow, Image Quality, and Sustainability (6 min)
Angela Motoyama Caiado; São Paulo / Brazil

Author Block: J. Mendonca, J. D. A. Batista Araújo Filho, A. G. ORMOND FILHO, T. R. Giacometti, A. Motoyama Caiado, B. A. Rocha, N. Y. Hashimoto, M. Nico, D. Bahia; São Paulo/BR
Purpose: To describe our institutional experience deploying a deep learning reconstruction (DLR) algorithm for musculoskeletal MRI in an outpatient setting, assessing its impact on MRI acquisition time, image quality, and collaborative workflow adaptation.
Methods or Background: This retrospective study evaluated MSK MRI exams performed at a large private radiology network in Brazil. Following vendor-guided scanner upgrades, a k-space-based DLR algorithm (AIR™ Recon DL) was integrated into native reconstruction pipelines across multiple systems. Workflow adjustments and protocol standardization were co-developed in collaboration with the vendor and internal radiologist leads. We compared MRI studies from 12 months before (Group 1) and after (Group 2) DLR implementation. Acquisition time was automatically calculated per exam. A subset of cases was randomly selected for blinded qualitative image review using a 5-point Likert scale. Estimated energy use and CO_2e emissions were calculated using scanner-specific consumption metrics and regional emission factors.
Results or Findings: A total of 22,165 MSK MRI scans were analyzed: 10,492 in Group 1 and 11,673 in Group 2. Median scan duration decreased by 53% post-implementation, with the most substantial reductions in shoulder (62%), wrist (59%), knee (52%), spine (38%) and hip (33%) scans. Workflow optimization reduced scanner idle time, improved patient throughput, and lowered anxiety- and motion-related interruptions. Radiologist image quality assessments remained stable, with occasional feedback on altered image texture. Annual energy savings exceeded 2.3 MWh per scanner, avoiding over 1 metric ton of CO_2e emissions.
Conclusion: This real-world implementation of AI-driven DLR demonstrated tangible workflow optimization, improved patient experience, and meaningful environmental benefits. Ongoing collaboration among vendors, radiologists, and technologists was essential for successful adoption, underscoring the importance of clinician–industry partnerships in ensuring safe and efficient AI deployment.
Limitations: Retrospective study with limited image quality sampling and no cost-effectiveness analysis.
Funding for this study: None

Accessible and Opportunistic Fracture Risk Prediction Using Chest Radiography: A Deep Learning Approach Compared with FRAX (6 min)
Yisak Kim; Seoul / Korea, Republic of

Author Block: Y. Kim[1], D. Lee[1], J. Kim[2], H. D. Chae[1], C. M. Park[1], S. H. Kong[3]; [1]Seoul/KR, [2]Daejeon/KR, [3]Seongnam/KR
Purpose: FRAX is widely used for fracture risk prediction but relies on dual-energy X-ray absorptiometry (DXA), limiting accessibility and responsiveness to short-term events. We developed a deep learning (DL) model based on chest radiographs (CXR) and evaluated an ensemble approach combining CXR DL with FRAX for predicting major osteoporotic fractures (MOFs).
Methods or Background: This multicenter retrospective study included 42,014 patients from Institution A (2008–2019) for model development, and 37,865 patients for external validation (31,821 from Institution B [2003–2022], 6,044 from Institution C [2013–2020]). CXR images were preprocessed using localized energy-based normalization, and convolutional neural network models were trained separately for original and normalized images. A logistic hazard loss function was used to directly model time-to-event data. Predictive performance was assessed by concordance index (C-index) and time-dependent AUROC at 2–10 years.
Results or Findings: In the internal test set (n=5,000), the ensemble model outperformed FRAX (C-index 0.859 vs 0.800, P<.001) and achieved AUROCs of 0.869–0.892 at 2–10 years, compared with 0.805–0.832 for FRAX. CXR DL alone performed slightly higher (C-index 0.867).
In the external validation set (n=37,865), the ensemble consistently surpassed FRAX (C-index 0.811 vs 0.772, P<.001; AUROCs 0.824–0.869 vs 0.780–0.804).
Subgroup analysis by baseline T-score confirmed superior performance of the ensemble over FRAX (normal: 0.878 vs 0.712; osteopenia: 0.792 vs 0.681; osteoporosis: 0.791 vs 0.709, P<.001). Gains were most pronounced in osteopenia, a group often near treatment thresholds, underscoring the value of opportunistic CXR-based prediction for earlier intervention.
Conclusion: The ensemble model of CXR DL and FRAX significantly improved MOF prediction compared with FRAX alone. By leveraging a widely available and low-cost imaging modality, this opportunistic approach expands access to early risk assessment and supports more sustainable fracture prevention.
Limitations: Retrospective design and vendor heterogeneity may affect generalizability.

3D isotropic FastView MRI Localizer allows reliable torsion measurements of the lower limb (6 min)

Felix Herr; Munich / Germany

Author Block: F. Herr, N. Hohmann, C. A. Dascalescu, V. M. Schäfer, H. Gildein, B. Hoppe, J. Ricke, J. Arnholdt, P. Reidler; Munich/DE
Purpose: To evaluate whether a 3D isotropic MRI localizer (FastView) can reliably and efficiently assess femoral and tibial torsion compared to a dedicated MRI protocol, offering a faster alternative to a conventional dedicated MRI protocol.
Methods or Background: In this retrospective single-center study, 60 lower limbs from 30 patients (mean age 27.1 ± 11.5 years; 19 female, 11 male) were examined using FastView and a dedicated MRI protocol. FastView imaged the entire lower limb in 17.4 seconds (voxel size 5×5×5 mm^3), whereas the standard protocol required nearly 7 minutes. Two independent readers measured femoral and tibial torsion angles. Agreement between methods was evaluated using intraclass correlation coefficients (ICCs), Bland–Altman plots, and Pearson's R^2.
Results or Findings: Across 60 limbs, no significant differences were observed in all measured angles between FastView and the dedicated protocol ($p > 0.05$). Femoral torsion showed excellent inter-modality agreement (ICC: 0.91–0.96), with mean differences ranging from –2.2 ± 3.4° ($p = 0.001$) to –3.7 ± 4.4° ($p < 0.001$). Tibial torsion also showed excellent agreement (ICC: 0.91–0.94), with mean differences from –1.2 ± 4.6° ($p = 0.16$) to –2.1 ± 4.6° ($p = 0.02$). Inter-reader agreement was consistently high for both modalities (ICC: 0.95–0.99). Bland–Altman analyses and Pearson's R^2 (range: 0.84–0.94) confirmed strong correlation and reliability.
Conclusion: FastView MRI localizer showed excellent agreement with the dedicated torsion protocol for femoral and tibial measurements. By reducing scan time and avoiding radiation, FastView promotes a more sustainable approach and may replace conventional multi-sequence protocols in practice.
Limitations: This retrospective single-center study has limited generalizability, and the sample size was relatively small. Although scan acquisition with FastView is reduced to ~17 seconds, preparation time remains similar to standard protocols.
Funding for this study: No funding was received for this study.

Ethics committee - additional information: This study was approved by the institutional review board (approval number: 23-0020; date of approval: 09 March 2023).

3D MRI- Based Virtual Radiographs Of The Pelvis For Assessment Of Acetabular Coverage And Version (6 min)

Florian Schmaranzer; Bern / Switzerland

Author Block: J. Roshardt[1], S. Steppacher[1], M. K. Meier[1], S. Sommer[2], R. Sutter[2], F. Schmaranzer[2]; [1]Bern/CH, [2]Zürich/CH
Purpose: Hip deformities require precise diagnosis before joint-preserving surgery, but standard radiographs and CT scans involve ionizing radiation, raising concerns about cumulative exposure, particularly in younger patients. MRI offers detailed, radiation-free imaging of bone morphology and soft tissues. Advances in deep learning enable automatic segmentation and MRI-based 3D pelvic modeling, allowing virtual radiographic-like projections. This study determined if standard radiographic parameters (lateral center-edge angle [LCEA], retroversion index [RI], and acetabular index [AI]) can be accurately measured on MRI-based projections compared to conventional anteroposterior (AP) pelvic radiographs.
Methods or Background: Fifty patients (100 hips, mean age 28 years) with symptomatic hip deformities underwent evaluation with standard AP pelvic radiographs and direct hip MR arthrography (including T1-w VIBE DIXON). Osseous pelvis was segmented using a validated 3D nnU-Net, cortical bone contrast augmentation and radiograph-like projections were generated using a cone beam projection algorithm. Arthrography and non-contrast sides were analyzed separately. Parameters were measured on both imaging modalities and compared using t-tests and Pearson's correlation.
Results or Findings: The LCEA showed no significant difference between conventional and MRI-based projections, with absolute mean differences of 0.2±1.2° (arthrography, p=0.71) and 0.6±1.7° (non-contrast, p=0.29). Similarly, AI showed no significant difference (0.6±1.5° arthrography, p=0.20); 1.±2.1° (non-contrast, p=0.075). For RI, absolute mean differences were 0.5±4% (arthrography, p=0.80) and 2.±5.3% (non-contrast, p=0.22), indicating no significant difference. Moderate to strong correlations were found between MRI-based and conventional radiographs (LCEA: r=0.84/0.77, AI: r=0.75/0.66, RI: r=0.60/0.66 for arthrography/non-contrast; all p<0.001).
Conclusion: MRI-based radiographic-like projections, whether with or without contrast agents, provide measurements comparable to AP pelvic radiographs for key hip morphology parameters. This approach eliminates radiation exposure while maintaining diagnostic accuracy, offering significant advantages for young patients requiring repeated imaging for hip deformity assessment and surgical planning.
Limitations: No external validation

Do All Scaphoid Fractures Need a CT Scan? Insights from a European Dual-Centre Study to Guide Clinical Decision-Making (6 min)

Maxim Avanesov; Hamburg / Germany

Author Block: M. Avanesov[1], C. Zickert[2], M. Stojkova[3], G. F. Peter[1], J. Yamamura[1], H. Ragab[1]; [1]Hamburg/DE, [2]Lüneburg/DE, [3]Duisburg/DE
Purpose: This dual-centre study analysed the additional value of CT imaging besides conventional radiography (x-ray) on the diagnosis and outcome of acute scaphoid fractures at two university medical centres in Europe.
Methods or Background: Two hundred and twelve consecutive patients (103 patients from Hamburg, Germany (mean age 38 ±19 years, 82 males) and 109 patients from Skopje, North Macedonia (mean age 38 ±18 years, 86 males)) who were diagnosed with scaphoid fractures were included in the European dual-centre study. All patients underwent conventional radiography in three views and all fractures were staged according to the dichotomic Herbert classification (Herbert A: stable fracture; Herbert B: unstable fracture). In Hamburg, all patients underwent additional CT imaging, whereas in Skopje only patients with suspected instability (Herbert Type B) underwent additional CT imaging. Demographics, treatment strategies, as well as clinical and functional outcomes were retrospectively compared between the two centres.
Results or Findings: All patients with a scaphoid fracture in Hamburg underwent additional CT imaging, whereas only 23 out of 109 patients (21 %) in Skopje had a complementary CT scan ($p < .001$). Fracture type distribution and stability were comparable between centres. While 42 out of 103 patients (41%) underwent surgical treatment in Hamburg, only 13 out of 109 patients (12%) were operated in Skopje ($p < .001$). However, there were no statistically significant differences in complication rates between the two sides ($p = .489$).
Conclusion: This dual-centre study suggests that using additional CT imaging only for unstable acute scaphoid fractures does not lead to worse clinical or functional outcomes or an increased rate of complications.
Limitations: Retrospective study design
Limited follow-up period
MRI imaging was not investigated
Funding for this study: No external funding sources.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Ethical approval was provided by the local institutional ethics committee. The requirement for written informed consent was waived due to the retrospective nature of the study. The study was performed in accordance with the ethical standards as laid down in the 1964 Declaration of Helsinki and its later amendments.

Deep Learning Accelerated MRI in Muscle Injuries of Professional Soccer Athletes: Enhancing Efficiency and Sustainability (6 min)

Scherwin Mahmoudi; Frankfurt / Germany

Author Block: S. Mahmoudi, K. Eichler, L. D. Grünewald, T. J. Vogl, I. Yel; Frankfurt/DE
Purpose: The purpose of this study was to investigate the impact of deep learning-accelerated MRI on acquisition time and image quality in muscle injuries of professional soccer athletes.
Methods or Background: 28 professional male soccer athletes (mean age 25.4±3.4) who underwent 3-Tesla-MRI of the lower limb due to suspicion of muscle injuries were included. Standard sequences were acquired consisting of PDw imaging in axial, paracoronal and parasagittal plane, as well as T1-weighted imaging in axial plane. Additionally, PDw imaging sequences were acquired using the deep learning algorithm (PDDL).
Subjective evaluation was independently performed by three blinded radiologists. 5-point Likert scales were utilized to subjectively assess diagnostic confidence, image quality, and lesion sharpness. Objective analysis encompassed time efficiency and quantitative imaging parameters, including signal-to-noise-ratio (SNR) and contrast-to-noise-ratio (CNR), as well as operational costs including electricity and personnel.
Results or Findings: MRI revealed structural injuries in 21 of 28 athletes (75%). Subjective evaluations of PDDL sequences revealed excellent diagnostic confidence (median 5, interquartile range (IQR): 5-5), image quality (median 5, IQR: 5-5), and lesion sharpness (median 5, IQR: 4.5-5). In 91.7 % of cases, PDDL sequences were favored over conventional PD imaging. Objective image analysis of PDDL revealed significant higher SNR (115.0±9.1) and CNR values (80.5±12.8) when compared to conventional PD sequences (81.3±5.9 and 54.3±5.4, respectively)($p<0.05$). Acquisition times could be reduced by an average of 39.7% using PDDL sequences.
Conclusion: Our findings suggest that deep learning MRI of muscle injuries among professional athletes allow a reduction in acquisition time while additionally improving image quality. The integration of these sequences may enhance operational efficiency and reduce ongoing costs, promoting a more sustainable and value-based approach in radiology.
Limitations: The study population is relatively small, which is attributable to the specific subcohort examined.
Funding for this study: No funding

Buddy Imaging in MSK: Adding Value to Routine Scans for a Greener Future (6 min)

Caixia Zhu; Lisboa / Portugal

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: C. Zhu[1], I. d. Mata[2], C. Zhu[3], E. Santana[2]; [1]Barcelos/PT, [2]Lisboa/PT, [3]Lisbon/PT
Purpose: Healthcare sustainability requires imaging strategies that maximize diagnostic yield while minimizing resource use. Musculoskeletal (MSK) findings are frequently visible on routine scans obtained for other indications, such as abdominal CT, pelvic MRI, or vascular imaging. Leveraging these “incidental windows” provides clinically relevant information without additional examinations, contributing to more efficient and environmentally responsible practice.
The aim of this presentation is to demonstrate how MSK findings can be opportunistically assessed on routine non-MSK scans, to discuss their role in the early detection of conditions such as osteoporosis or sarcopenia, and to illustrate how this approach contributes to sustainable imaging by reducing redundant examinations while enhancing patient care.
Methods or Background: A literature review and pictorial synthesis were performed, focusing on CT and MRI examinations where bone and soft-tissue structures are included but not primarily targeted. Examples include vertebral bone mineral density from abdominal CT, femoral muscle bulk in pelvic MRI, and vascular CT revealing both arterial calcifications and adjacent bone health.
Results or Findings: Analysis of routine scans demonstrates that clinically relevant MSK information can often be extracted without additional imaging. Vertebral Hounsfield units derived from abdominal CT correlate with osteoporosis risk, muscle cross-sectional area on pelvic MRI reflects sarcopenia, and joint or tendon morphology may be partially assessed on pelvic or vascular studies. Incorporating this opportunistic evaluation into structured reporting allows early recognition of disease, reduces the demand for dedicated MSK examinations, and contributes to a more sustainable imaging workflow.
Conclusion: “Buddy imaging” transforms routine scans into multipurpose tools, aligning clinical value with sustainability goals. Recognizing MSK features beyond the primary indication supports earlier intervention, avoids duplicate examinations, and exemplifies a greener radiology practice.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study.

A Unified Model for Mutlianatomy Musculoskeletal Image Synthesis in MRI (6 min)

Thomas Campbell Arnold; Philadelphia / United States

Author Block: T. C. Arnold[1], L. Wang[1], A. Shankaranarayanan[1], L. N. Tanenbaum[2]; [1]Menlo Park, CA/US, [2]RIVERSIDE, CT/US
Purpose: Musculoskeletal MR protocols include multiple sequences with different acquisition planes (axial, sagittal, coronal) and contrasts (T1w, T2w, T2w fat-sat, PD, PD fat-sat). The exact combination of sequences varies widely across institutions. Previously, we demonstrated the ability to synthesize sequences in knee protocols, thus enabling faster or more comprehensive exams. However, that algorithm's utility is limited to knee exams. In this study, we present a unified model capable of synthesizing sequences across a wide range of musculoskeletal anatomies.
Methods or Background: We retrospectively analyzed 554 musculoskeletal MR exams to identify image synthesis sets containing a target image, a sequence-type match, and an acquisition-plane match. We held out 55 subjects for testing, which spanned 6 target sequences, 8 musculoskeletal regions, and 39 target/sequence-type/acquisition-plane combinations. The remaining subjects were used to train a patch-based neural network. Model performance was quantitative assessed using peak signal-to-noise ratio (PSNR) and structural similarity index (SSIM).
Results or Findings: Across all synthesis combinations, average PSNR was 23.6±3.3 dB and SSIM 0.66±0.15. Averaging across target sequence, quantitative values ranged from PSNR=[22.5-25.7 dB] and SSIM=[0.59-0.80] with Ax PD FS having the highest (25.7±5.0 dB, 0.80±0.12) followed by Ax T2 FS (24.8±0.2 dB, 0.77±0.01). Across anatomies, values ranged from PSNR=[20.1-27.8 dB] and SSIM=[0.59-0.81] with elbow and ankle showing the best performance and wrist having the worst performance.
Conclusion: We provide a preliminary demonstration that a single model can synthesize a range of sequences from various musculoskeletal anatomies. This offers a flexible and generalizable approach that can match site-specific musculoskeletal protocols and adapt to protocol changes.
Limitations: Future studies should include a qualitative reader study by radiologists.
Funding for this study: Funding provided by Subtle Medical.

Optic Nerve Lesion Volume, White Matter Hyperintensities, and Brain Volumetrics in Multiple Sclerosis: A Multi-Sequence MRI-Based Analysis (6 min)
Adrian Korbecki; Wrocław / Poland

Author Block: A. Korbecki, T. Konopczyński, O. Hawro, A. Blachucik, K. Winiarczyk, K. Litwinowicz, M. Sobański, J. Bladowska, A. Zimny; Wroclaw/PL
Purpose: To examine the association between optic nerve lesion volume (ONLV) on double inversion recovery (DIR) MRI and other imaging biomarkers of disease burden in multiple sclerosis (MS), including white matter hyperintensities (WMHs), T1-weighted hypointensities, and brain volumetrics. The study explores whether ONLV reflects a more severe neurodegenerative profile and may serve as a marker of disease severity.
Methods or Background: In this cross-sectional study, 212 MS patients underwent 3T MRI including 3D T1-weighted, FLAIR, and DIR sequences. Optic nerve lesions were manually segmented on DIR and quantified volumetrically. Patients were categorized by optic nerve involvement: none (n = 59), unilateral (n = 60), or bilateral (n = 93). WMHs were segmented and anatomically classified using an AI-based tool. T1W hypointensities and brain volumetrics were extracted using FreeSurfer and a machine-learning algorithm applied to 3D T1W and FLAIR images. Models were adjusted for intracranial volume.
Results or Findings: ONLV positively correlated with periventricular ($r = 0.365$, $p < 0.001$), deep ($r = 0.165$, $p = 0.005$), and juxtacortical ($r = 0.163$, $p = 0.007$) WMHs. Bilateral involvement was associated with higher WMH burden, increased T1W hypointensities ($\beta = 10.91$, $p < 0.001$), and greater white-matter atrophy ($\beta = -107.02$, $p = 0.016$), particularly along visual pathways. Periventricular WMHs also correlated with global cortical and subcortical gray-matter loss.
Conclusion: ONLV is associated with greater lesion load and neurodegeneration in MS, supporting its potential as a biomarker of disease severity. Longitudinal studies are needed to confirm prognostic value.
Limitations: Cross-sectional design limits assessment of longitudinal progression; future studies should track ONLV evolution and its radiological/clinical impact.

Manual segmentation is prone to variability; AI-based tools could improve accuracy and reproducibility.

Integrating comprehensive clinical data and more uniform cohorts would strengthen future investigations.

Analysis of Spinal Cord MRI in Multiple Sclerosis: Implications for Monitoring Disease Progression (6 min)
Hana Larassati; London / United Kingdom

Author Block: H. Larassati[1], S. M. Sceppacuercia[2], A. H. M. E. Hammam[1], O. Sarwani[1], W. Brownlee[1], C. Auger[2], A. Rovira Cañellas[2], T. A. Yousry[1]; [1]London/UK, [2]Barcelona/ES
Purpose: To evaluate the benefits of spinal cord MRI in multiple sclerosis (MS) by assessing lesion dynamics over time, their relationship with brain lesions, and disability progression.
Methods or Background: This retrospective, multicentre longitudinal study included MS patients from London (UK) and Barcelona (Spain) who underwent brain and spinal cord MRI at baseline and follow-up. Clinical data included relapse history, Expanded Disability Status Scale (EDSS), and disease-modifying therapy (DMT) use. MRI reports were extracted from PACS, with independent reads by two neuroradiologists to assess inter- and intra-observer reliability. Regression models evaluated associations with disability.
Results or Findings: 127 patients (75.6% females, 24.4% males) were included, mean age of 43 years old, median follow-up interval at 19 months (11–29 months), 56.8% were on DMT at follow up. 82.7% of patients had spinal cord lesions at baseline, and 15.1% developed at least one lesion at follow-up. New spinal cord lesions were most frequent at 11–12 months (28.6%) and less common at later follow-ups (8–22%). New spinal cord lesions were more common in the relapsing MS, and was significantly associated with EDSS worsening (p=0.036). In progressive MS, new lesion incidence was lower and showed weaker correlation with disability progression. Spinal-only activity was present in 7.9% patients at baseline and occurred in additional cases at follow-up. Inter- and intra-rater agreement for lesion burden and new lesion detection was moderate to high (κ=0.60–0.83; ICC=0.56–0.94).
Conclusion: New spinal cord lesions predict disability worsening and reveal spinal-only activity missed on brain MRI. New spinal lesion accrual was relatively low and the benefit of spinal MRI may vary by patient phenotype and timing. A selective, phenotype- and timing-based approach to spinal cord imaging may optimise its use in MS monitoring.
Limitations: Small sample size, limited follow-up period

Paramagnetic Rim Lesions: Potential Biomarkers of Disease Activity and Prognosis in Multiple Sclerosis (6 min)

Mizgin Yamer; Istanbul / Turkey

Author Block: B. Atalay, M. Yamer, M. B. Doğan, I. Aydın Cantürk; Istanbul/TR
Purpose: To investigate the association of paramagnetic rim lesion subtypes—complete, incomplete, patch-like, which serve as biomarkers of chronic active lesions in multiple sclerosis—with the Expanded Disability Status Scale (EDSS) and multiple sclerosis subtypes.
Methods or Background: This retrospective study included patients with a confirmed diagnosis of MS who underwent brain MRI. PRLs were evaluated by count, type (complete rim, incomplete rim, or patch-like) and location using phase images from SWI sequences. The presence of active lesions was also noted. Statistical analyses examined associations between PRL characteristics and clinical parameters using non-parametric tests and Spearman correlations.
Results or Findings: Thirty-two patients (75% female; mean age 46.1 ± 15.7 years) were included. PRLs were present in 62.5% of patients, with 28.1% complete and 12.5% incomplete rims, and the remainder were patch-like. PRL count, type, and location did not differ significantly across MS subtypes ($p = 0.93$, 0.21, and 0.08, respectively). Patients with active lesions exhibited a significantly higher number of PRLs compared to those without ($p = 0.02$). However, PRL location and type were not associated with the presence of active lesions ($p = 0.07$ and $p = 0.15$). No significant correlations were observed between PRL count and either EDSS score or disease duration ($p = 0.83$ and $p = 0.87$). Likewise, EDSS score and disease duration did not significantly differ between patients with and without PRLs ($p = 0.23$ and $p = 0.14$, respectively).
Conclusion: PRLs are common in patients with MS and are associated with the presence of active lesions, but not with MS subtype, EDSS score, or disease duration. Their role in clinical prognosis should be clarified in larger, prospective studies.
Limitations: The limitations of our study include its retrospective design, the relatively small patient sample size.
Funding for this study: No funding for this study.

Effect of Lesion Filling on Brain Age Estimation in Multiple Sclerosis (6 min)

Salem Hannoun; Beirut / Lebanon

Author Block: S. Hannoun, G. Fayad, N. El-Ayoubi, S. Khoury; Beirut/LB
Purpose: To investigate whether lesion filling improves the accuracy and interpretability of brain age estimation in multiple sclerosis (MS), and to assess its associations with clinical disability and structural MRI markers.
Methods or Background: We retrospectively analyzed 571 relapsing-remitting MS patients. Brain age was estimated using the BrainAgeR pipeline on both non-lesion-filled and lesion-filled T1-weighted images. Bias correction was applied to adjust for age-related prediction bias, and the Brain Age Gap (BAG) was computed as the difference between corrected predicted age and chronological age. Agreement between approaches was assessed using Bland–Altman analysis, Pearson correlation, and intraclass correlation coefficient (ICC). Associations of BAG with disability measures (EDSS, 9HPT, SDMT, 25FWT) and volumetric MRI metrics (global and subcortical volumes) were evaluated using multivariable regression with Bonferroni correction.
Results or Findings: Lesion-filled and non-lesion-filled brain age estimates showed excellent agreement (r=0.97, ICC=0.962), with a mean difference of 1.23 years. The mean absolute error was slightly lower for lesion-filled predictions (8.12 vs 9.40 years). Both BAG measures were significantly associated with EDSS, 9HPT, and SDMT ($p<0.001$), but not with 25FWT. Lesion-filled BAG demonstrated stronger associations with gray matter, thalamic, and hippocampal volumes, with higher explained variance compared to non-lesion-filled BAG. These associations remained significant after multiple comparison correction.
Conclusion: Brain age estimation is robust to lesion effects in MS, with lesion filling offering modest improvements in alignment with structural imaging markers but limited impact on clinical correlations. Lesion correction should be considered when precise structural interpretability is required.
Limitations: This cross-sectional, single-center study included only relapsing-remitting patients without healthy controls. Scanner variability and potential circularity between lesion-filled volumetrics and brain age may have influenced associations. Longitudinal, multi-center studies are warranted.
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was approved by the American University of Beirut Biomedical Institutional Review Board (IRB), which explicitly waived the requirement for written informed consent due to the retrospective nature of the study and minimal risk to participants.

Deep Learning Algorithm Boosts Contrast Signal and Lesion Visualization in Multiple Sclerosis Patients: A Multi-Reader Clinical Performance Study (6 min)

Sonia Colombo Serra; Colleretto Giacosa / Italy

Author Block: S. Pasumarthi Venkata[1], C. Arnold[1], P. Gulaka[1], S. Colombo Serra[2], G. Erb[3], G. D'Anna[4], A. Shankaranarayanan[1], G. Zaharchuk[5]; [1]Menlo Park, CA/US, [2]Colleretto Giacosa/IT, [3]Konstanz/DE, [4]Milan/IT, [5]Stanford, CA/US
Purpose: In the treatment of Multiple Sclerosis (MS), contrast-enhanced (CE) images are crucial in differentiating between new and chronic lesions. Recently, an FDA-cleared contrast boosting (CB) deep learning algorithm was developed that boosted contrast signals present in T1w standard contrast-enhanced (SC) images, improving lesion visualization without increasing dosage. In this work, we evaluate the clinical performance of the CB algorithm on a public dataset consisting of T1w pre and CE images from MS patients.
Methods or Background: From the Open MS Dataset, T1w-pre and SC images from 30 patients (23 Females; 39±10) were used in this study. Contrast boosted (CB) images were generated from T1w-pre and SC using the CB algorithm. Three board-certified radiologists were asked to score the SC and CB images for lesion contrast enhancement, border delineation and internal morphology on a 4-point Likert scale. Readers also scored on any False Lesions (FL) found on CB images and their impact on diagnosis. Contrast-to-noise ratio (CNR), lesion-to-brain ratio (LBR) and contrast-enhancement-percentage (CEP) were computed on SC and CB images.
Results or Findings: The CB images were rated higher ($p<0.05$) than SC images for enhancement (3.66±0.56 vs 2.25±0.84), delineation (3.62±0.71 vs 2.25±0.84) and morphology (3.41±0.77 vs 2.12±0.89). CB images had higher ($p<0.01$) CNR, LBR and CEP. The readers found a few enhancing lesions that were almost missed on SC but were clearly visualized on CB. 12% of cases had FLs that could potentially impact diagnosis, but could be ruled out using T2-FLAIR.
Conclusion: We showed that the CB algorithm has superior clinical performance on MS lesions when compared to SC images. The CB algorithm clearly visualized a few lesions that were almost undetectable from the SC images.
Limitations: This study is limited to a small number of cases.

Diagnostic values of IVIM parametric maps in predicting disabilities for relapsing-remitting multiple sclerosis patients (6 min)

Othman Alomair; Riyadh / Saudi Arabia

Author Block: O. Alomair[1], S. A. Alghamdi[1], A. abujamea[2], M. S. Alshuhri[3], S. Aljarallah[1], N. Alkhawajah[1], H. Al-Mubarak[4], Y. Alashban[1], N. Kurniawan[5]; [1]Riyadh/SA, [2]riyadh/SA, [3]Al Kharj/SA, [4]Glasgow G61 1QH/UK, [5]Brisbane QLD 4072/AU
Purpose: In this abstract, we achieved three aims previously published in three papers. First, evaluate intravoxel incoherent motion (IVIM) diffusion and perfusion MRI metrics for various types of MS lesions, including enhanced, non-enhanced, and black hole lesions. Second, investigate the correlation and predictive values of the IVIM diffusion and perfusion MRI metrics with disability status. Third, utilise radiomics features to evaluate the predictive value of IVIM diffusion parameters in relation to disability severity.
Methods or Background: This cross-sectional study retrospectively analysed quantitative IVIM parameters and MRI data from 197 MS patients. Multiple linear regression was applied to identify independent predictors of EDSS score. Machine learning (ML) techniques, such as XGB, Random Forest, and ANN, were employed to explore the relationships between radiomic IVIM and clinical variables.
Results or Findings: In this abstract, we presented the results previously published in three papers. First, ADC, D, and D* values for MS black hole lesions were significantly higher ($p < 0.0001$) than those for other MS lesions. Second, in the multivariate regression analysis, only the number of MS lesions and relapses emerged as independent predictors of EDSS score (p-value < 0.001). Third, for disability prediction, IVIM-D and D* radiomics strongly correlated with EDSS: Random Forest achieved 89% accuracy (AUC = 0.90), while CNN achieved 90% accuracy (AUC = 0.95).
Conclusion: These three published studies demonstrate the utility of IVIM parameters in detecting microstructural alterations associated with MS impairment. Machine learning analyses of IVIM metrics provided independent predictors of functional impairment and disability in MS. It validated our results.
Limitations: This study has several limitations, which include a single time point study, and it was limited to analysis of MS lesions without considering normal-appearing white or grey matter.
Funding for this study: This research was funded by the King Salman Center for Disability Research through Research Group no. KSRG-2024-197.
The presented work based on three published paper; Investigating the Role of Intravoxel Incoherent Motion Diffusion-Weighted Imaging in Evaluating Multiple Sclerosis Lesions, The Utility of Intravoxel Incoherent Motion Metrics in Assessing Disability in Relapsing–Remitting Multiple Sclerosis and IVIM-DWI-Based Radiomics for Lesion Phenotyping and Clinical Status Prediction in Relapsing–Remitting Multiple Sclerosis.

Generalizable DIR-like Image Synthesis Across Multisite MRI Data for Improved Multiple Sclerosis Lesion Assessment (6 min)

Lawrence Neil Tanenbaum; RIVERSIDE / United States

Author Block: L. Wang, C. Arnold, Z. Zhou, L. Xiang, A. Shankaranarayanan, S. Bash, L. N. Tanenbaum, S. Pasumarthi Venkata; Menlo Park, CA/US
Purpose: Double inversion recovery(DIR) MRI provides superior gray–white matter differentiation and lesion visibility in multiple sclerosis(MS), but is rarely acquired in routine practice due to long scan times. We repurposed a synthesis model originally developed for STIR and applied it to multiple brain MS datasets to evaluate its cross-domain generalization. Despite being trained in a different anatomical setting, the model demonstrates strong performance in generating DIR-like (Syn-DIR) images, with consistent improvements across multisite MS datasets.
Methods or Background: The model was directly applied to T1-weighted and T2-FLAIR brain scans to generate DIR-like images without additional training. Two external datasets were analyzed: open_ms_data(30 subjects) and MSLesSeg(75 subjects). Evaluation included structural fidelity (SSIM and Dice scores on brain volume analysis), tissue contrast (gray-to-white-matter ratio and lesion-to-white-matter ratio), multisite consistency analysis, and longitudinal stability analysis.
Results or Findings: FLAIR and SynDIR showed high structural fidelity across sites (mean SSIM: 0.8719 ± 0.0217), with Dice scores >0.85 for all major brain structures.
SynDIR images exhibited significantly improved tissue and lesion contrast compared with FLAIR. Specifically,gray-to-white-matter ratio increased from 1.2688 ± 0.0617 to 1.6134 ± 0.1946, and lesion-to-white-matter ratio increased from 1.4035 ± 0.1309 to 1.9335 ± 0.3833 ($p < 0.001$).
The t-test on the ratio of gray-to-white-matter ratio to lesion-to-white-matter between the two cohorts showed no significant difference, indicating consistent performance across sites. In addition, the Wilcoxon signed-rank test showed no significant difference between time points ($p = 0.1478$).
Conclusion: A spine-trained synthesis model generalized effectively to brain MS cohorts, generating DIR-like images that enhanced lesion visibility and showed consistent performance across sites and timepoints. This repurposed approach enables advanced contrasts for MS studies without acquiring the DIR series.
Limitations: In future work, these methods should undergo qualitative review by radiologists.

The Role of AI in Multiple Sclerosis Follow-up: Improving Accuracy and Reducing Reporting Times (6 min)

Edoardo Masiello; Milan / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: E. Masiello[1], A. Diena[1], G. M. Agazzi[2], A. Falini[2], N. E. Anzalone[2]; [1]Milan/IT, [2]Milano/IT
Purpose: In multiple sclerosis (MS) MRI is essential for diagnosis and follow-up. Detecting new or enlarging lesions can be challenging and reporting is time-consuming. This study aimed to evaluate the role of an AI platform in lesion detection compared with neuroradiologists of different experience levels, while also assessing its impact on reading time.
Methods or Background: This retrospective observational study included 59 adult patients with relapsing–remitting MS who underwent two brain MRI examinations with standardized 3D-FLAIR sequences at baseline and follow-up. Two neuroradiologists with >10 years and 3 years of experience independently reviewed anonymized scans for new or enlarging lesions, blinded to AI output and each other. The AI software (TensorMedical, Spain) automatically quantified new and slowly expanding lesions by co-registering longitudinal scans. Consensus between the two radiologists was considered the ground truth. Diagnostic accuracy, Cohen's kappa agreement, and reading times with and without AI support were analyzed.
Results or Findings: The cohort included 40 females and 19 males (mean age=43.2 years). The average time interval between baseline and follow-up MRI was 14.2 months (range 2.3–51.1). The mean difference in lesion count compared to ground truth was 0.322±0.797 for the senior reader (N.A), 0.373±1.410 for the junior reader (A.D), and –0.763±4.440 for AI. Overall differences across groups were statistically significant (ANOVA, p=0.0409), but post-hoc comparisons didn't reach significance. Agreement with ground truth was almost perfect for the senior reader (κ=0.898), substantial for the junior reader (κ=0.695), and substantial for AI (κ=0.797). AI assistance reduced median reading time from 5.5 to 2.0 minutes
Conclusion: AI performance was comparable to that of an experienced neuroradiologist and superior to a junior reader. Integration of AI reduced reading time and enhance consistency, particularly for less experienced neuroradiologists.
Limitations: Retrospective, single-center, limited sample size.
Funding for this study: No funding.

Heterogeneous deep gray matter iron deposition patterns across multiple sclerosis subgroups defined by the clinico-radiological paradox (6 min)

Jinlin Jiao; Shenyang / China

Author Block: J. Jiao; Shenyang/CN
Purpose: This study aims to characterize neuropsychological profiles and deep gray matter (DGM) iron deposition patterns across multiple sclerosis (MS) subgroups defined by the clinico-radiological paradox (disability-T2 lesion volume [LV] mismatch), and to analyze factors influencing iron deposition and cognition.
Methods or Background: 121 MS patients were categorized into four subgroups based on median T2-LV and Expanded Disability Status Scale scores: Low-LV/Low-Disability (LL/LD), High-LV/Low-Disability (HL/LD), Low-LV/High-Disability (LL/HD), High-LV/High-Disability (HL/HD). 46 healthy controls (HCs) were included. We used quantitative susceptibility mapping (QSM) to assess iron content and 3D T1-weighted imaging to measure volumes in DGM structures. Cognitive performance was evaluated with the Montreal Cognitive Assessment and Symbol Digit Modalities Test (SDMT). Group differences and relationships were analyzed using ANCOVA, regression, and mediation analyses.
Results or Findings: Compared to HCs, high lesion burden groups (HL/LD, HL/HD) exhibited increased iron deposition and atrophy in the globus pallidus, putamen, and caudate. A significant group-by-volume interaction on iron deposition was found specifically in the putamen for the HL/LD and HL/HD subgroups. Crucially, putamen volume partially mediated (31.2%) the negative effect of iron deposition on SDMT performance across all MS patients, an effect most pronounced in the HL/HD subgroup.
Conclusion: DGM iron deposition is heterogeneously expressed across MS clinico-radiological subgroups. The putamen emerges as a critical structure where iron accumulation adversely impacts cognitive processing speed, partly via volume loss, elucidating a potential mechanism of the clinico-radiological paradox and informing targeted cognitive protection strategies.

TC 827 - Monitoring prostate cancer

Categories: Oncologic Imaging, Genitourinary

ETC Level: LEVEL III

Date: March 5, 2026 | 10:00 - 11:00 CET

CME Credits: 1

The session discusses the implications of overdiagnosis and overtreatment in prostate cancer management, with a focus on how biopsy regimens contribute to these challenges. Furthermore, it reviews the indications, adoption, and risk assessment in active surveillance in North America and Europe, and discusses differences. The attendees will learn about the recurrence assessment in localised and advanced prostate cancer with MRI and next-generation imaging.

Moderators:

Fiona M. Fennessy; Boston / United States

Tristan Barrett; Cambridge / United Kingdom

Chairpersons' introduction (4 min)

Fiona M. Fennessy; Boston / United States

Tristan Barrett; Cambridge / United Kingdom

Biopsy strategies in early detection of prostate cancer (14 min)

Andrei Saraiva Purysko; Cleveland / United States

MRI in active surveillance (14 min)

Tristan Barrett; Cambridge / United Kingdom

Prostate cancer recurrence assessment (14 min)

Quantitative Chemical Exchange Saturation Transfer (CEST) MRI for Diagnosing Thyroid-Associated Ophthalmopathy Activity: A Feasibility Study (8 min)
YunMeng Wang; Shanghai / China

Author Block: Y. Wang, Y. Xiao; Shanghai/CN
Purpose: This prospective study evaluated the feasibility of chemical exchange saturation transfer (CEST) MRI for assessing disease activity in thyroid-associated ophthalmopathy (TAO).
Methods or Background: A total of 88 patients with active TAO, 76 with inactive TAO, and 30 healthy controls were enrolled. CEST MRI-derived MTR and MTRasym at 1ppm, 2ppm, and 3.5ppm were calculated. Clinical data, MTR and MTRasym of extraocular muscles were compared across groups using the Wilcoxon signed rank test. Spearman's correlations were used to examine the associations between imaging parameters and the CAS. Logistic regression analysis was carried out to identify independent predictors, and ROC analysis (DeLong's test) was used to evaluate diagnostic performance for active TAO.
Results or Findings: Patients with active TAO showed lower MTR ($P<0.001$) and higher MTRasym_1ppm, MTRasym_2ppmand MTRasym_3.5ppm (all $P<0.001$). MTR was negatively correlated with CAS ($R=-0.402$; $P<0.001$), while MTRasym_1ppm, MTRasym_2ppm and MTRasym_3.5ppm ($R=0.369$; $R=0.350$; $R=0.349$; all $P<0.001$) were positively correlated. Both MTR and MTRasym_1ppm were independent predictors of TAO activity. The AUC for MTR and MTRasym_1ppm in discriminating active from inactive TAO were 0.772 and 0.730, respectively. Combining MTR with MTRasym_1ppm significantly improved diagnostic performance, achieving an AUC of 0.805 ($P<0.05$).
Conclusion: Our results showed MTR and MTRasym_1ppm independently distinguished active from inactive TAO. Their combination further enhanced diagnostic accuracy. These findings suggested that MTR and MTRasym_1ppm could serve as quantitative imaging biomarkers to guide treatments in patients with TAO.
Limitations: Firstly, it is a prospective single-center study. Secondly, the complex structure of the orbit, and the high risk associated with invasive surgery precluded the collection of histopathological samples, preventing direct confirmation of the relationship between GAGs/collagen content and MTRasym_1ppm of CEST in TAO patients

Comparison of Automatic Exposure Control Methods used in Fluoroscopy Systems in Cardiac Catheterization Laboratories (8 min)
Alexandra Holden; Oxford / United Kingdom

Author Block: A. Holden[1], R. Bradley[1], K. Rhode[2]; [1]Oxford/UK, [2]London/UK
Purpose: This project aims to establish a standardised testing procedure for the emerging technology of contrast-to-noise driven exposure controls (CEC) as seen on the Siemens ARTIS Icono. Additionally, the project will compare the performance of ARTIS Icono with that of its predecessor, namely the Siemens ARTIS Zee.
Methods or Background: The Siemens ARTIS Icono is an advanced fluoroscopy system used in cardiac catheterisation laboratories, where high-quality imaging is essential for precise interventions, while ensuring patient dose is kept as low as reasonably practicable. Unlike conventional dose-driven automatic exposure control (DEC) systems that maintain a constant detector dose, the ARTIS Icono employs OPTIQ©, a CEC where the system selects imaging parameters based on a predefined target image quality. Additionally, Structure Scout enables material-specific optimisation.
Results or Findings: A phantom has been designed to test the systems capability, containing a range of reference materials, including iron, platinum, and iodine. Using this phantom we can establish if the system maintains the target CNR with varying parameters. Additionally, a figure of merit has been established to compare a metric of visibility to one of dose. By conducting measurements on both CEC and DEC systems we will be able to assess the success of CEC. Preliminary results suggest an increase in image quality at comparable doses.
Conclusion: CEC presents an opportunity to improve image quality in fluoroscopic procedures while minimising patient dose. This could lead to a major breakthrough in optimising patient dose. However, there is currently no established method available for conducting quality assurance on the system. This project demonstrates a successful possible testing method for sites using the ARTIS Icono
Limitations: Static phantom study. No measurements of effect of movement.
Funding for this study: King's College London, School of Biomedical Engineering and Imaging Sciences

AI-Driven 3D MRI Image Analysis Enabling Precision in Multiple Sclerosis Diagnostics (8 min)

Filip Orzan; Cluj Napoca / Romania

Author Block: F. Orzan[1], L. Dioșan[2], Z. Bálint[1]; [1]Cluj Napoca/RO, [2]Cluj-Napoca/RO
Purpose: We aimed to build an AI-based decision support system for automatic segmentation and characterization of MS lesions from 3D MRI, with the long-term goal of personalized treatment. This study focuses on preprocessing and segmentation, providing the basis for future characterization and clinical integration.
Methods or Background: Our study evaluated a 3D U-Net segmentation model with four encoding-decoding levels, integrating attention gates and skip connections to improve lesion localization. The architecture employs BatchNorm3d, ReLU activations, and Dropout for regularization. Evaluation was conducted on 40 cases from the MICCAI 2021 dataset. Preprocessing included intensity normalization, isotropic resampling, N4 bias field correction, skull stripping, and rigid registration. Training used Adam optimization with BCE loss over 50 epochs, with early stopping, 5-fold cross-validation, and an 80/20 train-validation split.
Results or Findings: This study focuses exclusively on image preprocessing, model development, and lesion segmentation. Textural analysis, lesion classification, and the development of a user interface for fine-tuning will be addressed in future work.
The model showed a steady decrease in both training and validation loss, with stabilization after epoch 40. The close alignment between losses suggests minimal overfitting and good generalization - an essential property for clinical applications. The Dice score increased consistently, reaching 0.78 on training and 0.72 on validation data, confirming the model's ability to accurately segment MS lesions across diverse samples.
Conclusion: Our U-Net model with attention gates and skip connections shows promising performance for automated MS detection on 3D MRI. Future work will add textural analysis, lesion classification, user interface development, and validation on multi-vendor datasets for robustness and scalability.
Limitations: A key limitation of MS detection algorithms, including our study, is the scarcity of large imaging datasets, which limits performance relative to human experts.

Interventional Radiology and Artificial Intelligence: a future perfect combination (8 min)

Caterina Verde; Sant' Antimo / Italy

Author Block: C. Verde, L. Tarotto, S. Stilo, F. Fiore; Naples/IT
Purpose: Our purpose is to describe clinical use of Artificial Intelligence (AI) in the current and future practice of Interventional Radiology (IR).
Methods or Background: AI has demonstrated great potential in a wide variety of applications in IR.
Support for decision-making and outcome prediction, new functions and improvements in fluoroscopy, ultrasound, computed tomography, and magnetic resonance imaging have all been investigated.
Furthermore, AI represents a significant boost for fusion imaging and simulated reality, robotics, touchless software interactions, and virtual biopsy.
The procedural nature, heterogeneity, and lack of standardisation slow down the process of adoption of AI in IR. The full range of possibilities is yet to be explored.
A systematic review of the bibliography from the earliest possible date through March 2024 was performed.
Results or Findings: Perspectives in AI differ and are more complex for IR than for diagnostic radiology because IR encompasses diagnostic imaging, imaging guidance, and early imaging evaluation as well as therapeutic tools.
The integration of artificial intelligence in IR is an emerging field with transformative potential, aiming to make a great contribution to the health domain.
Based on the overview, the integration of AI in IR presents significant opportunities to enhance precision, efficiency, and personalization of procedures. AI automates tasks like catheter manipulation and needle placement, improving accuracy and reducing variability. It also integrates multiple imaging modalities, optimizing treatment planning and outcomes. AI aids intra-procedural guidance with advanced needle tracking and real-time image fusion.
Conclusion: The integration of these technologies makes interventional radiology more personalized, patient-centered and safe.
Limitations: No limitations were identified in this study.
Funding for this study: No funding was received for this study.

Diffuse idiopathic skeletal hyperostosis in the oncologic population: A Cross-sectional analysis of 1,053 patients (8 min)

Dina Seyedi; Tehran / Iran

Author Block: S. Kolahi, M. Shakiba, S. Rahmani, S. Nosrat Sheybani, D. Seyedi, H. Abdelmalik, S. Parviz, M. Malek, M. Tahamtan; Tehran/IR
Purpose: Diffuse idiopathic skeletal hyperostosis (DISH) is a systemic condition characterized by ligamentous ossification along the spine. While its prevalence has been well described in the general population, data on its occurrence in oncology patients remain limited. This study aimed to assess the prevalence and distribution of DISH and early-phase DISH in newly diagnosed cancer patients undergoing initial staging with Computed Tomography (CT).
Methods or Background: In this retrospective cross-sectional study, 1,053 adult oncology patients who underwent thoraco-abdominopelvic CT for initial staging were evaluated. DISH and early-phase DISH were diagnosed using established radiologic criteria. Vertebral body densities were measured, and associated extraspinal enthesopathies and ligamentous ossifications were documented.
Results or Findings: DISH was present in 30.3% of patients, including 13.8% with established DISH and 16.5% with early-phase DISH. Prevalence was higher in older patients and males ($p < 0.01$). Notably, renal (43.2%), gastric (37.5%), and colorectal (33.7%) cancers demonstrated significantly higher DISH rates, whereas esophageal cancer showed a lower prevalence (13.4%). DISH was associated with decreased vertebral bone density and frequent extraspinal enthesopathies. No significant correlations were found with BMI, diabetes, or hypertension.
Conclusion: DISH is common among oncology patients and often coexists with extraspinal enthesopathies and reduced bone density. These findings suggest possible shared pathogenic mechanisms and underscore the importance of further studies exploring the relationship between DISH and malignancy.
Limitations: The retrospective design introduced potential selection and information biases, as reliance on medical records limited access to comprehensive clinical histories and prior treatments, which may have confounded our results, including the DISH prevalence estimate and associations with enthesopathies and bone density.
Unbalanced cancer subgroups with small sample sizes limit the generalizability of some analyses.
The lack of serum biomarker data (e.g., FGF-23, DKK-1) precluded direct mechanistic investigation.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The research protocol was approved by our Institutional Review Board (Approval Code: IR.TUMS.IKHC.REC.1404.019).

AI-Driven Multi-Modal Imaging: Improving Quantitative Photoacoustic Analysis Using Ultrasound Priors (8 min)

Sumana Halder; Baidyabati / India

Author Block: S. Halder, K. Chaudhury, S. Mandal; Kharagpur/IN
Purpose: Photoacoustic (PA) imaging, when combined with ultrasound (US), offers a powerful hybrid modality providing high-resolution anatomical details and functional information such as oxygen saturation and tissue perfusion. However, challenges in delineating tissue boundaries, reconstruction, and functional quantification have limited its translational potential. This study aims to integrate deep learning to enhance segmentation accuracy while incorporating prior information from co-registered ultrasound images to enable accurate quantitative analysis and model optical fluence distribution in PA images.
Methods or Background: A multi-modal imaging framework was developed, combining anatomical US data with functional PA signals. Deep learning models such as Unet and nnUnet were trained to segment anatomical and minute vascular structures from US images of a mouse kidney. Evaluation metrics focusing on segmentation accuracy were co-validated using Doppler images. These segmentation priors were used to quantify the perfusion profiles in the intra-organ and inter-organ anatomical structures. Further, these priors have assisted in correcting the fluence in the PA images.
Results or Findings: The deep learning pipeline achieved precise anatomical segmentation with very high Dice coefficients of more than 90%, enabling clearer visualization of soft tissue boundaries. Functional imaging revealed accurate mapping of blood perfusion and oxygenation parameters, with strong agreement compared to Doppler-based measurements. Incorporation of multimodal priors in the pipeline reduced quantitative errors and could accurately estimate the fluence in the PA images, even at depths exceeding several centimetres.
Conclusion: The combination of deep learning–driven segmentation and prior-informed imaging pipeline could significantly enhance the performance of US-PA imaging, improving both anatomical and functional information.
Limitations: Current validation is restricted to preclinical studies. For broader adoption (Magnetic Resonance Imaging) MRI images could be integrated in this pipeline.
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The animal ethical had been taken for the studies.

A Comparative Study of Radiomics, Delta-Radiomics, and Clinical-Radiomics Models for Predicting Ki-67 Dynamics Changes Post-NAT in Breast Cancer via DCE-MRI (8 min)

Xuan Zhang; Lanzhou / China

Author Block: X. Zhang, H. F. Zhao, H. Zhang; Lanzhou/CN
Purpose: This study aims to predict ΔKi-67 after NAT in breast cancer patients using radiomic features from DCE-MRI.
Methods or Background: Ki-67 is a key biomarker of tumor proliferation in breast cancer. A reduction in Ki-67 following neoadjuvant therapy (NAT) reflects chemosensitivity and holds significant prognostic value. Therefore, pre-treatment assessment of Ki-67 dynamics during NAT is crucial for evaluating patient prognosis. This retrospective study of 148 patients (7:3 training/test split) aimed to predict ΔKi-67 (post- minus pre-NAT Ki-67), with the response cutoff determined by ROC analysis. Independent clinical predictors were identified using multivariable logistic regression ($P<0.05$). Radiomics features were extracted from pre-treatment DCE-MRI scans from the early, peak, and delayed phases, along with the corresponding phase differences (delayed–early, delayed–peak, peak–early). Following feature selection with PCA and RFE, models were built using SVM. The optimal radiomics model selected by DeLong test was combined with clinical factors into a hybrid model, evaluated via AUC, calibration, and DCA.
Results or Findings: In the testing cohort, the peak-to-early delta-radiomics model (10 features) achieved the best performance (AUC=0.802, 95% CI: 0.666–0.938), significantly outperforming the delayed-to-early (AUC=0.679, 95% CI: 0.519–0.839) and peak-phase (AUC=0.625, 95% CI: 0.458–0.793) models. Integration with significant clinical predictors (HER2 status, histological grade) yielded a combined model with a superior AUC of 0.858 (95% CI: 0.753–0.965), significantly exceeding both the clinical (AUC=0.785, 95% CI: 0.645–0.925) and radiomics models alone ($p<0.001$).
Conclusion: The integration of MRI delta-radiomics and clinical parameters offers a superior, non-invasive method for predicting Ki-67 downstaging after NAT, aiding personalized strategies and prognostic evaluation.
Limitations: (i) Single-center, retrospective nature and small sample limit generalizability, mandating multi-center prospective validation; (ii) Subtype-specific analyses were absent, warranting future validation; (iii) Semi-automated VOI delineation risks inter-observer bias, addressable by deep learning-based auto-segmentation.
Funding for this study: Not applicable

MD 8b - Early-stage prostate cancer: new developments in imaging and treatment - recommendations for clinical practice and directions for the future

Categories: Oncologic Imaging, Research, Genitourinary, Abdominal Viscera, Multidisciplinary
ETC Level: ALL LEVELS
Date: March 5, 2026 | 11:30 - 12:30 CET
CME Credits: 1

Moderator:
Emina Talakic; Graz / Austria

Chairperson's introduction (2 min)
Emina Talakic; Graz / Austria

1. To highlight new developments in imaging and treatment of early-stage prostate cancer.
2. To critically review recent evidence in imaging and put this in perspective with the new treatment developments.
3. To provide recommendations for clinical practice and directions for the future.

The urologist's perspective (8 min)
Harun Fajkovic; Vienna / Austria

The radiation oncologist's perspective (8 min)
Zoltan Löcsei; Graz / Austria

The radiologist's perspective (8 min)
Emina Talakic; Graz / Austria

Expert panel discussion (34 min)

PL 1 - AI in Radiology: Did we open Pandora's box?

Categories: Artificial Intelligence, President's Choice
ETC Level: ALL LEVELS
Date: March 5, 2026 | 11:30 - 12:30 CET
CME Credits: 1

Introduction (4 min)
Minerva Becker; Geneva / Switzerland

AI in Radiology: Did we open Pandora's box? (56 min)
Nina Kottler; Carlsbad / United States
Charles Edward Kahn; Philadelphia / United States

CUBE 9 - Women's health (UFE/PCS)

Categories: General Radiology, Interventional Radiology, Genitourinary
ETC Level: LEVEL II
Date: March 5, 2026 | 12:00 - 12:30 CET
CME Credits: 0.5

Moderator:
Florian Wolf; Vienna / Austria

Chairperson's introduction (2 min)
Florian Wolf; Vienna / Austria

Uterine fibroid embolisation (14 min)
Geert Maleux; Tienen / Belgium

1. To learn when UFE is the appropriate treatment option.
2. To understand the technical aspects of performing UFE.
3. To recognise the importance of peri- and post-procedural management, including optimal pain control.

Pelvic congestion syndrome (14 min)
Francesco Giurazza; Naples / Italy

1. To learn the typical clinical presentation and symptoms of PCS.
2. To understand how to diagnose and image PCS and the term "pelvic venous disorders".
3. To appreciate how interventional radiologists can effectively manage PCS.

AI-SC 9 - Post-market surveillance and quality assurance of AI tools

Categories: Professional Issues, Management/Leadership, Imaging Informatics, Artificial Intelligence
ETC Level: LEVEL II+III

Intention and concept of post-market surveillance (12 min)
Hugh Harvey; Banstead / United Kingdom

1. To learn what the medical device regulations in the EU mandate in regard to manufacturer responsibilities for PMS.
2. To appreciate the burden placed on hospitals to assist manufacturers in conducting PMS effectively.
3. To understand practical systems for managing AI post market surveillance.

Why PMS? Comparison of 3 AI lung nod detection systems (12 min)
Sarah Katharina Herber; Mainz / Germany

1. To learn how AI-based tools support lung nodule reporting, with particular strengths in detection and longitudinal follow-up.
2. To appreciate the limitations of histopathological assessment for pulmonary nodules and how AI can complement, but not replace, current diagnostic pathways.
3. To understand the clinical implications and future potential of AI-supported lung reporting, including workflow integration, patient management, and potential outcome improvement.

Solution overview on monitoring (12 min)
Sergey Morozov; Brussels / Belgium

1. To learn the fundamentals and techniques of continuous AI monitoring.
2. To appreciate the variability and utility of objective and subjective metrics.
3. To understand the practical approach to clinical AI monitoring.

Discussion with the audience: Post-market surveillance: How much do we need? (22 min)

EFRS WS 9b - Better practices mean better care in mammography

ST 12 - The Cube - 7 years of unconventional interventional teaching

Categories: Radiographers, Interventional Radiology, Vascular, Education, Sustainability

Date: March 5, 2026 | 12:30 - 13:00 CET

Initiated in 2018 and originally based in the basement of a nearby church, the Cube – Unconventional Interventional, ECR's popular Interventional Radiology event, is now entering its 7th season!

In this studio session, Max and Christian — the two chairpersons of the Cube subcommittee and part of the project since its inception — will look back on its evolution together with two long-standing partners and supporters.

During the session, they will reveal the origin of the brand name "The Cube" and share the stories behind iconic features such as the Unboxing Area, the Simulator Challenge, the Adventure Park, and more.

Moderator:

Conny Lee; Vienna / Austria

Interview (30 min)

Christian Loewe; Vienna / Austria

EFRS 9 - Postgraduate Learning for Clinical Impact and Leadership

Categories: Radiographers, Professional Issues, Education

Date: March 5, 2026 | 12:45 - 13:45 CET

CME Credits: 1

This session will highlight the critical role of postgraduate education in advancing clinical practice within radiography. Speakers will explore how specialised imaging programmes support advanced skills, how postgraduate qualifications can serve as a pathway to clinical leadership, and the transition from practitioner to advanced practitioner, demonstrating the tangible value of these roles in clinical settings. The session will provide practical insights into how education drives professional growth, leadership, and improved patient care.

Moderators:

Tiina Pauliina Nousiainen; Jyväskylä / Finland

Diego Catania; Milan / Italy

Chairperson's introduction (5 min)

Tiina Pauliina Nousiainen; Jyväskylä / Finland

Diego Catania; Milan / Italy

Advancing Clinical Practice: The Role of Postgraduate Education in Specialised Imaging (12 min)

Johan Kihlberg; Linköping / Sweden

1. Learn how postgraduate education enhances clinical competencies in specialised imaging modalities
2. Appreciate the impact of advanced academic training on improved decision-making, patient outcomes, interdisciplinary collaboration, and professional development
3. Understand the pathways, challenges, and opportunities involved in pursuing postgraduate education within the field of medical imaging

Bridging the Gap: Postgraduate Qualifications as a Pathway to Clinical Leadership (12 min)

Ciaran Walsh; Cork / Ireland

1. Understand how postgraduate education supports the transition from clinical practice to leadership roles.
2. Explore the competencies gained through advanced qualifications that empower clinical decision-making and team leadership.
3. Recognise the strategic value of academic progression in shaping the future of radiography departments.

From Practitioner to Advanced Practitioner: The value in clinical practice (12 min)

Marte Flatøy Lindgaard; Olso / No

1. Understand the key differences between practitioner and advanced practitioner roles in radiography.
2. Explore how postgraduate education supports the development of advanced clinical competencies and expanded responsibilities.
3. Recognise the impact of advanced practice on patient care and outcomes, quality of care and decision-making, and professional growth.

Panel Discussion (19 min)

AR 9 - How to improve head and neck cancer staging reports

Categories: Oncologic Imaging, Head and Neck, Professional Issues, President's Choice
ETC Level: LEVEL I+II
Date: March 5, 2026 | 13:00 - 14:00 CET

Challenges in nuclear medicine departments (12 min)
Karen Borg Grima; Naxxar / Malta

1. To identify key operational and clinical challenges faced by nuclear medicine departments, including staffing, workflow complexity, and patient communication.
2. To understand the impact of systemic and technological barriers on person-centred care, especially regarding patient experience, safety, and diagnostic efficiency.
3. To explore strategies for transformation, including interdisciplinary collaboration, digital innovation, and radiographer-led initiatives to improve care delivery and patient engagement.

Improving PCC in the diagnostic high-demand workload clinical environment (12 min)
Patrick Vorlet; Lausanne / Switzerland

1. To recognise the challenges of delivering person-centred care (PCC) in high-pressure diagnostic imaging settings with increasing patient volumes and time constraints.
2. To identify practical strategies to maintain empathy, communication, and individualised care without compromising workflow efficiency.
3. To explore innovations and team-based approaches to support sustainable care delivery and explore the role of radiographers as key agents for reflexive practice.

Coordinating and integrating changes in radiation therapy practice (12 min)
Gianfranco Brusadin; Villejuif / France

1. To identify key drivers of change in radiation therapy, including technological advancements, evolving clinical protocols, and patient-centred care priorities.
2. To understand strategies for effective coordination and integration of new practices, technologies, and workflows across multidisciplinary teams.
3. To recognise the radiographer's leadership role in managing change, supporting staff adaptation, and ensuring that innovations align with person-centred care principles.

CME Credits: 1

Moderator:
Maria Raissaki; Heraklion / Greece

Chairpersons' introduction (3 min)
Maria Raissaki; Heraklion / Greece

Unique spectrum of liver tumours in the AYAs population: what to expect? (15 min)
Stéphanie Franchi-Abella; Le Kremlin-Bicêtre / France

1. To review the most common benign and malignant liver tumours in adolescents and young adults (AYAs).
2. To understand age-related differences in tumour biology compared to paediatric and adult populations.
3. To highlight the role of clinical context and laboratory data in narrowing differential diagnoses.

Genetic syndromes predisposing to liver tumours in AYAs: what radiologists must know (15 min)
Greg Chambers; Leeds / United Kingdom

1. To review key genetic syndromes associated with liver tumours in adolescents and young adults (e.g. Beckwith-Wiedemann, FAP, Li-Fraumeni, Carney complex).
2. To describe typical imaging features of liver tumours in these syndromes.
3. To highlight the importance of recognising imaging patterns that suggest an underlying genetic disorder and prompt referral for genetic counselling.

When and how to intervene: imaging-guided decision-making (15 min)
Lil-Sofie Ording Müller; Oslo / Norway

1. To determine when biopsy or surgical referral is necessary based on imaging findings.
2. To discuss the role of radiology in treatment planning, including surgery, transplantation, and interventional options.
3. To explore multidisciplinary collaboration for AYAs' liver tumour management.

Panel discussion: Should we treat AYAs' liver tumours like adult tumours? (12 min)

RPS 901 - Advances in small bowel imaging: from ischaemia to perforation

Arterial occlusive acute mesenteric ischaemia: prevalence and prognosis of small bowel wall hypoenhancement on CT (6 min)
Lorenzo Garzelli; Paris / France

Author Block: S. Thavarajah[1], H. Garnier[1], S. Vilain[1], M. Ronot[1], L. Garzelli[2]; [1]Clichy/FR, [2]Paris/FR
Purpose: To evaluate the prevalence, imaging features, and prognostic significance of bowel hypoenhancement on CT in arterial occlusive acute mesenteric ischaemia (AOAMI).
Methods or Background: Retrospective, observational, single-centre study of 220 patients referred to our intestinal stroke unit between 2006 and 2023. All patients with AOAMI and available portal-venous phase abdominal CT were reviewed. Clinical, biological, treatment, and outcome data were retrieved from a prospective database. The primary objective was prevalence and imaging description of bowel wall hypoenhancement; the secondary objective was its association with bowel resection-free survival and other prognostic factors.
Results or Findings: Among 220 patients (median age 68 years; 55% men), bowel hypoenhancement was present in 127 (57%), predominantly in the ileum (95%). It was was more frequent in embolic than atherosclerotic occlusion (61% vs 38%) and was associated with decreased venous outflow in 58%. Compared with patients without bowel hypoenhancement, these patients had higher lactate (2.8 vs 1.7 mmol/L, p<0.001), more frequent leukocytosis >15G/L (63% vs 40%, p=0.001), and a greater prevalence of portomesenteric gas (14% vs 1%, p<0.001). Resection was more frequent (72% vs 31%, p<0.001) with longer segments removed (154 vs 85 cm, p=0.007), and patients more often required home parenteral nutrition (17% vs 5%, p=0.018). Resection-free survival was significantly lower in patients with hypoenhancement (log-rank p<0.001).
Conclusion: Bowel hypoenhancement on CT is frequent in AOAMI and constitutes a marker of disease severity. Its early recognition may help identify high-risk patients, and anticipate adverse outcomes.
Limitations: Limitations include retrospective, single-centre design, possible selection bias, and reduced reproducibility as hypoenhancement was assessed by a single reader.

Clinical value of the distribution and type of superior mesenteric lesions in acute occlusive arterial mesenteric ischaemia (6 min)
Lorenzo Garzelli; Paris / France

Author Block: S. Vilain[1], H. Garnier[1], M. Dioguardi Burgio[1], J. Gregory[1], M. Ronot[1], L. Garzelli[2]; [1]Clichy/FR, [2]Paris/FR
Purpose: The prognostic impact of superior mesenteric artery (SMA) lesion type and distribution on management and outcomes in acute occlusive arterial mesenteric ischaemia (AOAMI) remains uncertain.
Methods or Background: Retrospective single-centre study including patients treated for AOAMI between 2016 and 2024 in our intestinal stroke centre unit. Patients with incomplete SMA occlusion were excluded. SMA lesions were classified according to Tual et al. as proximal (S1), median (S2), or distal (S3), and graded as stenosis, occlusion with downstream patency, or occlusion without downstream patency. Lesion burden was defined as the number of occluded segments. Outcomes included revascularisation strategy, gastrointestinal morbidity (short bowel syndrome [SBS], home parenteral nutrition [HPN]), and mortality.
Results or Findings: One hundred forty-two patients were included (mean age 67 years, 60% men); 68% had embolic and 30% atherothrombotic AOAMI. Median lactate was 2.5 mmol/L; Revascularisation was attempted in 86%, and 85 patients required bowel resection. Overall mortality was 39%. At follow-up, 18% were alive without gastrointestinal sequelae, 22% had SBS, and 14% required HPN. The dominant lesions were most frequently S2 (48%), followed by S1 (37%) and S3 (15%); mean length was 51 mm, with 36% >50 mm. Occlusion without downstream patency occurred in 47%, and 23% involved >2 territories without patency. Lesion distribution influenced endovascular strategy: stenting mainly for S1 with downstream patency, thrombolysis for S3, and thrombectomy for S2–S3. Lesion burden correlated with gastrointestinal morbidity but not mortality. Mortality was significantly associated with inferior mesenteric artery occlusion and splanchnic arterial calcifications ($p=0.038$ and <0.01).
Conclusion: SMA lesion type and distribution determine endovascular strategy in AOAMI, while lesion burden predicts gastrointestinal morbidity.
Limitations: Retrospective design and potential selection bias

A Feasibility Study on Replacing Conventional True Non-contrast with Spectral CT Enterography Virtual Non-contrast for Small Bowel Imaging (6 min)

Yuqing Mao; Hangzhou / China

Author Block: Y. Mao[1], S. Zheng[1], S. Dong[2], X. Maosheng[1]; [1]Hangzhou/CN, [2]Beijing/CN
Purpose: To evaluate the feasibility of spectral CT enterography (CTE)-derived virtual non-contrast (VNC) images in replacing true non-contrast (TNC) scans for small bowel disease assessment.
Methods or Background: A retrospective analysis was conducted on 77 patients with endoscopically confirmed intestinal lesions at the First Affiliated Hospital of Zhejiang Chinese Medical University from December 2023 to November 2024, all of whom underwent dual-phase (arterial phase, venous phase) spectral CTE. VNC images were reconstructed from arterial (VNC-a) and venous (VNC-v) phases. Objective parameters (CT values, noise, SNR, CNR) and subjective image quality (5-point scale) were compared between TNC, VNC-a, and VNC-v. Radiation doses (DLP, ED) were calculated. Statistical analyses included ANOVA, Bland-Altman agreement analysis, and Friedman test.
Results or Findings: The noise differences between the VNC-v images of the aorta and the VNC-a and VNC-v images of the lesions and the TNC images are statistically significant. The SNR values of the three-phase images of the lesions are highest in TNC, while the SNR values of the three-phase images of the aorta (arterial vessels) are highest in VNC-a, but the differences are not statistically significant (all $P>0.05$). Compared with the conventional non-contrast scan protocol, performing CTE with enhanced two-phase virtual non-contrast images can reduce the radiation dose by approximately 34.7%.
Conclusion: Spectral CT-derived VNC, particularly arterial-phase VNC, provides reliable CT value measurements with reduced noise and radiation dose, supporting its potential to replace TNC in inflammatory bowel disease follow-up.

A Morbidity-Mortality Scale to Assess Outcome in Occlusive Arterial Acute Mesenteric Ischaemia (6 min)

Lorenzo Garzelli; Paris / France

Author Block: H. Garnier[1], S. Thavarajah[1], S. Vilain[1], M. Ronot[1], L. Garzelli[2]; [1]Clichy/FR, [2]Paris/FR
Purpose: Outcomes of arterial occlusive acute mesenteric ischaemia (AOAMI) are usually reported as short-term survival, which underestimates long-term morbidity. We aimed to propose a morbidity-mortality scale to provide a more comprehensive outcome measure for clinical trials in patients with AOAMI.
Methods or Background: Retrospective, single-centre study including patients admitted for AOAMI (2016–2023). Clinical, biological, imaging, treatment and outcomes data were analysed. A four-level morbidity-mortality scale was developed according to post-AMI status: 0 = bowel preservation, 1 = bowel resection, 2 = intestinal failure and 3 = death. The primary outcome was the distribution of the scale at 1, 3, 6 or 12 months.
Results or Findings: A total of 256 patients were included (median age: 68; 44% female). Overall, 149 (58%) underwent bowel resection and 73 (29%) developed short bowel syndrome during follow-up. Thirty-five patients (14%) required long-term parenteral nutrition, including 16 (6%) with >4 infusions per week. At last follow-up, one-third of patients (33%) had a digestive stoma. Scale distribution was as follows: scale 0 (bowel preservation) stable at 32%, 30%, 30% 30% at 1, 3, 6 and 12 months ; scale 1 (resection) stable at 24%, 24%, 25% 24% at 1, 3, 6 and 12 months ; scale 2 (intestinal failure) decreased from 25% to 15% from 1 to 12 months ; scale 3 (death) increased from 19% to 31% from 1 to 12 months.
Conclusion: This new morbidity-mortality scale captures both survival and functional outcomes, providing a comprehensive measure of disease burden in AOAMI. It could serve as a novel endpoint in future therapeutic trials.
Limitations: Limitations include the retrospective, single-centre design, which may entail missing data, selection bias, and limited generalisability.

Morphometric Analysis of Normal Small Bowel on CT: Variations by Age and Segment in More Than 500 patients (6 min)

Lorenzo Garzelli; Paris / France

Author Block: J. André[1], T. Pesce[2], C. Iosif[2], M. Ronot[3], M. Zappa[1], L. Garzelli[3]; [1]Cayenne/GF, [2]Fort de France/FR, [3]Paris/FR
Purpose: Normal CT dimensions of the small bowel are not established, although calibre and wall thickness are routinely measured in ischaemic, inflammatory, and obstructive diseases. This study aimed to define normative values in adults without intestinal abnormalities.
Methods or Background: In this prospective bicentric study, adults from French Guiana and Martinique (french overseas territories) undergoing portal venous phase abdominal CT between May and October 2023 were screened. Patients with abdominal abnormalities or previous surgery were excluded. Calibre and wall thickness were measured at six arterial landmarks (proximal, mid, and distal jejunum and ileum). Associations with age, sex, and geographic origin were analysed. Inter- and intra-observer reproducibility was assessed in 10% of cases using intraclass correlation coefficients (ICCs).
Results or Findings: Among 2,336 screened patients, 502 were included (mean age 52 years; 56% women; French Guiana n=249; Martinique n=253). Mean jejunal calibre and thickness were 24.6 mm (± 2.0) and 2.6 mm (± 0.4), compared with 19.8 mm (± 3.0) and 1.3 (± 0.2) mm in the ileum. Jejunal values were significantly greater than ileal ones ($p<0.01$). Calibre increased with age, whereas thickness decreased (both $p<0.01$; $r=0.70$ and $r=-0.64$). Neither sex (calibre $p=0.36$; thickness $p=0.63$) nor geographic origin (calibre $p=0.42$; thickness $p=0.54$) significantly influenced measurements. Reproducibility was substantial, with ICCs of 0.78 (intra) and 0.73 (inter) for calibre, and 0.70 (intra) and 0.72 (inter) for wall thickness.
Conclusion: This large bicentric study provides reference CT values for small bowel calibre and wall thickness by segment, showing a progressive reduction from proximal jejunum to distal ileum with variations across age. These benchmarks may enhance standardisation for clinical diagnosis and research.
Limitations: Limitations are underrepresentation of non-American populations, absence of anthropometric data, and potential bias from trauma cases.

Who needs MRI in suspected endometriosis? A retrospective observational diagnostic study of added value beyond TVUS (6 min)

Ghrayeb Shaden; Jerusalem / Israel

Author Block: G. Shaden, N. Lev-Cohain; Jerusalem/IL
Purpose: Magnetic resonance (MR) imaging is considered a second-line technique after transvaginal ultrasonography (TVUS) in suspected endometriosis. Updated MRI indications have recently been defined by the ESUR consensus. This study aimed to evaluate, in our institutional cohort, which patients benefit from MRI beyond TVUS, and to assess adherence to ESUR indications in routine practice.
Methods or Background: We retrospectively reviewed 103 women with suspected or confirmed endometriosis who underwent both TVUS and pelvic MRI between 2020 and 2025 at a tertiary endometriosis centre. All TVUS were performed by a single expert gynaecological sonographer, and all MRIs interpreted by the same senior radiologist specialising in endometriosis imaging. Findings were compared across compartments (anterior, middle, posterior, and extra-pelvic). Interpretations were categorised as: (1) normal TVUS with abnormal MRI; or (2) abnormal TVUS, with assessment of MRI's incremental diagnostic contribution.
Results or Findings: Among 23% of patients (24/103) with normal TVUS, MRI revealed deep endometriosis in 58% (14/24), confirming its added value in symptomatic women with negative ultrasound. When both modalities demonstrated endometriosis, MRI consistently contributed further diagnostic information. The clearest difference was in bowel assessment: MRI detected bowel involvement in 55% (28/51) of patients missed by TVUS, and in 29% (15/51) of those with TVUS-suspected bowel disease, MRI more accurately defined depth and extent of infiltration.
Conclusion: MRI is essential in symptomatic patients with negative TVUS, in line with ESUR consensus. In addition, when TVUS suggests deep endometriotic plaques—particularly in locations where ultrasound is less sensitive—MRI should be performed, as it provides superior delineation of disease extent and involvement.
Limitations: Retrospective single-centre design.
Variable TVUS–MRI intervals (median 35 days; 25% >6 months) may have influenced discrepancies.

A study on CT-based diagnosis of gastrointestinal perforation sites based on the anatomical relationships between the gastrointestinal tract and the peritoneum (6 min)

Xiujuan Liu; Zhuhai / China

Author Block: X. Liu, R. CHEN; Zhuhai, Guangdong, China./CN
Purpose: The selection of surgical approach and incision for gastrointestinal perforation depends on factors such as the location and etiology of the perforation. Accurate preoperative localization and etiological assessment are critical for optimal treatment planning. Currently, computed tomography (CT) is the unique preoperative method for localization; however, its accuracy is limited and it's time-consuming. Existing studies focus on specific imaging signs and adopt the mechanical anatomical grouping based on the sequence of gastrointestinal tract, neglecting the hydrodynamic characteristics of the peritoneal compartments. This study intends to group based on gastrointestinal-peritoneal relationships to evaluate the distribution pattern of free gas and characteristic CT signs of perforation in each group, in order to improve the preoperative localization accuracy and shorten the diagnostic time.
Methods or Background: In a retrospective study, 250 patients with surgically confirmed gastrointestinal perforations were classified into three anatomical groups: intraperitoneal, interperitoneal, and extraperitoneal. CT studies were reviewed using tailored window settings and multiplanar reconstructions to assess the distribution of free gas and specific imaging signs. Comparative statistical analysis was performed.
Results or Findings: Free gas distribution demonstrated strong anatomical dependence: intraperitoneal perforations primarily involved the supracolic compartment; interperitoneal perforations localized to the mesenteric root space; and extraperitoneal perforations were characterized by retroperitoneal gas. The most prevalent ancillary signs were ascites, tiny intra-abdominal gas bubbles, and fat stranding.
Conclusion: Leveraging anatomical and radiopathological correlations, this study proposes a novel diagnostic pathway: "pneumoperitoneum distribution → anatomical grouping → targeted lesion identification." This systematic approach facilitates efficient and accurate perforation localization by utilizing gas distribution patterns to prioritize anatomical segments. A stepwise evaluation sequence—beginning with the retroperitoneum, followed by the mesenteric sinuses, and finally the supracolic space—is recommended, augmented by attention to key CT signs and optimized windowing.

Gastrografin in the management of adhesional small bowel obstruction: scanned too soon? (6 min)

Utkarsh Dutta; Newcastle upon Tyne / United Kingdom

Author Block: U. Dutta, N. Chantima, I. Miglior, J. Chmelo, J. Brown, A. Phillips; Newcastle upon Tyne/UK
Purpose: To audit gastrografin use and timing of follow-up abdominal X-rays (AXRs) in adhesive small bowel obstruction (ASBO) management at a tertiary-care centre.
Methods or Background: The 2017 Bologna guidelines recommend water-soluble contrast in the conservative management of ASBO. Consensus favours obtaining a follow-up AXR at least 6 hours post-gastrografin administration to allow adequate bowel transit time.

We conducted a retrospective audit over a 6-month period of all acute surgical admissions with uncomplicated ASBO confirmed on computed tomography (CT). We examined gastrografin prescription, administration timing, and follow-up AXR intervals. Following educational interventions (departmental posters and teaching sessions), we re-audited practice between April-August 2025.
Results or Findings: Of 74 ASBO patients, 57 received gastrografin with follow-up AXRs. Nine patients (18%) were scanned <6 hours post-administration, with mean prescription-to-AXR time of 6.6 ± 2.0 hours and administration-to-AXR time of 4.9 ± 1.0 hours. Successful transit to colon was seen in approximately two-third of cases. Ten patients underwent multiple AXRs; eight received repeat gastrografin.
Root-cause analysis revealed that in 48/57 cases (84%), follow-up AXRs were requested at prescription rather than administration, failing to account for the mean 1.7 ± 1.0 hour prescription-administration delay. Re-audit demonstrated significant improvements better adherence to current recommendations: only 3/45 patients (7%) scanned <6 hours, with mean AXR timing improved to 7.0 ± 1.5 hours.
Conclusion: Enhanced communication between clinicians, nurses, and radiographers optimizes AXR timing in ASBO management.
Limitations: The paucity of national guidelines and indeed a local protocol on the use of gastrografin is a key limitation towards sustained improvement.

Association Between Myocardial Lipomatous Metaplasia and Sudden Cardiac Death in Patients with Prior Myocardial Infarction (6 min)
Kaisaierjiang·aisikaier Aisikaier; Beijing / China

Author Block: K. Aisikaier; Beijing/CN
Purpose: This study aims to noninvasively assess the prevalence of LM using cardiac magnetic resonance (CMR) and explore its association with sudden cardiac death (SCD) in patients with prior myocardial infarction (PMI).
Methods or Background: In this single-center retrospective study, 896 patients with PMI were included. PMI was confirmed by CMR evidence of subendocardial or transmural late gadolinium enhancement (LGE) in a coronary artery-specific distribution. LM was confirmed using frequency-based sequences (chemical shift or fat-water separation sequence) or T1 contrast-based sequences (short T1 inversion recovery [STIR] or pre-contrast T1-weighted sequence). The primary endpoint was a composite of SCD, aborted SCD, or appropriate implantable cardioverter-defibrillator (ICD) therapy.
Results or Findings: LM was detected in 127 (14.2%) patients. These patients had larger infarcts (23.4% vs. 19.9%, $p < 0.001$) and higher SCD event rates (11.8% vs. 6.1%, $p = 0.035$). Over 64 months median follow-up, 62 (6.9%) reached the endpoint. LM independently predicted SCD (adjusted HR: 2.28; 95% CI: 1.27–4.11; $p = 0.006$) after adjusting for after adjusting for age, sex, LVEF≤35%, gray zone, LGE extent, and end-diastolic volume index (EDVi). LM improved SCD risk prediction beyond LVEF≤35% (C-statistic: 0.58 to 0.62; log-likelihood: -398 to -394, $p = 0.007$) , especially in patients with LVEF >35% or LGE≤24.4%(optimal cutoff 24.4%; AUC=0.751, 95% CI 0.697–0.806) .
Conclusion: In patients with PMI, the presence of LM was independently associated with SCD risk, demonstrating incremental prognostic value beyond conventional risk markers, including LVEF. Furthermore, LM maintained significant predictive value in patients with preserved LVEF (>35%), suggesting its particular utility for risk stratification in the current guideline-defined lower-risk population.
Limitations: As a large retrospective cohort study conducted at a tertiary referral center, this investigation carries an inherent risk of referral bias.
Funding for this study: This study is supported by the National Key R&D Program of China (Nos. 2021YFF0501400 and 2021YFF0501404) and Key Project of National Natural Science Foundation of China (No. 82430066).

Nonlinear Associations Between Left Ventricular End-Diastolic Diameter and Myocardial Strain Parameters in Metabolic Syndrome: A Cardiac Magnetic Resonance Study (6 min)
Jia-ke Li; Chengdu / China

Author Block: J-k. Li, Y. Zhigang, R. Shi, W-r. Li; Chengdu/CN
Purpose: To investigate the nonlinear associations between left ventricular end-diastolic diameter (LVEDD) and left ventricular strain parameters derived from cardiac magnetic resonance (CMR) in patients with metabolic syndrome (Mets), and to determine the relative impact of metabolic factors including diabetes mellitus (DM), hypertension (HTN), and body mass index (BMI) on strain behavior.
Methods or Background: We retrospectively analyzed cine CMR data from August 2019 to November 2021 from patients with Mets. Global myocardial strain parameters—LV radial peak strain (LVPRS), circumferential peak strain (LVPCS), longitudinal peak strain (LVPLS), and early diastolic radial strain rate (LV0PDSR-L0)—were quantified. Nonlinear polynomial regression models were constructed to examine associations between LVEDD (short-axis view) and strain parameters, adjusting for sex, age, DM, HTN, and BMI.
Results or Findings: A total of 105 patients with Mets (51.64 ± 12.49 years, 70.5% male) were recruited. LVEDD exhibited a significant nonlinear association with all strain parameters, including LVPRS (R^2 = 0.507, p<0.001), U-shaped trend; LVPCS (R^2 = 0.491, p<0.001), inverted U-shaped; LVPLS (R^2 = 0.315, p=0.017), mildly inverted U-shaped; LV0PDSR-L0 (R^2 = 0.204, p=0.058), weak U-shaped trend. After adjusting for sex, age, DM, HTN, and BMI in Mets patients, LVEDD and its quadratic term were the only two significant predictors in LVPRS and LVPCS models(p<0.05). Among the covariates, only sex showed a significant independent association with LVPLS(p=0.033).
Conclusion: In patients with Mets, LVEDD is nonlinearly associated with myocardial strain parameters, reflecting complex remodeling dynamics. CMR-derived LV strain analysis may serve as a sensitive marker for subclinical myocardial dysfunction beyond traditional metabolic risk factors and early treatments could be given.
Limitations: Firstly, this is a retrospective single-center study with a limited sample size. Secondly, the causality and temporal sequence relationship between LVEDD and strain parameters cannot to be comfirmed.
Funding for this study: None.

Application of Four-dimensional flow cardiac magnetic resonance in risk stratification of connective tissue disease-associated pulmonary arterial hypertension (6 min)

Nan Xu; Jiangsu Province / China

Author Block: N. Xu, Y. Xu; Jiangsu Province/CN
Purpose: To explore the value of four-dimensional flow cardiovascular magnetic resonance (4D Flow CMR) in connective tissue disease-associated pulmonary arterial hypertension (CTD-PAH) risk stratification by comparing its diagnostic efficacy and parameter consistency with two-dimensional phase-contrast magnetic resonance imaging (2D PC-MRI).
Methods or Background: Eighty-five CTD-PAH patients were retrospectively enrolled and categorized into two groups per 2022 ESC/ERS guidelines: low/intermediate-low risk (Group 1, n=67) and intermediate-high/high risk groups (Group 2, n=18). All underwent 2D PC-MRI and 4D Flow CMR. Right ventricular (RV) function parameters and pulmonary artery [main (MPA), left (LPA), right (RPA)] hemodynamic parameters were extracted. Inter-group comparisons, logistic regression, ROC analysis (DeLong test), and consistency (intraclass correlation coefficient, ICC) analyses were performed.
Results or Findings: Compared with Group1, Group2 showed increased RV end-systolic volume index (RVESVI), RV end-diastolic volume index (RVEDVI), RV myocardial mass index (RVMMI) and decreased RV ejection fraction (RVEF) (all P<0.05). 2D PC-MRI revealed lower relative area change (RAC), peak velocity (PV) and mean velocity (MV) of MPA (all P<0.01). 4D Flow CMR revealed prolonged MPA vortex duration (24% vs 12%, P<0.01), and lower PV/MV in MPA/LPA/RPA (all P<0.05). Multivariate Logistic analysis showed MPA PV and vortex duration from 4D Flow CMR and MPA PV from 2D PC-MRI were independent factors for distinguishing medium-high/high-risk patients. The consistency of MPA PV between the two techniques was good (ICC=0.765), while that of MPA MV was moderate (ICC=0.562).
Conclusion: 4D-derived MPA PV and vortex duration are independent predictors for CTD-PAH risk stratification, the combined model based on 4D parameters has superior diagnostic efficacy over 2D PC-MRI, improving CTD-PAH risk stratification accuracy.

Evaluation of the effect of contrast agent use on cardiac functions in cine MRI (6 min)

Taha Yiğid Kılıç; Istanbul / Turkey

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: M. F. Kazanbaş, B. Tütüncüoğlu, T. Banaz, M. Kadıoğlu, F. Köse, T. Y. Kılıç, N. Okumuş, A. Arslan, S. Ozkök; Istanbul/TR
Purpose: This study aimed to evaluate the effect of contrast administration on volumetric and functional parameters of the left ventricle(LV) measured by cardiac magnetic resonance cine imaging, with particular emphasis on paired comparison and Bland–Altman agreement analysis.
Methods or Background: Cardiac cine MRI is a reference method for quantifying LV volumes and ejection fraction (EF). However, the influence of contrast administration on volumetric assessment remains debated. In this retrospective analysis, 42 patients undergoing both pre- and post-contrast cine underwent 1.5 Tesla CMR were included. LV end-diastolic volume index(EDVI), end-systolic volume index(ESVI), stroke volume index (SVI), ejection fraction(EF), and heart rate(BPM) were measured. ECG/Holter were used to assessed arrhythmia. Results were expressed as median(25th–75th percentile) and compared using paired analysis with Bland–Altman evaluation. Significance was set at $p<0.05$.
Results or Findings: Pre-contrast cine measurements demonstrated a median LV-EDVI of 72.5 mL/m2, LV-ESVI 27.5 mL/m2, LV-SVI 41.0 mL/m2, LV-EF 60.5%, and heart rate 86.5 bpm(68.0–101.8). Post-contrast, LV-EDVI was 69.0 mL/m2, LV-ESVI 36.5 mL/m2, LV-SVI 33.5 mL/m2, LV-EF 52.5%, and heart rate 87.5 bpm(76.8–111.3). Compared with pre-contrast, post-contrast cine demonstrated a significant reduction in LV-EF(Δ–10.4 ± 9.6%, $p<0.01$) and LV-SVI (Δ–9.0 ± 12.3 mL/m2, $p=0.02$), while changes in LV-EDVI and LV-ESVI were not significant. Heart rate significantly increased (Δ +12.8±21.3, $p=0.04$). Bland–Altman analysis confirmed systematically lower post-contrast values, with a mean bias of –10.4%(LoA –35.2 to +14.5) for LV-EF and –9.0 mL/m2(LoA –56.9 to +38.9) for LV-SVI, indicating wide inter-individual variability.
Conclusion: Contrast administration may lead to systematic underestimation of EF and SVI on cine MRI, whereas EDVI and ESVI remain stable. Awareness of this effect is important for consistent longitudinal follow-up and clinical decision-making.
Limitations: The small sample size of only 42 patients restricts the generalizability of the findings.
Funding for this study: No funding was received for this study.

Cardiac Magnetic Resonance Assessment — Functional and Tissue Characteristics in Antiphospholipid Syndrome (6 min)

KE XU; Nan Jing / China

Author Block: K. XU, W. Liu, Y. Xu; Nan Jing/CN
Purpose: To evaluate the value of multiparametric cardiac magnetic resonance (CMR) in assessing myocardial involvement in patients with antiphospholipid syndrome (APS).
Methods or Background: This retrospective study enrolled 30 APS patients and 30 healthy controls who underwent CMR between January 2022 and June 2025. CMR assessment encompassed biventricular structural and functional parameters, and myocardial tissue characterization parameters. Subgroup analyses were performed based on secondary APS (SAPS) or primary APS (PAPS), and positive or negative late gadolinium enhancement (LGE). Spearman correlation analysis was used to explore the correlation between CMR parameters and laboratory indicators.
Results or Findings: Compared with the control group,APS group showed reduced biventricular ejection fractions and increased left ventricular end systolic volume index (LVESVI), native T1, T2 values and extracellular volume (ECV) (all $P < 0.01$). Subgroup analysis revealed that right ventricular end diastolic volume index (RVEDVI), stroke volume index (SVI), cardiac index (CI), native T1, and ECV (32.55 ± 4.45% vs. 27.94 ± 1.86%, $P = 0.020$) in SAPS group were significantly higher than those in PAPS group (all $P < 0.05$). In addition, LGE in SAPS group was more frequently localized in the left ventricular anterior wall, inferior wall, and interventricular septum, and subendocardial involvement was more common. The LGE-positive group exhibited lower left ventricular ejection fraction (LVEF) and higher left ventricular end systolic volume index (LVESVI) and mass index (MI) (all $P < 0.05$). LGE burden positively correlated with logNT-proBNP ($r = 0.493$, $p = 0.006$).
Conclusion: CMR reveals biventricular dysfunction and myocardial fibrosis in APS. SAPS patients demonstrated more severe involvement, characterized by elevated LGE burden and distinct subendocardial patterns. The correlation between LGE and NT-proBNP indicates that CMR has important value in risk stratification and prognostic assessment in APS.

Ultra-High-Resolution Photon-Counting CT for Coronary Stenosis: Enabling Accurate Assessment Despite Severe Calcification (6 min)

Lichen Ren; Zhengzhou / China

Author Block: L. Ren, Z. Yonggao; Zhengzhou/CN
Purpose: To investigate the effect of improved spatial resolution on coronary stenosis assessment, using quantitative coronary angiography (QCA) as the reference standard.
Methods or Background: In this single-center study, 45 patients (50 vessels) with a vessel-level Agatston score ≥300 underwent photon-counting CCTA and invasive coronary angiography within 7 days. CCTA datasets were reconstructed into four types: UHR (0.2 mm, Bv72 kernel), SR at 60 keV and 100 keV (0.4 mm, Bv60), and simulated EID (0.6 mm, Bv44). Two blinded readers measured the minimum lumen diameter (MLD) and diameter stenosis (DS%). Agreement with QCA was evaluated using mean absolute error (MAE), Spearman's correlation coefficient (ρ), and the intraclass correlation coefficient (ICC). Diagnostic performance for detecting ≥50% stenosis was determined by ROC analysis.
Results or Findings: UHR CCTA demonstrated the smallest measurement error for DS% (MAE, 3.10%) and MLD (MAE, 0.20 mm), with the highest correlation (ρ = 0.97) and excellent agreement (ICC = 0.90) with QCA. SR at 60 keV performed comparably well (DS% MAE, 4.61%; ICC, 0.90; ρ = 0.94). However, SR at 100 keV showed increased errors (MAE, 6.28%; ICC, 0.88; ρ = 0.90), and simulated EID performed the poorest (MAE, 8.36%; ICC, 0.81; ρ = 0.84). Simulated EID significantly overestimated stenosis compared to UHR ($P < 0.01$ for all). ROC analysis showed the highest diagnostic performance for UHR (AUC = 0.97), followed by SR at 60 keV (AUC = 0.95), SR at 100 keV (AUC = 0.87), and simulated EID (AUC = 0.79).
Conclusion: UHR photon-counting CCTA provides the most accurate quantification of stenosis in heavily calcified vessels. SR CCTA at 60 keV may be a practical alternative when UHR is unavailable, whereas simulated EID reconstructions are less reliable.
Limitations: Small sample

An AI-Based Hybrid CNN–SVM and U-Net Platform for Automated Classification, Scar Quantification, and 3D Visualization in Cardiac LGE MRI (6 min)

Chin Yu Chen; Taipei / Taiwan, Chinese Taipei

Author Block: C. Y. Chen, F. Y. Yang, S-J. Chen, W-J. Lee, Y-S. Huang, Y-F. Tsai, P-Y. Chiang, Y. W. GUO, S. Y. Huang; Taipei/TW
Purpose: To develop and validate an AI platform integrating Hybrid CNN–SVM classification, U-Net segmentation, and 3D scar visualization for automated myocardial scar analysis in LGE cardiac MRI, aiming to reduce manual annotation workload and improve diagnostic consistency.
Methods or Background: Ninety LGE MRI datasets were analyzed. A convolutional neural network (CNN) with four convolutional layers was trained for feature extraction, followed by a support vector machine (SVM) classifier with five-fold cross-validation to distinguish ischemic from non-ischemic cardiomyopathy. Scar segmentation was performed using a U-Net and compared with manual annotations (2SD, 3SD, 5SD, FWHM). Performance metrics included accuracy, AUC, Dice coefficient, and concordance with manual references. Grad-CAM was applied for interpretability.
Results or Findings: The Hybrid CNN–SVM achieved an accuracy of 0.851 and an AUC of 0.920. U-Net segmentation demonstrated strong concordance with manual contours (Dice = 0.801 ± 0.021) while substantially reducing annotation workload. Automated analysis markedly shortened labeling time compared with manual delineation and improved reproducibility across observers. In addition, the platform generated 3D scar visualizations, providing intuitive assessment of scar burden and transmural extent.
Conclusion: This AI-based platform demonstrates robust performance for automated classification and scar segmentation in LGE MRI. By improving workflow efficiency, reducing inter-observer variability, and integrating 3D visualization, it offers strong potential for adoption into routine radiology practice for standardized CMR interpretation.
Limitations: While the platform demonstrated robust performance, limitations include the relatively small, single-center dataset and occasional segmentation errors in blood pool regions. Future studies with larger, multi-center cohorts are warranted.
Funding for this study: This research was funded by National Science and Technology Council of Taiwan (no. MOST 114-2314-B-031-001)

Feasibility of Artificial Intelligence Deep Learning-Based Accelerated Cardiac Magnetic Resonance Imaging: A Prospective Study (6 min)

Rong-Xue Shan; Jinan / China

Author Block: R-X. Shan[1], Y. Gao[1], B. Chen[1], X. Yue[2], X. Wang[1]; [1]Jinan/CN, [2]BeiJing/CN
Purpose: To evaluate the feasibility of an artificial intelligence (AI)-based Deep learning (DL) super-resolution (SR) compressed sensing (CS) technique in accelerating cardiac MRI acquisition, and to compare it with conventional approaches.
Methods or Background: DL reconstruction can improve image quality while reducing MRI acquisition time. However, the application of AI -based DL SR algorithms combined with CS technology in cardiac magnetic resonance (CMR) imaging has not been well investigated.This prospective study included 53 healthy volunteers. CMR imaging was performed using three methods: CSAI+SR, CS, and sensitivity encoding (SENSE). The three approaches were compared in terms of average acquisition time, heart rate (HR), subjective image quality scores, objective image quality measurements [signal-to-noise ratio (SNR) and contrast-to-noise ratio (CNR)], as well as cardiac morphological and functional parameters. Friedman's test was used for statistical comparisons.
Results or Findings: The acquisition times for CSAI+SR and CS were significantly shorter than those for the SENSE method (420 ± 12 s vs. 425 ± 12 s vs. 690 ± 14 s, $p < 0.001$). However, compared with CS and SENSE, the CSAI+SR method achieved the highest image quality scores, SNR, and CNR values (all $p < 0.001$). In addition, there were no significant differences in cardiac morphological and functional parameters among the three methods.
Conclusion: In healthy volunteers, compared with conventional approaches, the CSAI+SR technique reduced scan time while improving image quality.
Limitations: First, only healthy volunteers were included in our CMR study, and our scanning protocol did not involve the LGE sequence. Second, the number of experienced readers for subjective image quality assessment was limited, and we tested only one MRI scanner from a single vendor.

Promoting Sustainable Breast Imaging and Interventional Practices with an AI-Based Chatbot (6 min)
Gianmarco Della Pepa; Milan / Italy

Author Block: G. Della Pepa, G. Irmici, C. De Berardinis, E. D'Ascoli, L. Corradini, G. Rossini, C. Depretto, G. P. Scaperrotta; Milan/IT
Purpose: To develop and evaluate an educational chatbot powered by a low-footprint Large Language Model (LLM), aimed at increasing awareness and knowledge of sustainable clinical practices in breast imaging among radiology professionals.
Methods or Background: GreenBreastBot was developed as a Custom GPT using GPT-3.5, a pre-trained LLM, ensuring negligible energy consumption per interaction. The chatbot was populated with bilingual (Italian/English) structured content derived from the ESR Green Radiology position paper, WHO climate-health recommendations, and internal Breast Unit guidelines. The tool adapts its explanations based on user expertise and delivers microlearning units, interactive quizzes, flashcards, and clinical scenarios. A four-week pilot was conducted in a tertiary Breast Unit. Participants included radiologists, residents, and radiographers. Outcomes included usage frequency, satisfaction (5-point Likert scale), and self-reported awareness before and after interaction.
Results or Findings: Twenty-nine professionals participated: 12 consultants, 11 residents, and 6 radiographers. Users completed an average of 3.6 chatbot sessions per week. Overall satisfaction was high (mean 4.5/5); 91% found the chatbot useful or very useful. Post-intervention, 67% of participants reported improved awareness of sustainable imaging practices, with greatest gains in understanding paperless consent workflows, appropriateness in follow-up imaging, and environmentally conscious interventional preparation. No significant technical barriers were reported.
Conclusion: GreenBreastBot demonstrates that a pre-trained, low-energy LLM chatbot can effectively deliver eco-education in breast imaging. Its integration of institutional and international guidelines enables scalable, impactful, and environmentally coherent training for radiology teams.
Limitations: The main limitations are the monocentric design and the absence of objective performance measures.

Chatgpt for structured reporting in ct brain: resident experience (6 min)
Karanvir Singh Chhabra; Jalandhar / India

Author Block: K. S. Chhabra[1], D. B. Dahiphale[2], S. S. Sarda[2]; [1]Jalandhar/IN, [2]Aurangabad/IN
Purpose: To assess the feasibility and utility of ChatGPT in generating structured CT brain reports, evaluate its impact on reporting time and accuracy, and document resident perspectives in a tertiary care setting.
Methods or Background: This pilot study included 20 radiology residents who reported 200 CT brain examinations between January and April 2025. Each case was reported twice: once using conventional free-text reporting and once with ChatGPT-assisted structured reporting. Residents used a standardised prompt library covering common CT brain findings such as haemorrhage, infarct, mass effect, hydrocephalus, and extra-axial collections. Metrics assessed included reporting time, completeness (based on a 10-point checklist), inter-observer consistency, and resident satisfaction. Accuracy was validated against consultant-reviewed reference reports.
Results or Findings: ChatGPT-assisted structured reporting reduced mean reporting time from 14.2 minutes to 9.1 minutes (36% reduction). Completeness scores improved significantly (mean 9.3/10 vs 7.8/10, $p<0.01$), with better coverage of critical elements such as haemorrhage location, mass effect, and ventricular status. Inter-observer agreement improved, particularly for standardised terminology. Accuracy compared with consultant reports was maintained, with no significant increase in errors. Resident feedback highlighted improved clarity and confidence, though some noted occasional generic or redundant phrasing requiring manual refinement.
Conclusion: ChatGPT shows promise as a practical tool for structured reporting in CT brain studies, enhancing efficiency, completeness, and inter-observer consistency without compromising accuracy. While human oversight remains essential, integration of AI-driven structured templates can support radiology training and streamline reporting in high-volume settings.
Limitations: Single-centre pilot design.
Funding for this study: No funding was received for this study.

A Fine-Tuned Large Language Model Chatbot for Multi-Scenario Radiology Cancer Care: Randomized Controlled Trial on Interaction Optimization, Emotional Support, and Provider Burnout Reduction (6 min)

Liqiang Zhang; Chongqing / China

Author Block: L. Zhang; Chongqing/CN
Purpose: To develop and validate a scenario-specific fine-tuned LLM chatbot for optimizing clinical interactions between cancer patients and radiology healthcare providers (RHPs).
Methods or Background: A RCT across three hospitals collected 36,511 minutes of dialogue from 12 sites in three scenarios—Appointment Triage (AT), Pre-examination Preparation (PP), and Radiology Clinic Services (RCS)—transcribed and curated into 27,120 validated dialogues. REC was developed by fine-tuned DeepSeek R1 using 80% of dialogues and scenario-specific prompts. Two sub-trials evaluated REC: Sub-trial 1 included 1,424 patients in AT/PP; Sub-trial 2 included 638 in RCS. Both randomized patients 1:1 to RHP+REC or RHP. A total of 150 RHPs were similarly randomized. Primary outcomes were patient-rated dialogue quality (empathy, frustration, emotional regulation, factuality, integrity, and satisfaction); secondary outcomes included burnout and image quality.
Results or Findings: 1. Dialogue Quality:
AT/PP: RHP+REC significantly improved factuality (AT: 4.12 vs. 3.39; PP: 4.52 vs. 3.79; both $P < 0.001$), integrity, satisfaction, and reduced frustration (PP: 3.24 vs. 3.95, $P = 0.002$).
RCS: RHP+REC excelled in factuality (4.58 vs. 3.69, $P < 0.001$) and satisfaction (4.03 vs. 3.52, $P = 0.003$) but underperformed in empathy (3.88 vs. 4.42, $P = 0.002$).
2.Burnout:
RHP+REC reduced exhaustion (1.85 vs. 2.40, $P < 0.01$) and depersonalization (2.18 vs. 3.96, $P = 0.003$).
3.Image Quality:
REC improved CT (4.35 vs. 4.00, $P < 0.01$) and MRI (4.12 vs. 3.79, $P = 0.02$) quality.
Conclusion: REC optimized radiology workflows and reduced burnout.
Limitations: First, it requires provider validation, limiting scalability. Future versions should enhance autonomous validation while ensuring safety. Second, effectiveness relies on training data quality; continuous updates and broader datasets are needed for generalizability. Third, future work should improve clinical adaptability and multimodal integration (e.g., imaging, physiological data), with real-time feedback for continuous learning .

Ethics committee - additional information: The research protocol has been approved by the ethics review committees of all participating hospitals (H1, H2, H3), and the entire research process strictly follows the ethical principles of the Helsinki Declaration.

Achieving Truly Informed Consent? A Prospective Controlled Trial Using Retrieval-Augmented Generation Before CT Examinations (6 min)

Felix Busch; Munich / Germany

Author Block: F. Busch, T. Lemke, S. Ziegelmayer, M. Graf, A. W. Marka, P. Prucker, M. R. Makowski, K. K. Bressem, L. C. Adams; Munich/DE
Purpose: This prospective comparative study aimed to investigate the feasibility, usability, and effectiveness of a Retrieval-Augmented Generation (RAG)-powered Patient Information Assistant (PIA) chatbot for pre-CT information counseling, compared to standard physician-led consultation and informed consent procedures.
Methods or Background: Eighty-six patients scheduled for CT imaging (November-December 2024) were randomly assigned to either the PIA group (n=43), receiving pre-CT information via a RAG-powered chatbot, or the control group (n=43), receiving standard doctor-led consultation. Patient satisfaction, information clarity, comprehension, and concerns were assessed using six ten-point Likert-scale questions. Consultation duration was recorded, and patients in the PIA group indicated their preferred mode of future counseling. Two radiologists independently evaluated each PIA session based on five criteria: overall quality, scientific and clinical evidence, clinical usefulness and relevance, consistency, and up-to-dateness.
Results or Findings: Both groups reported similarly high ratings for information clarity (PIA: 8.64 ± 1.69; control: 8.86 ± 1.28; $p=0.82$) and overall comprehension (PIA: 8.81 ± 1.40; control: 8.93 ± 1.61; $p=0.35$). Physician-led consultations more effectively alleviated patient concerns (8.30 ± 2.63 vs. 6.46 ± 3.29; $p=0.003$). Patients in the PIA group required significantly shorter subsequent consultation times (median: 120 s [IQR: 100-140] vs. 195 s [IQR: 170-220]; $p=0.04$). Radiologists rated PIA chats favorably across all evaluated categories.
Conclusion: A RAG-powered PIA chatbot can effectively deliver pre-CT information while reducing physician consultation time. Although patient satisfaction and comprehension were comparable to standard consultations, physician-led interactions remained superior in addressing patient concerns. These findings highlight the potential of AI-based chatbot solutions to streamline patient counseling for imaging procedures. At the same time, physician engagement remains crucial for addressing patient worries, suggesting a complementary role for both approaches in clinical practice.
Limitations: Single-center, sample size, self-reported outcomes.
Funding for this study: None.

Ethics committee - additional information: Technical University of Munich (2024–469-S-KK)

The Resident, The Robot, and the Rules: Structured Prompts Drive Better AI Chest Readouts (6 min)

Dhanush Jayanna; Bangalore / India

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: D. Jayanna, S. Reddy Kankara, S. R. Kankara, A. Josephine, A. A. Monteiro, A. Mahesh Krishna, V. M. Tellis, R. S patel, S. D. Antoinette; Bangalore/IN
Purpose: To determine whether structured, role-specific prompting can reduce AI hallucinations and improve differential diagnosis (DDx) quality versus an unprompted baseline and a radiology resident reference across 120 thoracic imaging cases.
Methods or Background: Retrospective, paired, within-case evaluation of two advanced models (GPT-5 Thinking; Gemini 2.5 Pro) across six prompt tiers. Outcomes: DDx quality (grades 1–5) and hallucination burden (0–20 across four domains), scored by cardio-thoracic radiologist. Statistics: Friedman/Wilcoxon with multiplicity control; resident DDx served as fixed reference.
Results or Findings: Across 120 cases, DDx improved stepwise for both models (GPT-5: 2.78→4.49; Gemini: 2.98→4.45) while hallucinations declined (GPT-5: 6.95→0.54; Gemini: 8.02→1.04). Global prompt effects were decisive for DDx (χ^2=201.6 and 176.6; $p<10^{-35}$) and hallucinations (χ^2=279.0 and 261.3; $p<10^{-54}$). At the exemplar-guided, role-specific level (SR+ST+E), both AIs exceeded the resident's mean DDx (4.49/4.45 vs 3.85; $p<10^{-7}$), inverting their baseline inferiority. Head-to-head, GPT-5 showed fewer hallucinations than Gemini at no prompt (6.95 vs 8.02; $p\leq0.004$) and a borderline advantage at tier 6 prompt (0.54 vs 1.04; $p\approx0.06$); DDx was comparable between models at both extremes. Domain-level improvements (factual consistency, extraneous information, misinterpretation, clinical risk) paralleled total-score declines.
Conclusion: Prompt architecture is a powerful, controllable lever: structured, exemplar-guided, role-specific prompts markedly enhance DDx quality and suppress hallucinations to near-floor levels, enabling AI performance that matches or exceeds a resident reference with improved safety characteristics. These data support standardised prompting for safe, reliable deployment of general-purpose models in thoracic imaging workflows.
Limitations: Single-centre design with two human comparators may limit generalizability.
We used a novel four-domain, thresholded rubric—among the first studies to assess AI hallucinations in imaging diagnosis—which lacks external validation; despite rater calibration, some subjectivity and inter-rater variability may affect absolute scores and effect sizes.

AI-Supported MR Safety Assessment of Implanted Devices: First Clinical Evaluation (6 min)

Hanna Kreutzer; Aachen / Germany

Author Block: H. Kreutzer, D. Rashid, D. Truhn, S. Nebelung; Aachen/DE
Purpose: MR safety checks for patients with implanted devices are time-consuming and error-prone. Clinicians must identify the exact device model, retrieve the manufacturer's handbook, and extract applicable scanning conditions. We developed an AI-agent that streamlines device-specific MR eligibility assessment using manufacturer documentation and scientific literature.
Methods or Background: The agent is built in LangGraph with a router node classifying user queries. Device-specific queries are directed to a retrieval-augmented generation (RAG) pipeline that utilizes manufacturer handbooks. General MR safety queries are handled by a separate RAG pipeline that utilizes peer-reviewed scientific literature. A central GPT-4.1 node composes the final output. A web-based interface (chatbot-like) allows free-text queries or image uploads of implant ID-cards, which are analysed with GPT-4.1 Vision. The interface displays both the reasoning steps and the retrieved handbook/literature pages for transparency.
Evaluation was performed using consecutive patients with cardiac devices from our hospital. An MR-physicist documented the final safety decision (scan eligibility and protocol parameters), which served as the reference standard.
Results or Findings: The agent's recommendation was correct in 15/19 cases. In the remaining four cases, the system flagged missing documentation, thereby avoiding unsupported recommendations. Importantly, no incorrect recommendations were made. Correct guideline source pages were displayed in 13 of the 15 correct cases.
Conclusion: An AI-agent grounded in manufacturer guidance can reliably answer MR safety questions. Early testing demonstrates promising accuracy and interpretability, with transparent display of reasoning and sources. If scaled beyond cardiac devices and expanded into comprehensive device databases, such agents have the potential to fundamentally transform MR safety practice by accelerating workflows, reducing errors, and setting new standards for patient safety in radiology.
Limitations: Some device manuals were unavailable. Evaluation was restricted to cardiac devices. Use of GPT-4.1 requires anonymised data.

Evaluating The Role Of ChatGPT In Orthopaedic Virtual Fracture Clinics: Potential For Clinical Management And Decision Support (6 min)

Arnav Gupta; Birmingham / United Kingdom

Author Block: A. Gupta, R. Botchu; Birmingham/UK
Purpose: The Orthopaedic Virtual Fracture Clinic (VFC) is an innovative healthcare model that leverages digital technology to manage and triage patients with musculoskeletal conditions remotely. Advanced AI tools like ChatGPT have shown promise in assisting with patient triage by providing initial assessments based on patient-reported symptoms and history and offering detailed explanations of treatment protocols. Integrating ChatGPT into orthopaedic VFCs could significantly save time in patient triaging, thereby enhancing the VFC process. However, no study has yet investigated whether ChatGPT can aid clinicians in VFCs by generating adequate clinical management plans. This study explores the potential of ChatGPT in orthopaedic VFCs and examines whether it can replace or support clinicians during VFCs.
Methods or Background: We conducted a retrospective study reviewing 50 consecutive patient records referred to our virtual fracture clinic (VFC). We compared outcome measures between clinicians and ChatGPT 4, analysing the differences in decision-making.
Results or Findings: Our findings reveal distinct differences in the recommendations provided by ChatGPT 4 compared to human clinicians across various outcome measures, highlighting both the strengths and limitations of AI in this domain.
Conclusion: Significant differences were observed between ChatGPT's recommendations and those of human clinicians, with the AI tending toward more conservative approaches. While these tendencies could enhance patient care, they may also lead to unnecessary resource utilisation. Further refinement and calibration of ChatGPT's algorithms are necessary to align its recommendations with clinical best practices.
Limitations: Limitations include the small sample size of 50 cases and the retrospective design, which may affect generalizability. Additionally, ChatGPT’s conservative recommendations highlight the need for algorithm refinement, and the study does not assess real-time clinical integration or patient outcomes following AI-supported decisions

Energy Usage of Large Language Models and Segmentation Models in Radiology (6 min)

Martin Segeroth; Basel / Switzerland

Author Block: M. Segeroth, S. Yang, J. Wasserthal, J. Cyriac, T. Heye, E. M. Merkle, M. Bach, J. Vosshenrich; Basel/CH
Purpose: Neural networks, in particular large language models (LLMs), are increasingly valuable tools that support human tasks rather than simply automating them. However, their use requires substantial amounts of energy. In clinical practice, justified privacy concerns favor the evaluation of open-source models, which allows for assessing their energy consumption.
Methods or Background: Within our institutional healthcare network, we deployed privateGPT and Ollama as the primary platforms for LLM utilization, and Nora for image analysis. The models were hosted on a server equipped with eight NVIDIA A100 GPUs (80 GB each). For LLM experiments, we tested Llama3-70B, and for medical image segmentation, we used TotalSegmentator. Task scheduling was managed with Slurm 23.11.4, while energy consumption was monitored using nvidia-smi 550.163.01 and turbostat 2023.11.07. Additional overall server-level measurements were performed.
Results or Findings: The server’s eight GPUs allow a maximum power of 400 W each, yet during our tests total peak power consumption reached 4235 W, with more than 1000 W attributable to non-GPU components. Idle consumption was 63 W per GPU and 1150 W for the full server. A single LLM request consumed 5.94 Wh (95% CI: 5.87–5.98 Wh), with GPU utilization at 86.39% (CI: 86.39–86.39%). TotalSegmentator training for MRI segmentations required 8389.14 Wh (CI: 8193.84–8730.37 Wh), with GPU utilization at 78.93% (CI: 78.93–78.93%). Inference with TotalSegmentator consumed 0.96 Wh (CI: 0.96–0.97 Wh) per case for tissue types, and complete MRI segmentation required 1.47 Wh (CI: 1.47–1.48 Wh).
Conclusion: Neural networks in clinical deployment consume a noticeable amount of energy, with individual tasks requiring 1–6 Wh, several times more than a typical Google search (~0.2 Wh). Nonetheless, their ability to augment clinical performance and support decision-making can justify the additional energy expenditure.
Limitations: Additional models and hardware are under evaluation.

Non-Invasive Monitoring of BRAF-MEK Inhibitor Therapy in a Human Melanoma Mouse Model Using [18F]-ML-10 PET/CT (6 min)
Jonathan Stock; Munich / Germany

Author Block: J. Stock, A. C. Klose, F. Herr, M. J. Antons, R. Werner, J. Ricke, M. Heimer, P. M. Kazmierczak, C. C. Cyran; Munich/DE
Purpose: To evaluate whether the PET tracer [18F]-ML-10 enables early, non-invasive in vivo assessment of therapy-induced apoptotic changes in BRAF-mutant malignant melanoma under combined BRAF/MEK inhibitor treatment.
Methods or Background: A human melanoma xenograft model (A375) in 15 immunodeficient mice was used to evaluate [18F]-ML-10 PET/CT for monitoring BRAF-MEK inhibitor therapy (treatment: n = 7; control: n = 8). PET/CT scans were performed at baseline and day 7. Quantitative analysis assessed target-to-background ratios (TBR-BP, TBR-M). Histological validation included cleaved caspase-3 immunohistochemistry, TUNEL assay, and CD31 staining for microvessel density.
Results or Findings: [18F]-ML-10 PET/CT demonstrated a marked increase in [18F]-ML-10 uptake in the treatment group between baseline and follow-up but no significant change in the control group. Quantitative PET analysis revealed significantly higher TBR-BP (23.48 ± 20.61 vs. 5.81 ± 3.63; p = 0.015), and TBR-M values (42.04 ± 42.25 vs. 11.36 ± 9.54; p = 0.031) in the treatment group at follow-up. Histologically, no significant differences in apoptotic cell counts were observed between groups with cleaved caspase-3 (239.4 ± 102.7 vs. 270.4 ± 101.4 cells/HPF; p = 0.33) or TUNEL-staining (83.3 ± 34.0 vs. 64.5 ± 21.9; p = 0.29), however mean values showed a similar trend to PET results. CD31-immunohistochemistry demonstrated a significantly lower microvessel density in the treatment group (30.7 ± 10.2 vs. 43.6 ± 14.7; p = 0.041), consistent with the anti-angiogenic effects of BRAF-MEK inhibition.
Conclusion: [18F]-ML-10 PET/CT may enable non-invasive detection of therapy-associated changes suggestive of increased apoptosis in melanoma xenografts under BRAF-MEK inhibitor therapy. The findings support the potential of [18F]-ML-10 PET/CT for early therapy monitoring in targeted cancer treatment.
Limitations: Small sample size and the restriction to a single imaging time point may have limited the detection of transient apoptotic effects.

Imaging the Breakdown of Tumor-Promoting Desmoplasia via Adoptive Transfer of Fibroblast Activation Protein-Directed CAR T Cells (6 min)
Yumeng Sun; Nanjing / China

Author Block: Y. Sun, Q. Sang, L. Yize, Z. Xiao; Nanjing/CN
Purpose: The therapeutic potential of chimeric antigen receptor (CAR) T-cell therapy in solid malignancies is frequently limited by inadequate infiltration, suboptimal localization, and functional exhaustion of T cells within the tumor microenvironment (TME). Previous studies have shown that targeting tumor stroma with fibroblast activation protein (FAP)-specific CAR T cells can promote T-cell penetration and suppress tumor growth in pancreatic ductal adenocarcinoma (PDAC). However, the temporal dynamics of FAP-CAR T-cell migration and their interactions with stromal and extracellular matrix (ECM) components remain poorly defined. The objective of this study was to characterize these processes to guide optimization of CAR T-cell performance in solid tumors.
Methods or Background: Multiplex immunostaining combined with intravital two-photon microscopy of PDAC tumor explants was used to assess FAP-targeted CAR T-cell behavior at defined time points. Analyses focused on localization, activation status, and migration patterns in relation to stromal and ECM structures.
Results or Findings: Within 1–3 days post-transfer, FAP-CAR T cells accumulated predominantly in stromal regions encasing tumor nests but were largely excluded from the nests themselves. In these stromal zones, CAR T cells displayed activation and migrated through areas of loosely organized collagen, whereas movement was severely hindered in dense ECM. At tumor margins, aligned collagen fibers guided T-cell migration but restricted entry into tumor nests. By day 5, depletion of immunosuppressive stromal cells and disruption of peritumoral fibrillar collagen were observed, enabling penetration of CAR T cells into tumor nests. Co-treatment with hyaluronidase further enhanced infiltration.
Conclusion: These findings indicate that stromal remodeling, achieved by depletion of FAP^+ stromal cells and degradation of ECM, facilitates CAR T-cell accumulation and functional engagement within the desmoplastic architecture of PDAC.
Limitations: No limitations

The Role of [^{68}Ga]Ga-FAPi -2286PET/CT in the Evaluation of Treatment Response in Gastrointestinal System Malignancies (6 min)

Gamze Beydagi; Istanbul / Turkey

Author Block: N. Alan Selcuk, G. Beydagi, K. Akcay, A. Görmez, T. Toklu, L. Kabasakal; Istanbul/TR
Purpose: This study aimed to investigate the potential efficacy of [^{68}Ga]Ga-FAPi PET/CT in evaluating treatment response in patients with gastrointestinal system malignancies.
Methods or Background: Patients with gastrointestinal malignancies who underwent [^{68}Ga]Ga-FAPi PET/CT for treatment response assessment were included. The maximum standardized uptake values (SUVmax), total tumor volumes, and total lesion FAP expression values, tumor marker levels were recorded. Imaging responses were assessed separately according to PERCIST criteria on [^{68}Ga]Ga-FAPi PET/CT and RECIST criteria on CT. Survival outcomes were analyzed using Kaplan–Meier method, and their association with treatment response was assessed using Log-Rank (Mantel–Cox) test.
Results or Findings: A total of 100 [^{68}Ga]Ga-FAPi PET/CT scans were performed in 50 patients, both before and after treatment. Among the included patients, 70% had gastric cancer, 14% had colon cancer, 8% had pancreatic cancer, 4% had appendiceal cancer, 2% had hepatocellular carcinoma, and 2% had cholangiocellular carcinoma. A strong correlation was found between tumor volumes and total lesion FAP expression and the corresponding serum tumor markers (AUC = 0.875). There was a statistically significant and near-perfect concordance between [^{68}Ga]Ga-FAPi PET PERCIST and CT RECIST criteria (Kappa = 0.833, $p < 0.05$). Moderate agreement was found for primary tumors (Kappa = 0.526) and bone metastases (Kappa = 0.657), while excellent agreement was observed for lymph node (Kappa = 1.0), peritoneal (Kappa = 0.815), and visceral metastases (Kappa = 1.0). Treatment response assessed by [^{68}Ga]Ga-FAPi PET/CT was predictive of overall survival (p=0.02). Median overall survival was 7.6 months in patients with progressive disease, 19.8 months in those with stable disease and not reached in patients showing partial or complete response, as defined by PERCIST criteria.
Conclusion: [^{68}Ga]Ga-FAPi PET/CT appears to be an effective tool for assessing treatment response and monitoring gastrointestinal malignancies.

First clinical experience of 68Ga-FAPI PET/CT in Kazakhstan (6 min)

Madina Gabdullina; Almaty / Kazakhstan

Author Block: Z. J. Zholdybay, M. Gabdullina, Z. Zhakenova, G. Alisherov, Z. M. Amankulov; Almaty/KZ
Purpose: We aimed to investigate the use of 68Ga-FAPI PET/CT in patients with various oncological diseases by analyzing the pathological uptake in tumors as well as physiological uptake of the tracer.
Methods or Background: Inclusion criteria included: 1) age ≥ 18 years; 2) confirmed diagnosis or clinical suspicion of a primary solid malignancy; 3) referral for cancer staging or evaluation of suspected recurrence; 4) written informed consent. Exclusion criteria included: 1) pregnancy or lactation; 2) lymphoma or melanoma; 3) known hypersensitivity or adverse reaction to the 68Ga-FAPI; 4) refusal to undergo biopsy or surgery; 5) renal impairment.
Results or Findings: Between January 10, 2024, and February 28, 2025, a total of 199 cancer patients aged 24–80 years (mean age 52.6 ± 15.4 years) were included in the study. The majority of patients (64%) were female. Indications for 68Ga-FAPI PET/CT included evaluation of primary solid tumors arising in the breast, hepatobiliary system, gastrointestinal tract, lung, head and neck region, ovary, and pancreas; a smaller subset of patients underwent imaging for less common malignancies such as choroidal tumors, histiocytic disorders, seminoma, renal neoplasms and others.
68Ga-FAPI-04 demonstrated minimal physiological uptake in normal brain regions and intestinal loops, with comparatively low activity in the liver and oropharynx. Uptake was also low in the thyroid gland, salivary glands, lung parenchyma, esophagus, myocardium, and glandular breast tissue, thereby enhancing lesion contrast in these organs.
Conclusion: In conclusion, 68Ga-FAPI-04 appears to be a promising radiotracer for the molecular imaging of most malignant neoplasms.
Limitations: First, biopsies could not be performed for all detected lesions, limiting histopathological confirmation. Second, the study was conducted in a single center. Finally, there was no direct comparison with 18F-FDG PET/CT.

Stability, Biodistribution, and Patient Dosimetry of [177Lu]Lu-FAP-2286 Radionuclide Therapy (6 min)

Gamze Beydagi; Istanbul / Turkey

Author Block: K. Akcay, T. Toklu, G. Beydagi, L. Kabasakal, B. Caner, N. Alan Selcuk; Istanbul/TR
Purpose: Fibroblast activation protein (FAP) is an attractive target for tumor imaging and therapy. While ^{68}Ga-labeled FAPi-04 and FAPi-46 are widely used diagnostically, their brief retention limits therapeutic use. FAP-2286 has emerged as a candidate for radionuclide therapy. This study evaluated the in-vitro/in-vivo stability, biodistribution, and organ/tumor dosimetry of [^{177}Lu]Lu-FAP-2286.
Methods or Background: Seven treatments were administered to five patients (mean age 61.0±15.3 years; F/M: 2/3) with positive uptake on [^{68}Ga]Ga-FAPi-46 or [^{68}Ga]Ga-FAP-2286. The mean administered activity was 215±14.7 mCi. Whole-body anterior/posterior planar scans and SPECT/CT were obtained at 4, 24, 72, and 120 h post-infusion with corrections for attenuation, scatter, and detector/collimator response. Blood samples up to 120 h supported red marrow dosimetry and in-vivo stability assessment. Whole-body ROIs and VOIs for kidneys, liver, and lesions were segmented. Time-activity curves were fitted with mono- or bi-exponentials in MATLAB R2013a to derive cumulated activities. Absorbed doses were estimated using IDAC-Dose 2.1.
Results or Findings: Two patients had pancreatic adenocarcinoma, one neuroendocrine carcinoma, and two soft-tissue sarcoma. In-vitro stability was at least 41 h; in-vivo blood stability persisted ≥24 h. Mean absorbed doses were 0.50±0.19 Gy/GBq (kidneys), 0.030±0.014 Gy/GBq (liver), and 0.054±0.014 Gy/GBq (red marrow). The mean tumor dose was 5.97±3.85 Gy (range 1.10–18.52 Gy).
Conclusion: No adverse events occurred, and all patients tolerated therapy well. At the administered activities, renal and marrow toxicity thresholds were not exceeded. Bone marrow doses were comparable to the only published series, whereas renal doses were lower. Because prior data reported doses only for bone metastases, direct comparison with the soft-tissue tumor doses presented here is not possible. Overall, [^{177}Lu]Lu-FAP-2286 shows favorable stability, dosimetry, and safety, supporting its potential as a therapeutic option across multiple malignancies.
Limitations: N/A

A glypican-3 targeted diagnostic radiopharmaceutical for hepatocellular carcinoma molecular imaging (6 min)

Honghui Guo; Changsha / China

Author Block: H. Guo, X. Ma; Changsha, Hunan/CN
Purpose: Glypican-3 (GPC3) is upregulated in hepatocellular carcinoma (HCC), is implicated in tumor progression, and correlates with poor prognosis. These properties make it promising for both targeted immunotherapy and early detection via PET imaging. Here, we developed a novel cyclic peptide molecular probe via Phage Display Biopanning and validated the imaging ability in HCC xenografts and explored its application for HCC patients.
Methods or Background: The novel novel cyclic peptide molecular probe, namely ZSQT-3B010, was labeled with Gallium-68 (68Ga) to obtain [68Ga]Ga-ZSQT-3B010. Cell uptake assays, small-animal PET imaging, and biodistribution studies were performed to evaluate its targeting ability. Pharmacokinetics studies were confirmed in healthy volunteers (HV, n=6). In the first-in-human study, 17 patients (10 HCC and 7 Non-HCC patients) underwent [68Ga]Ga-ZSQT-3B010 PET/MR scan. Radiotracer uptake in tumors and normal tissues was quantified, and tumor-to-liver ratios (TLR) were calculated.
Results or Findings: [68Ga]Ga-ZSQT-3B010 was synthesized with high radiochemical purity and exhibited specific uptake and efficient internalization in GPC3-positive cells. [68Ga]Ga-ZSQT-3B010 effectively visualized HCC tumors, reaching a peak SUV uptake of 5.09 at 4h p.i., 3.40 and 50.00 fold higher than in GPC3 moderate and low expression tumors. The [68Ga]Ga-ZSQT-3B010 demonstrated favorable pharmacokinetics and a low radiation dose in HV. In preliminary clinical studies, no adverse events was observed. Totally 29 lesions were detected and the mean SUVmax was 15.80±3.14 at 60 min p.i. and 19.16±4.26 at 120min p.i., with a minimum detectable lesion size ≤1 cm. The TLR is 4.53-to-28.67. Further, a positive correction between GPC3 expression and SUVmax (R=0.84, P<0.05). Notably, the stomach uptake is very low compared to other reported targeted GPC3 agents.
Conclusion: The [68Ga]Ga-ZSQT-3B010 has high GPC3 binding affinity and specificity for HCC detection, and may further benifit GPC3 targeting therapy.
Limitations: No limitations were identified.
Funding for this study: Funding was provided by the Project of Research on New Targeted Peptide Radioactive Drugs for Tumor (A-202406-026-CD).

Optimal scan time for [18F]SiTATE PET/CT imaging of patients with neuroendocrine tumors (6 min)

Ricarda Ebner; Munich / Germany

Author Block: R. Ebner, F. Herr, K. Klimek, J. Ricke, C. C. Cyran, R. Werner, G. Sheikh; Munich/DE
Purpose: Somatostatin receptor (SSR)-targeting tracer [^{18}F]SiTATE is gaining momentum in clinical use as a promising alternative to commonly used gallium-68-labelled SSR-targeting compounds, demonstrating excellent image quality and clinical utility. Currently, imaging is performed 90 minutes after tracer injection, complicating integration into a multi-tracer PET environment, where most tracers are imaged 60 minutes after tracer injection. We therefore investigated whether comparable image quality and quantification can be achieved at earlier time points more compatible with clinical routine.
Methods or Background: Eight patients with histologically confirmed metastasized GEP-NET received [^{18}F]SiTATE-PET/CT with repeated scans 60, 90, and 120 minutes post-injection. SUVmax, SUVpeak and SUVmean were measured in visceral organs and 49 SSR-positive lesions (lymph node, liver, bone), and tumor-to-background ratios were calculated. Statistical comparison was performed across time points. Scans were visually assessed for noticeable differences by four readers of varying experience.
Results or Findings: No significant differences in tumor-to-background ratios were observed across timepoints for liver (p=0.6613), lymph nodes (p=0.5413), bone (p=0.8478), or overall lesion assessment (p=0.7248). Post hoc multiple comparisons using tukey's test revealed no significant pairwise differences (p=0.5103–0.999). Readers did not report qualitative visual difference between the time points, all lesions could be clearly identified against the surrounding background.
Conclusion: The results demonstrate consistent tracer uptake over time, with minimal variation in tumor-to-background contrast across metastatic sites. Imaging at 60 minutes post-injection provides equivalent lesion detectability and quantitative contrast compared to 90 and 120 minutes. These findings highlight the clinical utility of early [^{18}F]SiTATE imaging for NET patients, facilitating workflow and improving patient comfort without compromising diagnostic accuracy.
Limitations: The main limitation of our study is the small sample size and its single-center design, which may limit generalizability of the findings.
Funding for this study: None.

18F-FES-PET/MRI for Axillary Staging in ER+ Breast Cancer: Diagnostic Accuracy and Optimal SUVmax Cutoff (6 min)

Thomas Spiegel; Vienna / Austria

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: T. Spiegel[1], D. A. Resch[1], S. Rasul[1], O. Lafcı[1], N. Pötsch[1], P. Clauser[1], P. A. Baltzer[1], K. Pinker-Domenig[2], T. H. Helbich[1]; [1]Vienna/AT, [2]New York, NY/US

Purpose: 18F-Fluoroestradiol (18F-FES) is a novel radiotracer, and little is known about its role in axillary lymph node (LN) staging in estrogen receptor (ER)-positive breast cancer (BC) on PET/MRI. This study aims to evaluate the diagnostic performance of 18F-FES-PET/MRI for axillary LN staging in ER+ BC and to define optimal thresholds.

Methods or Background: This retrospective analysis of prospectively acquired single-center study data includes 37 female patients with 38 ER+ BCs, who underwent 18F-FES-PET/MRI using a Biograph mMR system (Siemens, Germany). Semiquantitative PET parameters including SUVmax of axillary LNs were assessed by placing a volume of interest (syngo.via, Siemens) on the most suspicious LN identified on MRI. Histopathology from biopsy or surgery served as the reference standard. Statistical analysis included Shapiro-Wilk test, t-test, and ROC analysis with AUC and Youden's index; $p<0.05$ was considered significant.

Results or Findings: Histopathology confirmed 21 metastatic and 17 benign LNs. Metastatic LNs showed higher uptake (mean SUVmax 2.60, 95% CI 1.91-3.29) than benign LNs (0.98, 95% CI 0.81-1.16; $p<0.001$), with an AUC of 0.852. An SUVmax cutoff of ≥1.56 yielded a specificity of 100% (17/17), sensitivity of 66.7% (14/21), PPV of 100% (14/14), NPV of 70.8% (17/24), and accuracy of 81.6% (31/38). Lower thresholds improved sensitivity but markedly reduced specificity. Subgroup analysis showed a trend toward higher uptake of metastatic LNs in invasive lobular carcinomas (ILC, n=5, mean SUVmax 3.61, 95% CI 1.33-5.89) compared to invasive ductal carcinomas (IDC, n=16, mean SUVmax 2.29, 95% CI 1.59-2.98; $p=0.087$).

Conclusion: 18F-FES-PET/MRI allows reliable LN characterization in ER+ BC. An SUVmax cutoff of ≥1.56 offers excellent specificity and overall accuracy, with higher uptake trends in lobular compared to ductal carcinoma.

Limitations: Retrospective, single-center design, and limited sample size.

Multiparametric MRI biomarkers predicting atypical pituitary adenomas: Correlation with surgical complexity and histopathologic markers of aggressive behavior (6 min)
Roja Hiregouja Eranna; Chikmagalur / India

Author Block: S. Nalubolu, R. Hiregouja Eranna; Bengaluru/IN
Purpose: While most pituitary adenomas are indolent, a subset exhibit atypical morphology characterized by increased firmness, invasiveness, and proliferative histopathology. These features contribute to surgical complexity and early postoperative recurrence. Preoperative identification of such atypical adenomas using quantitative MRI biomarkers—particularly diffusion, T2 signal, and enhancement pattern—may aid surgical planning and risk stratification.
Methods or Background: A retrospective review was conducted on 128 surgically resected pituitary adenomas (2020–2023). Preoperative 3 T MRI (T1, T2, DWI/ADC, dynamic contrast-enhanced sequences) and CT were assessed for cavernous sinus invasion (Knosp grade), dural contact, margin irregularity, T2 signal, cystic/necrotic change, and osseous invasion. Mean ADC values (b = 0, 1000 s/mm²) were measured from tumour ROIs. Atypicality was defined by intraoperative firmness and/or proliferative indices (Ki-67 > 3%, p53 positivity). Interobserver agreement (κ) and ROC analyses were performed. Follow-up MRI and hormonal data (6–18 months) assessed persistence or progression.
Results or Findings: Atypical lesions had a substantially lower mean ADC than typical ones (0.72 ± 0.09 vs. $0.91 \pm 0.11 \times 10^{-3}$ mm²/s; $p < 0.001$).T2 hypointensity occurred in 63% versus 31% ($p = 0.002$), correlating with intraoperative firmness ($\kappa = 0.81$).Cavernous sinus invasion (sensitivity 85%, specificity 82%) and irregular margins (74%, 68%) were strong predictors. The combined model with T2 hypointensity + invasion and ADC $< 0.80 \times 10^{-3}$ mm²/s had an AUC of 0.91. Early progression was seen in 17% of atypical versus 4% of typical adenomas ($p = 0.03$).
Conclusion: Atypical pituitary adenomas exhibit a reproducible MRI signature—low ADC, T2 hypointensity, and invasive margins—reflecting fibrous, highly cellular tissue. These multiparametric MRI biomarkers predict surgical difficulty and early recurrence, supporting their integration into preoperative evaluation and biologically guided management.
Limitations: Single-center limitation.

Identifying Pituitary Microadenomas Using Dynamic Enhancement Patterns: A Descriptive Study (6 min)
Daniel Alfonso Zambrano; Pamplona / Spain

Author Block: D. A. Zambrano, A. M. Delgado Brito, C. D. Solano, M. R. López De La Torre Carretero, J. M. Rodríguez Ortega, M. Calvo Imirizaldu; Pamplona/ES
Purpose: Describe and quantify dynamic perfusion-curve patterns in pituitary lesions (mainly microadenomas) and compare them with normal pituitaries.
Methods or Background: Pituitary microadenomas (<10 mm) are benign, often asymptomatic tumors with low clinical risk, typically identified through MRI and hormonal evaluation. However, their small size and subtle enhancement can lead to diagnostic uncertainty. Dynamic contrast-enhanced (DCE) MRI curve patterns (types I–III) have been proposed as diagnostic aids.

This retrospective descriptive study included 30 patients (20 with pituitary microadenomas and 10 controls) evaluated between January 2022 and December 2024. Imaging was performed on 3T and 1.5T scanners using 3D T1-weighted DCE sequences, followed by motion correction and temporal signal-intensity curve analysis. Regions of interest (ROIs) were placed in the lesion and contralateral pituitary tissue (or bilaterally in controls). Perfusion curves were classified as type I, II, or III for descriptive comparison between microadenomas and normal pituitaries.
Results or Findings: In this study of 30 patients (20 with microadenomas, 10 controls), 95% of microadenomas exhibited a type II DCE curve, whereas all controls showed normal physiological curves. These results indicate a strong association between microadenomas and type II perfusion patterns, suggesting that DCE-curve analysis may support visual diagnosis in uncertain cases. However, due to the retrospective design and small sample size, findings are exploratory. Further research is needed to standardize metrics, evaluate reproducibility, and validate diagnostic performance before adopting type II curves as a formal criterion.
Conclusion: Most pituitary microadenomas exhibited a type IIb DCE pattern, suggesting that perfusion-curve analysis may aid in their detection. Further studies are needed to validate these findings.
Limitations: Retrospective design and small sample size render findings exploratory. Standardization of quantitative metrics, interobserver reproducibility testing, and validation in larger prospective studies are required before clinical adoption.

Diffusion Tensor Imaging of Optic Pathways as a Predictor of Visual Outcome in Pituitary Macroadenoma Surgery (6 min)

Aditya Chauhan; Bangalore / India

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: A. Chauhan; Bangalore/IN
Purpose: To assess preoperative diffusion tensor imaging (DTI) metrics of optic nerves and chiasm in predicting postoperative visual recovery following transsphenoidal resection of pituitary macroadenomas.
Methods or Background: Fifty patients underwent preoperative DTI (3T) with FA and MD mapping of the optic nerves/chiasm. Visual field (VF) testing was performed pre- and 6-months postoperatively. Correlations between DTI parameters and VF improvement were analyzed using logistic regression.
Results or Findings: Patients with higher preoperative FA (>0.35) and lower MD ($<1.2\times10^{-3}$ mm²/s) demonstrated significant postoperative visual improvement ($p<0.01$). DTI-based model predicted visual recovery with AUC 0.88. Fiber tractography visualized axonal integrity and compression zones.
Conclusion: Preoperative DTI provides quantitative biomarkers for predicting visual recovery potential in pituitary adenoma surgery, assisting surgical planning and patient counseling.
Limitations: Limited by small cohort and inter-scan variability in optic nerve imaging.

MRI imaging spectrum in hypophysitis (6 min)

Bhanupriya Singh; Lucknow / India

Author Block: B. Singh, V. SINGH, Z. NEYAZ, S. Verma, S. KANT, A. Gupta; Lucknow/IN
Purpose: Necessary to make a distinction b/w hypophysitis and macroadenoma based on clinical and radiological grounds, as the management varies. Hypophysitis can be managed medically in the form of hormone replacement with or without corticosteroids Whereas macroadenomas warrant surgical resection.
Methods or Background: 20 cases of hypophysitis and 21 cases of pituitary macroadenomas that presented to our hospital between January 2025 and October 2025.
Results or Findings: Two radiologists independently reviewed the MRI images provided to them.
Both radiologists were aware that imaging was being performed for the detection of hypophysitis or adenoma.
However, they were unaware of the clinical history, lab results, and HPE reports of the cases. Covariates were evaluated by multiple logistic regression analysis.
Each covariate was assigned a signed number proportional to its regression coefficient, thereby yielding a cumulative score for each patient that summarized the predictive diagnostic ability of the model.
A positive number suggested a diagnosis of macroadenoma (CODED as 1), whereas a negative number indicated a diagnosis of hypophysitis (CODED as 0).
The accuracy of the score was evaluated by using the receiver operating characteristic (ROC) analysis, which computes the sensitivity and specificity of the score.
The resulting sensitivity and 1-specificity values are then plotted on a graph and joined by straight lines to form the ROC curve. The area under the curve (AUC) is finally calculated.
Conclusion: The possible values of the score ranged from a minimum of -13 to a maximum of +8.
In hypophysitis , score ranged from -13 to +2, had a median of -5 and comprised most of the patients (~75%) with values < -2.
Limitations: Can be conducted on a larger sample size.

Craniopharyngioma magnetic resonance imaging, progression, gender, age and histologic aspects: a retrospective cohort (6 min)

Marcia Oliveira Sousa; São Luís / Brazil

Author Block: M. O. Sousa, R. Silva; São Luís/BR
Purpose: Evaluate magnetic resonance imaging (MRI) craniopharyngioma diagnosis patients, correlating them with histological subtypes, age and gender. Furthermore, observe differential diagnosis, and the disease evolution based on MRI aspect.
Methods or Background: Retrospective cohort analysis of 111 MRIs from 34 craniopharyngioma diagnosis patients performed between 2018 and 2025, comparing histological diagnosis, age, gender and progression. Descriptive statistical analysis, Kruskal-Wallis test and Fisher's exact test were performed using Stata software.
Results or Findings: Most females patients ranging from 2 to 71 years old, median of 13, interquartile range (IQR) = 8-24 years old. Twenty-nine were craniopharyngioma confirmed, two pituitary macroadenoma, two suprasellar pilocytic astrocytoma, and one Rathke's pouch cyst. Adamatinomatous craniopharyngiomas (86,67%), papillary (12,33%). Kruskal-Wallis test being statistically significant for the association between the histological type and age group (P = 0,27) but not for progression (P = 0,53). Fisher's exact test demonstrated no association between progression and histological type (P = 1,0).
Conclusion: In this study sample, we observed a predominance of adamatinomatous subtype craniopharyngiomas in children and young adults, with a small percentage of elderly individuals affected by the papillary subtype, predominantly female.
These lesions presented challenging imaging diagnoses and was confused with macroadenomas, Rathke's pouch cysts, and pilocytic astrocytomas. Although most presented reduction, many progressed despite treatment, and some died, characterizing the aggressive aspect of the tumor.
Limitations: The study was limited by the small sample size given the rarity of the disease. Other limitations were the high number of missing information on histological subtype and the lack of follow-up in some cases.
Funding for this study: No funding

Facial nerve characterisation in CPA tumors: from tractography to multimodal predictive models (6 min)

Simonetta Gerevini; Cremona / Italy

Author Block: A. Mangili[1], A. Arrigoni[1], G. Pezzetti[2], B. Frigeni[2], R. Bivona[2], S. Capelli[1], G. Danesi[2], A. Caroli[1], S. Gerevini[2]; [1]Ranica/IT, [2]Bergamo/IT
Purpose: Cerebellopontine angle (CPA) tumors are often benign but can compress adjacent structures, including the facial nerve (FN). Surgical resection is standard treatment but carries a risk of iatrogenic injury and facial palsy. This study investigates the role of anatomical and diffusion-weighted MRI (DW-MRI) in presurgical planning, focusing on FN reconstruction. Radiomic features and diffusion tensor imaging (DTI) biomarkers were extracted and integrated with clinical variables to train machine learning models predicting FN integrity, postoperative outcomes, and long-term function.
Methods or Background: Forty-seven CPA patients who underwent preoperative MRI and surgery were analyzed. MRI protocols included DW-MRI AP (b0 and 1500; 50 directions; voxel size 2×2×2 mm), b0 PA, post-contrast volumetric T1-w, and volumetric T2-w scans. A custom pipeline, implemented in Python with MRtrix3Tissue and FSL, corrected noise and artifacts, segmented lesions, and performed a SS3T-CSD-based tractography using the iFOD2 algorithm with anatomically guided seeding.
Results or Findings: The FN was successfully reconstructed in all patients. The tumor-affected side showed higher fractional anisotropy (FA) and lower mean diffusivity (MD) than the contralateral side. Diffusion metrics correlated with conventional prognostic markers, including blink reflex and Koos grade. Compound Muscle Action Potential (CMAP) correlated inversely with diffusion values and FN tract length. Postoperative and 1-year House-Brackmann (HB) grades were significantly associated with lesion volume, FN length, and CMAP. Machine learning models achieved accuracies of 0.76 for predicting FN adherence, 0.82 for postoperative HB, and 0.90 for 12-month HB outcomes.
Conclusion: Diffusion tractography enhances CPA presurgical planning. Combined radiomic, clinical, and neurophysiological data improve prediction of FN integrity, short-term function, and long-term outcomes after resection.
Limitations: The study is limited by its single-center design, modest sample size, and lack of external validation.
Funding for this study: The study didn't receive any funding.

The Impact of Diffusion-Weighted Imaging of the Pituitary Gland Based on Small Field of View and Saturated Band Segmented Readout Echo-Planar Imaging on Image Quality (6 min)

Zuonian Hu; Guiyang / China

Author Block: Z. Hu; Guiyang/CN
Purpose: To explore the value of diffusion-weighted imaging (DWI) based on reduced field of view (rFOV) and saturated band segmented echo-planar imaging (SS-EPI) techniques in improving pituitary image quality and reducing artifacts, compared with conventional full field of view (fFOV) DWI.
Methods or Background: Thirty patients with clinically suspected pituitary lesions were enrolled. All patients underwent scanning of the pituitary region using both the conventional fFOV DWI sequence and the rFOV SS-EPI DWI sequence. Two radiologists performed blind subjective scoring (on a 5-point scale) of the two sets of images, assessing anatomical structure clarity, susceptibility artifacts, and overall diagnostic confidence. In addition, objective measurements were conducted, including the contrast-to-noise ratio (CNR) and the standard deviation of apparent diffusion coefficient (ADC) values.
Results or Findings: The images obtained by the rFOV SS-EPI sequence showed significantly higher scores in all subjective evaluation indicators than those from the conventional fFOV DWI sequence, with good inter-observer consistency. Objective measurements revealed that the rFOV SS-EPI images had a higher CNR and a lower standard deviation of ADC values; meanwhile, image geometric distortion and susceptibility artifacts were significantly suppressed.
Conclusion: The EPI sequence using reduced field of view and saturated band segmented readout techniques can significantly improve the image quality of pituitary DWI, effectively reduce artifacts at the skull base bone-air interface, and provide more reliable diffusion functional information for the accurate diagnosis of pituitary lesions.
Limitations: The number of studies is insufficient.

Predictive Assessment of Pituitary Neuroendocrine Tumor Recurrence Using MRI Fractal Analysis and Radiomics (6 min)

Chunhui Chen; LanZhou / China

Author Block: C. Chen, J. Zhou; LanZhou/CN
Purpose: Although most pituitary neuroendocrine tumors (PitNETs) are benign with good postoperative outcomes, they frequently recur despite multidisciplinary treatment. Early prediction of PitNET recurrence is clinically vital. This study aims to explore the value of preoperative assessment of PitNET recurrence based on MRI fractal analysis and radiomic features.
Methods or Background: A retrospective study included 123 PitNET patients who underwent MRI, divided into recurrence (n=50) and non-recurrence (n=73) groups based on follow-up. Clinical, pathological, and conventional MRI data were collected. Fractal dimension was calculated from sagittal CE-T1WI using ImageJ. Radiomic features were extracted from whole-tumor images on axial T2, sagittal CE-T1WI, and coronal CE-T1WI sequences via Darwin platform. Group differences in fractal parameters, radiomic features, clinical/MRI/pathological traits were analyzed to construct an optimal predictive model.
Results or Findings: Statistically significant differences in fractal dimension were observed between the two groups ($P < 0.001$). Among clinical features, preoperative ACTH levels, tumor texture, extent of tumor resection, presence of tumor apoplexy, and CSF leakage all differed significantly (all $P < 0.05$). For conventional MRI signs, statistically significant differences were found in maximum tumor diameter/height, tumor hemorrhage, carotid artery encasement, and cavernous sinus invasion (all $P < 0.05$). Pathologically, P53 positivity showed a significant difference ($P = 0.03$). The SVM model based on radiomic features outperformed others. The SVM model constructed using statistically significant fused features achieved the highest performance, with AUC values of 0.951 in the test set and 0.778 in the validation set .
Conclusion: Combining MRI fractal analysis, radiomics, and clinical/pathological data enhances clinical decision-making to improve treatment and patient quality of life.
Limitations: This is a retrospective study.
Multi-dimensional parameters such as molecular omics and genomics will be integrated to refine the model.

18F-FES-PET/MRI in Breast Cancer: Distinguishing ER Status and Subtype Uptake Patterns (6 min)
Thomas Spiegel; Vienna / Austria

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: T. Spiegel[1], D. A. Resch[1], S. Rasul[1], O. Lafcı[1], N. Pötsch[1], P. Clauser[1], P. A. Baltzer[1], K. Pinker-Domenig[2], T. H. Helbich[1]; [1]Vienna/AT, [2]New York, NY/US
Purpose: 18F-Fluoroestradiol (18F-FES) is a novel radiotracer primarily used for staging ER-positive breast cancer (BC). However, understanding its uptake characteristics in both benign and malignant breast lesions is essential. This study evaluates 18F-FES-PET/MRI uptake patterns across receptor status, molecular BC subtypes, and benign breast lesions.
Methods or Background: This retrospective analysis of prospectively acquired data includes 41 women with 48 breast lesions (42 malignant, 6 benign) who underwent 18F-FES-PET/MRI. All patients underwent simultaneous 18F-FES-PET/MRI performed using a Biograph mMR system (Siemens, Germany). Quantitative PET parameters, including SUVmax, and lesion size were assessed. Histopathology in malignant tumors and histopathology or follow-up >2 years in benign lesions was the reference standard. Mann-Whitney U test and ROC analyses were performed; $p<0.05$ was considered significant.
Results or Findings: Among 42 BCs, 39 were ER-positive (8 Luminal A, 31 Luminal B) and 3 triple-negative breast cancers (TNBC). ER-positive BCs had statistically significantly higher SUVmax (median 2.40, IQR 1.31-3.59) than ER-negatives (SUVmax <1.00, $p=0.014$). 6 ER-positive BCs with lesion sizes <9 mm failed to show any uptake. AUC for SUVmax in lesions ≥10 mm to differentiate between ER-positive and ER-negative BCs was 1.00 and when including all lesions AUC 0.902. SUVmax tended to be higher in Luminal B than Luminal A ($p=0.173$), both exceeding TNBC ($p<0.001$ and $p=0.036$). Benign lesions (n=6) showed SUVmax values between 0.72-1.57, statistically significantly lower than in BCs ($p<0.001$).
Conclusion: 18F-FES uptake is predominantly observed in ER-positive breast cancers and reliably distinguishes ER-positive from ER-negative tumors ≥10 mm. However, overlap exists among molecular subtypes, particularly Luminal A and B, and benign lesions may also show variable uptake.
Limitations: Retrospective design and small sample sizes in certain subgroups.

Comparison of PET/CT with 18F-FDG and 68Ga-FAPI in the detection of liver tumors (6 min)
Maria Aleksandrovna Komarova; Shakhovskaya / Russia

Author Block: M. A. Komarova, V. E. Sinitsyn, A. Martinovich, O. Ryzhova; Moscow/RU
Purpose: To compare the diagnostic accuracy of FAPI PET/CT and FDG PET/CT in patients with liver tumor.
Methods or Background: 15 patients (mean age 57,5 y.o, 7male/8 female) diagnosed with liver cancer who underwent FAPI and FDG PET/CT between 7 days were included in the study. 4pts were examined to detect progression of the underlying disease (had the previous treatment). The all liver lesions had morphological verification (11pts had cholangiocarcinoma G1-3, 2pts. - hepatocellular carcinoma, 1- intraductal papillary tumor of the bile duct and 1pts - calcifying nested stromal-epithelial tumor). Uptake intensity(SUVmax) and target-to-background ratio(TBR) of the primary liver tumor and lymph nodes metastasis were compared between two imaging modalities. Sensitivity(Se), specificity(Sp), positive predictive value(PPV), negative predictive value(NPV) and accuracy(Ac) were calculated for each modality on a per-region basis.
Results or Findings: 14 pts were found primary tumor and 3 pts of them had metastases in regional lymph nodes or lung. There was a better contrast with 68Ga-FAPI, with SUVmax of the liver tumors of 14,9 [8,94-23,48] compared with SUVmax of 7,81 [3,55-10,21] of liver tumors with 18F-FDG (p=0,02). The TBR of primary tumor were higher in 68Ga-FAPI compared with 18F-FDG - 10,56[4,15-16,46] vs. 2,5[1,17-3,67] respectively, p=0,0014. For detection of primary liver tumor and metastasis on region based level Se, Sp, PPV, NPV and Ac of Ga-68 FAPI PET/CT were higher than F18-FDG PET/CT (97,3%, 71,43 %, 90,00%, 90,91% and 90,20% vs. 78,38%, 57,14%, 82,86%,50,00% and 72,55 %, respectively).
Conclusion: FAPI PET-CT is a very promising tool for evaluation of patients with liver tumor because more accurate than FDG PET-CT. High level of FAPI uptake in the primary hepatic lesions is indicate the potential of FAP-targeted radionuclide therapy.
Limitations: No

Toward Structured Axillary Nodal Staging in Breast Cancer: Prospective Correlation of the Proposed Axillary Node Reporting and Data System (AN-RADS) with PET-CT and Histopathology (6 min)

Nidhi Atulbhai Umretiya; Chennai / India

Author Block: N. A. Umretiya, V. Mahajan, R. Arafath; Chennai/IN
Purpose: To evaluate the diagnostic performance of the proposed Axillary Node Reporting and Data System (AN-RADS) ultrasound classification for axillary nodes in breast cancer staging and to correlate AN-RADS categories with PET-CT and histopathology.
Methods or Background: This prospective observational study enrolled 15 patients with biopsy-proven breast carcinoma undergoing baseline staging between 1st August and 1st September 2025. All patients underwent axillary ultrasound with AN-RADS scoring (categories 1–5) and 18F-FDG PET-CT. PET positivity was defined as SUVmax ≥2.5. Histopathology (SLNB, core, or excision biopsy) or FNAC was available in 13/15 patients; 2 were excluded from diagnostic accuracy calculations due to lack of biopsy. AN-RADS ≥4 was considered ultrasound-positive. Statistical analysis included malignancy rates per category, diagnostic accuracy metrics with exact 95% confidence intervals, and Cohen's κ for concordance.
Results or Findings: Median patient age was 54 years (range: 42–68). AN-RADS distribution was: category 2 in 5 patients (33.3%), category 3 in 1 (6.7%), category 4 in 3 (20.0%), and category 5 in 6 (40.0%). Among 13 evaluable cases, 8/13 (61.5%; 95% CI 31.6–86.1) demonstrated metastatic nodes. Malignancy rates were 0% in AN-RADS 2 and 100% in AN-RADS 4–5. With AN-RADS ≥4 as threshold, ultrasound achieved sensitivity, specificity, PPV, NPV, and accuracy of 100%. PET-CT using SUVmax ≥2.5 showed identical diagnostic performance. Ultrasound, PET-CT, and histopathology showed perfect concordance (κ = 1.0).
Conclusion: The proposed AN-RADS system demonstrates a clear malignancy gradient and excellent correlation with PET-CT and histopathology, suggesting its potential as a structured, reliable framework for axillary nodal staging in breast cancer.
Limitations: Small sample size, short study period, and selection bias limit generalizability. The perfect performance observed is likely influenced by the restricted dataset.
Funding for this study: No external funding was received.

Diagnostic performance of whole-body MRI (wb-MRI) and 68Ga-PSMA PET/CT for staging and re-staging of high-risk prostate cancer (PCa) (6 min)

Riccardo Regazzo; Bologna / Italy

Author Block: R. Regazzo, A. Cattabriga, C. Gaudiano, A. Bardelli, L. Bianchi, A. Farolfi, S. Fanti, R. Schiavina, C. Mosconi; Bologna/IT
Purpose: PSMA-PET is the gold standard for staging and restaging high-risk prostate cancer (PCa), while whole-body MRI (wb-MRI) may represent a radiation-free alternative despite limited evidence. This prospective single-center study aimed to assess the diagnostic non-inferiority of wb-MRI compared to PSMA-PET for metastatic evaluation in high-risk patients at primary treatment and in those with biochemical recurrence (BCR).
Methods or Background: We enrolled 89 PCa patients: 47 high/very high-risk men undergoing radical prostatectomy with extended pelvic lymph node dissection (RARP + ePLND, Group 1) and 42 men with PSA persistence or BCR after surgery (Group 2). All patients underwent PSMA-PET and wb-MRI within 30 days. Reference standards were histopathology in Group 1 and clinical/imaging follow-up in Group 2. Sensitivity, specificity, PPV, NPV, accuracy, and AUC from ROC analyses were compared between modalities.
Results or Findings: In Group 1, pathological N1 disease was found in 42%. PSMA-PET vs wb-MRI for nodal staging showed sensitivity 53% vs 41%, specificity 90% vs 87%, and AUC 0.71 vs 0.64, with no significant differences.
In Group 2, 21% had PSA persistence and 79% BCR (median time 28 months, median PSA 0.3 ng/mL). PSMA-PET vs wb-MRI detected local recurrence in 17% vs 29%, nodal disease in 12% vs 19%, and distant metastases in 33% vs 19%. Diagnostic performance was comparable (sensitivity 54% vs 46%, specificity 86% vs 89%, AUC 0.80 vs 0.78).
Conclusion: Wb-MRI demonstrates diagnostic performance comparable to PSMA-PET for staging and restaging high-risk PCa and may represent a valid alternative in selected patients.
Limitations: Preliminary single-center results; limited sample size; heterogeneous follow-up in the BCR group.
Funding for this study: No funding was received for this study.

Predictive Value of Baseline Metabolic Tumor Volume (MTV) and Total Lesion Glycolysis (TLG) in Oncologic PET/CT (6 min)

Farook Abubacker Sulaiman; Chennai / India

Author Block: F. Abubacker Sulaiman; Chennai/IN
Purpose: To assess the prognostic and predictive value of baseline metabolic tumor volume (MTV) and total lesion glycolysis (TLG) derived from ^18F-FDG PET/CT in patients with solid malignancies, and to correlate these volumetric biomarkers with treatment response and progression-free survival (PFS).
Methods or Background: A prospective study was performed on 75 patients with biopsy-proven malignancies, including gynecologic, gastrointestinal, and thoracic cancers, who underwent baseline ^18F-FDG PET/CT prior to therapy. Quantitative parameters—SUVmax, SUVmean, MTV, and TLG—were obtained using semi-automated segmentation (SUV threshold ≥41% of SUVmax). Treatment response was assessed using PERCIST criteria at 3 and 6 months. Patients were followed up for 12 months to evaluate PFS. Statistical analysis included Kaplan–Meier survival curves, Cox regression, and Pearson's correlation.
Results or Findings: Baseline MTV and TLG values demonstrated strong predictive correlation with treatment outcomes and PFS. Patients with high MTV (>120 cm^3) and TLG (>850 $g \cdot cm^3$) showed significantly lower response rates and shorter PFS (median 6.4 months) compared to those with low MTV/TLG (median 14.8 months; $p < 0.001$). While SUVmax alone failed to predict long-term outcome, combined volumetric parameters (MTV + TLG) achieved the highest prognostic accuracy (AUC = 0.91). Multivariate analysis confirmed MTV and TLG as independent predictors of disease progression.
Conclusion: Baseline metabolic tumor volume and total lesion glycolysis are robust quantitative biomarkers for predicting treatment response and survival, outperforming conventional SUV metrics in oncologic PET/CT.
Limitations: Single-center design, heterogeneous tumor population, and short follow-up duration limit generalizability. Multicentric studies with standardized segmentation protocols are warranted.
Funding for this study: No external funding was received for this study.

Correlation of FDG-PETCT derived Metabolic Tumor Volume (MTV) with DWI MRI for the assessment of colon cancer liver metastases (6 min)

Numan Cem Balci; Istanbul / Turkey

Author Block: N. C. Balci, G. Iuppa, A. K. Ansari, C. Hajj, A. Khan; Abu Dhabi/AE
Purpose: FDG-PETCT derived MTV is determinant parameter in oncologic assessment in colon cancer liver metastases. This study aims to identify if DWI can provide correlative results.
Methods or Background: FDG PETCT and DWI MRI of 50 patients with colon cancer liver metastases were retrospectively enrolled in the study, PETCT derived MTV was measured using automated software . DWI MRI was acquired in the scanner with highest b value of 800 mm2/sec and synthetic higher b value images were created in workstation with the values of 1000 mm2/sec, 1500 mm2/sec and 2000 mm2/sec. For each patient, the total number of liver lesions, total MTV and total lesion volumes on DWI MRI were calculated both on PETCT and on four different b value images. Correlation of total liver lesions was made with Pearson's r test. Correlation of MTV with DWI was made using paired t-test.
Results or Findings: Average number lesions for each patient were: 3.04 for PETCT, 3.67 for b= 800 mm2/sec (Pearson r=0.97), 3.45 for b=1000 mm2/sec (Pearson r=0.98), 3.07 for b=1500 mm2/sec (Pearson r= 0.99) and 2.97 for b=2000 mm2/sec (p Pearson r=0.98). The average total MTV was 56.25 cc, average total tumor volumes on DWI were 59.98 cc for b=800 mm2/sec, $p < 0.001$ (significantly higher than PET-CT); 58.41 cc for b=1000 mm2/sec, $p < 0.001$ (significantly higher than PET-CT); 56.41 cc for b=1500 mm2/sec, $p = 0.021$ (least significant difference); and 54.22cc for b=2000 mm2/sec, $p < 0.001$ (significantly lower than PET-CT).
Conclusion: The result of this study reveals significant correlation of number of lesions and total tumor volume compared to PETCT lesion count and MTV when b value of 1500 is assessed on DWI.
Limitations: Histopathology correlation of all metastases missing.

Enhanced accuracy in differentiating recurrent tumor from radiation necrosis in brain metastases after Gamma Knife radiosurgery using multiparametric 18F-FET PET/MRI feature analysis (6 min)

Jie Bai; Beijing / China

Author Block: J. Bai, J. Lu; Beijing/CN
Purpose: To evaluate the diagnostic potential of multiparametric 18F-FET PET/MRI (mpPET/MRI) features in distinguishing tumor recurrence from radiation necrosis (RN) in brain metastases (BMs) following Gamma Knife radiosurgery (GKRS) using machine learning techniques.
Methods or Background: PET/MRI data were obtained from 74 patients with 114 suspected lesions after GKRS included CE-T1WI, ADC, CBF, and FET PET. We extracted 1,080 original and transformed first-order features from these specified modalities using the eXtreme Gradient Boosting (XGBoost) classifier and Spearman correlation analysis. Shapley Additive Explanations (SHAP) evaluated their significance. Six machine learning classifiers were built based on mpPET/MRI data. The diagnostic performance of the mpPET/MRI model and each single-modality submodel was compared using the area under the curve (AUC).
Results or Findings: Fifteen important first-order features (6 from FET PET, 3 from CE-T1WI, 3 from ADC, and 3 from CBF) were selected. XGBoost was chosen as the optimal classifier. The diagnostic performance of the mpPET/MRI model (training/validation AUC = 0.93/0.92) was higher than that of CE-T1WI (AUC = 0.85/0.82), ADC (AUC = 0.86/0.84), CBF (AUC = 0.86/0.83) and FET PET (AUC = 0.87/0.87) models. Moreover, the mpPET/MRI model improves diagnostic accuracy by 14% over the standard Response Assessment in Neuro-Oncology criteria (89.90% vs. 75.43%). SHAP analysis highlighted significant predictors such as log- and wavelet-transformed first-order features of FET PET.
Conclusion: The XGBoost model developed from mpPET/MRI data may be a promising approach to identify the distribution of RN and recurrent tumor in patients with BMs after GKRS. Particularly, FET PET played a significant role.
Limitations: The limited sample size and single-center design of this study restrict subgroup analyses and generalizability. Future work should incorporate advanced machine learning techniques such as texture analysis and ensemble learning to enhance model predictive performance.

Prospective assessment of baseline staging and treatment response in newly diagnosed multiple myeloma with combined 18F-FDG PET/CT and Whole-Body Diffusion-Weighted MRI (6 min)

Arrigo Cattabriga; Bologna / Italy

Author Block: A. Cattabriga, M. Talarico, C. Nanni, R. Regazzo, G. Pertile, S. Brocchi, S. Fanti, E. Zamagni, C. Mosconi; Bologna/IT
Purpose: The aim of this study was to compare the diagnostic performance of PET/CT and WBMRI in the diagnosis and staging of smoldering multiple myeloma (SMM) and newly diagnosed multiple myeloma (NDMM), to correlate both imaging modalities with markers of disease burden and prognostic features and to validate in clinical practice the imaging response criteria IMPeTUs and MY-RADS.
Methods or Background: 205 patients (74 SMM, 131 NDMM) were prospectively enrolled between October 2022 and April 2025. All underwent baseline assessment with WBMRI and FDG-PET/CT. In NDMM, baseline-positive imaging was repeated before maintenance in transplant-eligible patients and after one year of treatment in transplant-ineligible patients. Deauville/IMPeTUs and MY-RADS criteria were applied to define focal lesions (FLs), diffuse disease and treatment response. Imaging findings were correlated with biochemical parameters and prognostic scores (ISS/R-ISS).
Results or Findings: FLs and paraskeletal disease were detected more frequently by WBMRI vs PET/CT ($p<0.05$). Both modalities showed concordance in detecting extramedullary disease ($\kappa=1$). WBMRI-detected FLs significantly correlated with worse prognosis by ISS/R-ISS. Diffuse disease was detected more frequently by PET/CT ($p<0.05$). However, WBMRI-defined diffuse disease correlated with multiple clinical parameters (hemoglobin <10 g/dL, bone marrow plasma cells, paraprotein, urinary protein), whereas PET-defined diffuse disease did not. In SMM, detection of FLs and diffuse disease was similar across techniques. In the preliminary analysis of the first 45 reassessed patients, WBMRI and PET/CT showed good concordance in response assessment ($\kappa=0.69$).
Conclusion: WBMRI was superior to PET/CT in detecting FLs and paraskeletal disease and correlated better with disease burden and prognosis. Both modalities showed concordance for extramedullary disease and response assessment.
Limitations: Main limitations are the small sample size in some subgroups (extramedullary disease, post-treatment reassessment). These cohorts are expected to expand; updated data will be presented.

Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The institutional ethics board of our institution (IRCCS Policlinico di Sant'Orsola, Bologna) approved this study prior to patient enrollment

Can the PET PSMA Primary Score offer similar performance to the PIRADS V2.1 from Multiparametric Magnetic Resonance to detect suspicious lesions of prostate cancer to guide prostate biopsy ? (6 min)

Margarita Garcia Fontes; Montevideo / Uruguay

Author Block: M. Garcia Fontes, M. RODRIGUEZ PARODI, L. Valuntas, E. Otero, L. Mouro, V. Gigirey, L. Servente, G. Dos Santos; Montevideo/UY
Purpose: The detection of suspicious lesions of prostate cancer using Multiparametric Magnetic Resonance(mpMRI) is challenging because of the many pitfalls that often lead to unnecessary biopsies.
The aim of the present study is to compare the concordance of the PIRADS Scale V 2.1 of mpMRI with the PRIMARY SCORE of the PSMA PET CT in the detection of suspicious lesions of clinically significative prostate cancer to determine if it can add sensitivity or specificity in order to guide more effective biopsies.
Methods or Background: Fifty patients aged between 48 and 85 years were included. They underwent mpMRI using 3T equipment, fusion biopsy using MRI and ultrasound, and PSMA PET/CT for initial staging.
The number of PIRADS lesions detected by mpMRI were compared with the uptake areas using the PRIMARY PSMA Score and both methods were correlated with the pathological anatomy findings.
Results or Findings: A statistically significant correlation was found between PIRADS 4 and 5 lesions on mpMRI and SCORE 3 and 4 lesions on PSMA PET for Gleason 7 and higher grades found in the pahtologic anatomy.
In one patient with a hip prosthesis, the PET PSMA Primary Score allowed the detection of suspicious lesions that were very doubtful due to artifacts in the mpMRI.
Conclusion: The analysis of multiparametric prostate MRI using the PIRADS V2.1 and the PSMA PET Primary Score has similar sensitivity for detecting suspicious lesions for prostate cancer to guide prostate biopsy.
The PET PSMA Primary Score has slightly higher specificity than PIRADS V2.1 of mpMRI for clinically significant cancers.
Both methods could be use together to detect suspicious lesions of prostate cancer increasing sensitivity.
In patients with contraindications for mpMRI, PSMA PET SCORE seems to be a useful tool.
Limitations: Not aplicable

TC 927 - Population to precision oncology in prostate cancer

Categories: Oncologic Imaging, Genitourinary

ETC Level: LEVEL III

Date: March 5, 2026 | 13:00 - 14:00 CET

CME Credits: 1

The attendees will learn about the basis for the European screening recommendations from the European Union's Beating Cancer Plan and discuss the challenges and controversies of prostate cancer screening vs early detection, based on guidelines (EAU/AUA/NCCN). The session will review the role of imaging biomarkers in the detection and characterisation of prostate cancer, guidance of personalised treatment planning, prediction and assessment of response to therapy, and detection of disease recurrence. Furthermore, it will explore the emerging image-guided focal therapies as methods for personalised treatment of prostate cancer based on risk criteria and optimisation of oncologic and life quality outcomes.

Moderators:

Staffing levels: are specific levels required for safety, and can these be defined and enforced? (14 min)
Francis Zarb; Msida / Malta

1. To learn about current evidence and policy recommendations regarding radiographer staffing levels and their impact on patient and staff safety.
2. To appreciate the challenges and implications of defining and enforcing minimum-staffing standards across diverse European healthcare systems.
3. To understand how staffing levels influence service quality, workforce sustainability, and compliance with safety regulations.

Postgraduate education opportunities: are minimum levels required? Do we need a European framework? (14 min)
Joana Santos; Coimbra / Portugal

1. To learn about the current landscape of postgraduate radiography education across Europe and its variation in content and recognition.
2. To appreciate the value of harmonised postgraduate frameworks for advancing professional roles and enabling cross-border mobility.
3. To understand the need for structured pathways and minimum standards in postgraduate education to support advanced practice, research, and leadership in radiography.

Managing interdisciplinary relationships (14 min)
Julie Michelle Nightingale; Sheffield / United Kingdom

1. To learn about strategies and best practices for effective interdisciplinary collaboration in radiography-related services.
2. To appreciate the importance of mutual respect, clear communication, and defined roles within multidisciplinary teams.
3. To understand how strengthened interdisciplinary relationships can enhance professional autonomy, patient outcomes, and workplace dynamics.

Steps to improve professional recognition and autonomy (14 min)
Graciano Paulo; Coimbra / Portugal

1. To learn about key enablers and barriers to professional recognition of radiographers at national and European levels.
2. To appreciate the role of education, regulation, advocacy, and research in advancing radiographer autonomy and visibility.
3. To understand strategic actions radiography leaders and organisations can take to enhance recognition and professional status.

Panel discussion: What do radiographers need to do to embrace change? (29 min)

EFRS WS 10 - Better practices mean better care in mammography

Categories: Imaging Methods, Breast, Radiographers, Education, President's Choice
Date: March 5, 2026 | 14:30 - 16:00 CET
CME Credits: 1.5

Moderator:
Ayda Yildiz; Basel / Switzerland

Best practices for positioning during mammography examinations: presentation (25 min)
Ayda Yildiz; Basel / Switzerland

Best practices for positioning during mammography examinations: hands-on practice and Q&A (65 min)
Ayda Yildiz; Basel / Switzerland
Sibylle Trettel; Kirchheim unter Teck / Germany
Heide Dörrie; Bad Arolsen / Germany

Workshop assistants
Mary Catherine Murray; Belfast / United Kingdom
Fadime Bugra Cakir; Basel / Switzerland

EIBALL 10 - Building a quantitative imaging research study: a practical session

Categories: Imaging Methods, Oncologic Imaging, Research, Molecular Imaging, President's Choice
ETC Level: LEVEL II+III
Date: March 5, 2026 | 14:30 - 16:00 CET
CME Credits: 1.5

Moderator:
Gudrun Zahlmann; Neumarkt / Germany

Introduction: the EIBALL and QMIC initiative (10 min)
Gudrun Zahlmann; Neumarkt / Germany

Hypothesis generation: including primary/secondary endpoints and ground truth inclusion, exclusion criteria (20 min)
Laure S. Fournier; Paris / France

1. To learn about introducing quantitative imaging endpoints in clinical research studies.
2. To appreciate the relationship between measured biomarkers, ground truth and clinical endpoints.
3. To understand the principle of reliable quantitative imaging biomarkers (QIBs) and their relation to clinical endpoints.

Making the measurement: including precision, reproducibility, and validation (20 min)
Gudrun Zahlmann; Neumarkt / Germany

1. To learn about the use of metrology concepts in quantitative imaging.
2. To appreciate terms like precision, accuracy, bias, reliability and reproducibility in quantitative imaging measurements.
3. To understand the necessity of standardised imaging procedures for measuring QIBs.

Statistical considerations: including study type, main tesoutcome measurements, biases (20 min)
Daniel Bos; Rotterdam / Netherlands

1. To learn about appropriate statistical concepts for the use of QIBs in clinical research studies.
2. To appreciate the accuracy and bias of QIBs and their statistical representation.
3. To understand the selection of useful statistical hypotheses and tests for one or multiple biomarkers based on clinical study outcome assessment.

Practical issues: including ethics and leg funding, and planning (20 min)
Michael Vinzenz Knopp; Cincinnati / United States

1. To learn how to plan, manage and analyse QIB-based clinical research studies.
2. To appreciate the organisational setup and requirements to provide reliable and reproducible results.
3. To understand the challenges of quantitative imaging biomarker studies and how to use them successfully.

ESR/ESTRO - Individualised treatment of rectal cancer

Categories: Oncologic Imaging, GI Tract, Education, Multidisciplinary

ETC Level: ALL LEVELS

Date: March 5, 2026 | 14:30 - 16:00 CET

CME Credits: 1.5

The session aims to present and familiarise attendees with the revised rectal cancer imaging guidelines. After attending the session, attendees will be able to understand the treatment strategy for high- and low-risk rectal cancer and learn about the factors important for treatment decision-making.

Moderators:

Regina G.H. Beets-Tan; Amsterdam / Netherlands

Cihan Gani; Tübingen / Germany

Chairpersons' introduction (4 min)

Regina G.H. Beets-Tan; Amsterdam / Netherlands

Cihan Gani; Tübingen / Germany

How to stratify rectal cancer: an update of the revised rectal cancer imaging guidelines (20 min)

Monique Maas; Amsterdam / Netherlands

Treatment strategies: perspectives from a radiation oncologist (12 min)

Cihan Gani; Tübingen / Germany

Treatment strategies: perspectives from a surgical oncologist (12 min)

Geerard L. Beets; Maastricht / Netherlands

Case-based panel discussion (42 min)

Elleke Raphaëla Dresen; Leuven / Belgium

ESR Research 10 - Real-world applications of imaging biomarkers: from hypothesis to clinical practice

Categories: Research, Evidence-Based Imaging, Translational Imaging, Multidisciplinary, Artificial Intelligence

ETC Level: ALL LEVELS

Date: March 5, 2026 | 14:30 - 15:30 CET

CME Credits: 1

This session will explore the journey of imaging biomarkers from research to clinical implementation, focusing on trial design, validation, regulatory challenges, and the role of AI in biomarker development. Experts will share insights from real-world trials and discuss the future of AI-driven imaging biomarkers.

Moderators:

Savvas Andronikou; Athens / Greece

Raquel Perez Lopez; Barcelona / Spain

Chairpersons' introduction (5 min)

Savvas Andronikou; Athens / Greece

Raquel Perez Lopez; Barcelona / Spain

From pixels to patients: biomarker trial design and beyond (15 min)

Saskia Litière; Brussels / Belgium

Challenges and lessons from implementing imaging biomarkers in multicentre clinical trials (15 min)

Fiona J. Gilbert; Cambridge / United Kingdom

Dow-Mu Koh; London / United Kingdom

Artificial intelligence (AI) and radiomics: deciphering the future of imaging biomarkers (15 min)

Mireia Crispin Ortuzar; Cambridge / United Kingdom

Panel discussion: How can multidisciplinary collaboration in imaging drive the future of research? (10 min)

EU 10 - ESR iGuide, clinical decision support: challenges and opportunities

Categories: Professional Issues, EuroSafe Imaging/Radiation Protection, Evidence-Based Imaging, Imaging Informatics
ETC Level: ALL LEVELS
Date: March 5, 2026 | 14:30 - 16:00 CET
CME Credits: 1.5

Moderator:
Jacob Sosna; Jerusalem / Israel

Chairperson's introduction (5 min)
Jacob Sosna; Jerusalem / Israel

HIO Cyprus implementation of ESR iGuide clinical decision support (15 min)
Maria Papapanayidou; Nicosia / Cyprus

1. To learn the need to improve the prescription of imaging studies.
2. To describe the national plan to implement iGuide.
3. To understand the challenges and opportunities of a nationwide programme.

Clinical decision support and generative AI: new possibilities in imaging utilisation management (15 min)
Adrian Brady; Cork / Ireland

1. To learn about the role of guidelines in referral practice.
2. To learn about the standards for appropriate imaging utilisation in different parts of the world.
3. To describe the plans for the convergence of evidence-based radiology guidelines.

Norway shows the way on addressing the overuse of medical imaging (15 min)
Aslak Bjarne Aslaksen; Bergen / Norway

1. To learn about a CDS-driven regional intervention in Norway.
2. To appreciate the impact of comprehensive imaging utilisation management.
3. To understand the potential for expanded adoption of guidelines and CDS in clinical practice.

The future of CDS: incorporating LLMs into clinical practice (15 min)
Ronan P Killeen; Dublin / Ireland

1. To learn about the incorporation of LLMs in decision support software.
2. To understand the application of CDS for referral vetting.
3. To learn about using CDS for clinical audit of radiology referrals.

Panel discussion (25 min)

E³ 20C - Chest x-ray revisited

Categories: Chest, Artificial Intelligence, President's Choice
ETC Level: LEVEL I+II
Date: March 5, 2026 | 14:30 - 15:30 CET
CME Credits: 1

Moderator:
Cornelia M. Schaefer-Prokop; Amersfoort / Netherlands

Chairperson's introduction (5 min)
Cornelia M. Schaefer-Prokop; Amersfoort / Netherlands

Chest x-ray reading: tips and tricks (15 min)
Marie-Pierre Revel; Paris / France

1. To learn about the quality criteria to assess before reading.
2. To learn how to recognise abnormal mediastinal contours.
3. To understand the importance of a structured reading guide.

Common pitfalls and missed diagnosis (15 min)
Nigel Howarth; Carouge / Switzerland

1. To learn which lung areas are more challenging to interpret.
2. To recognise pitfalls caused by external objects.
3. To understand the limitations of chest x-ray.

AI-assisted chest x-ray reading (15 min)
Giorgio Maria Masci; Rome / Italy

1. To learn how to use AI for detecting lung nodules.
2. To appreciate its role in identifying small pneumothoraces.
3. To understand the challenges in validating AI findings.

Panel discussion: How to get the most out of chest x-ray? (10 min)

E³ 1023 - Cardiac and vascular

Categories: Vascular, Cardiac
ETC Level: LEVEL I+II
Date: March 5, 2026 | 14:30 - 16:00 CET
CME Credits: 1.5

Moderator:
Marco Francone; Rome / Italy

Chairperson's introduction (6 min)
Marco Francone; Rome / Italy

Cardiovascular imaging: coronary arteries (28 min)
Matthias Eberhard; Zurich / Switzerland

1. To understand the anatomy, normal variants, and abnormalities of the coronary arteries.
2. To describe the technical aspects and methodology of cardiac CT.
3. To understand the clinical role of cardiac CT in the main clinical scenarios: coronary stenoses and imaging post-revascularisation.

Cardiovascular imaging: myocardium (28 min)
Federica Catapano; Milan / Italy

1. To describe the diagnostic evaluation and imaging presentation of ischaemic heart disease.
2. To understand the diagnostic evaluation and imaging presentation of myocarditis.
3. To become familiar with the heterogeneity and corresponding main imaging findings of myocarditis.

Cardiovascular imaging: valves, endocardium, and aorta (28 min)
Christian Loewe; Vienna / Austria

1. To recognise the imaging presentation of the different forms of valvular disease.
2. To understand the causes and imaging presentations of endocarditis.
3. To describe the diagnostic evaluation and imaging presentation of common diseases of the great vessels, including aortic dissection and aneurysms.

HW Ui 10 - Interventional ultrasound: guided biopsy and fine needle aspiration (FNA) techniques

Categories: Musculoskeletal, General Radiology, Breast, Interventional Radiology, Abdominal Viscera
ETC Level: LEVEL I+II
Date: March 5, 2026 | 14:30 - 16:00 CET
CME Credits: 1.5

Moderator:
Liat Appelbaum; Jerusalem / Israel

Introduction: tips and tricks (25 min)
Liat Appelbaum; Jerusalem / Israel

1. To learn about the basic principles of performing an ultrasound guided biopsy and fine needle aspiration (FNA).
2. To become familiar with the types of biopsy needles and needle size for FNA.
3. To understand the different techniques of FNA and how to spread and prepare slides.
4. To learn about the potential pitfalls to avoid.

Hands-on demonstration (65 min)

Demonstrators
Boris Brkljačić; Zagreb / Croatia
Keshthra Satchithananda; London / United Kingdom
Liat Appelbaum; Jerusalem / Israel
Neeral Patel; London / United Kingdom
Adnan Kabaalioğlu; Istanbul / Turkey
Caroline Ewertsen; Copenhagen / Denmark
Dean Huang; London / United Kingdom
Elene Gotsiridze; Tbilisi / Georgia
Ortansia Doryforou; Athens / Greece
Gibran Timothy Yusuf; London / United Kingdom
Mustafa Seçil; Izmir / Turkey
Hila Fruchtman-Brot; Jerusalem / Israel

Workshop assistant
Mitesh Naik; London / United Kingdom

IT 10 - Enterprise imaging in practice: unifying radiology, pathology, and IT

Categories: Imaging Informatics
ETC Level: LEVEL II
Date: March 5, 2026 | 14:30 - 16:00 CET
CME Credits: 1.5

Moderator:
Michael Valante; Westport / United States

Chairperson's introduction (5 min)
Michael Valante; Westport / United States

Imaging as an enterprise asset, the value of bringing it all together (20 min)
Sara Elliott; Newcastle / United Kingdom

1. To learn how to design and govern imaging as an enterprise asset, unifying radiology and other imaging domains into a cohesive, standards-based enterprise imaging strategy.
2. To appreciate the clinical, operational, and financial value created when imaging data is consistently managed, shareable, and accessible across the organisation.
3. To understand the key requirements and lessons learned for successfully "bringing it all together" into a scalable, future-ready enterprise imaging ecosystem.

Building on success, the requirements for expanding PACS for digital pathology and other images (20 min)
David S. McClintock; Rochester / United States

1. To learn the essential technical, workflow, and integration requirements for expanding an existing PACS environment to support digital pathology and other clinical images.
2. To appreciate how to build on prior enterprise imaging success while recognising the unique needs, constraints, and stakeholders involved in digital pathology.
3. To understand the key lessons learned, risks to avoid, and practical strategies for creating a unified, scalable imaging ecosystem that spans radiology, pathology, and additional image-rich specialities.

Introducing AI into the image management equation: what do we need to know (20 min)
Mark D. Zarella; Philadelphia / United States

1. To learn where AI fits into the imaging and image-management workflow, and what is required to integrate it safely with existing systems.
2. To appreciate how AI can enhance efficiency, quality, and scalability in image management while recognising its limitations, risks, and impact on daily practice.
3. To understand a practical framework for evaluating, selecting, and governing AI tools in imaging so they can make informed decisions about deployment.

Enterprise planning, lessons learned from the IT perspective (20 min)
Fabian Allmendinger; Heidelberg / Germany

1. To learn the key elements of successful enterprise imaging planning from the IT perspective, including infrastructure, integration, data migration, security, and governance.
2. To appreciate the complexity of the IT work behind enterprise imaging and how close collaboration with radiology directly affects workflow, usability, and clinical outcomes.
3. To understand the common pitfalls and lessons learned from real-world projects, and how radiology leaders can partner with IT to build a resilient, future-ready enterprise imaging environment.

Panel discussion (5 min)

MD 10 - Brain tumours: new developments in imaging and treatment - recommendations for clinical practice and directions for the future

Categories: General Radiology, Imaging Methods, Neuro, Research, Multidisciplinary
ETC Level: ALL LEVELS
Date: March 5, 2026 | 14:30 - 15:30 CET
CME Credits: 1

Moderator:
Marion Smits; Rotterdam / Netherlands

Chairperson's introduction (2 min)
Marion Smits; Rotterdam / Netherlands

1. To highlight new developments in the treatment of brain tumours.
2. To critically review recent developments in imaging and put this in perspective of the treatment and other diagnostic developments.
3. To provide recommendations for clinical practice and directions for the future.

The neurosurgeon's perspective (8 min)
Eelke M Bos; Rotterdam / Netherlands

The neuro-oncologist's perspective (8 min)
Maarten Wijnenga; Rotterdam / Netherlands

The radiologist's perspective (8 min)
Marion Smits; Rotterdam / Netherlands

Expert panel discussion (34 min)

MS 10 - Lumbar pain: from symptom to diagnosis

Categories: Musculoskeletal, General Radiology, Neuro, Evidence-Based Imaging, Multidisciplinary, President's Choice
ETC Level: LEVEL II+III
Date: March 5, 2026 | 14:30 - 16:00 CET
CME Credits: 1.5

Moderator:
Sana Boudabbous; Geneva / Switzerland

Chairperson's introduction (3 min)
Sana Boudabbous; Geneva / Switzerland

The limitations of imaging in chronic spine pain patients (18 min)
Stéphane Genevay; Geneva / Switzerland

1. To appreciate the difference in the concept of normality between radiology and clinical practice and the consequences for patients with lumbar pain.
2. To learn the difference between nociception and pain.
3. To appreciate the limitations of radiological findings as the source of nociception in patients with chronic lumbar pain.

Imaging of lumbar spine osteoarthritis (18 min)
Ali Guermazi; West Roxbury / United States

1. To learn the complex pattern in imaging of lumbar spine osteoarthritis.
2. To appreciate the specific correlation between imaging and lumbar spine osteoarthritis pain.
3. To understand the role of imaging in the diagnostic strategy of lumbar spine osteoarthritis pain.

What does a surgeon want to know for lumbar pain? (18 min)
Dennis E. Dominguez; Geneva / Switzerland

1. To learn about spinal static: the fundamentals and its usefulness.
2. To appreciate the relationship between spinal static and lumbar pain.
3. To understand what the surgeon wants to know before and after surgery.

Imaging clues to non-degenerative spinal disorders: rethinking lumbar pain (18 min)
Kay-Geert A. Hermann; Berlin / Germany

1. To recognise that lumbar pain may arise from both non-degenerative and atypical degenerative spinal conditions, including axial spondyloarthritis, chronic non-bacterial osteomyelitis (CNO), osteochondrosis, and diffuse idiopathic skeletal hyperostosis (DISH).
2. To identify distinguishing imaging features of non-degenerative spinal disorders and mimicking entities through illustrative cases.
3. To evaluate the role of radiologic imaging in differentiating inflammatory, developmental, and degenerative pathologies of the lumbar spine.

Multidisciplinary case discussion (15 min)

NM 10 - Harnessing generative AI in academic publishing (highlight session)

Categories: Students, Research, Education, Artificial Intelligence

ETC Level: LEVEL I+II

Date: March 5, 2026 | 14:30 - 16:00 CET

CME Credits: 1.5

This section first reviews the various ways that generative AI can be used to make the writing and publishing process more efficient. Then, we discuss ethical and editorial guidelines on the responsible use of generative AI to establish best practices in academia. Lastly, we cover the importance of effective prompt engineering to ensure that you obtain the expected output along with various prompt engineering patterns that can be used to achieve different goals.

AI in academic publishing (90 min)

Jeffrey Robens; Kawasaki / Japan

OF 10Ya - Making the most of the ESOR scholarship and fellowships in Europe and beyond

Categories: General Radiology, Professional Issues, Research, Management/Leadership

ETC Level: LEVEL II+III

Date: March 5, 2026 | 14:30 - 15:30 CET

CME Credits: 1

This session is addressed to young radiologists aiming or planning for a fellowship abroad, and to hosts and tutors being involved within the ESOR scholar-and fellowship program. The idea of this session is to approach fellowships from different viewpoints and angles. Former scholars and fellows but also hosts and tutors will share their experiences and will provide the attendees with insights, tools, and practical guidance needed to fully benefit from the opportunities offered by the European School of Radiology. You'll also hear reflections from past fellows on how these programs have influenced their careers and broadened their perspectives. Whether you're planning to apply, considering hosting, or simply curious about what ESOR has to offer, this session is your chance to learn, ask questions, and connect with a community committed to excellence in radiology education and exchange.

Rachel Gerson; Seattle, WA / United States

Transformation to a green imaging department (15 min)

Sarah Lucy Sheard; London / United Kingdom

1. To learn about the ESR Green ID framework for sustainable radiology.
2. To appreciate the foundations required to make sustainable transformations in your practice.
3. To understand how to take the first steps.

Contrast and water pollution (15 min)

Heleen Dekker; Nijmegen / Netherlands

1. To understand the impact of contrast media use on the environment.
2. To learn about potential methods to reduce the discharge of contrast agents.
3. To learn about the first practical steps to extract contrast media from wastewater.

Energy: switch it off. But automation or behaviour change? What can we do? (15 min)

Michael Jackson; Edinburgh / United Kingdom

1. To learn practical solutions to deliver energy savings within and beyond the radiology department.
2. To appreciate that, whilst tackling the climate crisis as an individual can feel insurmountable, meaningful change is achievable as a coordinated effort.
3. To understand that psychological barriers, as well as organisational inertia, can impede such efforts, but can be overcome.

Life-cycle assessment (15 min)

Reed Omary; Nashville / United States

1. To name one outcome measure for an environmental life cycle assessment.
2. To list the imaging modality which produces the most carbon pollution within a diagnostic radiology department.
3. To propose one approach to reduce carbon pollution within diagnostic radiology.

Panel discussion: First steps: where do we begin? (25 min)

RPS 1002 - Breast cancer screening: technology, tools, and trends

Categories: Oncologic Imaging, Breast, Radiographers, Artificial Intelligence
Date: March 5, 2026 | 14:30 - 16:00 CET
CME Credits: 1.5

Moderator:
Sophia Zackrisson; Malmö / Sweden

Evaluation of recall rates in the Irish National Breast Screening Programme: Insights from two million screening mammograms (6 min)
Sophie Murphy; Dublin / Ireland

Author Block: S. Murphy, T. Mooney, N. Phelan, A. Smith, A. Connors, A. Larke, S. Mcnally, P. Fitzpatrick, M. Mullooly; Dublin/IE
Purpose: To examine recall patterns and characteristics within the population-based breast screening programme in Ireland.
Methods or Background: Breast cancer screening aims to reduce breast cancer mortality and morbidity through early detection and treatment. Recall rate is a key performance indicator of population-based breast screening, representing the proportion of women recalled for further evaluation. Guidance on acceptable recall rates vary internationally.

An anonymous aggregate retrospective study of 2,031,995 mammography screening examination results, was conducted between 2000 and 2019. Descriptive patterns of recall rates and characteristics were examined and stratified by prevalent and incident examinations. Differences across the time-periods (2000-2008, 2009-2017 and 2018-2019) were assessed using Chi-square tests.
Results or Findings: Recall rate for screening examinations conducted during the full study period was 4.05% (n=82,338/2,031,995). Across three time-periods examined, recall rates among the prevalent screening examination group, increased, from 5.5% to 8.0% to 10.0% and within the incident group from 2.3%->2.8%->3.0%. Recalls due to calcifications and asymmetry increased over the time periods, most notably within the prevalent examinations where recalls due to calcification increased from 6.0/1,00->9.0/1,000->13.4/1,000($p<0.001$),whilst recalls due to asymmetry increased from 17.1/1,000->31.3/1,000->41.0/1,000($p<0.001$). Overall, among both prevalent and incident screening examinations, an increase in the cancer detection rate (CDR) was observed($p=0.005$ and $p<0.001$ respectively). However, the overall positive predictive value(PPV) remained relatively stable.
Conclusion: This study highlights the upward trajectory of recall within Ireland's national breast screening service. The findings highlight the need for discussions among a diverse range of stakeholders, including national and international screening networks, to determine the optimal recall rate to ensure the benefits of screening are maximised and all potential harms are minimised.
Limitations: Lack of information regarding detailed characteristics of the cancers detected and information regarding breast density.
Funding for this study: No
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: As this study utilises existing anonymised data, formal ethical approval was not required in accordance with local ethics review board guidelines.

Recall Rate and Cancer Detection Rate of the first round of Digital Breast Tomosynthesis screening in a Dutch population-based trial (6 min)
Lindy Kregting; Nijmegen / Netherlands

Author Block: L. Kregting, L. Pennings, M. J. A. Smid-Geirnaerdt, A. Bluekens, J. Gommers, S. D. Verboom, I. Sechopoulos, M. Broeders; Nijmegen/NL
Purpose: To evaluate the short-term screening performance of Digital Breast Tomosynthesis (DBT) in the first round of the DBT with Advanced Reading Methods (STREAM) prospective screening trial being performed in the Dutch Breast Cancer Screening Programme.
Methods or Background: The Dutch screening programme includes biennial four-view digital mammography (DM) for women 50 to 75 years old. All examinations are independently double-read by screening radiologists with consensus reading or arbitration in case of disagreement. STREAM trial participants underwent the first of two rounds of four-view DBT screening instead of DM between July 2023 and May 2024. A contemporaneous control group received regular DM screening. Current analyses include first round results for recall rate (RR) , stratified by Breast Imaging Reporting and Data System (BI-RADS) category 0, 4, or 5, and cancer detection rate (CDR) .
Results or Findings: Out of 44,682 invited screenees, 18,186 participated in STREAM (41%). Among them, 488 were recalled (RR: 26.8 per 1,000), of whom 199 (1.1%) were assessed as BI-RADS 0, 257 (1.4%) as BI-RADS 4, and 32 (0.2%) as BI-RADS 5. Of the recalled women, 166 women were diagnosed with screen-detected breast cancer (CDR: 9.1 per 1,000). The control group consisted of 95,052 participants of DM screening. Among them, 2,252 were recalled (RR: 23.7 per 1,000), of whom 661 were diagnosed with breast cancer (CDR: 7.0 per 1,000). This results in an increase in RR of 2.9 per 1,000 (p=0.012) and an increase in CDR of 2.1 per 1,000 (p=0.002) for DBT screening compared to DM.
Conclusion: First round results suggest a modest increase in RR and an increase in CDR for DBT screening compared to DM in the Dutch breast cancer screening programme.
Limitations: Interval cancer and second round data not available yet.
Funding for this study: This study is funded by ZonMW (grantnr.:5550402130002) and KWF (grantnr.:13710).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Trial approved by the Dutch Minister of Health, Welfare and Sport in view of the Population Screening Act (WBO). (registrationnr.:3574709-1044141-PG).

Missed cancers at mammography: histological and biological characterisation in the P.I.N.K. study (6 min)

Ludovica Anna Incardona; Florence / Italy

Author Block: L. A. Incardona[1], M. Franchini[2], S. Molinaro[2], S. Pieroni[2], J. Nori[3], G. P. Scaperrotta[4], A. Nicolucci[3], E. Cassano[5], E. Montrucchio[1]; [1]La Spezia/IT, [2]Pisa/IT, [3]Florence/IT, [4]Milano/IT, [5]Milan/IT
Purpose: Mammography (MX) is the cornerstone of breast cancer screening but has limited sensitivity in specific subgroups. The P.I.N.K. Study was designed to evaluate the role of multimodality imaging in breast cancer diagnosis. This sub-analysis aimed to characterise cancers missed by MX and detected only by additional imaging.
Methods or Background: The P.I.N.K. database included 29,360 women undergoing 60,270 integrated diagnostic exams between 2017 and 2025. Among 1,246 surgically confirmed breast cancers, 233 (18.7%) were not visible on MX and were diagnosed exclusively by ultrasound (US), digital breast tomosynthesis (DBT), or magnetic resonance imaging (MRI). Breast density, histology and biological subtype were analysed.
Results or Findings: Missed cancers accounted for 233 of 1,246 cases (18.7%). Most were invasive (80%, 186/233), multifocal in nearly one third (32%, 74/233), and predominantly found in dense breasts (75%, 175/233). Younger women under fifty years were affected (40%). Histologically, invasive lobular carcinoma represented about 20% (47/233), while invasive ductal carcinoma accounted for the majority. Regarding biological profile, Luminal A was the most frequent subtype (55%, 128/233), followed by Luminal B (25%, 58/233), with HER2-positive (12%, 28/233) and triple-negative tumours (8%, 19/233) less common. US detected 142 of 233 missed cancers (60.9%), DBT 56 (24.0%), and MRI 35 (15.0%). These findings indicate that missed cancers are clinically significant and not indolent.
Conclusion: In this large multicentre cohort, almost one in five breast cancers were missed by MX but detected through integrated imaging. Their profile (dense breasts, younger women, invasive histology, and distinct biological features) highlights the clinical relevance of multimodality approaches. P.I.N.K. shows that the value of integrated imaging is both quantitative and qualitative, preventing missed cancers from becoming interval cancers and supporting personalised diagnostic strategies.
Limitations: This was a retrospective analysis of observational data.
Funding for this study: No funding was received for this study.

Supplemental MRI screening for women with extremely dense breasts: results of three screening rounds of the DENSE trial (6 min)

Sophie Van Grinsven; Utrecht / Netherlands

Author Block: S. V. Grinsven[1], E. Monninkhof[1], R. Mann[2], W. B. Veldhuis[1], C. Van Gils[1], F. T. D. T. S. G. -[1]; [1]Utrecht/NL, [2]Nijmegen/NL
Purpose: To study the effect of supplemental MRI screening for women with extremely dense breasts on advanced breast cancers.
Methods or Background: Dutch women with extremely dense breasts and a negative mammogram were pre-randomized to either the MRI-invitation (n=8,061) or control group (n=32,312, standard mammography). In the first (prevalent) round, supplemental MRI led to higher cancer detection and fewer interval cancers. The rate of advanced breast cancers in subsequent (incident) screening rounds serves as a further important measure to assess the impact on health outcomes. Since many women randomized to MRI-invitation did not participate, intention-to-treat analyses dilute the true effect. Therefore, our main analysis is a per-protocol approach, comparing advanced breast cancer (TNM stage II+) rates, adjusted for age and socioeconomic status using inverse probability weighting. Rate differences (RD) were calculated with 95% confidence intervals.
Results or Findings: As expected, in the first round, the advanced breast cancer rate per 1000 women was similar between MRI participants and controls (RD: 0.8 [95% CI: -0.6, 2.2]). In the second round, the rate was lower in the MRI group but not yet statistically significant (RD: 1.4 [95% CI: -0.3, 3.2]). By the third round, the rate in the MRI group was significantly lower than in the control group (RD: 2.6 [95% CI: 0.9, 4.3]).
Conclusion: From the second round, MRI participants had lower advanced cancer rates, reaching significance in the third round. These findings show that the health benefits of MRI screening likely extend beyond lowering interval cancers.
Limitations: The primary outcome used a per-protocol and not an intention-to-treat approach. As mortality could not be studied due to limited sample size and follow-up, advanced breast cancer was used as a surrogate. These results will inform mortality modelling.
Funding for this study: Supported by the University Medical Center Utrecht (project number, UMCU DENSE), the Netherlands Organization for Health Research and Development (project numbers, ZonMW-200320002-UMCU and ZonMW Preventie 50-53125-98-014), the Dutch Cancer Society (project numbers, DCS-UU-2009-4348, UU-2014-6859, and UU-2014-7151), the Dutch Pink Ribbon–A Sister's Hope (project number, Pink Ribbon-10074), Bayer Pharmaceuticals (project number, BSP-DENSE), and Stichting Kankerpreventie Midden-West. For research purposes, Volpara Health Technologies provided Volpara Imaging Software, version 1.5, for installation on servers in the screening units.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The Dutch Minister of Health, Welfare and Sport, who was advised by the Health Council of the Netherlands (2011/2019 WBO, The Hague, The Netherlands), approved the DENSE trial on November 11, 2011.

Enhancing Accuracy in Mammographic Screening with AI-Assisted Breast Cancer Detection and Reporting (6 min)

Shweta Tyagi; Bengaluru / India

Author Block: S. Tyagi, M. M. Jabeer, J. Singh, A. Chandalia; Bengaluru/IN
Purpose: Breast cancer is the most commonly diagnosed cancer among women worldwide, accounting for 11.6% of all cases and 6.9% of cancer-related deaths (GLOBOCAN 2022). Despite advances in therapy, early detection remains the cornerstone of improving survival outcomes. Mammography is the standard screening tool, yet its effectiveness is limited by interpretive variability, radiologist shortages, and increasing case volumes that strain healthcare systems. This study aims to develop and evaluate an artificial intelligence (AI) model for automated detection and structured reporting of breast cancer in mammograms, with the goal of enhancing diagnostic accuracy, consistency, and accessibility.
Methods or Background: A retrospective dataset of 100,000 biopsy-confirmed mammographic images, including both benign and malignant cases, was used to train the AI model. The dataset was curated to capture diverse tumor types and breast densities. A convolutional neural network (CNN) architecture was employed for automated detection and classification. In addition to image analysis, the system generates structured reports summarizing suspicious findings and relevant diagnostic information. Model performance was assessed using sensitivity, specificity, and area under the receiver operating characteristic curve (AUC). Results were benchmarked against experienced radiologists to determine clinical relevance.
Results or Findings: On an independent test set of 300 cases, the AI system achieved an AUC of 0.92, sensitivity of 96.4%, and specificity of 87.7%. The overlay and report results were independently reviewed and verified by an expert radiologist, confirming clinical reliability.
Conclusion: The AI system demonstrates strong potential for accurate and efficient breast cancer detection in mammography. Integration into clinical workflows could facilitate earlier diagnoses, reduce diagnostic delays, and alleviate radiologist workload, particularly in high-volume or resource-limited settings.
Limitations: Broader and multi-center prospective studies are required to confirm generalizability across diverse imaging environments.
Funding for this study: No funding was obtained for this work.

From Screening to Clinical Diagnosis: Can AI Match Expert Eyes in Mammography? (6 min)

Manuel Rafael López De La Torre Carretero; Pamplona / Spain

Author Block: M. R. López De La Torre Carretero[1], D. A. Zambrano[1], A. M. Delgado Brito[1], C. D. Solano[1], A. Elizalde[1], L. J. Pina Insausti[1], P. Martinez Miravete[2]; [1]Pamplona/ES, [2]Zaragoza/ES
Purpose: To evaluate the performance of an artificial intelligence (AI) tool in classifying mammograms from opportunistic screening versus clinical populations when compared with expert radiologist interpretation.
Methods or Background: This prospective multicenter study included 2,574 patients who underwent digital mammography, tomosynthesis, and targeted ultrasound when indicated. Patients were stratified into opportunistic screening (76.7%) or clinical setting (symptomatic, oncologic follow-up...) groups. Mammograms were analyzed by a commercially available AI tool, which categorized studies as “normal” or “suspicious”. Radiologists also classified studies as “normal”/”suspicious”, blinded to AI.
The reference standard was histopathology (when available) or the final radiologist assessment after ultrasound. Performance was compared using chi-square and McNemar tests, both globally and across patient subgroups.
Results or Findings: Mean age was 56.4 years (55.4 in screening, 59.7 in clinical).
The AI classified 38% of cases as suspicious (31.1% in screening and 58% in clinical patients; $p < 0.0001$). Meanwhile, radiologists classified 20% of cases as suspicious (22% in screening vs 13% in clinical; $p < 0.0001$).
In the global analysis, AI sensitivity was 87.9%, with limited specificity (63.9%), with 64.4% accuracy. Radiologists showed 91.3% sensitivity, with significantly higher specificity (86.3%), overall precision (86.5%), and agreement with the reference standard (kappa = 0.20 vs. 0.06 for AI).
Stratified analysis showed that AI performed better in screening (sensitivity 94.3%, specificity 70.1%) than in clinical settings (sensitivity 84.6%, specificity 43.4%). In clinical cases, radiologists achieved 98% sensitivity and 81.2% specificity (kappa = 0.27), outperforming AI across all measures. All comparisons between AI and radiologists were statistically significant ($p < 0.0001$).
Conclusion: AI demonstrated robust performance in screening settings. However, its limited specificity and lower accuracy in clinical scenarios highlight the need for substantial improvements before it can match expert radiologist diagnosis.
Limitations: Retrospective

Screen-detected high-risk lesions of the breast: adherence to surveillance and probability of breast cancer development (6 min)

Eline Leontine Van Der Veer; Krimpen aan den IJssel / Netherlands

Author Block: E. L. Van Der Veer[1], A. Bluekens[1], A. M. P. Coolen-Janssen[1], W. Vreuls[2], A. Voogd[3], L. Duijm[2]; [1]Tilburg/NL, [2]Nijmegen/NL, [3]Maastricht/NL
Purpose: The prevalence of breast lesions of uncertain malignant potential, commonly referred to as high-risk lesions (HRLs), detected at screening mammography is increasing, which stresses the importance of the recently published guidelines on their management. In this study, we present the incidence, upgrade rate, adherence, and follow-up outcomes in a screened population.
Methods or Background: A total of 17,809 recalled women, who took part in the Dutch screening program between January 2009 and July 2019, were included in this retrospective analysis of a prospectively obtained database. A HRL was identified in 537 recalled women and their incidence rate, diagnostic work-up and follow-up, and any upgrade to (pre)malignancy after surgical excision and during follow-up were examined.
Results or Findings: The incidence rate of HRLs was 0.87 per 1,000 screens and 3.02 per 100 recalls. The majority of HRLs consisted of papillary lesions (32.4%) and atypical ductal hyperplasia (ADH) (21.6%). Surgical excision was performed for 254 (47.3%) of the 537 HRLs, resulting in 59 (23.2%) HRLs being upgraded to (pre)malignancy. Invasive tumors were mainly found in papillary lesions with atypia (n=9/17) and ADH (n=6/17). Of the women diagnosed with an HRL, 60.7% had an indication for radiologic follow-up. Of these women, 79.1% actually underwent follow-up with 43.0% undergoing 5-year surveillance. During follow-up, 28 (10.9%) of the women with an HRL developed a (pre)malignancy.
Conclusion: Of women with screen-detected HRLs, 16.2% developed breast cancer, either after surgical excision or during follow-up. Less than half of the women completed the 5-year surveillance, highlighting the importance of continued attention to obtain maximal follow-up adherence.
Limitations: ADH diagnosis varies between observers due to its similarity to low-grade DCIS, with biopsy type and sample size affecting outcomes. Some subgroups were too small for comparison with guidelines.
Funding for this study: This research did not receive any funding.

Factors that impact upon mammographic interpretation: differences between Radiography Advanced Practitioners and Radiologists caution against inter-cohort generalisations (6 min)

Patrick Brennan; Sydney / Australia

Author Block: N. F. Clerkin[1], C. Ski[1], P. Brennan[2], R. M. Strudwick[3]; [1]Belfast/UK, [2]Sydney/AU, [3]Ipswich/UK
Purpose: Radiography Advanced Practitioners (RAPs) have interpreted mammograms in the United Kingdom since 1995 (1). Evidence on factors influencing RAP diagnostic performance remains limited. This study aimed to identify reader and image-based factors affecting RAP performance in mammography interpretation.
Methods or Background: The research comprised of three components. First, a systematic literature review, identifying 38 studies on performance variation in mammography. Second, experimental work which involved 18 UK based RAPs interpreting 60 cloud hosted mammograms with known truth; results were analysed against reader characteristics. Third, a comparative observer study focussed on factors that impact performance, RAPs (n=18) and radiologists (n=24) interpreted the same cases. Difficulty indices were calculated for all cases using an established methodology and causal agents influencing performance were explored.
Results or Findings: The review highlighted a paucity of RAP specific performance data. A range of findings included, higher ROC values with: less compared with more than 10 years' experience (p=0.004); more compared with less than 100 cases read per week (p=0.036); consistent rather than sporadic use of prior mammograms (p=0.0231); recent rather than distant eye testing (p=0.021). Specificity was lower amongst RAPs who stated their emotional mindset impacted their reading (88) compared to those who did not (66.5) (p=0.034). Strong correlations were found between RAPs and radiologists for cases with specific levels of difficulty (cancer: r = 0.83; normal: r = 0.73), uniquely to RAPs, soft tissue cancers compared with calcifications as well as cases without prior images were more challenging.
Conclusion: For the first time, factors that impact performance of RAPs have been identified. Whilst some factors are common for radiologists and RAPs, some are unique, suggesting that extending findings to both must be done with caution.
Limitations: Limitations included questionnaire responses and gender representation.
Funding for this study: None
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Ethical approval was gained from the University of Suffolk Post Graduate Research Committee on the 14th of January 2022 (RETH(P)21/006) .
NHS Ethical considerations were achieved through the NHS Health Research Authority (HRA). The HRA confirmed no Research Ethics Committee review was required.
Ethical exemption was also provided by the University of Sydney to include radiologist performance data in the study.

Adaptive Training of Breast Screening Readers Using Bayesian Intelligent Algorithms (6 min)

Sarah Jayne Lewis; Penrith / Australia

Author Block: P. D. (. Trieu, M. Dimigen, M. Barron, S. Lewis; Sydney/AU
Purpose: To explore the effectiveness of an intelligent, adaptive training approach based on Bayesian methodology for improving diagnostic performance among breast screening readers using training test sets.
Methods or Background: Seven breastscreen readers, including radiologists, breast physicians, and radiology trainees, participated in adaptive training sessions using the BREAST screening mammogram database which comprised 1,753 test set completions by 618 breast screening readers. Training was delivered on the BREAST (Breastscreen-REader-Assessment-STrategy) platform. The newly developed AI-driven Bayesian algorithm dynamically selected normal and cancer cases tailored to each reader's current performance level. Training continued until each reader achieved a diagnostic threshold of ≥90% in both sensitivity and specificity, or ROC AUC. Readers' performance before and after training was compared using the Wilcoxon signed-rank test.
Results or Findings: All readers reached the performance goal after 2 to 5 training sessions over the period from 3 to 6 months. Statistically significant improvements were observed in key diagnostic metrics, including overall case sensitivity (from 0.822±0.079 to 0.943±0.044; P=0.015), lesion-level sensitivity (0.764±0.103 to 0.886±0.073; P=0.043), ROC AUC (0.861±0.029 to 0.935±0.034; P=0.016), and JAFROC (0.082±0.038 to 0.895±0.049; P=0.018). The improvement in sensitivity was consistent across various breast density levels and lesion types, including irregular masses, calcifications, and small lesion sizes (15%-to-18%; P<0.05).
Conclusion: This study demonstrates that an AI-based Bayesian adaptive training algorithm effectively enhances breast image interpretation performance. The personalized selection of training cases significantly improved diagnostic accuracy across multiple performance metrics and lesion characteristics. These findings support the integration of intelligent, adaptive training models into breast screening education to optimize reader performance and diagnostic outcomes.
Limitations: Although the number of participating readers is currently limited, the study is ongoing with additional readers being recruited. Expanded data and updated results will be presented at the conference.

Participation of the transgender population in breast and prostate cancer screening (6 min)

Teresa Jezek; Vienna / Austria

Author Block: T. Jezek[1], A. Beck-Toelly[1], N. Miłecki[1], N. Ailec[1], N. Pötsch[1], A. D'Angelo[2], P. A. Baltzer[1], T. H. Helbich[1], P. Clauser[1]; [1]Vienna/AT, [2]Rome/IT
Purpose: The objective of the study was to assess the participation of the transgender (TG) population in breast and prostate cancer screening programs.
Methods or Background: This retrospective, monocentric study was approved from the local ethics committee. All transgender patients attending the dedicated local clinic were included. Data on breast imaging examination and prostate specific antigen (PSA) controls were retrieved by three investigators from the local information system. Exclusion criteria were lack of data in the system, no hormonal therapy. Data retrieved were type and duration of the hormonal therapy, family history for breast and prostate cancer, personal history of breast or prostate cancer and previous PSA and mammography exams. Descriptive statistics was used to present the data.
Results or Findings: To date, 750 TG individuals have been evaluated (mean age 34.7, standard deviation SD 16.9; 389 TG male and 361 TG female). 68 had a positive family history for breast or ovarian cancer (9.1%), and 16 (2.1%) for prostate cancer. Only one individual with a personal history of breast cancer was identified (TG male). Of the 209 individuals above 40 years old (mean age 53.6, SD 9.5), only 13 (one TG male, 12 TG female) participated in mammography screening (6.2%). Among the 126 TG females, 50 underwent a PSA test (39.7%). No breast or prostate cancers were diagnosed during or after the transition.
Conclusion: Our findings show a very low participation in breast cancer screening among the TG population, even in individuals with a positive family history. Participation in prostate cancer testing was higher, most likely because it is conducted through a simple blood test. This indicates a widespread lack of awareness regarding available screening programs and their relevance.
Limitations: Retrospective study involving many patients with incomplete data.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the local ethics committee (1183/2023).

Radiofrequency-Based Imaging for Breast Screening: Interim Analysis Results from MammoScreen Clinical Trial (6 min)

Gianluigi Tiberi; Perugia / Italy

Author Block: G. Tiberi[1], D. Álvarez Sánchez-Bayuela[2], N. Ghavami[1], R. Loretoni[1], T. Frauenfelder[3], C. Alves[4], M. A. B. Álvarez Benítez[5], M. Calabrese[6], A. S. Tagliafico[6], J. Lubinski[7], C. Romero Castellano[2]; [1]Perugia/IT, [2]Toledo/ES, [3]Zürich/CH, [4]Lisbon/PT, [5]Córdoba/ES, [6]Genoa/IT, [7]Szczecin/PL
Purpose: To present interim results of the study “A Clinical Investigation to Evaluate Microwave Imaging via MammoWave in a Population-based Screening Program for Early Breast Cancer (BC) Detection” (ClinicalTrials.gov ID:NCT06291896), activated within HORIZON-MISS-2021-CANCER-02-01 scheme.
Methods or Background: Women undergoing routine screening mammograms were invited to join the study. After providing informed consent, participants underwent microwave breast imaging using MammoWave. MammoWave’s output was automatically labelled by an artificial intelligence (AI) model (based on hierarchical machine-learning approach), classifying each breast as “NSF” (no-suspicious findings, no lesion or lesion with low suspicion) or “WSF” (with-suspicious findings, indicating presence of a suspicious lesion). MammoWave’s results are compared to a reference standard, defined as the outcome of the conventional breast examination pathway—including histological confirmation—with a two-year follow-up. Reference standard will be classified as ‘positive’ when BC is confirmed by histology, and ‘negative’ otherwise. Primary outcomes are sensitivity/specificity of MammoWave’s AI model in BC detection.
Results or Findings: We report findings from the first 3,000 volunteers enrolled at 9 hospitals across 5 European countries. The interim analysis was performed on 5,896 breasts (12 ‘positive’ cases), from 2,967 subjects included in full analysis set population (mean age 57.2 years±7.5 [SD]). This interim analysis allowed us to evaluate AI model’s performance, with 42% sensitivity [95%CI:13.8-69.6] and 75% specificity [95%CI:74.1-76.3]. We proceeded to update AI model by fusing information of hierarchical machine-learning approach and statistical classifiers. Updated AI model allowed us to (retrospectively) reach: 67% sensitivity [95%CI:29–99] (80% in dense breasts [95%CI:45–99]); 81% specificity 95%CI:79.2-83.2] (80% in dense breasts [95%CI:77–83]).
Conclusion: MammoWave’s AI model demonstrates promise in breast cancer screening, particularly in terms of specificity; sensitivity requires further optimization. Final results of this trial on 10,000 volunteers will provide more insights.
Limitations: Non-randomized design; small cancer sample size.
Funding for this study: This work was supported by the funding received by the MammoScreen project, co-funded by the European Union’s Horizon research and innovation framework programme, Grant agreement 101097079.

Breast Arterial Calcifications on Mammography as a Surrogate Marker for Coronary Artery Disease in Women Aged 40–50 Years: A TriNetX Database Study (6 min)

Vivek Batra; Rochester, New York / United States

Author Block: V. Batra, J. Harvey; Rochester, New York, NY/US
Purpose: Breast arterial calcifications (BAC) on mammography are frequently underreported. Growing evidence suggests that BAC correlate with coronary artery disease (CAD) and may serve as a surrogate marker of cardiovascular risk in women undergoing routine breast cancer screening. In women without a known history of cardiovascular disease, consistent recognition and reporting of BAC could facilitate early risk stratification and preventive intervention.
Methods or Background: Using the TriNetX database, we conducted a retrospective analysis of women aged 40–50 years who underwent screening mammography, identified through ICD-10 codes. We quantified the total number of screening exams, the proportion with reported calcifications, and the subset of patients with documented CAD. We also examined the potential underestimation of BAC prevalence due to their frequent classification as BI-RADS 1 (negative) rather than BI-RADS 2 (benign findings).
Results or Findings: Across 109 U.S. healthcare organizations, 6,783,908 screening mammograms were performed in women aged 40–50 years. Of these, 2,396,182 examinations were reported as abnormal or inconclusive. A total of 6,070,184 women in this age group had a diagnosis of CAD. The intersection of women with both BAC and CAD included only 4,420 patients—substantially lower than expected—suggesting significant underreporting likely related to BI-RADS coding variability.
Conclusion: Coronary artery disease remains the leading cause of death among women in the United States. The inconsistent reporting of vascular calcifications on mammography may obscure an important opportunity for early cardiovascular risk detection. Standardizing the reporting of BAC as BI-RADS 2 could enhance identification of subclinical atherosclerosis and support earlier, targeted cardiovascular prevention in women without known heart disease.
Limitations: This study is limited by its retrospective design and reliance on ICD-10 coding within the TriNetX database, which may lead to underreporting or misclassification of vascular calcifications and coronary artery disease.
Funding for this study: None

AI-Enabled Detection of Breast Arterial Calcifications in Mammography: Diagnostic Performance and Impact of Image Quality in a Large Real-World Screening Population (6 min)

Jonathan Sänger; Zurich / Switzerland

Author Block: J. Sänger[1], J. Happe[1], A. Dudle[2], C. Ruppert[2], A. Weber[3], A. Ciritsis[2], T. Frauenfelder[1], A. Boss[3]; [1]Zürich/CH, [2]Zurich/CH, [3]Wetzikon/CH
Purpose: To determine the prevalence of breast arterial calcifications (BAC) in a large cohort of opportunistic mammography breast cancer screening using artificial intelligence (AI) and to highlight both their potential diagnostic overlap with grouped microcalcifications and their role as an opportunistic biomarker for cardiovascular risk assessment.
Methods or Background: This retrospective study included 4692 women who underwent a total of 6,061 mammographic examinations with a total of 24,519 mammographic images between 2011 and 2017 at a tertiary centre. A YOLO-based object detection algorithm was trained on standard mammographic projections (CC and MLO) to detect and differentiate BAC and non-vascular calcifications, assigning BI-RADS categories to the latter.
Results or Findings: BAC was found with AI-based analysis in 652 of 4,692 women (13.9%, 95% CI 12.9–14.9). Among 6,061 individual examinations, BAC were present in 800 (13.2%, 95% CI 12.4–14.1). Considering all 24,519 mammographic images, BAC was detected in 1,644 images (6.7%, 95% CI 6.4–7.0). At the time of the first mammogram, BAC-positive woman had a mean age of 66.6 ± 10.9 years, whereas those without BAC had a mean age of 56.3 ± 11.3 years ($p < 0.001$).
Conclusion: Artificial intelligence applied to mammography revealed that one in seven women has BAC. Early BAC can be challenging to distinguish from suspicious grouped microcalcifications, and systematic AI-based screening during routine breast imaging may aid differentiation. Moreover, BAC recognition is clinically relevant as it correlates with CAC and cardiovascular risk. Embedding automated BAC detection into established breast cancer screening programmes may therefore provide a low-cost, scalable opportunity for opportunistic cardiovascular risk assessment, with the potential to enable earlier identification of women at risk and contribute to risk reduction.
Limitations: The limitations of the study are the retrospective design and the single-centre setting.
Funding for this study: Funding was provided by the Swiss Cancer League (KFS-5524-02-2022) and the Clinical Research Priority Program “Artificial Intelligence in oncological Imaging” of the University of Zurich.

Novel Deep Learning-Reconstructed cardiac susceptibility-weighted imaging for early prediction of Intramyocardial hemorrhage and functional recovery after acute myocardial infarction (6 min)
Shiwei Lai; Guiyang / China

Author Block: S. Lai; Guiyang/CN
Purpose: To evaluate the diagnostic value of a novel approach combining 3.0T cardiac Susceptibility-Weighted Imaging (SWI) with a deep learning reconstruction algorithm (DeepRecon) for the early detection of intramyocardial hemorrhage (IMH) following reperfusion in acute myocardial infarction (AMI). A further objective was to investigate the correlation between quantitative SWI parameters and subsequent functional recovery.
Methods or Background: This prospective study enrolled 50 AMI patients (32 men, 18 women; age 58±9) post-emergency PCI. Cardiac MRI was performed within 72 hours post-reperfusion, including a respiratory- and cardiac-gated 3D GRE SWI sequence. Images were reconstructed using the DeepRecon model for noise suppression and resolution enhancement. LGE defined infarct area, T2-mapping assessed edema, and Cine imaging measured function.
Two blinded radiologists analyzed SWI images to identify hypointense foci (IMH), measure hemorrhage volume, and quantify susceptibility values, using LGE as the reference standard.
Statistical analyses employed: McNemar's test (detection rates), t-test/Mann-Whitney U test (continuous variables), ROC analysis (AUC/sensitivity/specificity), ICC/Cohen's kappa (agreement), and Pearson correlation (hemorrhage volume vs. LVEF recovery).
Results or Findings: Detection: SWI+DeepRecon IMH rate: 68% (34/50) vs. T2* 44% (22/50) (P=0.002).
Diagnostic Performance (vs LGE): Sensitivity 94.1%, Specificity 93.8%, AUC 0.96 (0.91–0.99) vs. conventional SWI AUC 0.82 (0.74–0.89).
Quantification: IMH susceptibility: 0.27±0.08 ppm vs. remote 0.05±0.03 ppm (P<0.001).
Prognosis: IMH volume □ strongly correlated with 90-day LVEF recovery (r=-0.73, P<0.001).
Quality/Agreement: SNR ↑41% (28.4±3.6 vs. 20.1±2.9; P<0.001); Inter-observer ICC 0.92 (vs. 0.75), κ=0.87.
Conclusion: Deep learning-reconstructed cardiac SWI significantly enhances early IMH detection sensitivity post-AMI. Quantitative susceptibility mapping enables hemorrhage severity assessment, while IMH volume demonstrates a strong negative correlation with functional recovery (r=-0.73, P<0.001). This approach provides a validated imaging biomarker for early risk stratification and personalized management in reperfused AMI.
Limitations: Moderate sample size; requires longitudinal validation.

Cardiac MRI-based investigation of the protective effects of epigallocatechin-3-gallate on ventricular remodeling after myocardial infarction in rats (6 min)
Qi Zhu; Chengdu / China

Author Block: Q. Zhu, L. Wang, F. Gao; Chengdu/CN
Purpose: To explore the Value of Magnetic Resonance-Tagging for Assessing the Effect of Epigallocatechin Gallate (EGCG) on Ventricular Remodeling in Rats after Myocardial Infarction-Induced Heart Failure.
Methods or Background: Fifty male SD rats were randomly divided into four groups: the control group (8 rats), the MI group (14 rats), the EGCG group (14 rats), and the ARB group (14 rats). Excluding the control group, the remaining groups underwent coronary artery ligation to establish a rat model of heart failure. Two weeks after surgery, the ARB group and the EGCG group were gavaged with corresponding drugs for 28 days, while the control group and the MI group were gavaged with an equal volume of physiological saline. Cardiac magnetic resonance cine sequences were scanned at two weeks and six weeks. Perform strain analysis to determine the protective effects of EGCG on ventricular remodeling in a rat model of post-infarction heart failure.
Results or Findings: Compared with the control group, the MI group showed a significant decrease in left ventricular ejection fraction (LVEF) and overall strain parameters at 6 weeks postoperatively, while the ARB group and the EGCG group exhibited improvements in LVEF, Circumferential, longitudinal, and radial strains relative to the MI group. In addition, histological analysis showed reduced myocardial injury and fibrosis in the ARB and EGCG groups compared with the model group.
Conclusion: The feasibility and diagnostic value of MR-FT for dynamic monitoring of a rat model of post-infarction heart failure were investigated, and the effects of EGCG on ventricular remodeling in these rats were assessed.
Limitations: Although a longitudinal study was conducted to examine the effects of different intervention time points on cardiac function in rats, additional observation time points were not added for more comprehensive monitoring.

Left Ventricular Ejection Fraction Partially Mediates the Relationship Between Myocardial Replacement Fibrosis and Sudden Cardiac Death Post Myocardial Infarction (6 min)

Kaisaierjiang·aisikaier Aisikaier; Beijing / China

Author Block: K. Aisikaier, P. Zhou; Beijing/CN
Purpose: To evaluate the potential mediating role of left ventricular ejection fraction (LVEF) in the relationship between replacement fibrosis (assessed by late gadolinium enhancement (LGE)) and sudden cardiac death (SCD) in patients post-myocardial infarction (MI), and also to assess this mediation effect in subgroups based on LVEF≤35% and>35% according to implantable cardioverter-defibrillator (ICD) selection criterion.
Methods or Background: A retrospective analysis was conducted on 917 post-MI patients (mean age: 56.3±11.0 years, 88.8% male) who underwent cardiac MR from January 2017 to August 2021. The endpoint for SCDs included SCD, aborted SCD, and appropriate ICD discharges. The association of LGE with LVEF was quantified using linear regression models. The associations of LGE and LVEF with SCDs were evaluated using competition risk models. Mediation analysis was then used to decompose the total effect of LGE on SCDs into direct and indirect (mediated through LVEF) effects using accelerated failure time models.
Results or Findings: Over a median follow-up of 63.3 (IQR, 43.6 to 76.6) months, 65 patients (7.1%) experienced SCDs. LGE was significantly associated with lower LVEF (β=-0.35, $p<0.001$). Both LGE and LVEF independently predicted SCDs (sHR=1.06, $p<0.001$; sHR=0.95, $p=0.03$, respectively). Mediation analysis showed that LVEF accounted for 19.7% of the total effect of LGE on SCDs ($p<0.001$). This mediation effect was 40.4% in patients with LVEF>35% ($p=0.02$), while no mediation was observed in patients with LVEF≤35% ($p=0.08$).
Conclusion: LVEF partially mediated the effect of LGE on the SCD, accounting for less than one-fifth of the total effect. LVEF alone inadequately captured the whole SCD risk, irrespective of whether LVEF is greater than 35% or 35% or less.
Limitations: Due to the retrospective nature of the study, the interval between the last MI and CMR varied, which may introduce selection bias.
Funding for this study: This study is supported by the National Key R&D Program of China (Nos. 2021YFF0501400 and 2021YFF0501404), the Key Project of National Natural Science Foundation of China (No. 82430066), and the China International Medical Foundation (No. Z-2014-07-2101).

Effect of metabolic syndrome on left and right ventricular deformation and myocardial energetic efficiency in patients with myocardial infarction: a 3.0T CMR study (6 min)

Jing Liu; Chengdu / China

Author Block: J. Liu, L. Peng, Y. Zhigang; Chengdu/CN
Purpose: To investigate the effects of metabolic syndrome (MetS) on left and right ventricular (LV and RV) deformation and myocardial energetic efficiency (MEE) in patients with myocardial infarction (MI) using cardiovascular magnetic resonance-feature tracking (CMR-FT).
Methods or Background: A total of 194 MI patients (85 MetS+ and 109 MetS-) and 140 age- and gender-matched controls (70 MetS+ and 70 MetS-) who underwent 3.0T CMR examination were included. CMR-derived RV and LV strains, sphericity index, global function index (LVGFI), and indexed MEE (MEEi) were assessed among the groups. Multivariate linear regression analysis was used to evaluate the independent determinants of RV and LV CMR parameters.
Results or Findings: There was no interaction between MetS and MI on the RV and LV changes ($P > 0.05$). The main effect of MetS indicated that compared with MetS-individuals, RV and LV deformation, LVGFI, and MEEi in MetS+ individuals were decreased ($P < 0.05$), while the effect of MetS on LVEF, RVEF and sphericity index was not significant ($P > 0.05$). Compared with controls, the MI patients showed impaired RV and LV function, MEEi and higher LV sphericity index. Linear regression analysis indicated that after adjusting for gender, age, heart rate, smoking, each component of MetS or right coronary artery occlusion, MetS was associated with the LV and RV circumferential strains and MEEi in MI patients (β = -0.165, -0.235, and -0.154, all $P < 0.05$). In addition, the RV strians were independently correlated with the LV strians, RVESV, LVESV and inferior MI (all $P < 0.05$).
Conclusion: MetS may further damage the LV and RV deformations and myocardial energetic efficiency in MI patients. CMR-FT can identify subclinical cardiac dysfunction impairment in patients with MetS before RVEF and LVEF decline.
Limitations: Cross-sectional study

Cardiac Spectral PCCT Radiomics and Clinical Data for Optimizing Cath Lab Triage in ACS (6 min)

Ulrich Schmid; Tübingen / Germany

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: U. Schmid, A. S. Brendlin; Tübingen/DE
Purpose: Many ACS patients undergo cardiac CT and same-day catheterization, yet only a subset require stenting, leading to possible resource overuse. Photon-counting detector CT (PCCT) provides unique spectral data. We evaluated five classification approaches: clinical data alone (C), radiomics from mixed (M) or spectral high/low energy bins (HL), and early fusion of clinical with mixed (CM) or spectral (CHL) data. We hypothesized PCCT's inherent informational gain could enhance resource stratification.
Methods or Background: We retrospectively analyzed PCCT cardiac scans from 96 patients undergoing same-day catheterization (15 stented). Clinical data and radiomics from automated AHA myocardial segments (Syngo.via) entered an identical ML pipeline: SMOTETomek, StandardScaler, sequential feature selection (univariate, XGBoost importance, ElasticNet, correlation filtering, RFECV), and an XGBoost classifier with BayesSearchCV tuning. Performance was assessed on a held-out test set via Matthews Correlation Coefficient (MCC), with Bayesian (posterior distributions, BFs, HDIs) and frequentist (bootstrap, adj. p) comparisons.
Results or Findings: Clinical data (C) alone was limited (MCC: 0.427, HDI [0.321–0.530]). Radiomics-only spectral (HL: MCC 0.726, HDI [0.617–0.826]) outperformed mixed (M: MCC 0.513, HDI [0.393–0.626]), confirmed by frequentist ($P<0.001$) and Bayesian analyses (BF10=2.56). Fused models performed best: CHL (MCC 0.966, HDI [0.929–0.996]) and CM (MCC 0.954, HDI [0.911–0.991]). Bayesian comparisons showed CHL superior to C, M, and HL (BF10>100) but not decisively over CM (Δ=0.012, HDI [−0.049–0.069]; BF10=0.04, P=0.737).
Conclusion: Clinical data alone is insufficient. Spectral radiomics outperform mixed, and fusion (CM, CHL) markedly improves classification. Fusing clinical with spectral radiomics shows highest accuracy, supporting optimized post-CT stratification and cath lab triage.
Limitations: Retrospective single-center design, small cohort, and vendor-specific PCCT/AID implementation. Radiomics extraction and ML pipeline choices may limit generalizability. Clinical endpoints were surrogates without outcome validation. Findings require external validation across centers, scanners, algorithms, and larger populations.

The zero that misleads: severe coronary arteries disease despite an Agastone score of zero– a retrospective imaging study (6 min)

Simona Bobric; Iasi / Romania

Author Block: S. Bobric, M-L. BAEAN, L. Gheorghe; Iasi/RO
Purpose: The calcium score plays a crucial role in identifying and assessing coronary artery disease (CAD). However, soft plaque lesions—less common and often overlooked—are not captured by the Agatston calcium score. In this context, multidetector computed tomography angiography (MDCT) is essential, providing detailed visualization of both calcified and non-calcified coronary plaques.
Methods or Background: This study aims to evaluate the clinical and imaging significance of severe coronary artery lesions in patients with minimal or zero Agatston calcium scores, which may lead to an underestimation of cardiovascular risk. We retrospectively analyzed 320 coronary CT angiography scans performed between January and August 2025 at the ScanExpert Medical Imaging Center in Iași, using a 256-slice dual-source CT scanner, in patients aged 45 to 75 years. Imaging findings were correlated with clinical data and compared with existing literature. In selected cases, non-invasive fractional flow reserve computed tomography (FFR-CT) was used to assess the functional significance of detected lesions.
Results or Findings: Of the 320 patients evaluated, 188 (58.7%) had calcified plaques, 70 (21.9%) had mixed plaques, and 42 (13.1%) had soft plaques. Soft plaques were further classified into clinically significant and silent lesions. A subset of patients underwent FFR-CT to evaluate the hemodynamic relevance of intermediate or uncertain lesions.
Conclusion: The Agatston calcium score is an important indicator of coronary artery disease, but it does not capture the full spectrum of coronary pathology. Severe coronary lesions, classified as CAD-RADS 4 or 5 (Coronary Artery Disease), may be present despite low or absent calcium scores. Early and comprehensive diagnosis using MDCT and functional assessment with FFR-CT can guide appropriate treatment and potentially reduce complications. Regardless of the treatment approach, a thorough evaluation of the coronary arteries is essential.
Limitations: No major limitations were identified.
Funding for this study: It was not necessary.

Diagnostic performance of a coronary CT angiography-based Deep Learning Model for the prediction of vessel-specific ischemia (6 min)

Benjamin Peters; Schilde / Belgium

Author Block: B. Peters[1], R. Symons[2], A. Nchimi Longang[3], O. Ghekiere[1]; [1]Schilde/BE, [2]Olv-Waver/BE, [3]Strassen/LU
Purpose: Intracoronary pressure measurement is the standard of care for assessing vessel specific ischemia of coronary stenosis. New techniques using artificial intelligence emerge to compute Fractional Flow Reserve(FFR) based on coronary computed tomography angiography(CCTA) images(FFRAI).
We assess a new FFRAI Deep Learning Model for the prediction of vessel specific ischemia compared to two validated invasive physiological measurements.
Methods or Background: We retrospectively selected 322 vessels from 275 patients at two different centers who underwent CCTA and intracoronary catheter measurements with FFR or instantaneous wave-free ratio(iFR) within three months. Two radiologist at each center generated curvilinear reformats of each coronary artery for FFRAI≤0.80 prediction. Sensitivity, specificity, positive predictive value(PPV), negative predictive value(NPV) and diagnostic accuracy of FFRAI were calculated using FFR≤0.80(n=224) and iFR≤0.89(n=238) as standards of reference. Radiologists' concordance was assessed with Cohen's κ. A multinomial logistic regression model including all FFRAI false-positive and false-negative was built to evaluate the influence of patient- and CCTA-related parameters on the diagnostic value of FFRAI.
Results or Findings: Sensitivity, specificity, PPV, NPV, and diagnostic accuracy of FFRAI in predicting FFR≤0.80 and iFR≤0.89 were 85%(58/68) and 91%(78/86), 82%(128/156) and 78%(119/152), 67%(58/86) and 70%(78/111), 93%(128/138) and 94%(119/127), and 83%(186/224) and 83%(197/238), respectively. Concordance between senior and junior radiologists' supervision was substantial(κ=0.725,P<0.001). Calcium score of the stenotic vessel has a significant detrimental effect (p<0.001;OR,1.002;95%CI1.001–1.003) on the diagnostic value of FFRAI.
Conclusion: FFRAI has a high diagnostic performance and reliability for the diagnosis of vessel specific coronary ischemia compared to two intracoronary catheter assessments. Missed FFRAI diagnoses were associated with coronary calcifications.
Limitations: Retrospective design.
CT-FFRAI relies on manually adjusted cMPR images, introducing susceptibility to user,.
CT-FFRAI uses a dichotomous outcome with a threshold of 0.80, which overlooks clinical information pertaining to lesions in the grey-zone.

Patterns in Use of Diagnostic Imaging and Initiation of Medical and Revascularisation Therapies for Patients with Suspected Chronic Coronary Syndrome in the Contemporary Era (6 min)

Makiko Takeichi; Osaka / Japan

Author Block: T. Kido[1], H. Taniguchi[2], M. Takeichi[2], H. Fujii[3], T. Fujioka[2], N. Fujikawa[2], T. Yamada[2], S. Okami[2], S. Kohsaka[3]; [1]Toon, Ehime/JP, [2]Osaka/JP, [3]Tokyo/JP
Purpose: Purpose: For patients with suspected chronic coronary syndrome (CCS), selecting appropriate imaging examinations is crucial for accurate diagnosis and improved outcomes. Advancements in CCTA technology, such as higher resolution and lower radiation doses, have led to new guideline recommendations and changes in reimbursement. However, comprehensive analyses of patient trajectories and practice shifts in the contemporary era have been scarcely studied. The JOURNEY study aims to elucidate these patterns of imaging, medication, and revascularization in real-world settings.
Methods or Background: Methods: The JOURNEY study is a retrospective observational study utilising Japanese hospital administrative database provided by Medical Data Vision Co., Ltd. Patients aged ≥40 years who underwent their first imaging examination (i.e., CCTA, SPECT or CAG) for suspected CCS between 01 March 2015 and 31 January 2023 were included. Patients were followed from the date of their first imaging examination to Day 90. Multivariate logistic regression analysis was performed to examine factors associated with the use of CCTA.
Results or Findings: Results: A total of 123,050 patients with suspected CCS were included. The mean age was 70.0 (SD 10.7) years, and 56.2% were male. CCTA was the first imaging examination for 61.2% of patients, followed by SPECT (19.7%) and CAG (19.1%). Among the patients, 15.7% required the second imaging examination. By Day 90, 20.7% initiated antiplatelet therapy, 17.4% were confirmed to have CCS, and 9.0% received revascularization therapy. Recently enrolled patients underwent CCTA more often than those enrolled earlier (index year 2021-2023 versus 2015-2017, adjusted OR: 1.48 [95% CI: 1.43-1.53]).
Conclusion: Conclusion: CCTA was the most commonly performed initial imaging examination for suspected CCS, with increased usage in recent years.
Limitations: Limitations: The MDV data, collected for reimbursement rather than research, may introduce biases in data accuracy and representativeness.
Funding for this study: Funding was provided by Bayer AG (Leverkusen, Germany).

Introducing a new score to quantify the distribution of coronary artery calcification based on coronary CT angiography (6 min)

Márk Di Giovanni; Budapest / Hungary

Author Block: M. Di Giovanni, L. Száraz, S. Beke, K. Nagy, N. Nagy, H. Balogh, S. Veres, J. Simon, P. Maurovich-Horvat; Budapest/HU
Purpose: The coronary artery calcium score (CACS) is an independent predictor of mortality. However, CACS does not provide information on the spatial distribution of calcified plaques. The aim of the present study is to determine the predictive value of the coronary calcium entropy score proposed by our research group taking into account the distribution of calcified plaques regarding the need for further testing after coronary CT angiography (CCTA).
Methods or Background: We retrospectively included consecutive patients who underwent CCTA for suspected coronary artery disease (CAD). We used multivariate logistic regression to fit three diagnostic models. Model 1 included clinical data (age, gender, type of angina, heart rate, and rhythm), which was augmented by CACS (Model 2) and CACS and calcium entropy score (Model 3). Chi-squared test was used to compare the models.
Results or Findings: After exclusion, data from 325 patients was analyzed (35.1% female, 63.7±10.6 years); 55 patients (16.8%) were recommended for further testing. For the clinical parameters (Model 1), presence of arrhythmia significantly increased the likelihood of further investigation. For Model 2, a CACS greater than 100 was a significant predictor (101-400: p=0.029, 401-1000: p=0.02, >1000: p<0.001). When supplemented with the calcium entropy score (Model 3), even a moderately high entropy score (>33th pc) was found to be a significant predictor (34th-66th percentile: p=0.034, >67th percentile: p=0.003). Overall, Model 3 significantly outperformed Model 2 (p<0.001).
Conclusion: The coronary calcium entropy score was found to be a significant predictor of the need for further testing following CCTA beyond clinical data and CACS. Based on our results, the formula developed for the distribution of calcified plaques may have a potential role in the investigation of CAD.
Limitations: This was a single-center study with a retrospective study design.
Funding for this study: M.D.G. received a Research Excellence Grant from Semmelweis University (EFOP-3.6.3-VEKOP-16-2017-00009) and was supported by the New National Excellence Program of the Ministry of Innovation and Technology of Hungary (ÚNKP-23-2-III-SE-43).
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The study was approved by the Scientific and Research Ethics Committee of the Hungarian Medical Research Council (IV/665-3/2022/EKU) and was carried out in accordance with the tenets of the Declaration of Helsinki.

Assessment of Left Ventricular Function with Reduced Phase Cardiac CT Reconstructions: Preliminary Results from the CT-STEMI Study (6 min)

Marta Moretti; Torino / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: M. Moretti[1], F. Troise[2], A. Maiorana[1], L. Blasi[1], D. Verna[1], T. D'Angelo[3], M. Olivieri[4], R. Faletti[1], M. Gatti[1]; [1]Torino/IT, [2]Bari/IT, [3]Messina/IT, [4]Chieti/IT
Purpose: To evaluate the agreement between cardiac computed tomography (CCT) and cardiac magnetic resonance (CMR) in assessing left ventricular (LV) function in post-STEMI patients, and to investigate the impact of CCT acquisitions on restricted R–R intervals, with a view toward potential prospective protocols.
Methods or Background: Forty-eight patients (mean age 62 ± 11 years, 87.5% male) were prospectively enrolled in the multicenter CT-STEMI study (NCT05941585, November 2023 – October 2024). Patients were randomized to undergo either CCT or CMR at 6.8 ± 1.8 days after STEMI, followed by the complementary exam within 5.3 ± 2.8 days. LVEDV, LVESV, and LVEF were measured using CVI42 software. The inclusion of true systolic and diastolic phases was assessed across 40–80%, 30–90%, and 30–100% R–R ranges, along with their corresponding functional estimates.
Results or Findings: Full-cycle CCT demonstrated excellent concordance with CMR (LVEF: 46 ± 11% vs 45 ± 10.9%, p=0.40). The 40–80% interval included 26/48 systolic and 2/48 diastolic phases, with a mean LVEF underestimation of –8.7% (p<0.0001). The 30–90% interval captured all systolic but only 5/48 diastolic phases, leading to an underestimation of –3.4% (p<0.0001). The 30–100% range consistently included both systolic and diastolic phases in all patients (48/48), providing functional measurements comparable to CMR.
Conclusion: CCT shows high agreement with CMR in the evaluation of LV function. However, a 40–80% acquisition window significantly underestimates LVEF. When precise functional assessment is required, extending the reconstruction range to 30–100% allows comprehensive and reliable analysis.
Limitations: These results should be interpreted in light of study limitations, including the small sample size, preliminary nature of the data, variable imaging timing after STEMI, reliance on a single software platform, and lack of outcome or radiation analysis.
Funding for this study: This research was supported by a grant from the Italian Ministry of Health under the "Ricerca Finalizzata 2021 – Giovani Ricercatori" program, project number GR-2021-12372092. The funding was allocated to the project titled "Cardiac Computed Tomography for Comprehensive Risk Stratification of Arrhythmic, Atherothrombotic, and Heart Failure Events Following Reperfused ST-Segment Elevation Myocardial Infarction". The funder had no role in the design, data collection, analysis, or interpretation of this study

Biventricular Imbalance in STEMI Based on Global Longitudinal Strain Ratios: New Insight from Combined Dual-Chamber Function Assessment (6 min)

Yun Zhao; Shanghai / China

Author Block: Y. Zhao, L. Wu; Shanghai/CN
Purpose: The purpose is to investigate the association between biventricular imbalance, as reflected by the left and right ventricle global longitudinal strain (GLS) ratio derived from cardiac magnetic resonance (CMR) feature tracking, and all-cause death in isolated LVMI.
Methods or Background: A total of 1308 patients with isolated LVMI who underwent CMR examination were enrolled in this multicenter, retrospective study. The primary endpoint was all-cause mortality. The GLS ratio was defined as the ratio of left and right ventricular GLS.
Results or Findings: In the derivation cohort (919 participants, age, 59 [51, 66] years, 83.7% male), 90 (9.8%) patients developed death over a median follow-up period of 60.9 (IQR: 47.7–83.6) months. GLS ratio was the strongest independent predictor for all-cause death (adjusted HR: 1.687 [95%CI, 1.447-1.968] and 1.357 [95%CI, 1.155-1.595], respectively; both P < 0.01). The model along with clinical, conventional imaging, right ventricular (RV) GLS, and GLS ratio demonstrated improved discrimination (C-statistic: .82 [95% CI, .76–.87], 5-year AUC: .81 [95% CI, .75-.87]) and calibration ($\chi 2$ value: 71.88). GLS ratio > .95 was responsible for four-fold death risk after multivariable adjustment. In those with normal RVGLS (HR, 2.43 [95%CI, 1.15-5.10]; P = .020), reserved LVGLS (HR, 5.38 [95%CI, 2.46-11.79]; P < .001), and both (HR, 7.76 [95%CI, 2.16-11.90]; P = .002), high GLS ratio (>.95) still predicted all-cause death.
Conclusion: In population with isolated LVMI, elevated GLS ratio allowed for the prediction of all-cause death. A comprehensive assessment of biventricular function may provide additional prognostic information in clinical decision-making.
Limitations: The retrospective study design may be subject to selection bias because we excluded patients without CMR examinations. The subtle differences in imaging caused by scanners may affect the calculation of GLS, which could be a confounding factor.
Funding for this study: This study was supported by the National Youth Talent support program, National Natural Science Foundation of China (No.82471931, No82171884), Shuguang Program supported by Shanghai Education Development Foundation and Shanghai Municipal Education Commission, Shanghai Municipal Commission of Science and Technology Medical Innovation Research Special Project (23Y11906900), Shanghai "Yiyuan New Star" Outstanding Youth Talent (Excellent Program).

Machine learning of Coronary Wall Radiomics Reveals Hidden CAD Phenotypes on CCTA (6 min)

Francesco Pisu; Milan / Italy

Author Block: F. Pisu[1], D. Vignale[1], D. Serra[1], A. Palmisano[1], L. Saba[2], A. Esposito[1]; [1]Milan/IT, [2]Cagliari/IT
Purpose: Perivascular imaging seeks to quantify inflammation, fibrosis, and remodeling linked to coronary artery disease (CAD). Fat-related biomarkers (e.g., mean attenuation of perivascular adipose tissue) are promising, yet their sensitivity to scanner, protocol and body habitus variations limits reproducibility. Coronary wall (CW) radiomics may reveal more reproducible and subtler remodeling beyond mean attenuation. We tested whether unsupervised machine learning (ML) of CW radiomics can separate obstructive from non-obstructive CAD (ObCAD/NObCAD) and generalize across cohorts.
Methods or Background: We analyzed 40 CCTA cases (public ASOCA dataset: 20 patients with CAD, median stenosis 30% [IQR 25–70], 20 controls). CW radiomics were extracted from the proximal 5 cm of the LAD, RCA, and LCx and harmonized for site/scanners differences. We clustered patients using two principal components from the seven most informative features. Alignment with ObCAD status (≥50% stenosis) and Agatston coronary calcium (CAC) was assessed. Generalizability was tested by projecting 49 institutional patients (38 CAD patients ≤70% stenosis, CCTA for suspected CAD) into the learned cluster space.
Results or Findings: Two radiomic phenotypes separated CAD status with high rule-out performance (specificity 94%, NPV 91%). In the external cohort, 34/49 (69%) mapped to the NObCAD-like and 15/49 (31%) to the ObCAD-like phenotype (specificity 78%, NPV 85%). Misclassified cases had borderline stenosis (50–65%), older age (median 75y) and had more CV risk factors. CAC did not differ between phenotypes (median CAC 0[0–130] vs 18[0–95], p=0.76), supporting remodeling beyond calcium burden.
Conclusion: Machine learning of CW radiomics yields data-driven coronary phenotypes that separate obstructive from non-obstructive CAD and generalize across cohorts, indicating a feasible pathway to subclinical risk stratification beyond stenosis.
Limitations: Small, retrospective cohorts with limited clinical data and no adjudicated outcomes; obstructive CAD defined by stenosis only; residual site/scanner effects despite harmonization.

Added Value of T2 Fat-Saturated MRI Sequences in detection of Nerve Involvement in Lateral Deep Pelvic Infiltrating Endometriosis (6 min)
Sara Viganò; MIlan / Italy

Author Block: S. Viganò, S. Annibali, C. Cazzella, P. A. Bonaffini, P. Marra, S. Sironi; Bergamo/IT
Purpose: To assess the added diagnostic value of T2-weighted fat-saturated (T2-FS) MRI sequences for the detection of nerve involvement in lateral deep infiltrating endometriosis (DIE), in comparison to the standard MRI protocol.
Methods or Background: Patients who underwent a pelvic MRI for clinical and/ or ultrasound lateral DIE suspicion were retrospectively enrolled (February 2021- April 2023). Two radiologists, with 10 and 2 years of experience respectively, independently assessed the presence of lateral DIE and of nerve involvement, first evaluating the standard MRI protocol and then with the addition of T2-FS sequences. The findings of the senior reader were considered the reference standard. Interobserver agreement was assessed with Cohen's kappa.
Results or Findings: Fifty-one patients (mean age 34 years) were included. The senior radiologist detected nerve involvement in 13/51 patients (25,5%) with the standard protocol, increasing to 17/51 patients (33,3%) at re-evaluation with the addition of T2-FS sequences. Nerve structures most frequently involved were the sacral plexus, particularly the pudendal nerve. Interobserver agreement increased from poor with the standard protocol to moderate with T2-FS sequences. The additional T2-FS sequences particularly enhanced the junior radiologist's ability to identify indirect sign of nerve involvement, improving diagnostic confidence.
Conclusion: T2-FS MRI sequences may provide added value in the evaluation of nerve involvement in lateral DIE. Although radiological experience remains crucial, their inclusion in pelvic MRI protocols may support less experienced radiologists and should be considered when nerve involvement is suspected.
Limitations: The limited sample size. Lack of surgical correlation.
Funding for this study: None.

The Diagnostic Value of High-Resolution 3D T2-Weighted MRI in Preoperative Evaluation and Classification of Herlyn-Werner-Wunderlich Syndrome: A Prospective Study (6 min)
Yafei Qi; Beijing / China

Author Block: Y. Qi, Y. Zhang, X. Gao, P. Zhang, Y. He, S. Wang, H. Xue, L. Zhu; Beijing/CN
Purpose: HWWS is a rare triad of didelphys uterus, oblique vaginal septum and ipsilateral renal agenesis. Accurate preoperative diagnosis and classification are crucial for surgical planning, This study aims to investigate the diagnostic value of high-resolution three-dimensional T2-weighted MRI in the preoperative evaluation and classification of HWWS.
Methods or Background: The study prospectively enrolled 70 patients clinically diagnosed with HWWS between 2020 and 2024. All patients underwent pelvic MRI examinations, including high-resolution 3D T2WI (1 mm slice thickness) and conventional T2 TSE sequences, supplemented by large-FOV T2 coronal imaging for urinary system evaluation and full-spine X-ray examinations for skeletal assessment. Two radiologists blinded to clinical data recorded uterine morphology, obstruction level and communications, and related complications. Consistency analysis was performed between imaging findings and surgical results in 52 surgical patients.
Results or Findings: The results showed the following uterine morphological classifications: didelphys uterus (54 cases, 77.1%), complete septate uterus (14 cases, 20%), and bicornuate uterus (2 cases, 2.9%). Among surgical patients, 31 cases had vaginal-level obstruction (18 Type I, 11 Type II, and 2 Type III), while 21 cases had cervical-level obstruction (19 Type IV and 2 special Type III+IV). 3D-T2 detected 7/11 vaginal-septum fistulas that TSE missed; both sequences showed 2 cervical communications. Associated anomalies including ipsilateral renal agenesis 69 (99%), ovarian endometriosis 16 (type IV predominance), hematosalpinx 16, scoliosis 26 (37%), mild scoliosis 29 (41%).
Conclusion: Sub-millimeter 3D-T2 MRI significantly outperforms TSE in identifying vaginal communications and precisely localizing HWWS obstruction, enabling confident surgical planning. Routine adoption of high-resolution 3D protocols plus renal/spinal imaging is recommended.
Limitations: Despite 3D MRI's clear benefit for detecting cervix–septum fistulas, collapsed vaginal walls occasionally obscured the tract; with consent, we will trial gel distension to sharpen vaginal anatomy.

Mri based #enzian classification as a preoperative guide in deep infiltrating endometriosis - a comparative study with intraoperative findings (6 min)

Palak Dhakar; Udaipur / India

Author Block: P. Dhakar, A. Bose, V. Mishra, P. Sukhani, J. Chowdhary; Jaipur/IN
Purpose: Evaluate the efficacy of the ENZIAN score by comparing magnetic resonance imaging (MRI) results with intraoperative findings in cases of deep infiltrating endometriosis
Methods or Background: This retrospective study examined 50 patients with endometriomas and suspected deep infiltrating endometriosis of age ranging from 25 to 52 years (mean age 38.5 years), who underwent surgery between October 1, 2025 and September 31, 2024, at our institution (n = 50). The study compared preoperative MRI findings with intraoperative results using the #ENZIAN score and assessed the sensitivity , specificity , positive predictive value and negative predictive value of this approach.
Results or Findings: The diagnostic accuracy of MRI in detecting various endometriotic lesions by application of #ENZIAN Score was evaluated, with results confirmed through surgical findings. Sensitivity and negative predictive values of MRI confirmed by surgery were 98% and 92.6% (endometriomas), 95.2% and 91.7% (lesions in the vaginal/rectovaginal space), 78.4% and 56% (uterosacral ligaments), 91.4% and 89.7% (rectum/sigmoid colon), 57.1% and 94.1% (myometrium), 85.7% and 98.3% (bladder), and 73.3% and 92.2% (intestine), respectively
Conclusion: The #ENZIAN score serves as a detailed anatomical map that closely aligns with surgical findings, thereby facilitating more effective surgical planning. It demonstrates a strong correlation between MRI and intraoperative results, enhancing diagnostic efficacy, and serves as a valuable communication tool between radiologists and gynecologists.
Limitations: Despite its high sensitivity and NPV, MRI has limitations in detecting certain forms of DIE, particularly those involving the uterosacral ligaments and myometrium. Additionally, MRI's ability to accurately assess the severity of lesions in each compartment may be influenced by the operator's experience, the quality of the imaging, and the resolution of the MRI sequences used.

The clinical usefulness of the preoperative #Enzian score for estimating operative time in endometriosis surgery (6 min)

Hannah Maartje Maria Smid; Den Haag / Netherlands

Author Block: H. M. M. Smid, O. d. f. Henneman; Den Haag/NL
Purpose: Analysing clinical usefulness of preoperative #Enzian score as predictor for operative time planning in endometriosis surgery.
Methods or Background: Retrospective study in which 369 patients with deep infiltrating endometriosis had a procedural time planning in a multidisciplinary meeting. #Enzian score was used to assess endometriosis in abdominal compartments with preoperative transvaginal ultrasound (TVUS) and MRI. Procedural time was estimated (EPT) after discussing patient history, symptoms, physical examination and #Enzian-scored imaging.
Difference between EPT and actual operating time (AOT) was calculated. Accurate EPT was defined as AOT within 30 minutes of EPT. Sensitivity and specificity of dichotomised imaging #Enzian scores were calculated for individual compartments. Correlating and non-correlating MRI and surgical #Enzian scores were analysed per compartment, in relation to three outcomes: AOT >30 minutes shorter than EPT, accurate AOT (+/- <30 minutes of EPT) and AOT >30 minutes longer than EPT.
Results or Findings: Sensitivity and specificity of pre-operative imaging differs between compartments and is lower in most compartments compared to literature.
In total, 39.3% of operations were shorter than accurate EPT, 48.2% were within accurate EPT and 12.5% were longer than accurate EPT. There was no significant difference in AOT distribution in individual compartments comparing correlating and non-correlating #Enzian scores.
Conclusion: There is no correlation between mismatch in pre-/peroperative #Enzian scores in individual compartments and non-accurate EPT. As the EPT is set in a multidisciplinary meeting, personal experience of surgeon, patient history and physical examination play a large role in assessing EPT, next to the imaging results. The complexity of accurate EPT cannot only be defined in one (preoperative) classification.
Limitations: Retrospective study

Diagnosis in time saves nine - Cesarean Scar Pregnancies! (6 min)

Amritha Asokan; Coimbatore / India

Author Block: A. Asokan[1], D. George[2], R. M. Kuruvilla[2], V. K. Jagan[1], A. Anbarasu[1], M. Farooque[3], A. N. Parimalai[4], A. Chellathurai[4]; [1]Coimbatore/IN, [2]Abu dhabi/AE, [3]Kochi/IN, [4]Chennai/IN
Purpose: Cesarean scar pregnancies (CSPs) are a type of ectopic pregnancy that occur when an embryo implants within the fibrous scar tissue of a previous cesarean surgery. If not promptly detected and treated, CSPs can result in serious maternal complications, such as uterine rupture and hemorrhage.

TVUS (transvaginal ultrasonography) represents the imaging of choice for the diagnosis of CSPs; however, recent studies proposed a complementary role of MRI due to its capability in soft tissue characterization that may impact the therapeutical decision-making process.
Methods or Background: Structural assessment of the uterus employing ultrasound involves:
• Scan the entire uterus from left to right
• Scan the entire uterus from cervix to fundus
• 3D may help to recognize abnormal localisation
• If no intra-uterine pregnancy: use power doppler!
Further, we have included MRI in our study to see if it offers any additional role to 3D Ultrasound Imaging & advanced ultrasound imaging.
Results or Findings: CSP types:
Localisation according to two imaginary lines
1) uterine cavity line
2) serosal line

Type 1: Largest part towards the uterine cavity
Type 2: Largest part embedded in myometrium
& is not crossing serosal line
Type 3: Partly protruding outside the serosal line

Does CSP classification change treatment?

• CSP type 1: D&C or expectant & risk on PAS
• CSP that does not cross the serosal line lower risk on complications:
D&C under US guidence (±intrauterine folley/temporary cerclage):
low risk on complications
• CSP that crosses serosal line:
laparoscopic niche resection
Conclusion: Early diagnosis of CSP is extremely important since treatment options depend on the classifications of CSP and available expertise.
Limitations: Nil

Transvaginal Ultrasound versus MRI for Assessment of Lower Uterine Segment Cesarean Scars: A Prospective Comparative Study (6 min)

Farook Abubacker Sulaiman; Chennai / India

Author Block: R. Praveenkumar, F. Abubacker Sulaiman, J. Lydia, D. Velan; Chennai/IN
Purpose: To compare the accuracy of transvaginal ultrasound (USG) and magnetic resonance imaging (MRI) in measuring lower uterine segment (LUS) scar thickness and detecting defective or thinned cesarean scars, and to assess their predictive value for uterine rupture or dehiscence in subsequent pregnancies.
Methods or Background: In this prospective study, 60 women with a history of one previous cesarean section and planned repeat delivery were enrolled. LUS scar thickness was measured using transvaginal USG and 1.5T MRI (T2-weighted sequences). Presence of scar defects such as niches or thinning was documented. Imaging findings were correlated with intraoperative observations at the time of repeat cesarean delivery. Statistical analysis included paired t-tests for scar thickness comparison and sensitivity/specificity calculation for defect detection.d
Results or Findings: Mean scar thickness measured by USG was 3.8 ± 1.1 mm, while MRI measured 4.1 ± 1.2 mm ($p = 0.04$). MRI detected scar defects in 22/60 patients, whereas USG detected defects in 14/60. MRI demonstrated higher sensitivity (88%) and specificity (92%) for detecting scar defects compared to USG (sensitivity 64%, specificity 85%). All cases of intraoperative dehiscence ($n = 4$) were correctly identified preoperatively by MRI, whereas USG identified 2/4.
Conclusion: MRI provides superior detection of defective or thinned cesarean scars and offers more reliable prediction of uterine dehiscence than USG. Transvaginal USG remains useful for routine scar thickness assessment, but MRI may be recommended for high-risk patients to guide clinical management.
Limitations: Single-center study with a small sample size; operator dependency of USG; MRI limited to 1.5T; findings may not generalize to women planning VBAC

Ultrasound-Guided Sclerotherapy with Lauromacrogol for Ovarian Endometriomas: A Prospective Study of Efficacy, Safety, and Ovarian Reserve (6 min)

Yingxin LUO; Guangzhou / China

Author Block: Y. LUO, M. Zhang, Z. Huang, X. Zhang; Guangzhou/CN
Purpose: To prospectively assess the efficacy, safety, and impact on ovarian reserve of ultrasound-guided lauromacrogol sclerotherapy (UGLS) for ovarian endometriomas (OE).
Methods or Background: This prospective study enrolled patients undergoing UGLS between April 2024 and April 2025. Preoperative assessment comprised cyst maximum diameter, cyst volume, serum cancer antigen 125 (CA-125), serum anti-Müllerian hormone (AMH), and visual analogue scale (VAS) pain scores. The UGLS procedure involved cyst aspiration, irrigation, and instillation of 1% lauromacrogol. Follow-up assessments at 1, 3, and 6 months evaluated cyst reduction rate, relevant biomarker levels, and pain scores.
Results or Findings: This study enrolled 78 patients (106 lesions) undergoing UGLS. The mean age of the participants was 30.17 ± 3.75 years. At baseline, the mean VAS scores were 4.66 ± 2.82 for dysmenorrhea and the mean volume was 105.06 ± 96.65 ml. After the operative, the technical success rate was 97.81%. Significant reductions in cyst volume was observed at 6 months ($P<0.001$), with volume reduction rates of 81.51 ± 15.65%(1 month), 90.63 ± 12.02%(3 months), and 93.21 ± 9.51% (6 months), and the mean cyst volume was 18.53 ± 74.24 ml at 6 months. CA-125 levels decreased postoperatively, while no significant change in AMH levels was observed (P□0.05). The incidence of mild complications was 5.13%, which were relieved after observation.
Conclusion: UGLS is an effective, minimally invasive treatment for OE that successfully preserves ovarian reserve, and demonstrating promise for patients with diminished ovarian reserve.
Limitations: This article is a single arm, single center study

Concordance and Diagnostic Accuracy of Repeat Placental MRI for the Assessment of Placental Accreta Spectrum Disorder (6 min)

Yoon Ho Song; Melbourne / Australia

Author Block: Y. H. Song, A. Chua, S. Tan, D. Richmond, E. E. Alibrahim, J. Keene, C. Shadbolt, S-F. Oon; Melbourne/AU
Purpose: While placental MRI is well-established as a useful diagnostic tool for the evaluation of placenta accreta spectrum disorder (PASD), the optimal gestational age for assessment and diagnostic value of repeat MRI remains uncertain. The aim of this study was to retrospectively assess the utility of routine repeat placental MRIs performed at a tertiary Specialist Women's Imaging referral centre. We evaluated inter-study concordance and diagnostic accuracy of MRI performed at 28- and 32-weeks gestation at diagnosing PASD, using placental pathology as the reference standard.
Methods or Background: We retrospectively reviewed all placental MRI studies performed from 2015-2025, identifying patients who underwent two placental MRIs for PASD assessment beyond 24-weeks gestation. Diagnostic accuracy was assessed by comparing dichotomised MRI findings with placental pathology at delivery. Sensitivity and specificity with 95% confidence intervals (CIs) were calculated for the initial and repeat studies. Inter-study concordance was assessed using Cohen's kappa coefficient with 95% CIs for disease severity (normal, accreta/increta, or percreta) and diagnosis of PASD.
Results or Findings: Between 2015 and 2025, 61 women had two placental MRI studies beyond 24-weeks gestation for PASD assessment. For diagnosis of PASD, the initial scan (median gestation 29-weeks) demonstrated 97.4% sensitivity (95% CI 86.5–99.5) and 60.0% specificity (95% CI 31.3–83.2). The repeat scan (median gestation 31-weeks) demonstrated 100.0% sensitivity (95% CI 90.8–100.0) and 50.0% specificity (95% CI 23.7–76.7). Inter-study concordance was substantial for disease severity ($\kappa = 0.72$, 95% CI 0.58–0.87), PASD diagnosis ($\kappa = 0.77$, 95% CI 0.59–0.96), and placenta percreta diagnosis ($\kappa = 0.77$, 95% CI 0.63–0.95).
Conclusion: There is comparable accuracy and substantial concordance between initial and repeat placental MRI studies performed beyond 24-weeks gestation. This suggests limited diagnostic benefit in routinely repeating MRI for the diagnostic evaluation of PASD, but larger studies would be required to confirm this.
Limitations: The study results are limited by a small sample size but could contribute to future meta-analyses.
Funding for this study: No funding was provided for this study.

Comparing Intraplacental Vascular Impairment and Microperfusion in patients with hypertensive disorders of Pregnancy using IntraVoxel Incoherent Motion MRI of the placenta (6 min)

Elizaveta Aleksandrovna Kirillova; St. Petersburg / Russia

Author Block: E. A. Kirillova, I. Mashchenko, P. Kozlova, N. Osipova, V. Markina, I. Zazerskaya, G. Trufanov; St. Petersburg/RU
Purpose: Hypertensive disorders of pregnancy (HDPs) are major causes of maternal morbidity worldwide. A hallmark of these conditions is impaired placental perfusion. Intravoxel incoherent motion (IVIM) MRI enables non-invasive quantification of placental microcirculation and may serve as a useful biomarker of placental disorders in this cohort. The study aimed at comparing IVIM parameters in whole placenta and maternal/foetal compartments in patients with or without HPDs.
Methods or Background: 16 women aged 26-43 years underwent placental IVIM-MRI, including ten patients in the HDP group and six patients in the control group. Mean gestational age at the time of 3T-MRI was 31.6 weeks (95% CI: 29.4–33.8) in the HDP group and 30.5 weeks (95% CI: 27.6–33.3) in the control group. A multi-b-value DWI protocol (0–800 s/mm²) was applied. Group differences and subgroup trends were analysed descriptively. Subgroups included patients with severe preeclampsia (PE) ± chronic hypertension (CH), moderate PE ± CH, and isolated CH.
Results or Findings: Whole-placenta perfusion fraction (f) value reflecting villous vascularity was reduced in patients with HDPs (19.2%, 95% CI 15.2–23.1) vs controls (24.8%, 95% CI 16.0–33.7). Maternal f (18.6% vs 24.0%) and foetal f (19.2% vs 25.8%) values showed similar decreases. The diffusion coefficient (D and D*) parameters indicating water diffusion in the tissue and the microvascular flow, respectively, also tended to be lower in the HDP group. The subgroup analysis revealed the most pronounced reductions of all IVIM parameters in severe PE ± CH vs controls.
Conclusion: IVIM parameters of the placenta showed consistent reductions in patients with HDPs compared to the control group, reflecting impaired placental microperfusion in this cohort.
Limitations: The limitation of the study was a small sample size.
Funding for this study: No funding was received for this study
Has your study been approved by an ethics committee? Yes

Therapeutic Decision-Making in Patients with Bowel Endometriosis: The Clinical Value of MRI (6 min)

Roberta Valerieva Ninkova; Rome / Italy

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: R. V. Ninkova, F. Curti, S. Riccardi, C. Cutonilli, M. Gennarini, F. Frezza, C. Amoroso, C. Catalano, L. Manganaro; Rome/IT
Purpose: To evaluate the role of magnetic resonance imaging (MRI) in guiding treatment choice between medical and surgical management in patients with bowel endometriosis, based on detailed analysis of lesion morphology and anatomical involvement.
Methods or Background: A retrospective study was conducted on 215 patients with bowel endometriosis who underwent MRI between 2017 and March 2024, with at least one year of follow-up. Among them, 135 received surgical treatment (alone or combined with medical therapy), while 80 underwent exclusive medical treatment.
MRI evaluation focused on lesion location (low, mid, or upper rectum; rectosigmoid junction; extrapelvic sites), number of nodules, longitudinal extension, thickness, and circumferential involvement. Clinical symptoms were recorded using the NRS scale, comparing pre- and post-treatment scores. The occurrence of bowel obstruction and post-surgical complications were also documented.
Results or Findings: The upper rectum was the most frequently affected site (33%), followed by the rectosigmoid junction (22%) and mid-rectum (20%). Bowel obstruction occurred in 5.1% of cases, exclusively in lesions ≥10 cm from the anal verge with ≥4/8 circumferential involvement. Surgical treatment achieved a significantly greater reduction in symptom severity in patients with lesions >14 mm and ≥4/8 circumferential extension (mean NRS reduction = 4.3 ± 1.2 vs. 2.1 ± 1.0; $p < 0.001$). In smaller or less extensive lesions, outcomes were comparable between medical and surgical therapy.Postoperative complications occurred in 65.2% of surgical cases, most commonly bladder incontinence (26.7%).
Conclusion: MRI proved essential for precise lesion characterization and for guiding personalized therapeutic decision-making based on features associated with symptom severity.
Limitations: This study is limited by its retrospective, single-center design and the absence of randomization, which may introduce selection bias. The follow-up duration and subjective assessment of symptoms using the NRS scale could also affect result consistency.
Funding for this study: None

Post-abortion Complications: How Not to Be Misled ! (6 min)

Mohamed Bouhlali; Plaisir / France

Author Block: M. Bouhlali, P. Verpillat; Lille/FR
Purpose: To understand the clinico-biological principles of post-abortion follow-up.
To recognize simple trophoblastic retention on imaging.
To detail the main differential diagnoses of trophoblastic retention.
To differentiate trophoblastic retention from acquired arteriovenous fistula.
Methods or Background: Pelvic ultrasound and/or MRI evaluation was performed at Lille University Hospital, in patients after induced abortion, in cases of metrorrhagia or abnormal decline of β-hCG levels.
Results or Findings: Trophoblastic retention should be suspected in cases of metrorrhagia or plateauing β-hCG levels persisting more than 3 weeks after abortion.
An empty uterine cavity with a thin endometrium and negative β-hCG excludes trophoblastic retention.
Trophoblastic retention appears as heterogeneous echogenic intrauterine material, respecting the endometrium–myometrium interface, with vascularization on color Doppler, peak systolic velocities generally not exceeding 40 cm/s.

Major role of color Doppler ultrasound in differential diagnoses:
Intrauterine clot: strictly intracavitary echogenic mass, avascular on color Doppler, with negative β-hCG.
Arteriovenous fistula: endo-myometrial lesion with marked hypervascularization on color Doppler, peak velocities exceeding 1 m/s.
Ectopic pregnancy : empty uterine cavity, thickened gravid endometrium, β-hCG > 1500, with or without direct visualization of an extrauterine gestational sac

MRI may reveal signs of an arteriovenous fistula on dynamic contrast-enhanced sequences, such as early venous return in the gonadal vein and helps differentiate it from a refluxing gonadal vein
Molar pregnancy or gestational trophoblastic tumor (GTT) should be suspected based on clinico-biological criteria (very high β-hCG levels) and imaging features.
Conclusion: Preserved endometrium–myometrium interface with PSV < 40 cm/s → trophoblastic retention.
Myometrial invasion with PSV > 1 m/s → acquired AVF/AVM, with early venous return on dynamic MRI.
Empty uterine cavity + β-hCG > 1500 → ectopic pregnancy until proven otherwise.
Very high β-hCG → molar pregnancy or GTT until proven otherwise.
Limitations: Comorbidity
Funding for this study: Lille university Hospital

Associations Between Pelvic Fat Distribution and Severity of Deep Infiltrating Endometriosis: A Retrospective MRI-based Analysis (6 min)

Ann-Katrin Kaufmann-Bühler; Graz / Austria

Author Block: A-K. Kaufmann-Bühler[1], M. Kopetzky[1], M. Puseljic[1], I. Vlasicek[1], B. Catalano[2], M. Fuchsjäger[1], M. Wölfler[1], W. Schöll[1], E. Talakic[1]; [1]Graz/AT, [2]Rome/IT
Purpose: To investigate whether the distribution of pelvic fat compartments, such as subcutaneous fat (SCF), intramuscular fat (IMF), and pelvic visceral fat (PVF), is associated with the severity of deep endometriosis (DE), based on pelvic MRI volumetry.
Methods or Background: In this retrospective single-center study, 71 women (mean age 33.4 ± 6.5 years) with surgically and/or histologically confirmed DE underwent standardized pelvic MRI between 2021-2023. Volumes of SCF, IMF, PVF, and gluteus maximus muscle (MV), were segmented semi-automatically using 3D Slicer software. Disease severity was classified according to the #Enzian system. Spearman's correlation and non-parametric group comparisons were used to assess associations between body composition and disease severity. Multivariate linear regression models served to identify independent predictors of disease severity.
Results or Findings: PV correlated negatively with severity in compartment B (uterosacral ligaments/pelvic wall; $r = -0.28$, $p = 0.008$). IMF correlated positively with extragenital disease (compartment F; $r = 0.26$, $p = 0.015$) and with the overall #Enzian score ($r = 0.21$, $p = 0.047$. No significant associations were found for SCF or MV. Linear regression models identified IMF($\beta = 4.87$, $p = 0.023$) and IMF/MV ratio ($\beta = 31.6$, $p = 0.023$) as independent predictors of #Enzian score, with a stronger normalized effect of IMF relative to MV.
Conclusion: Correlating with compartment-specific and overall disease severity, MRI-based pelvic fat and muscle volumes may serve as a novel non-invasive biomarker of disease burden in DE. These findings support the hypothesis that pelvic fat distribution reflects underlying pathophysiological mechanisms and could support non-invasive staging strategies. Prospective validation and integration with hormonal and clinical markers are warranted.
Limitations: Limitations of this study include its retrospective and cross-sectional design, precluding causal inference.
Funding for this study: None
Has your study been approved by an ethics committee? Yes

Intraprocedural assessment of treatment efficacy using intravoxel incoherent motion (IVIM)-analysis during magnetic resonance-guided focused ultrasound (MRgFUS) treatment of uterine fibroids (6 min)

Loes Knorren; Zwolle / Netherlands

Author Block: L. Knorren[1], J. D. J. Slotman[1], I. M. Nijholt[1], J. Schutte[1], J. Huirne[2], C. M. Tax[3], L. W. Bartels[3], M. F. Boomsma[1]; [1]Zwolle/NL, [2]Amsterdam/NL, [3]Utrecht/NL
Purpose: Reliable intraprocedural assessment of treatment efficacy during magnetic resonance–guided focused ultrasound (MRgFUS) for uterine fibroids may optimize outcomes and reduce procedure time. The non-perfused volume ratio (NPVr) is conventionally calculated post-treatment using contrast-enhanced T1-weighted imaging (CET1w). However, contrast administration precludes further ablation. In this explorative pilot study, the potential of intravoxel incoherent motion (IVIM)-derived perfusion fraction (f)- and apparent diffusion coefficient (D)-maps for real-time MRgFUS treatment monitoring was evaluated.
Methods or Background: Women undergoing MRgFUS treatment between September 2024 and July 2025 at our institution were consecutively enrolled. DWI was obtained at baseline, at 45-minute intervals during ablation and after final sonication. CET1w was subsequently performed and used to calculate NPVr from manual 3D segmentations of the total fibroid volume and non-perfused volume. IVIM-maps were generated post-procedurally using non-linear least-squares fitting. Explorative visual analysis was performed by two experienced researchers, with CET1w as reference for the final IVIM-maps.
Results or Findings: Fourteen women were included with a median of five DWI-scans per patient (range 3-6). Mean NPVr was 43,7±25,9% (range: 4,4-97,6%). In thirteen cases, progressive hypointense regions on f-maps and hyperintense regions on D-maps were observed intraprocedurally. In one patient, a global hypointense pattern on the f-map appeared 45 minutes after the start of treatment and persisted, corresponding to complete ablation (NPVr 97,6%). Absent or minimal changes on IVIM were associated with low NPVr (<10%, n=2). In eleven cases partial changes of the fibroid on IVIM-maps were observed, visually corresponding with intermediate ablation outcomes on CET1w (NPVr 12,3–66,7%).
Conclusion: Intraprocedural visual changes of fibroid tissue on f- and D-maps shows potential as a tool for visualizing intraprocedural progression of MRgFUS treatment. Clinical applicability will be evaluated in a future study.
Limitations: Small sample size

Validation of a Web-Based Device Compatibility Program for Neurointervention (6 min)
Joon Ho Choi; Seoul / Korea, Republic of

Author Block: J. H. Choi, B. Kwon, Y. Song, D. H. Lee; Seoul/KR
Purpose: Neurointerventional procedures often require simultaneous use of multiple devices, necessitating compatibility checks. Because device specifications are reported in mixed units (e.g., catheter ID in inches, OD in French, wire OD in inches), direct calculation is difficult. In addition, when more than two devices are used in a guiding catheter, simply summing outer diameters can be misleading. This study evaluated the usefulness of a self-developed, web-based compatibility checking program.
Methods or Background: A device database was built using specifications of neurointerventional devices in use since 2016. Spatial compatibility was assessed with circle geometry, and length compatibility incorporated catheter hub length and additional device placement. Clinical experience with specific combinations was also integrated. Program performance was tested using cases from 2020 to 2024 in which compatibility checks were required. Results were compared with actual clinical use or in-vitro testing to determine sensitivity, specificity, accuracy, and predictive values. Three users also measured the time required for compatibility evaluation using the program versus manual calculation.
Results or Findings: A total of 355 compatibility checks were analyzed: 126 with one insert device, 173 with two, and 56 with three. The program showed sensitivity of 94.6%, specificity of 86.4%, accuracy of 91.4%, positive predictive value of 91.5%, and negative predictive value of 91.2%. Evaluation time with the program was consistently shorter than with manual calculation across all users.
Conclusion: This web-based compatibility program provides rapid access to device specifications and supports optimal device selection by combining mathematical modeling with clinical data. Broader use across centers and accumulation of additional clinical experience are expected to enhance its reliability and clinical value.
Limitations: Although the database was constructed based on specifications provided by the manufacturers, the acceptable tolerance ranges of the devices were not specified.

Risk of Clopidogrel Resistance in Endovascular Aneurysm Stenting (6 min)
Mitchell Stanton; Brisbane / Australia

Author Block: M. Stanton; Brisbane/AU
Purpose: Thromboembolic complications remain a significant risk in endovascular aneurysm stenting, with clopidogrel resistance implicated as a major contributing factor. This study aims to evaluate thromboembolic outcomes in clopidogrel-resistant patients undergoing endovascular aneurysm stenting and to assess whether switching to ticagrelor mitigates these risks.
Methods or Background: This single-centre retrospective cohort study included 228 patients treated between 2020 and 2024. All patients underwent VerifyNow P2Y12 testing prior to the procedure. Clopidogrel non-responders (<40% inhibition) were switched to ticagrelor. The primary endpoint was thromboembolic complication, defined as radiological or clinical infarct, aiming to capture all patients with thromboembolic complication, whether symptomatic or not. Secondary analyses evaluated aneurysm characteristics and associated risk factors.
Results or Findings: Of the 228 patients, a significant 122 patients (54%) were found to be non-responders and switched to ticagrelor. No statistically significant differences were observed in rates of clinical infarct (13% vs 11%, p=0.7) between clopidogrel responders and ticagrelor-treated non-responders. Evidence of radiological infarct was included to incorporate any asymptomatic patients and also was found to have no difference between groups (19% vs 12%, p=0.2) . Larger aneurysm size correlated with both higher number of radiological (p=0.011) and clinical infarcts (p=0.002). Diabetes and advanced age were associated with multiple aneurysms. Younger patients with prior subarachnoid haemorrhage were more likely to undergo stent-assisted coiling.
Conclusion: Preoperative platelet function testing and switching clopidogrel non-responders to ticagrelor resulted in comparable thromboembolic complication rates to clopidogrel responders. These findings support the role of routine platelet function testing and individualized antiplatelet management in endovascular aneurysm treatment.
Limitations: Limitations for this study are that it's a single centre, retrospective study. Although powered adequately, some subgroup analyses may still be underpowered.
Funding for this study: No funding was received for this study

Small versus Large Woven EndoBridge Devices for Intracranial Aneurysms: Results from the WorldWideWEB Multicenter Study (6 min)

Franja Dugar; Zurich / Switzerland

Author Block: F. Dugar[1], T. D. L. Nguyen-Kim[1], A. Dmytriw[2], D. Coluccia[1], M-N. Psychogios[3], P. Sporns[1]; [1]Zurich/CH, [2]Boston, MA/US, [3]Basel/CH
Purpose: Smaller Woven EndoBridge (WEB) devices (≤ 4.5 mm) for the treatment of intracranial aneurysms are technically challenging to deploy, and data on their safety and efficacy remain scarce. This study compared functional, anatomic, and safety outcomes of small WEBs with those of large (> 4.5 mm) and very large (> 7.5 mm) devices.
Methods or Background: The WorldWideWEB consortium is a retrospective, multicenter collaboration across 30 international institutions, including adults with intracranial aneurysms treated with WEB. Patients were stratified into small (≤ 4.5 mm) and large (> 4.5 mm) groups; a subanalysis compared small and very large (> 7.5 mm) devices. The primary outcome was retreatment rate. Secondary outcomes comprised mRS, anatomic outcomes periprocedurally and at last follow-up (FU), and safety events, including intracranial hemorrhage (ICH) and thromboembolic complications (TECs).
Results or Findings: Among 1473 patients, 229 (15.5%) received a small WEB. Baseline characteristics were similar. Retreatment was less frequent (4.3% vs 8.8%, p = 0.037) and complete occlusion higher with small WEBs (periprocedurally: 57.1% vs 36.6%, p < 0.001; last FU: 76.2% vs 58.5%, p < 0.001). Median mRS at last FU was comparable (1 [1–2] vs 1 [1–2], p = 0.88), as were safety events (ICH 2.6% vs 0.9%, p = 0.102; TECs 3.1% vs 3.9%, p = 0.686). Very large WEBs had higher retreatment (16.1%, p < 0.001) and lower complete occlusion (periprocedurally: 32.2%, p < 0.001; last FU: 50.5%, p < 0.001), with comparable safety outcomes (ICH 0.9%, p = 0.266; TECs 4.5%, p = 0.512).
Conclusion: Small WEBs showed superior anatomic outcomes and lower retreatment rates compared with large devices, without significant differences in functional or safety outcomes.
Limitations: Absence of core laboratory adjudication for anatomic outcomes and retrospective design.
Funding for this study: No funding was provided for this study.

A Comparison of Mechanical Thrombectomy Outcomes between M2 occlusion and M1 occlusion (6 min)

Feyza Zengin; Istanbul / Turkey

Author Block: N. Çetinkaya, F. Zengin, U. Erdem, E. Çamurcuoğlu; Istanbul/TR
Purpose: Mechanical thrombectomy has been shown to be effective for large vessel occlusions in the anterior circulation, but its safety and success in treating distal vasculature remain unclear. This study evaluates outcomes of M2 versus M1 occlusions in acute ischemic stroke.
Methods or Background: A retrospective analysis of prospectively collected data was performed on patients with similar NIHSS scores who underwent stent retriever-based mechanical thrombectomy for isolated M1 or M2 MCA occlusions. Between March 2022 and May 2024, 198 patients were treated: 134 (67.7%) with M1 and 64 (32.3%) with M2 occlusions. Primary outcomes included recanalization success (TICI 2b/3), periprocedural complications, hemorrhage, 90-day mRS scores, and mortality.
Results or Findings: Mechanical thrombectomy is a safe, effective treatment for MCA occlusions in both M1 and M2 segments. Recanalization rates were higher in M1 (88%) than M2 (70.3%). Procedure time averaged 91.2 minutes for M1 and 104.6 for M2. Fewer attempts were required in M2 cases (1.57 vs. 2.4). Anticoagulant use occurred in 44.2% of M2 and 40.1% of M1 cases. M2 patients were slightly older (73.0 vs. 71.8 years). Despite lower recanalization, M2 outcomes and complication rates, including hemorrhage and mortality, were comparable. NIHSS scores at admission did not differ significantly ($p = 0.296$). Aspiration showed high efficacy in both groups.
Conclusion: The findings indicate that. M2 thrombectomy is safe, with many patients achieving good outcomes. Angiographic and clinical results were similar to M1. Endovascular treatment of severe M2 cases does not increase procedural risk or bleeding. Poor outcomes were linked to older age and prior anticoagulant use. Therefore, stent-retriever thrombectomy should be considered for severe acute M2 occlusion.
Limitations: This study was limited by its single-center design and lack of outcome assessment beyond 90 days.
Funding for this study: This research received no specific grant from any funding agency.

Neurovascular Stent-Assisted Coil Embolization for Wide-Neck Visceral Artery Aneurysms: The NEVAR Technique (6 min)

Claudio Sallemi; Brescia / Italy

Author Block: C. Sallemi, C. Viola, F. Bodini, M. Pegorer, R. Bellosta; Brescia/IT
Purpose: To describe a novel endovascular approach using low-profile neurovascular stents for coil embolization of wide-neck visceral artery aneurysms (VAAs), with focus on a dual-stent “kissing” configuration for bifurcation aneurysms and tortuous anatomy.
Methods or Background: Thirteen patients (12 women, 1 man; mean age 57 years) with wide-neck VAAs were treated between 2020 and 2025 using intracranial remodeling stents (Solitaire AB, Medtronic; Neuroform Atlas, Stryker) adapted for visceral circulation. Aneurysm locations included splenic (n=7), renal (n=3), hepatic (n=1), and pancreaticoduodenal (n=2) arteries. A dual-stent “kissing” configuration was used in eight anatomically complex cases (bifurcation aneurysms n=6, severe tortuosity n=2). All patients received dual antiplatelet therapy with aspirin and clopidogrel (Duoplavin) starting 5 days before the procedure, continued for 1 month postoperatively, followed by aspirin monotherapy for 6 months. Technical success, periprocedural events, and contrast-enhanced CT follow-up at 6, 12, and 24 months were assessed.
Results or Findings: Technical success was achieved in all cases (100%). Mean procedural time was 95 minutes, with radiation exposure consistent with comparable endovascular procedures. Dual-stent cases involved larger aneurysms (mean 22 mm) and required more coils (mean 7.8) than single-stent cases (mean 19.8 mm; 3.2 coils). No periprocedural complications or delayed ischemic events occurred. Median hospital stay was 2 days. Follow-up CT at 6, 12, and 24 months confirmed durable aneurysm exclusion, preserved parent artery flow, and maintained stent patency in all patients.
Conclusion: The NEVAR technique is a safe and effective solution for wide-neck visceral aneurysms. The dual-stent “kissing” configuration provides stable scaffolding and precise coil delivery while maintaining branch perfusion. This approach may represent a paradigm shift for treating complex visceral aneurysms previously requiring open surgery or parent vessel sacrifice.
Limitations: Single-center, retrospective design with a small cohort; long-term validation is warranted.
Funding for this study: No external funding was received for this study
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: This study was approved by the Territorial Ethics Committee Lombardia 6 (Pavia, Italy), in the session held on July 29, 2025 (Protocol No. NEVAR, Prot. 0049213/25).

CT Black-Blood Imaging for Follow-Up After Flow-Diverter Stenting in Intracranial Aneurysms: A Feasibility Study (6 min)

Zhiman Lai; Guangzhou / China

Author Block: R. Xu, H. Ma, Z. Lai, D. Xie, H. Cai; Guangzhou/CN
Purpose: To evaluate the feasibility and diagnostic performance of CT black-blood imaging, derived from contrast enhancement boost (CE-boost), for follow-up of intracranial aneurysms treated with flow-diverter stents.
Methods or Background: Twenty-eight patients were prospectively enrolled; 22 underwent both CT angiography (CTA) and digital subtraction angiography (DSA) during follow-up, while 6 underwent CTA only within 48h post-procedure. All CTA data were retrospectively processed with CE-boost to generate black-blood images. Two blinded neuroradiologists scored image quality and diagnostic confidence on a 4-point scale; inter-observer agreement was assessed with Cohen's κ. Diagnostic accuracy for in-stent restenosis (ISR) was evaluated per patient against DSA. Subjective scores were compared using the Wilcoxon test. CT radiation dose (CTDIvol, mGy) and DSA dose–area product (Gy·cm²) were recorded descriptively.
Results or Findings: Black-blood imaging yielded higher scores for image quality (median 4 vs. 3, $p < 0.01$) and confidence (4 vs. 3, $p < 0.01$). ISR was confirmed in 10 patients. Conventional CTA achieved sensitivity 90.0% (95% CI 55.5–99.7), specificity 36.4% (10.9–69.2), and accuracy 63.6% (40.7–82.8). Black-blood imaging achieved 100% sensitivity, specificity, and accuracy (95% CIs 69.2–100), with $\kappa = 1.00$. Mean CTA CTDIvol was 67.2 ± 7.7 mGy versus DSA mean DAP 498.2 ± 118.7 Gy·cm². CTA acquisition time was 3.5 ± 0.7 min versus 8.5 ± 7.5 min for DSA fluoroscopy.
Conclusion: CE-boost–derived CT black-blood imaging provides excellent image quality and high diagnostic consistency with DSA in ISR detection, with shorter scan times and lower procedural burden.
Limitations: Larger studies are needed for validation.

Primary Coiling Revisited: Safety and Efficacy for Ruptured Intracranial Aneurysms (6 min)

Furkan Ozden; Sakarya / Turkey

Author Block: F. Ozden, İ. Özer, U. MUSTAK, O. Taydaş, M. Ozdemir, E. Arık, V. Taşçi, Ö. F. Topaloğlu, M. H. Öztürk; Sakarya/TR
Purpose: To evaluate the current role and effectiveness of primary coiling in managing acute aneurysmal subarachnoid hemorrhage (aSAH).
Methods or Background: We conducted a retrospective single-center study involving all patients who were admitted with aSAH and treated with primary coiling between January 2019 and March 2025. The information extracted included patient demographics, such as age and sex, as well as specific details about the aneurysm, including its location, size, and morphology. The immediate angiographic outcomes were assessed based on the grade of aneurysm occlusion. Our primary focus was on two key endpoints: the rebleeding rate following the procedure and the overall mortality rate one year post-treatment.
Results or Findings: A total of 127 patients (mean age 57.0 ± 12.6 years; 76 female, 65%) who underwent primary coiling for aSAH were included in this study. The most common location for the aneurysms was the internal carotid artery (ICA) at 35.5%. The mean size of the aneurysms was 9.0 ± 5.6 mm. Immediate post-procedural angiography showed complete aneurysm occlusion (Raymond-Roy Class 1) in 35 patients (27.6%). Partial occlusion (Raymond-Roy Class 2 or 3) was observed in the remaining 92 patients (72.4%). During the 1-year follow-up period, the overall mortality rate was 20.5% (26 of 127 patients). Rebleeding from the treated aneurysm occurred in 2 patients (1.6%).
Conclusion: Primary coiling is a safe and effective method for managing aSAH. Its minimally invasive nature makes it one of the preferred treatments for aneurysms.
Limitations: Firstly, the retrospective design of this study introduces inherent selection bias and depends on the accuracy of medical records. Secondly, the lack of a direct comparative group, such as surgical clipping, prevents us from making definitive conclusions about the superiority of the treatment.
Funding for this study: This study did not receive funding from any external sources.

Effect of Copper Filtration on Radiation Dose in Cerebral 3D Rotational Angiography During Endovascular Aneurysm Treatment (6 min)

Niclas Schmitt; Heidelberg / Germany

Author Block: N. Schmitt[1], A. Berting[2], C. Herweh[1], T. Hilgenfeld[1], F. Preisner[1], L. Wucherpfennig[1], M. Bendszus[1], D. F. Vollherbst[1], M. Möhlenbruch[1]; [1]Heidelberg/DE, [2]Forchheim/DE
Purpose: Cerebral angiography remains the gold standard for diagnosing and endovascular management of cerebral aneurysms. Three-dimensional rotational angiography (3D-RA) provides superior ana-tomical detail compared to conventional 2D imaging; however, it is associated with relatively high radiation exposure, raising concerns regarding patient safety. This study aimed to evaluate the potential of copper (Cu) filtration to reduce radiation dose in 3D-RA.
Methods or Background: Forty subsequent patients undergoing endovascular treatment of unruptured cerebral aneu-rysms were included. All underwent 3D-RA using the ARTIS icono angiography system (Siemens Healthineers). In 20 patients, standard hardware with a 0.8mm aluminum (Al) filter was applied; in the subsequent 20, the Al filter was replaced by a 0.1mm Cu filter. Image quality was assessed quantitatively via contrast-to-noise ratio (CNR) and qualitatively using a five-point scale. Radiati-on dose was evaluated using entrance-skin dose (mGy) and dose-area product (Gy·cm²).
Results or Findings: Image quality was preserved in both groups with no differences in CNR (CNR±SD, Al: 20.72±1.82 vs. Cu: 20.66±1.54; p=0.93) or qualitative scoring (score±SD, Al: 4.55 ± 0.54 vs. Cu: 4.63±0.46; p=0.75). Total radiation dose was lower with Cu filtration (e.g., mGy±SD, Al: 110.63±10.75 vs. Cu: 68.70±6.03; Gy·cm²±SD, Al: 6.26±1.57 vs. Cu: 3.35±0.6733, p<0.001 respectively), corre-sponding to a dose reduction of 38% (entrance-skin dose) and 46% (dose-area product). These findings highlight Cu filtration as an effective and easily implementable strategy for dose opti-mization in 3D-RA. Given its compatibility with existing imaging protocols and its capacity to reduce patient exposure without compromising image quality, this approach is especially valu-able in young patients or in patients requiring repeated imaging.
Conclusion: Copper filtration substantially reduces radiation dose during 3D-RA while preserving image qua-lity, supporting its adoption as a practical improvement for patient safety in clinical practice.
Limitations: Retrospective. Single-center study.
Funding for this study: This study was supported by research funding from Siemens Healthineers. The authors declare no other conflicts of interest.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Approval for data collection was obtained from the local ethics committee and written informed consent was provided by all participants.

Management of Intracranial Dural AV Fistulas: Endovascular Approach and Outcome Analysis (6 min)

Maciej Szmygin; Lublin / Poland

Author Block: M. Szmygin, T. Roman, P. Szmygin, M. Zbroja-Putowska, M. Czeczelewski, R. Rola; Lublin/PL
Purpose: Intracranial dural arteriovenous fistulas (DAVFs) are rare vascular malformations characterized by abnormal connections between meningeal arteries and dural venous sinuses or cortical veins. They might result from trauma, surgery, or infection. Clinical presentation varies widely, ranging from benign symptoms to life-threatening intracranial hemorrhage. This study aims to present our center's experience with the endovascular management of DAVFs, with emphasis on technical aspects of the procedures and associated clinical outcomes.
Methods or Background: We retrospectively reviewed all patients with intracranial DAVFs Cognard grade IIb-V treated via endovascular embolization at our institution in last 10 years. DAVFs characteristics, demographics as well as procedura and clinical data were collected and evaluated. Complications and mortality rate was calculated.
Results or Findings: In total 48 patients (19 female, mean age of 53 years) were included. Most common presenting symptoms include tinnitus, headaches and neurological deficits. In majority of cases, embolizations were carried out via arterial access and treatment decisions were based by fistula angioarchitecture and venous drainage patterns. All fistulas were treated with liquid embolic (glue and ethylene vinyl alcohol copolymers). Targeted vessels included middle meningeal artery, occipital artery and meningohypophyseal trunk. Obliteration of >90% of fistula was observed in 71% of cases. Satisfactory clinical outcome (defined as >75% symptoms alleviation) was achieved in 79%. Procedural complications occurred in 2 cases. One patient died due to intracranial hemorrhage caused by embolization.
Conclusion: Endovascular embolization is a safe and effective first-line therapy for intracranial DAVFs. Careful evaluation of fistula angioarchitecture, especially venous drainage and individualized procedural planning are essential for optimal clinical outcome.
Limitations: Relatively small sample size, monocentric and retrospective character of the study as well as lack of control arm with patients treated with different methods.
Funding for this study: None
Has your study been approved by an ethics committee? Yes

Reperfusion Therapy in Anterior Cerebral Artery Occlusions: Insights from a Multicenter Cohort (6 min)

Maciej Szmygin; Lublin / Poland

Author Block: M. Szmygin[1], P. Luchowski[1], M. Zbroja-Putowska[1], M. Czeczelewski[1], T. J. Popiela[2]; [1]Lublin/PL, [2]Krakow/PL
Purpose: While mechanical thrombectomy (MT) is an established treatment for acute ischemic stroke due to large vessel occlusion, its role in anterior cerebral artery (ACA) occlusions remains uncertain due to their rarity and conflicting clinical outcomes. This study aims to evaluate outcomes of MT in patients with primary or secondary ACA occlusions across two tertiary stroke centers in Poland.
Methods or Background: This retrospective, multicenter study included patients treated with MT for ACA occlusions between 2016 and 2024. Inclusion criteria included: ACA occlusion (segments A1–A4), NIHSS ≥6, age ≥18, and pre-stroke mRS ≤3. Clinical and procedural parameters, reperfusion success, complications and functional outcomes at 90 days were analyzed.
Results or Findings: Of the 134 patients (median age 74; 57% female), 63% had primary ACA occlusions. Risk factors included hypertension (78%), coronary artery disease (67%), and atrial fibrillation (51%). The average baseline NIHSS was 18. Intravenous thrombolysis was administered in 58% of cases. Successful reperfusion (mTICI 2B-3) was achieved in 86% of cases, with a first-pass effect in 40%. Symptomatic intracranial hemorrhage (sICH) occurred in 5% of patients . At 90 days, favorable functional outcomes (mRS 0–2) was observed in 41 patients (31%) and overall mortality rate was 37%. Higher NIHSS scores at admission and the presence of sICH were identified as independent predictors of 90-day mortality.
Conclusion: MT for ACA occlusions demonstrates high rates of successful recanalization and acceptable safety profiles. However, the moderate rate of favorable outcomes and relatively high mortality rate underscore the need for further prospective studies to define its efficacy compared to best medical therapy in this patient subgroup.
Limitations: Retrospective design of the study, absence of a control group treated with intravenous rt-PA alone and high percentage of aspiration used as a primary technique.
Funding for this study: None

Analysis of malignant thyroid nodules that do not meet all recommended criteria for fine-needle aspiration according to the six existing international TIRADS guidelines (6 min)

Ayşegül Görmez; Ataşehir / Turkey

Author Block: A. Görmez, B. Uzunoğlu, T. Orhan, O. M. Topcuoğlu; Istanbul/TR
Purpose: The American College of Radiology Thyroid Imaging and Reporting Data System (ACR-TIRADS), Kwak-TIRADS, Korean TIRADS (K-TIRADS), European TIRADS (EU-TIRADS), American Thyroid Association (ATA), and China (C-TIRADS) provide recommendations for fine needle aspiration biopsy (FNAB) based on ultrasound findings and size in thyroid nodules. However, some malignant nodules do not meet the biopsy criteria and are missed. This study aimed to evaluate the sonographic features and clinical outcomes of malignant thyroid nodules that do not meet the biopsy criteria of the six existing international guidelines.
Methods or Background: Ultrasound images of pathologically proven malignant thyroid nodules between January 2007-2025 were retrospectively evaluated by two radiologists with 15 years of experience in thyroid ultrasonography and two radiology assistants. Nodules were classified according to ACR-TIRADS, Kwak-TIRADS, K-TIRADS, EU-TIRADS, ATA, and C-TIRADS. Categorical variables were expressed as percentages, and continuous variables as mean ± standard deviation. Chi-square and Mann–Whitney U tests were used for intergroup comparisons.
Results or Findings: A total of 277 malignant nodules with a mean diameter of 14.8±10.6 mm (range 3–74 mm) were included. Pathological confirmation was obtained by FNAB in 123 nodules and by surgery in 154 nodules. A total of 129 nodules were classified as ACR-TIRADS 5, and 56.6% of these were <10 mm. Similarly, 218 nodules were classified as EU-TIRADS 5, and 50.4% of these were <10 mm. Overall, 110 malignant nodules (39.7%) were ≤10 mm. Only 6 nodules were in TR3 category, while the remaining 104 nodules (94.5%) were in TR4 or TR5 category. However, due to the size criterion, biopsy was not recommended.
Conclusion: The current thresholds for performing and following up on FNAB are debatable. Larger study populations may determine the optimal size threshold for thyroid nodule management.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study.

Expanding the Role of Pre-Operative Transarterial Embolization of Thyroid Arteries in Hyperthyroidism Patients: A Proposal for Thyroid Specimen Weighting over 120 grams (6 min)

Tzu Chi Yeh; Kaoshiung City / Taiwan, Chinese Taipei

Author Block: T. C. Yeh, C-K. Wang, W-C. Lin; Kaoshiung City/TW
Purpose: According to a previous study by Kosho Yamanouchi et al., thyroids that weigh more than 200 grams present as a predictive factor for excessive bleeding during surgery for Graves' disease. We would like to propose that preoperative transarterial embolization (pre-op TAE) can effectively improve the intraoperative and postoperative outcomes in hyperthyroidism patients undergoing thyroidectomy, especially those with a thyroid weight of more than 120 grams.
Methods or Background: This is a single-center, retrospective study in which patients with clinically diagnosed overt hyperthyroidism that eventually underwent thyroidectomy were selected. We divided the patients into two subgroups, patients that underwent direct surgical resection and patients that underwent pre-operative embolization of thyroid arteries.
Results or Findings: A total of 55 patients were enrolled, including 36 in the resection-only group and 19 in the pre-op TAE group. The mean intraoperative blood loss in the pre-op TAE group was significantly reduced (99.5 ml) compared with the resection-only group (210.7 ml; p= 0.041) with a p-value of . Similarly, the mean postoperative hospital stay was shorter in the pre-op TAE group (1.18 days vs. 2.15 days; p<0.001). Postoperative pain, evaluated by the numerical rating scale, was also less severe in the pre-op TAE group (scores of 1–2) compared with the resection-only group (scores of 2–3; p<0.001). All differences reached statistical significance. Further stratification by thyroid specimen weight supported the hypothesis that patients with glands weighing more than 120 grams particularly benefited from pre-op TAE.
Conclusion: Pre-operative thyroid TAE can reduce the amount of intraoperative blood loss, shorten the length of hospital stay and lessen the degree of wound pain compared to those that underwent thyroidectomy directly.
Limitations: Small sample size. Potential bias in pain evaluation.
Funding for this study: This study received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

Predicting therapeutic response to thermal ablation for benign thyroid nodules using a nomogram: A multicenter retrospective investigation (6 min)

Xuexia Shan; Shanghai / China

Author Block: X. Shan; Shanghai/CN
Purpose: To develop and validate a nomogram based on clinical and ultrasound (US) parameters for preoperative prediction of the complete absorption rate following thermal ablation (TA) in benign thyroid nodules (BTNs).
Methods or Background: This multicenter retrospective study included 372 patients with 395 BTNs treated with TA from May 2018 to September 2021. Complete absorption was defined as a volume reduction rate (VRR) of 100% at 12 months. Predictors were identified by logistic regression with LASSO selection and incorporated into a nomogram. Model performance was assessed with receiver operating characteristic analysis, calibration, decision curve analysis, and external validation.
Results or Findings: Of the 395 nodules included, 87 (22.0%) nodules achieved complete absorption at the 12-month follow-up after TA. Predictive factors included in the nomogram are location between nodule and dangerous triangle area (OR, 0.36 [95% confidence interval [CI]: 0.15, 0.84]; P =0.018), morphology (OR, 0.18 [95% CI: 0.05, 0.65]; P =0.009), vascularity (OR, 0.32 [95% CI: 0.11, 0.92]; P <0.034), volume (OR, 0.08 [95% CI: 0.01, 0.69]; P =0.021), enhancement mode (OR, 0.25 [95% CI: 0.11, 0.59]; P =0.001). This prognostic nomogram showed great calibration and discrimination with an AUC of 0.818 (95% CI, 0.759–0.878) and 0.710 (95% CI, 0.597–0.823) in the training and external validating sets, respectively.
Conclusion: A clinical nomogram was successfully established to preoperatively and noninvasively predict the complete absorption rate for nodules undergoing TA. The model might guide physicians in evaluating the efficacy of TA and to facilitate developing individualized treatment and prognostic plans.
Limitations: The number of cases is not large enough.

CT- and Fluoroscopy-Guided Transfacet Fixation Under Local Anesthesia: A Minimally Invasive Alternative to Lumbar Fusion after Laminectomy (6 min)

Kevin Desalos; Nice / France

Author Block: K. Desalos, N. Amoretti; Nice/FR
Purpose: To evaluate the feasibility, safety, and clinical outcomes of percutaneous transfacet screw fixation under local anesthesia as a minimally invasive alternative for post-laminectomy instability.
Methods or Background: Prospective monocentric study (2022–2025) including 30 patients with lumbar segmental instability after laminectomy. All underwent CT- and fluoroscopy-guided percutaneous transfacet fixation under local or regional anesthesia. Pain (VAS) and quality of life (EQ-5D) were assessed preoperatively and at 1, 6, and 12 months and 2 years follow-up.
Results or Findings: Technical success rate: 100%. Significant pain reduction (mean VAS −3 points, $p<0.05$) and improved EQ-5D (median reduction of 2 points) were observed at 6 and 12 months. No major adverse events were reported. No cases required conversion to open fusion. Screws could be safely repositioned or removed if needed
Conclusion: CT- and fluoroscopy-guided transfacet fixation under local anesthesia is safe, feasible, and effective. It provides durable pain relief and improved quality of life, while avoiding general anesthesia, conventional surgery, and prolonged hospitalization.
Limitations: Single-center, limited sample size, and relatively short follow-up for some patients. Larger multicenter trials are required to validate long-term outcomes
Funding for this study: No funding was received for this study.

Repeat Imaging Trends over a Decade: Entering a New Era of Imaging Surveillance (6 min)
Jędrzej Sarnecki; Basel / Switzerland

Author Block: J. Sarnecki, M. T. Meyer, T. Heye; Basel/CH
Purpose: To investigate trends in per-patient imaging utilization and follow-up intervals over the last decade
Methods or Background: Trends in imaging utilization per patient and the time intervals between examinations were analyzed for 332’008 adult patients who underwent 1’660’034 studies (CR, US, CT, MRI, PET-CT) between 2014-2024 at a tertiary referral hospital. Patients were categorized into two age groups: <65yrs. and ≥65yrs.
Results or Findings: Over the last decade, examinations per patient increased by 12% for inpatients (1.66 to 1.86) versus 2.7% for outpatients (1.30 to 1.35). The main driver of change was CT imaging, with 12.0% (<65yrs.) and 12.7% (>65yrs.) increase among inpatients (MRI: -4% and +1.6%, respectively). The strongest increase was in CTs of abdomen/pelvis (+14%), chest (+12.5%), and chest-abdomen-pelvis (+8.9%).
Exemplarily, the number of patients with 5 examinations rose by 31.9% (7’183 to 9’477), those with 15 by 112.4% (1’875 to 3’983), with 30 examinations by 341.5% (342 to 1’510).
In 2014 the most frequent repeat-imaging modality was CR; in 2024, CR, US, CT were similar, with CT most frequent in the older group.
Median time between CT examinations decreased by 29.1%, from 70 days in 2014 to 49.7 days in 2024 (25th percentile: 11.8 to 7 days). Among inpatients, the reduction was greater at 55.4% (36 to 16 days) versus 7.7% among outpatients (91 to 84 days).
Repeat CT examinations increased across all follow-up intervals: within 7 days (+53.3%), within 30 days (+46.9%), within 90 days (+52.6%), and >90 days (+47%).
Conclusion: The results show an increase in imaging utilization per patient and a reduction in the time between examinations, underscoring the growing role of radiology in patient care. The most significant increase is seen in CT imaging during inpatient stays.
Limitations: Retrospective, single-centre study.

Variability in CT Referral Data Completeness: Insights from the EU-JUST-CT Project (6 min)
Jacob Sosna; Jerusalem / Israel

Author Block: C. Singer[1], M. Saban[2], L. Bergovoy-Yellin[1], B. Brkljačić[3], A. Karoussou-Schreiner[4], J. Sosna[5]; [1]Ramat Gan/IL, [2]Tel Aviv/IL, [3]Zagreb/HR, [4]Luxembourg/LU, [5]Jerusalem/IL
Purpose: To evaluate the quality and completeness of CT referrals using audited data from the EU-JUST-CT project across seven European countries: Belgium, Denmark, Estonia, Finland, Greece, Hungary, and Slovenia (n=6,734 referrals).
Methods or Background: Each referral was evaluated using seven binary indicators: Clinical data sufficient; Examination specified; Referrer specialty; Prior exams; Patient status (in-/outpatient); Patient gender and age. We computed a Completeness Score (sum of all seven indicators) and a Critical Score based on four essential items (clinical data, exam type, gender, and age). We examined the distribution of both scores by country and calculated the proportion of fully complete referrals (Completeness Score = 7) and fully critical-complete referrals (Critical Score = 4).
Results or Findings: The median Completeness Score was 7 in Denmark; 6 in Belgium, Greece, Hungary, and Slovenia; 5 in Estonia; and 4 in Finland. Denmark had the highest mean Completeness Score (6.6), while Finland had the lowest (4.3). The proportion of fully complete referrals ranged from 60.6% (Denmark) to 0.3% (Finland). For the Critical Score, all countries had a median of 4, but inter-country variation in the proportion of referrals with full critical data was observed: (67-98%). The mean Critical Score was highest for Belgium (3.98) and lowest for Slovenia (3.64).
Conclusion: Incomplete information on CT referrals was prevalent, with differences observed between countries. The results presented raise the need for unified protocols and standards, possibly anchored in the national legislation, which dictates what minimal information is required in a CT referral in order to be approved.
Limitations: Our dataset, while large and geographically diverse within Europe, may not generalize to other regions with different healthcare structures, referral styles, or disease prevalence. Additionally, this study did not assess the clinical consequences of incomplete referrals.
Funding for this study: No
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: local research ethics committees or IRBs at each of the 125 participating imaging facilities across the seven countries. At each site, the IRB either approved the study or waived the requirement for informed consent due to the retrospective nature and de-identification of the data.

Referring Physicians' Perspectives on Radiology Appointment Management: A Cross-sectional Survey of General Practitioners and Hospital Physicians (6 min)

Philipp Reschke; Frankfurt / Germany

Author Block: P. Reschke, K. Eichler, T. Vogl, A. M. Bucher; Frankfurt/DE
Purpose: Radiology appointment delays compromise healthcare efficiency and patient satisfaction, yet referring physicians' perspectives on scheduling challenges remain underexplored. This study investigates these perspectives and identifies targeted strategies for improvement, comparing general practitioners (GPs) and hospital physicians.
Methods or Background: We conducted a cross-sectional survey across Germany from June 2023 to June 2024, recruiting 220 actively practicing physicians via systematic random sampling. This included 79 GPs, who regularly refer outpatients to hospital-based radiology departments, and 141 hospital physicians, who coordinate imaging for inpatients. An anonymous online questionnaire assessed the perceived impact of imaging delays and coordination difficulties (7-point Likert scales), preferred improvement strategies (multiple choice), and prioritization of quality metrics (weighted ranking).
Results or Findings: GPs had significantly more clinical experience than hospital physicians (20 ± 14 vs. 7 ± 9 years; $p < 0.001$), with no gender differences ($p = 0.67$). GPs reported a greater impact of imaging delays on patient care (4.39 ± 1.50 vs. 4.02 ± 1.49; $p = 0.02$) and more coordination challenges (4.55 ± 1.42 vs. 4.30 ± 1.50; $p < 0.05$). Hospital physicians preferred real-time workflow tracking (34.8% vs. 9.1%; $p < 0.001$) and automated reminders (20.2% vs. 6.1%; $p = 0.007$), while GPs favored centralized scheduling (33.3% vs. 19.1%; $p = 0.03$) and urgent case prioritization (42.4% vs. 23.6%; $p = 0.008$). Short-term appointment availability was the top priority across both groups (24.9%; $\chi^2(4) = 107.2$, $p < 0.001$).
Conclusion: Radiology scheduling delays remain a key barrier to timely patient care. The findings support the implementation of referrer-specific appointment management strategies in order to optimize imaging coordination.
Limitations: Our analysis focused exclusively on referring physicians' perspectives, excluding viewpoints from radiologists, administrative staff, and patients.
Funding for this study: None
Has your study been approved by an ethics committee? Not applicable

Exploring Care of People Who Identify as Transgender or Non-binary [TGNB] Accessing Radiology/Radiotherapy Services in the UK and the Republic of Ireland (6 min)

Tracy Miller; Castlederg / United Kingdom

Author Block: T. Miller[1], N. Cook[1], J. Daly Lynn[1], L. McLaughlin[2], S. L. Mcfadden[1]; [1]Derry/Londonderry/UK, [2]Cork/IE
Purpose: It is a legal requirement to verify biological sex and pregnancy status prior to exposing people to the dangers of ionising radiation. Sensitivities that exist when ascertaining pregnancy status can result in ethically challenging scenarios for healthcare workers (HCWs) and leave TGNB people uncomfortable with their care.
Methods or Background: Two validated surveys were conducted: one assessing the radiology/radiotherapy experiences of TGNB people and the other examining HCWs attitudes towards TGNB identities. The surveys were disseminated via professional conferences, social media, and voluntary support organisations.

Data collection will be completed on 31st December 2025. SPSS version 28 is being used to conduct descriptive and inferential statistics.
Results or Findings: To date 76 HCWs and 53 TGNB participants have responded to the surveys.

Preliminary results report 37% (n=28) of HCWs had experienced transphobic behaviours from colleagues. While 20% (n=15) disagreed or strongly disagreed that knowing the gender identity of the person in their care was important. Of the TGNB respondents 51% (n=27) had not experienced affirming interactions with staff. Meanwhile 62% (n=33) had not been asked about their chosen name and 66% (n=35) had not been asked about their preferred pronouns. Additionally, 25% (n=13) of TGNB respondents did not understand the significance of pregnancy status questions.
Conclusion: Further education is needed for both sets of participants TGNB communities must be educated on the rationale for pregnancy status questions and HCWs must be provided with the tools to uphold legal obligations while maintaining the dignity of TGNB identities.
Limitations: This is a very sensitive topic which may hinder patients from participating. Hence, resulting in a limited sample size. The data is representative of the UK and Ireland population only and may not be fully reflective of the international opinion.

Interventions to reduce MRI access time – a systematic review on the existing scientific evidence (6 min)

Charles Debats; Maastricht / Netherlands

Author Block: C. Debats, M. Van Deursen - Luijten, C. Adang, F. Van Kasteren, N. Visschers, E. Peters, F. M. Zijta, J. E. Wildberger, T. Van Nijnatten; Maastricht/NL
Purpose: Growing demand for advanced imaging techniques like MRI has resulted in long waiting lists and delayed patient diagnosis by exceeding facility capacity, with consequently prolonged MRI access time. This study defines MRI access time as the time-interval between requesting an MR exam and the performance of the MR exam. The aim of this systematic review was to provide an overview of the available evidence on interventions to reduce MRI access time.
Methods or Background: Pubmed, Embase, Cochrane and Web of Science databases were searched up to September 1st 2025. Two reviewers independently screened all studies and performed data extraction. Eligible studies were original investigations reporting on MRI access times and provided results before and after the proposed intervention to reduce access time. Reviews, meta-analyses, conference papers, editorials, technical reports and case reports were excluded.
Results or Findings: The literature search yielded 3875 records, of which 29 records were fully reviewed, and 10 met inclusion criteria. Five studies evaluated simulated interventions, three studies reported implemented interventions. Reported interventions can be subdivided in three categories: matching capacity and demand (e.g., increasing MRI capacity); waiting list segmentation (e.g., grouping patients with similar characteristics to reduce coil-changing time); and operational redesigns of the MRI scheduling process (e.g., implementing a decentralized integrated online booking system). Sample sizes ranged from 264 until 172,000 patients. Reported effectiveness of interventions varied widely: most successful solution combined multiple interventions, achieving a reduction in MRI access time of 73.3 days. Multiple intervention studies did not show any measurable improvement to reduce MRI access time.
Conclusion: Current interventions to reduce MRI access time have shown limited success, with insufficient evidence supporting the impact of specified interventions, necessitating urgent research on novel interventions to be performed.
Limitations: N/a

Radiation exposure during CT: Patients´ knowledge, perception and request for information (6 min)

Nathalie Seiß; Berlin / Germany

Author Block: N. Seiß, M. Mohamed, F. Yavuz, F. Biavati, M. Rief, T. A. Auer, M. Dewey, A-C. Stahl; Berlin/DE
Purpose: To assess patients' existing knowledge and their desired level of information about radiation exposure during CT.
Methods or Background: This single-centre survey was conducted at a large European university hospital. Patients (≥ 18 years) capable of giving informed consent and scheduled for a clinically indicated CT were eligible for inclusion. A 17-question survey covering demographic data, radiation exposure of different imaging examinations, and patients' desired level of information was used to assess patients´ existing knowledge and requests for information about radiation exposure. Analysis was done by calculating frequencies of given answers. As not all patients answered all questions, the denominators differ. Chi-Square and Mann-Whitney U tests were performed to determine differences between genders.
Results or Findings: 285 questionnaires were collected with recruitment still ongoing. The median age of the patients was 62 years (IQR: 53-73), with 42% (118/280) being female. The majority, 81% (171/211) correctly stated that CT is an examination with radiation exposure, with no significant difference between female and male (85% vs. 77%, p=0.187). Interestingly, also 35% (74/211) selected MRI as an examination involving radiation exposure. Patients estimated that the radiation exposure of a thoracic CT would only be two times higher (IQR: 1-4) than that of a thoracic X-ray in two planes, again without significant gender differences (p=0.794). Overall, 71% (147/206) felt to be sufficiently to very well informed about the radiation exposure of CT and 36% (78/219) requested to receive further information.
Conclusion: While most patients are aware that CT involves radiation exposure, they tend to underestimate this exposure compared to X-rays. Most of the patients felt adequately informed with a relevant number of patients still wishing for further information.
Limitations: This is a single-centre study limiting the generalisability of the results.
Funding for this study: No funding was received for this study.

Do doctors routinely working with ionising radiation have adequate knowledge of radiation safety and risk? (6 min)

Hadil Said; London / United Kingdom

SPEAKER SUPPORTED BY INVEST IN THE YOUTH ESR

Author Block: H. Said; Chelmsford/UK
Purpose: To explore physician knowledge regarding radiation doses, the different modalities used, and important safety precautions. To determine the follow up research necessary to improve safety.
Methods or Background: Radiology is a growing specialty, and ionising radiation is increasingly being used by physicians across specialties. It is essential to understand basic radiation safety and take necessary precautions. This review synthesises the evidence on whether doctors have adequate knowledge of radiation safety and risk.

A systematic review was performed, following PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. Boolean operators were used to search Embase and PubMed databases. Inclusion criteria: English language articles within the last 10 years. Exclusion criteria: case reports, editorials, case presentations, animal studies, mammography articles. All relevant papers involved surveys; therefore a thematic analysis was performed.
Results or Findings: The initial search gave 52 results, after applying inclusion and exclusion criteria this reduced to 25 results. 11 articles were relevant to the research question.
Doctors' knowledge of radiation safety and risk was inadequate across specialties, and geographical locations. Safety measures (e.g. providing and wearing appropriate personal protective equipment) were either ignored, or inadequate, despite clear legislation within this area. Seniority did not translate to better knowledge or safety practices.
Conclusion: The evidence demonstrates that doctors have inadequate knowledge of radiation safety. The provision of radiation safety training for physicians working with ionising radiation is inadequate. Standards and guidelines should follow national/international guidelines, rather than local policy.
Limitations: This review used Braun & Clarke's reflexive thematic analysis, in which it is good practice to enlist a single coder. This means that there is one consistent approach throughout the review, but it lacks other reviewers and perspectives to corroborate paper selection and agree on the analysis.
Funding for this study: No funding was received for this study.

Ethical approval was not required as this was an systematic review using publicly available data.

Health Hazards Among Radiology Professionals: A Descriptive Survey (6 min)

Johnbosco Lydia; Chennai / India

Author Block: J. Lydia, F. Abubacker Sulaiman, R. Praveenkumar, M. Nivitha, D. Dharshini, D. Velan, A. Raashid Ibrahim, A. Selvam; Chennai/IN
Purpose: Radiology professionals are exposed to various health hazards due to the nature of their work. Occupational risks include radiation, chemical exposure, infections, and musculoskeletal strain, while non-occupational risks stem from sedentary work, screen exposure, shift duties, and stress.
Methods or Background: A structured Google Forms survey was conducted among radiologists, radiographers, and nurses to assess occupational and non-occupational hazards. Responses were analyzed, and the prevalence of each risk factor was expressed as a percentage. Preventive measures were also evaluated.
Results or Findings: The most common occupational hazards were radiation exposure (78%), musculoskeletal strain (65%), chemical/contrast exposure (42%), biological hazards (38%), and work-related stress (55%). Non-occupational risks included sedentary lifestyle (70%), eye strain (62%), sleep disturbances (48%), and lifestyle-related stress (50%). Key preventive strategies included personal protective equipment, ergonomic adjustments, vaccination, optimized shift schedules, and lifestyle modifications
Conclusion: Radiology professionals face multiple health hazards. Awareness and implementation of safety protocols, ergonomic practices, and healthy lifestyle measures are essential to reduce risks and ensure long-term professional well-being.
Limitations: The study relied on self-reported data from a limited sample, which may introduce bias and limit generalizability. Objective measurements of exposure and long-term effects were not included.
Funding for this study: No funding was provided

ECG-less Scanning with Deep Learning Reconstruction for Triple-Rule-Out CT Angiography in Acute Chest Pain: A Prospective Study (6 min)

Wei Li; Guiyang / China

Author Block: W. Li; Guiyang/CN
Purpose: To evaluate the clinical feasibility of an ECG-less triple-rule-out CT angiography (TRO-CTA) protocol combined with a deep learning reconstruction (DLR) algorithm in patients presenting with acute chest pain.
Methods or Background: In this prospective study, 180 patients referred for TRO-CTA between December 2024 and August 2025 were enrolled and randomly allocated into two groups using a GE Revolution CT scanner.

Group A (n=90): Underwent a standard ECG-gated protocol with 100 kV tube voltage and automated tube current modulation.

Group B (n=90): Underwent an ECG-less protocol with a low tube voltage of 80 kV, automated tube current modulation, and DLR for image reconstruction. Contrast medium injection parameters were identical in both groups.

Objective image quality (CT attenuation, noise) in the coronary, pulmonary, and aortic arteries, subjective image quality (5-point scale), and examination time were compared.
Results or Findings: The ECG-less protocol with DLR (Group B) demonstrated significant advantages. It yielded images with substantially lower noise (33.5 vs. 61.3, Group B vs. A) and higher subjective scores, particularly for small peripheral pulmonary arteries, with excellent inter-observer agreement (Kappa > 0.85). The use of 80 kV enhanced vascular contrast, potentially allowing for contrast medium reduction, and substantially reduced radiation exposure. Furthermore, eliminating ECG lead placement shortened the total examination time by approximately 20%.
Conclusion: The ECG-less TRO-CTA protocol with low-dose scanning and DLR provides superior image quality, enhances patient safety by lowering radiation and contrast medium requirements, and significantly improves examination efficiency. This optimized approach is highly suitable for the rapid assessment of patients with acute chest pain in emergency settings.
Limitations: The single-center design and limited sample size may restrict the generalizability of findings and subgroup analyses.
Funding for this study: This study was supported by the internal resources of GuiQian International General Hospital
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Ethical approval: This prospective study was approved by the Institutional Review Board (IRB) of GuiQian International General Hospital

Virtopsy with Photon-Counting CT: New Perspectives in Forensic Post-Mortem Imaging (6 min)

Emma Solinas; Sassari / Italy

Author Block: E. Solinas, L. Piscopo, G. De Paula, D. Turilli, M. Scaglione, S. A. Masala; Sassari/IT
Purpose: Virtopsy, or virtual autopsy, is an established method in post-mortem investigations, offering a non-invasive alternative to conventional autopsy. The recent introduction of photon-counting CT (PCCT) provides new perspectives in forensic medicine, thanks to its ability to directly convert incident photons into electrical charges, thereby reducing electronic noise and improving spatial resolution and offering spectral imaging, improving tissue and material characterization.
Methods or Background: We performed 15 post-mortem examinations using PCCT, comparing image quality and diagnostic performance with conventional CT, focusing on fracture detection, identification of foreign bodies, and differentiation of metallic materials. Particular attention was given to firearm-related deaths, where metallic artifacts often compromise conventional CT.
Results or Findings: PCCT provided high-definition images even at low energies, enabling detailed assessment of skeletal structures and soft tissues without contrast medium. Metallic artifact reduction allowed reliable discrimination between different bullets' type, significantly enhancing firearm injury evaluation. Improved visualization of trauma patterns and organ damage further support the diagnostic value. Compared to conventional CT, PCCT demonstrated superior accuracy, reproducibility, and artifact reduction.
Conclusion: Virtopsy with PCCT is a rapid, reliable, and body-preserving imaging method with clear advantages over conventional CT. Our preliminary series of 15 cases highlights its potential to improve forensic investigations and forensic anthropology, with promising applications in both forensic and academic contexts.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study.
Has your study been approved by an ethics committee? Not applicable

Radiological Imaging and Image-Guided Procedures in Palliative Inpatients: A Retrospective Review at a Tertiary Centre (6 min)

Ruth Cusack; Kilmacthomas / Ireland

Author Block: R. Cusack, E. Jones, J. Drought, C. Murphy, S. O'Neill, R. Kernan, N. Sheehy, N. O'Leary; Dublin/IE
Purpose: Radiology plays a key role in diagnosis, monitoring, and intervention for advanced disease, yet its value at the end of life is debated. Prior studies have shown high imaging utilisation with limited impact on management[1,2]. This study evaluated the utilisation and clinical value of radiological imaging and image-guided procedures in palliative inpatients, aiming to identify opportunities to optimise practice in end-of-life care.
Methods or Background: We retrospectively reviewed inpatients who died in St James's Hospital between January and December 2023. Patients were identified using the hospital's RIP Excel Report, and imaging data were extracted from electronic records. Radiological investigations in the last four weeks of life were included: plain radiography, CT, MRI, ultrasound, nuclear medicine, and image-guided procedures (ultrasound- and interventional radiology–guided). Frequency, modality, timing, and interval between last imaging and death were recorded. Imaging was classed as high-value if it established a new diagnosis that altered management or informed prognosis; otherwise, it was low-value.
Results or Findings: A total of 260 patients were included. The median number of investigations was 5. Plain radiography (median 3) and CT (median 1) were most common, while MRI (n=32), ultrasound (n=41), and nuclear medicine (n=10) were less frequent. Forty-two image-guided procedures were performed. The median interval between last imaging and death was 4 days. Of imaging within three days of death, 44 (25%) were high-value and 131 (75%) low-value.
Conclusion: Imaging and procedures are common in the last month of life, often close to death, but most were of limited clinical value from a radiological perspective. Greater collaboration between radiology and palliative care may help reduce low-yield imaging.
Limitations: This study is limited by its retrospective, single-centre design and reliance on clinical documentation.
Funding for this study: No external funding was received.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Ethical approval was granted by the St James's Hospital/Tallaght University Hospital Joint Research Ethics Committee.

Clinical and Economic Impact of 3D Volumetric Reconstruction in Major Abdominal Surgery Planning: A Systematic Review and Meta Analysis of Outcomes and Reimbursement Policies (6 min)

Lama Abdullah Alyahya; Jeddah / Saudi Arabia

Author Block: L. A. Alyahya, D. Aljohani, F. Alqarni; Jeddah/SA
Purpose: (3D)volumetric reconstruction has emerged as a transformative tool in surgical planning.Its clinical precision is well documented,but its economic justification and reimbursement integration remain poorly established
Methods or Background: This PRISMA-guided systematic review analyzed clinical,economic,and reimbursement outcomes from 19 studies across hepatobiliary,colorectal,thoracic,neurosurgical, and orthopedic oncology.Quality appraisal employed ROBINS-I,RoB 2,AMSTAR-2,and NIH tools.
Results or Findings: Across 3,402 hepatectomy cases (Zeng et al., 2024),3D-assisted planning significantly reduced operative time,morbidity, and postoperative liver failure while improving recurrence-free survival (RFS PSM p=0.043; IPTW p<0.001).Prospective hepatobiliary data (Yao et al., 2024, n=62)showed halved complication indices (CCI 8.7 vs. 20.9) and reduced major complications(6.5% vs. 22.6%). Randomized evidence(Lu et al., 2023, n=50) confirmed shorter operative time(118.4±28.2 vs. 142.7±25.6 min),reduced blood loss (82.5±19.3 vs. 126.2±27.4 mL),and decreased length of stay(9.5 vs. 10.9 days).Similar benefits were observed in colorectal, thoracic, and pancreatic surgeries.Economic modeling (Ballard et al., 2020) estimated per-case savings of $3,720 for 3D models and $1,488 for surgical guides based on OR time reduction.Model costs ranged <$1–$146 per unit (Serrano et al., 2020).Despite clear perioperative benefits, 68% of included studies exhibited moderate-to-high risk of bias,and reimbursement remained inconsistent,with most payers classifying 3D reconstruction as investigational.
Conclusion: 3D volumetric reconstruction improves operative efficiency and precision across major surgeries,offering potential cost savings. However,heterogeneous evidence and fragmented reimbursement policies hinder its widespread,economically sustainable adoption in surgical practice.
Limitations: Future integration should prioritize three areas.One is rigorous randomized evidence to solidify causal inference,especially regarding long-term survival and cost-effectiveness.Another is standardized reporting of segmentation time,printing cost,and workflow requirements,enabling comparative economic analyses across systems.Finally, policy frameworks should evolve toward recognizing 3D reconstruction as a distinct reimbursable service when clinical evidence supports measurable benefit.Pilot bundled-payment models or demonstration projects could provide the necessary health economic data to bridge the current evidence-policy gap.

Radiology in Crisis: Preparing for Catastrophes, Conflict Zones, and Military Actions (6 min)

Uliana Pidvalna; Lviv / Ukraine

Author Block: U. Pidvalna, D. Beshley; Lviv/UA
Purpose: Radiologists play an important, but often underrecognized, role in managing the medical consequences of crises: from natural disasters and mass-casualty events to armed conflicts and war zones. As global instability rises, the need for a structured and resilient radiology response becomes paramount.
Methods or Background: This abstract addresses the practical, technical, and ethical challenges faced by radiologists working under extreme conditions. It is not limited to power outages, air raid sirens, infrastructure damage, limited internet access, triage, and scarce resources, but also to moral and ethical issues.
Results or Findings: Drawing on experiences from war zones, this discussion provides a realistic, system-based overview of radiological practice in unstable environments. How to maintain imaging services during power outages? Do we need to adapt workflows without PACS/RIS systems? Should we ensure communication in the absence of digital networks? Managing triage imaging in high-pressure scenarios? Emphasis on the mental and physical strain placed on radiology teams, as well as the need for international cooperation, modular protocols, and mobile radiology units.
Conclusion: Sharing pragmatic strategies and organizational insights equips radiologists with the tools and mindset necessary to prepare for and function effectively during crises, wherever they may arise.
Limitations: Limitations include the variability of crisis settings, the lack of standardized protocols, and the reliance on personal experiences.
Funding for this study: No funding.

Injuries That Speak: Detecting Non-Accidental Injury in Paediatric Imaging (8 min)
Ioannis Stergios Trapotsis; Athens / Greece

Author Block: I. S. Trapotsis, F. Georgopoulos; Nicosia/CY
Purpose: The aim of this presentation is to review specific radiological signs suggestive of Non-Accidental Injury (NAI) across different imaging modalities. Furthermore, it addresses the role of the radiologist in detecting and diagnosing NAIs in paediatric patients while emphasizing the importance of adherence to established imaging protocols as well as to an effective interdisciplinary communication with other physicians.
Methods or Background: This presentation examines current radiological protocols and imaging modalities used in suspected cases of paediatric NAI, including X-ray, CT, MRI, and ultrasound. The importance of a systematic approach for early detection and documentation of injury patterns suggestive of abuse is highlighted, alongside an overview of the typical injury patterns and their distinguishing features.
Results or Findings: Paediatric NAIs can be divided into CNS, skeletal and abdominal injuries. CNS injuries include most commonly subdural haematomas which are assessed with US, CT and MRI. Spinal cord injuries include spine compressions and subdural haematomas found along the spine, especially in the lumbar region. These are evaluated with MRI. Retinal haemorrhages are documented after an ophthalmologic examination alongside an MRI. Skeletal injuries, identified on X-ray, involve metaphyseal avulsion fractures [corner, bucket-handle], rib fractures [posterior, lateral], diaphyseal fractures and skull fractures described as 'eggshell' or occipital impression fractures. Abdominal injuries such as liver, duodenal and pancreatic lacerations are visualized on CT. Differential diagnoses include Accidental trauma, Coagulopathies, Osteogenesis imperfecta, Menke's disease, Spondylometaphyseal dysplasia, Caffey's disease, and Normal variants. An initial and a follow-up skeletal survey should always be performed.
Conclusion: All these radiologic signs, protocols and interdisciplinary communication play a critical role in the early diagnosis and treatment of NAIs. It is essential that every radiologist is well-versed in these aspects to avoid misdiagnosis and ensure best treatment.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study.

Pixels and Pigs: The beginning of a paradigm shift in the field of osteochondritis dissecans (8 min)
Saumith Bachigari; Eden Prairie / United States

Author Block: S. Bachigari, A. R. Menezes, T. Nguyen, A. W. Kajabi, J. Ellermann; Minneapolis, MN/US
Purpose: To reexamine the pathogenesis of juvenile osteochondritis dissecans by introducing novel MRI-based approaches that allow earlier detection, improved classification and effective treatment.
Methods or Background: JOCD has been traditionally understood as a stress-related subchondral bone disorder where focal areas of bone fragmentation lead to decreased vascularity and eventual detachment of subchondral bone. This view has shaped current paradigms, however, current clinical MRI has demonstrated limited reliability in guiding management. Emerging evidence through ultra high field MRI (Pixels) and pig models of subchondral vascular channels (Pigs) suggests that JOCD actually arises from disruptions in vascular supply within the epiphyseal cartilage. This understanding is crucial for improving diagnostic accuracy and treatment.
Results or Findings: Our advanced MRI techniques, particularly, quantitative susceptibility mapping and high-resolution T2* imaging at 9.4T enabled visualization of epiphyseal cartilage canal vessels, hence, identifying watershed areas that become future sites of JOCD. Comparative animal studies validated pig knee models as they closely resemble human vascular networks. MRI protocols incorporating T2* mapping then revealed early stages of JOCD as focal arrests of endochondral ossification within cartilage rather than late-stage osseous defects. Our clinical longitudinal also studies show that T2* metrics can identify non-operative patients as early-stage JOCD lesions maintain intact articular cartilage, conferring excellent prognosis if diagnosed before structural collapse.
Conclusion: Our findings reframe JOCD as a disease of epiphyseal cartilage vascular origin with subsequent osseous manifestation. Healing requires sequential steps through endochondral ossification stages. Novel MRI biomarkers can enable early identification, monitoring and prognosis, thereby providing the foundation for a paradigm shift in clinical management. Early, cartilage-focused diagnosis has the potential to preserve joint integrity, reduce unnecessary surgical interventions, and improve long-term outcomes for affected patients.
Limitations: No limitations were identified in this study

Fibroblast Activation in Mitral Annular Calcification (8 min)

Alex Jordan; Edinburgh / United Kingdom

Author Block: A. Jordan, N. Craig; Edinburgh/UK
Purpose: Mitral annular calcification (MAC) associates with increased all-cause and cardiovascular mortality, yet its pathophysiology is incompletely understood, and no pharmacotherapy has altered its progression. This study aimed to investigate the relationship between fibroblast activation, a driver of aortic valve calcification, and MAC using the novel PET radiotracer [68Ga]FAPI-46.
Methods or Background: This observational, longitudinal cohort study comprised 93 participants (mean age 72 ± 8, 29% female) across the spectrum of aortic stenosis (severe=25, moderate=24, mild=24), aortic sclerosis (n=11) and controls (n=9). All participants underwent clinical assessment, transthoracic echocardiography and hybrid [68Ga]FAPI-46 PET-CT. A subset of patients received repeat imaging following a median of 453 days. CT calcium scoring quantified the presence and burden of MAC. [68Ga]FAPI-46 uptake (TBRmax) was measured in the mitral annulus.
Results or Findings: 35 (38%) participants had MAC. Patients with MAC were older ($p<0.001$) and had a higher NT-proBNP ($p<0.01$). Of the 87 participants with analysable PET images, 50 (57.5%) had visually discernible mitral annular [68Ga]FAPI-46 uptake, which was significantly higher in patients with MAC (81.8% positive, median TBRmax 1.45 [IQR 1.27-1.72]) than in those without (42.6% positive, median TBRmax 1.37 [IQR 1.17-1.42]; $p<0.001$). At follow-up, mitral annular [68Ga]FAPI-46 TBRmax increased over time ($p<0.001$) and positively correlated with faster annualised mitral annular calcium score progression ($r=0.52$, $p<0.05$).
Conclusion: This study provides novel in vivo evidence of fibroblast activation in MAC, suggesting an active disease process that may precede and predict disease progression. [68Ga]FAPI-46 PET-CT represents a promising tool for early risk stratification and monitoring the efficacy of therapies aimed at halting MAC progression.
Limitations: Limited to patients with calcific aortic valve disease, our sample size was modest. Follow-up attrition may also affect generalisability. Future studies should include more diverse cohorts and assess observer variability.

Robustness of cyst fluid spectral measurements for classifying pancreatic cysts on photon-counting CT (8 min)

Zsófia Somogyiné Nagy; Budapest / Hungary

Author Block: Z. Somogyiné Nagy[1], B. K. Budai[2], A. I. Vigh[1], Á. Szücs[1], M. Benke[1], A. Szijártó[1], P. Maurovich-Horvat[1], I. Dudás[1]; [1]Budapest/HU, [2]Heidelberg/DE
Purpose: Differentiating pancreatic cystic lesions (PCLs) is a persistent diagnostic challenge. Photon-counting detector CT (PCD-CT) provides spectral imaging with virtual monoenergetic images (VMI) that enable quantitative assessment. This study evaluated whether mucinous and non-mucinous PCLs exhibit distinct spectral absorption patterns on postcontrast scans and examined the reproducibility and robustness of region of interest (ROI) measurements.
Methods or Background: We retrospectively analyzed 53 mucinous cystic neoplasms and 23 non-mucinous PCLs, each with arterial, pancreatic, and venous phase PCD-CT scans. Cyst fluid densities were measured on 40 keV and 70 keV VMIs, and the difference (HUΔ40–70keV) was calculated. Diagnostic performance was assessed with ROC curve analysis. After measuring 10-10 ROIs, bootstrap-based sampling and repeated five-fold cross-validation were used to determine the optimal number of ROIs and evaluate the stability of classification thresholds, sensitivity, specificity, and accuracy.
Results or Findings: We observed significantly higher HUΔ40–70keV values for mucinous PCLs across arterial ($p=0.017$), pancreatic ($p<0.0001$), and venous ($p<0.0001$) phases. The pancreatic phase yielded the best diagnostic performance (AUC 0.93, accuracy 82%, sensitivity 75%, specificity 96%). Robust classification required at least four ROI measures per lesion, with mean aggregation providing stable prediction probabilities and validation AUCs of 0.88–0.89.
Conclusion: Spectral measurements of cyst fluid using HUΔ40–70keV on PCD-CT VMI reconstructions differentiate mucinous from non-mucinous PCLs with promising accuracy. Using multiple ROI samples enhances reproducibility, suggesting that this non-invasive approach could serve as a complementary tool in the diagnostic evaluation of pancreatic cysts.
Limitations: This was a single-center study with a retrospective study design.
Funding for this study: No funding was received for this study.

Impact of Prior Hysterectomy on Bone Mineral Density in Postmenopausal Georgian Women: A Retrospective DEXA-Based Study (8 min)

Davit Jagashvili; Rustavi / Georgia

Author Block: D. Jagashvili; Rustavi/GE
Purpose: The purpose of this study was to evaluate the association between prior hysterectomy and the prevalence of osteopenia and osteoporosis in postmenopausal Georgian women, using dual-energy X-ray absorptiometry (DEXA).
Methods or Background: A retrospective cohort analysis was performed on DEXA results from 730 patients, focusing on 585 postmenopausal women aged 31-85 years, who underwent scanning at our facility between 2024-2025. The study focused on analyzing the BMD status of the patients with a history of hysterectomy. Data collected included patient age, number of osteoporosis risk factors (e.g., alcohol use, smoking, prior fractures, parental hip fracture, glucocorticoid therapy, rheumatoid arthritis, thyroid disorders, diabetes), and previous/on-going osteoporosis treatment. BMD was classified as normal, osteopenia, or osteoporosis based on WHO criteria.
Results or Findings: Among the 585 postmenopausal women scanned, 140 (23.90%) had normal BMD, 262 (44.8%) were diagnosed with osteopenia and 183 (31.30%) with osteoporosis. Of our patients, 27.9% women had undergone a hysterectomy. Within the hysterectomy group (n=163), 37 (22.7%) were diagnosed with osteoporosis and 78 (47.9%) with osteopenia, while 48 (29.4%) had normal BMD. The most commonly affected age group for poor BMD was 60–70 years. Among the 25 patients who had previously received osteoporosis treatment, 28% continued to meet the diagnostic criteria for osteoporosis. These patients typically had ≥2 additional risk factors, including prior fractures and/or glucocorticoid therapy.
Conclusion: A history of hysterectomy is significantly associated with decreased bone health, increasing the prevalence of both osteopenia and osteoporosis in postmenopausal Georgian women. These findings emphasize the importance of routine BMD screening using DEXA in this high-risk group, particularly with additional risk factors such as glucocorticoid therapy, which may influence treatment response and disease progression.
Limitations: A retrospective study.

Is Routine Ultrasound Warranted After the First Urinary Tract Infection in Children (8 min)

Tjas Zvar; Senovo / Slovenia

Author Block: T. Zvar, P. Slak, D. Plut; Ljubljana/SI
Purpose: Female sex and congenital anomalies of the kidney and urinary tract (CAKUT) are major risk factors for urinary tract infections in children. UTI in combination with CAKUT increase the risk of developing chronic kidney disease. Ultrasound (US) is the first-line imaging tool for detection of CAKUT, but guidelines differ on its timing. The aim of our study was to evaluate US findings in children with first-time UTI.
Methods or Background: This observational, single-centre retrospective study included 1460 children who underwent urinary tract US following their first UTI between 2014 and 2024. We reviewed initial US results and all subsequent imaging. Based on US, children were classified into five groups: normal US, US signs of acute infection without CAKUT, CAKUT without dilatation, CAKUT with dilatation, and other. Children were further stratified by age into three groups. Categorical variables were analysed with chi-square test and group proportions with the two-proportion z-test.
Results or Findings: Girls predominated in the 7–24 month and >24 month groups ($p<0.001$). US detected CAKUT in 6.9% of children, 3.5% with dilatation which was more common in boys ($p=0.003$) and those ≤6 months ($p=0.04$). Normal US was most frequent in children 7–24 months ($p<0.001$), while US signs of acute infection without CAKUT were more common in those >24 months ($p=0.011$). Urinary tract dilatation was the most frequent CAKUT finding ($p<0.001$), with vesicoureteral reflux (VUR) the leading cause (1.6%). VUR was confirmed in 24 children after US, and another 34 were diagnosed during follow-up for recurrent UTIs, despite normal initial US.
Conclusion: Our findings suggest the current screening approach for CAKUT is not effective. US could be limited to children under 6-months and those with recurrent UTIs.
Limitations: Not all children had urine culture; pathogen–CAKUT association unanalysed.
Funding for this study: No funding was provided for this study.

Development of a 3D MRI microvascular mapping tool for breast surgical planning (8 min)

Luana Ramos; Lagoa / Portugal

Author Block: L. Ramos[1], H. I. d. S. Guerreiro[2], M. G. C. V. Cartucho[3], D. A. P. D. A. P. Silva[2], C. N. M. d. Santos[2]; [1]Lagoa/PT, [2]Faro/PT, [3]Portimão/PT
Purpose: To develop and validate a 3D non-contrast breast MRI protocol (1.5T) for breast vascularization preoperative mapping establishing acquisition parameters, image quality criteria, and clinical reproducibility.
Methods or Background: Preoperative characterization of breast vascularization is crucial to preserve the viability of the skin flap and the nipple-areolar complex (NAC), preventing complications such as ischemia or necrosis.
The protocol was developed using a Philips Ingenia 1.5T Omega HP scanner, involving 10 female volunteers selected by strict inclusion and exclusion criteria. TOF and REACT sequences were employed, optimized to maximize acquisition time, vessel-to-tissue contrast, vascular border sharpness, fat suppression, and minimize artifacts, allowing precise characterization of the number of perforators, minimum detectable diameter, subcutaneous path, continuity to the NAC, distance to the NAC, anastomoses, and relevant anatomical variants.
Results or Findings: The optimized 3D non-contrast acquisitions enabled clear visualization of the internal mammary artery, measuring 2.6 mm in diameter, and perforator branches as small as 0.8 mm—a relevant finding since vessels <1.0 mm are usually described only in contrast-enhanced MRI. A continuous vascular path to the NAC was observed in both breasts analyzed.
Conclusion: The 3D non-contrast MRI technique proved effective in identifying clinically relevant vascular structures, enabling delimitation of areas of higher vascularization to preserve, planning incisions to avoid dominant vessels, and personalized ischemia risk assessment of the NAC. Future plans include integrating vascular maps into mixed reality platforms (e.g., Microsoft HoloLens) for preoperative marking/planning and intraoperative support, after validation with a larger sample.
Limitations: Small, healthy sample; single center; sequences still being optimized; not a diagnostic study nor a screening replacement.
Funding for this study: No funding.

Assessment of Minimal Iodine Requirements in Contrast-Enhanced Mammography: Development of 3D-Printed Inserts for a Modular Phantom (8 min)

Masar Al-muttairi; Vienna / Austria

Author Block: M. Al-muttairi, E. Salomon, S. Schröter, P. Homolka, J. Hummel; Vienna/AT
Purpose: The clinical adoption of contrast-enhanced mammography (CEM) raises concerns regarding cumulative iodine exposure and patient safety. Lowering the required contrast dose without compromising lesion visibility is a key priority. To support this, we developed and evaluated a 3D-printed contrast–detail phantom for systematic assessment of lesion detectability at decreasing iodine concentrations.
Methods or Background: Iodine-doped resin inlets were prepared by mixing Iomeron 400 (49% iodine) with a commercial resin to achieve seven concentrations (0.353–2.854 mg/cm²). Cylindrical test objects (1–5 mm, 2 mm thick) were fabricated, sanded, and mounted into a precision-cut PMMA plate, then integrated into an L2 phantom background. Dual-energy CEM imaging (TiCEM, Siemens Mammomat Revelation, 28–32 kV, AEC) was performed. A 4-alternative forced choice (4AFC) study was conducted with eight readers, each assessing 12 images per condition. Scores were aggregated into perception probabilities. Psychometric functions were fitted to determine 62.5% detection thresholds. Data were further analyzed to generate contrast-detail and size-detail curves.
Results or Findings: Detection followed the expected inverse relationship between lesion size and iodine concentration. At high concentrations (≥1.420 mg/cm²), 1 mm lesions were consistently detected. At 1.063 mg/cm², 1 mm lesions remained detectable for most readers. At 0.708 mg/cm², only lesions ≥3 mm reached threshold, while no lesions were detected at 0.353 mg/cm². Seven of eight readers detected 3 mm lesions at 0.708 mg/cm²; one required 1.063mg/cm². Similarly, seven readers detected 1 mm lesions at 1.063 mg/cm², while one required 1.420 mg/cm². Inter-reader variability was modest at high contrasts but increased at lower levels.
Conclusion: The phantom enabled reproducible and quantitative evaluation of CEM detectability, supporting protocol optimization towards reduced iodine dose.
Limitations: This study was limited to a single phantom and eight observers. Inter-phantom variability and clinical patient-related factors were not assessed.
Funding for this study: This project is part of, and is funded by the CD Laboratory for Patient-Centered Breast Imaging.

Correlation between radiological parameters in computed tomography (CT) and histopathological findings in small size renal tumors (8 min)

Emīls Līcis; Kalngale / Latvia

Author Block: E. Līcis, A. Kratovska, N. Zdanovskis, A. Silovs; Riga/LV
Purpose: The accurate differentiation of renal tumor subtypes remains a clinical challenge. The aim of this single-center retrospective case-control study was to compare the radiological parameters of multiphase CT and histopathological subtypes and grades of renal tumors.
Methods or Background: A cohort of 40 patients with suspected renal tumors underwent multiphase CT imaging followed by histopathological verification with core biopsy. Demographic, morphological, and clinical data were collected. CT findings were analyzed for tumor size, location, radiological features, and HU values across CT phases. Statistical analyses included descriptive statistics, chi-square tests, Kruskal–Wallis tests with Bonferroni correction, independent-samples t-tests, and Spearman correlations.
Results or Findings: The most frequent renal tumor was clear cell renal cell carcinoma (RCC) (41.1%), followed by oncocytoma (12.5%) and papillary RCC (10.7%). The avarage tumor size was 2,24 ± 0,82cm, which did not significantly correlate with histological subtype ($p = 0.961$) or grade ($p = 0.341$). Morphological CT features (intratumoral necrosis, hemorrhage, fat, calcifications) showed no significant association with histological type or grade ($p > 0.05$), though tumor localization demonstrated a trend toward correlation with grade ($p = 0.061$).
Multiphase HU analysis revealed significant differences in enhancement across RCC subtypes in the arterial ($p = 0.012$) and venous phases ($p = 0.042$). ΔHU values confirmed papillary RCC showed consistently lower contrast enhancement, while oncocytomas demonstrated uniform and marked arterial enhancement (>20 HU) in all cases, similar to clear cell RCC.
Conclusion: In larger renal masses, specific radiological features often aid diagnosis, but these are typically absent in small tumors. Therefore ΔHU values become essential in differential diagnosis, especially for papillary RCC. Nevertheless, distinguishing small oncocytomas from clear cell RCC requires biopsy for verification.
Limitations: The limitations of the study are primarily related to the small cohort size.
Funding for this study: No funding was provided for this study.

Use of a segmented atlas as an index reference to detailed anatomy, cases and educational tutorials (8 min)

Robert Hardwick; Tewkesbury / United Kingdom

Author Block: R. Hardwick, A. Rasul; Oxford/UK
Purpose: Anatomical competency is essential for progression in medical education and remains a core skill for doctors and allied health professionals throughout their careers. In clinical practice, anatomy is frequently encountered through radiological studies; however, students and healthcare professionals often face challenges in translating theoretical anatomical knowledge into accurate interpretation of imaging—especially when abnormalities are present.
This project aimed to develop a segmented radiology atlas framework that links individual anatomical structures to detailed anatomy references, relevant clinical cases, and instructional educational tutorials.
Methods or Background: A custom, web-based platform was created to ensure universal access. The initial phase focused on musculoskeletal (MSK) MRI studies. Normal MRI scans were selected, uploaded, and systematically segmented to identify key anatomical structures. For each segmented structure, we wrote comprehensive anatomical factsheets, curated common clinical cases, and produced instructional tutorials. Subject matter experts contributed to the knowledge base, which was cross-referenced with each anatomical segment. A diverse group of users—including students and clinicians—were invited to test the platform and provide feedback on usability, educational value, and clinical applicability. The authors' role was limited to the academic evaluation of the platform; they were not involved in its design, development, or ownership.
Results or Findings: User feedback indicated that the platform was intuitive and easily navigable. Participants reported improved confidence in interpreting radiological images and found that the segmented atlas provided clear and relevant access to anatomical and clinical information. The educational content was targeted and supported deeper understanding of both normal anatomy and radiologic interpretation.
Conclusion: This project is a user-friendly, scrollable segmented radiology atlas framework that serves as an index linking anatomical structures to detailed references, clinical cases, and educational tutorials. This innovative and novel approach has the potential to significantly enhance anatomy and radiology education. The platform is currently hosted at radiologyplus.com, and future development aims to expand content coverage.
Limitations: No limitations were identified.
Funding for this study: No funding was received for this study.

SA 10 - State-of-the-art imaging in inflammatory bowel disease (IBD)

Categories: GI Tract, Abdominal Viscera, Artificial Intelligence, President's Choice

ETC Level: LEVEL III

Date: March 5, 2026 | 14:30 - 16:00 CET

CME Credits: 1.5

The aim of the session is to illustrate the "state-of-the-art" imaging in Crohn's disease with emphasis on the small bowel manifestations. The last ECCO-ESGAR imaging guidelines will be reviewed, and the role of intestinal ultrasound and MR-enterography will be discussed. Future developments in imaging of IBD will be illustrated by considering the most interesting and challenging issues, such as the role of quantitative imaging, AI applications, and the imaging of fibrosis.

Moderator:
Pasquale Paolantonio; Roma / Italy

Chairperson's introduction (5 min)
Pasquale Paolantonio; Roma / Italy

Review of the updated ECCO-ESGAR guidelines (20 min)
Stuart Andrew Taylor; Prestwood / United Kingdom

IUS vs MR enterography: when and why? (20 min)
Isabelle De Kock; Ghent / Belgium

Fibrosis assessment (15 min)
Martina Scharitzer; Vienna / Austria

Quantitative imaging of IBD: disease activity and beyond (15 min)
Jordi Rimola Rimola Gibert; Barcelona / Spain

Panel discussion: Imaging challenges in IBD (15 min)

SF 10 - Liquid biopsy: implications for oncologic imaging

Categories: Oncologic Imaging, Research, Interventional Oncologic Radiology, Translational Imaging, Multidisciplinary
ETC Level: LEVEL II+III
Date: March 5, 2026 | 14:30 - 16:00 CET
CME Credits: 1.5

Moderator:
Wolfgang Gerhard Kunz; Munich / Germany

Chairperson's introduction (3 min)
Wolfgang Gerhard Kunz; Munich / Germany

Liquid biopsy: the oncologist's perspective (25 min)
Kathrin Heinrich; Munich / Germany

1. To learn the basics about liquid biopsy.
2. To appreciate the complexity of liquid biopsy methods.
3. To understand the oncologist’s perspective on liquid biopsy.

LB-RECIST: liquid biopsy response evaluation (25 min)
Kathrin Heinrich; Munich / Germany

1. To learn about liquid biopsy as a tool for response evaluation.
2. To appreciate the complexity of response patterns in liquid biopsy.
3. To understand the framework of LB-RECIST.

The relationship of liquid biopsy and oncologic imaging (25 min)
Patrick D Sutphin; Dallas / United States

1. To learn how liquid biopsy and oncologic imaging reflect cancer burden.
2. To appreciate the differences between liquid biopsy and imaging as an assessment tool.
3. To understand the opportunities of combining parameters from both methods.

Panel discussion: Can we combine liquid biopsy results and imaging-based response criteria? (12 min)

AI-SC 10 - Measuring AI’s true value and impact beyond raw performance

Categories: Imaging Methods, Evidence-Based Imaging, Artificial Intelligence

ETC Level: LEVEL II+III

Date: March 5, 2026 | 14:45 - 15:45 CET

CME Credits: 1

The session will address and discuss the divide between raw accuracy metrics, typically reported for AI medical devices and actual clinical impact metrics we should be focusing on like number of increased/avoided biopsies, number of increased/missed disease detection.

Moderator:

Anton Becker; New York City / United States

Chairperson's introduction (5 min)

Anton Becker; New York City / United States

Panel discussion (45 min)

Christian Blüthgen; Palo Alto / United States

Michail Klontzas; Heraklion / Greece

Jacob Johannes Visser; Rotterdam / Netherlands

Q&A: Numbers don’t lie, but do they misdirect? (10 min)

AR h10 - How to improve your head and neck cancer staging reports in practice

Categories: Oncologic Imaging, Head and Neck, Professional Issues, President's Choice
ETC Level: LEVEL I+II
Date: March 5, 2026 | 15:00 - 16:00 CET
CME Credits: 1

Moderator:
Ho Sang Leung; Hong Kong / Hong Kong SAR China

Introduction (3 min)
Ho Sang Leung; Hong Kong / Hong Kong SAR China

Basic principles (7 min)
Ann Dorothy King; Hong Kong / China

1. To learn how to structure head and neck cancer reports so that findings are easily extractable and clinically relevant.
2. To appreciate the importance of concise and clear language in improving communication and decision-making.
3. To understand how to tailor reports to specific head and neck cancer types, ensuring completeness without omissions.
4. To learn techniques for addressing uncertainty in imaging findings while minimising ambiguity and avoiding errors.

Cases review, interactive discussion and critiquing of reports (50 min)
Ho Sang Leung; Hong Kong / Hong Kong SAR China
Ann Dorothy King; Hong Kong / China

1. To critique reports and suggest ways of improving them.
2. To show how to make reports brief yet clinically pertinent.

EIBIR 3 - EIBIR Stage bonus session 3

Categories: Hybrid Imaging, Imaging Methods, Oncologic Imaging, Professional Issues, Multidisciplinary, Artificial Intelligence
Date: March 5, 2026 | 15:00 - 16:00 CET
CME Credits: 1

Moderator:

Deep learning for differentiating Progressive Supranuclear Palsy from Corticobasal Degeneration using T1w-MRI (9 min)
Radhika Juglan; Dresden / Germany

Author Block: R. Juglan[1], A. Robasco[1], Z. I. Carrero[1], H. H. Kitzler[1], D. Truhn[2], J. Kather[1]; [1]Dresden/DE, [2]Aachen/DE
Purpose: Progressive Supranuclear Palsy (PSP) and Corticobasal Degeneration (CBD) are rare neurodegenerative disorders that present with overlapping clinical phenotypes, yet differ in underlying neuropathology. Accurate differentiation remains challenging with conventional MRI assessment. We investigated whether a brain MRI foundation model can enable automated and interpretable classification of PSP versus CBD.
Methods or Background: A self-supervised foundation model pre-trained on 42,000 UK Biobank T1-weighted MRIs was used as a feature extractor. A linear classification layer was trained on the 4RTNI cohort to separate PSP and CBD. Model performance was evaluated on a held-out test set with independent subjects using AUROC, AUPRC, and threshold-based diagnostic metrics. Interpretability was assessed with Grad-CAM heatmaps and atlas-based regional quantification. Longitudinal analyses examined prediction score trajectories and t-SNE embeddings across baseline, 6-month, and 12-month follow-up scans.
Results or Findings: In classifying PSP from CBD, the model achieved an AUROC of 0.78 (95% CI: 0.67–0.88) and AUPRC of 0.73 (95% CI: 0.58–0.87). At the optimal threshold determined by Youden's J (0.53), the model achieved an accuracy of 0.75 with sensitivity of 0.78, specificity of 0.72, and F1 score of 0.75. With time progression, discrimination between the two diseases improved with AUROC increasing from 0.68 at baseline to 0.81 at 1-year follow-up, along with greater divergence in the embedding space. Grad-CAM localized highest attention to atlas-derived midbrain and thalamic structures, consistent with PSP pathology.
Conclusion: A lightweight linear classifier built on a foundation model distinguished PSP from CBD with good accuracy. Model-derived attention maps aligned with known disease-specific neuroanatomical patterns, supporting the potential of MRI foundation models to aid stratification in rare neurodegenerative syndromes.
Limitations: The limitation of the study is that it was restricted to a single cohort.
Funding for this study: Funding was provided by the the European Union EU's Horizon Europe research and innovation programme (ODELIA, 101057091; GENIAL, 101096312), German Cancer Aid DKH (DECADE, 70115166), the German Federal Ministry of Research, Technology and Space BMFTR (PEARL, 01KD2104C; CAMINO, 01EO2101; TRANSFORM LIVER, 031L0312A; TANGERINE, 01KT2302 through ERA-NET Transcan; Come2Data, 16DKZ2044A; DEEP-HCC, 031L0315A; DECIPHER-M, 01KD2420A; NextBIG, 01ZU2402A), the German Research Foundation DFG (CRC/TR 412, 535081457; SFB 1709/1 2025, 533056198), the German Academic Exchange Service DAAD (SECAI, 57616814), the German Federal Joint Committee G-BA (TransplantKI, 01VSF21048), the European Research Council ERC (NADIR, 101114631), the National Institutes of Health NIH (EPICO, R01 CA263318) and the National Institute for Health and Care Research NIHR (Leeds Biomedical Research Centre, NIHR203331).

Can radiomic features derived from T1- and T2-weighted MRI improve differentiation of benign and malignant soft-tissue tumours? (9 min)
Matthew Marzetti; Leeds / United Kingdom

Author Block: M. Marzetti[1], M. P. A. Starmans[2], P. Robinson[1], D. L. Buckley[1], A. Scarsbrook[1], S. Klein[2]; [1]Leeds/UK, [2]Rotterdam/NL
Purpose: Soft-tissue sarcomas (STSs) are rare malignant tumours, while benign soft-tissue tumours (STTs) are common. Differentiation by imaging is challenging, often requiring invasive biopsy or resection. This study evaluated whether radiomics applied to MRI can reliably distinguish STSs from benign STTs, potentially accelerating diagnosis, reducing patient anxiety and diagnostic workload.
Methods or Background: A large retrospective dataset of 951 patients referred to a sarcoma multidisciplinary team (2007–2023) was selected. Tumours were automatically segmented using a deep-learning model on T1-weighted and T2-weighted fat-suppressed MRI, with manual corrections applied when necessary, before radiomic feature extraction. Nested cross-validation was used to train and test a logistic regression classifier. Performance was measured using area under the receiver operating characteristic curve (AUC). To reduce false negatives, a classification threshold ensuring ≥95% sensitivity was selected using the training dataset in the inner cross-validation. Final models from each outer cross-validation fold were ensembled and tested on two independent datasets:
1. Prospectively acquired data from the local centre (n=154).
2. External data from open-access sources and collaborators (n=155).
Results or Findings: The model achieved a mean AUC of 0.88 (range: 0.86-0.90) across the outer folds of the nested cross-validation. A threshold was calculated that provided a sensitivity of 95% and specificity of 57%. The model performed well on the external dataset (AUC=0.84, sensitivity=94%, specificity=45%) and the prospective dataset (AUC=0.80, sensitivity=91%, specificity=49%). Further analysis demonstrated variation in model performance across STT subtypes, which was investigated.
Conclusion: Radiomics can identify a significant proportion of benign lesions while maintaining high sensitivity for malignancy (≥91%), supporting its potential to reduce diagnostic workload with minimal risk to patient safety.
Limitations: The model was developed using data from a single centre, although tested on external data. Benchmarking against radiologist performance is still required.
Funding for this study: This study/project is funded by the NIHR Doctoral Clinical and Practitioner Academic Fellowship (NIHR302901).
The views expressed are those of the author(s) and not necessarily those of the NIHR or the Department of Health and Social Care.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: The retrospective training and test dataset received institutional and Caldicott guardian approval but indicated this did not require formal ethics committee approval as it was considered as a service evaluation project. The independent prospective dataset used for model validation was approved by Yorkshire & The Humber - South Yorkshire Research Ethics Committee (Ref 23/YH/0151)

DigitalTwin for Breast Cancer Risk Monitoring from Mammography (9 min)

Alberto Mosconi; Milano / Italy

Author Block: F. Darvizeh[1], A. Mosconi[2], M. Interlenghi[2], A. Venturi[2], C. Salvatore[2], M. Alì[1], S. Papa[1], I. Castiglioni[1], D. Fazzini[1]; [1]Milan/IT, [2]Milano/IT
Purpose: To validate a Digital Twin (DT) platform for the automatic monitoring of Breast Cancer (BC) risk in patients subjected to mammography.
Methods or Background: Female patients undergoing mammography for assessing BC risk, between November 2024 and May 2025, were included. The vendor-neutral DT platform (Trace4DigitalTwin™) was integrated in RIS-PACS of 3 centers (CDI-Centro Diagnostico Italiano, SME Varese, and Bionics; 2 mammography systems from 2 vendors). The platform includes a deep-learning model for automatic ACR breast density prediction. DT-predicted breast density was compared with radiologist classification.
Results or Findings: The DT automatically monitored 14,736 patients, for a total of 29,472 images (Medio-Lateral-Oblique projections). Agreement with radiologists' classification was 81.2% for DT-predicted breast density in the ACR four classes A, B, C, and D (Cohen's kappa 62.6%). ACR BI-RADS 1 was 79.7% in DT-predicted class A, 67.9% in B, 65.8% in C, 66.1% in D. BI-RADS 2 was 18.3% in DT-predicted class A, 28.6% in B, 31.0% in C, and 30.0% in D. No BI-RADS 5 was found in DT-predicted class A. The DT-predicted D-to-B ratio of BI-RADS 5 was more than 200%.
Conclusion: We demonstrated that a RIS-PACS integrated, DT platform, including a deep-learning model for automatic breast density and ACR BI-RADS reporting, is feasible, supporting efficient and standardized breast patient monitoring and breast cancer risk assessment.
Limitations: Risk stratification considering other risk factors should be included.
Funding for this study: No funding was received for this study.

CNNs for Automated Detection of Lung Emphysema in Chest CT studies (9 min)

Matteo Interlenghi; Milan / Italy

Author Block: F. Darvizeh, E. Schiavon, M. Interlenghi, A. Mosconi, A. Lad, A. Venturi, C. Salvatore, D. Fazzini, I. Castiglioni; Milan/IT
Purpose: Development and evaluation of Convolutional Neural Networks (CNNs) for automatic detection of pulmonary emphysema from chest CT studies
Methods or Background: Chest CT studies from two radiology departments (Centro Diagnostico Italiano-CDI Milano n=320, Centro SME Varese n=90) were retrospectively collected (StudyID 1944 approved 8/2/2021). Patients signed informed consent.
A pipeline was developed including automatic image preprocessing and classification via CNNs mimicking visual assessment of radiologists for emphysema or non-emphysema detection.
Four ResNet-18 were trained with different image: 2D lung-density maps of segmented lungs (Otsu thresholding) and color-windowing in three density-zones: low (<−950 HU), normal [−950 to −810 HU], and high (>−810 HU) density, with automatic selection of most representative coronal slice (ResNet2DM) (1); full 3D lung-density maps (ResNet3DM) (2); full 3D-CT volumes without (ResNet3D) (3) and with lung segmentation (ResNet3DSL) (4), with preprocessing window (1500 HU width, −600 HU level) for (3) and (4).
Cases were divided in training (146-141, emphysema and non-emphysema, respectively), validation (41-40), and external-testing (22-21), with Ground-truths assigned by board-certified radiologists and a trained engineer, based on diagnostic reports. McNemar's test was used for comparison of performance (sensitivity, specificity) of the CNNs.
Results or Findings: The performance achieved are: ResNet2DM 0.77 sensitivity, 0.86 specificity; ResNet3DM 0.82 and 0.81; ResNet3D 0.86 and 0.81; ResNet3DSL 0.77 and 0.76.
No significant differences in performance were found between ResNet3D, and ResNet3DM (best models). ResNet2DM and ResNet3DSL performance was significantly inferior. Radiologist preference indicated ResNet3DM for higher explainability.
Conclusion: Lung emphysema can be automatically detected with 3D CNNs on chest CTs. 3D ResNet-18 is a valid solution, with high explainability when used with lung-density coloured-maps.
Limitations: Increasing the sample size from multiple centers will be recommended for further validation
Funding for this study: No funding was received for this study.

Development of an auto-segmentation model for dose accumulation in repeated liver brachytherapy (9 min)

Anna Sophie Duque; Munich / Germany

Author Block: A. S. Duque, M. Rottler, P. Rogowski, F. Fuchs, C. C. Cyran, J. Ricke, M. Seidensticker, C. Kurz, S. Corradini; Munich/DE
Purpose: In order to assess clinical outcome of repeated CT-guided high-dose-rate liver brachytherapy administered over several years, accurate calculation of accumulated dose is needed. To drive image registration, an AI model was developed to facilitate liver segmentation while minimizing distortions by brachytherapy catheters.
Methods or Background: For 35 patients with multiple liver brachytherapy sessions, first-session planning CTs were segmented using commercial AI algorithms for radiotherapy organs-at-risk delineation (algorithms A, B). Resulting liver contours were corrected by experienced radiation oncologists, serving as ground truth. The patient set was split into training and validation set (n=30) and test set (n=5). Training was performed using nnU-Net with five-fold cross-validation. Ground truth contours were compared to algorithms A, B, an additional pre-trained open-source AI algorithm (C) and the resulting custom model (D*) in terms of Dice Similarity Coefficient (DSC) and 95th percentile Hausdorff Distance (HD95).
Results or Findings: D* showed a higher robustness towards brachytherapy catheters compared to the other algorithms (Fig. 1). After cross-validation, a mean DSC of 0.965 and mean HD95 of 4.1 mm was reached by D*. After applying AI algorithms A-C to the validation set, mean DSCs ranged from 0.921 (B) to 0.947 (C) (Fig. 2) . Mean HD95 ranged from 7.4 mm (C) to 12 mm (A) (Fig. 3). On the test set, the DSC was 0.969 (D*), 0.954 (A), 0.968 (B) and 0.962 (C). Mean HD95 was 3.1 mm (D*), 7.0 mm (A), 4.0 mm (B) and 5.4 mm (C).
Conclusion: A custom model for liver brachytherapy segmentation was developed, providing contours less disrupted by catheters compared to existing auto-segmentation algorithms.
Limitations: The patient data sets were comparably small. Since clinical contours were obtained by correcting results of algorithms A and B, the comparison could be biased.
Funding for this study: No funding or industrial support was received for this study.

Developing an Artificial Intelligence Algorithm for T-staging Rectal Cancer MRI: a Pilot Study (9 min)

Seema Toso; Geneva / Switzerland

Author Block: S. Muncner[1], A. Wahd[1], N. Frymire[1], R. MacEwan[1], S. Toso[2], S. Liu[1], A. Hareendranathan[1], H. Wang[1], J. L. Jaremko[1]; [1]Edmonton/CA, [2]Geneva/CH
Purpose: Pelvic MRI is the preferred imaging modality for staging rectal cancer (RC). Accurate staging is critical for treatment decision-making, and detemines if patients require neoadjuvant treatment. However, interpretation can be challenging despite review by multidisciplinary teams (MDT). Techniques to improve MRI staging may improve RC patient outcomes. In this pilot study, we evaluated the performance of a novel AI algorithm for RC MRI interpretation.
Methods or Background: Two expert interpreters labelled RC T-stage on 99 2D MRI images each (1.5T, T2-weighted) from 34 unique patients. 156 images(27 patients) were allocated for training and 42 images(seven patients) for testing, to prevent data leakage. An adapted version of Meta's SAM2 foundation model was used to perform visual in-context learning (ICL) for image segmentation. Dice scores and diagnostic performance of AI T-stage (≥T3) prediction vs. human labels was calculated. Finally, an expert user awarded AI results a qualitative score (grade-A: incorrect T-stage; grade-B:correct T-stage, incorrect contours; grade-C: correct T-stage, correct contours).
Results or Findings: Of 42 test images, average Dice score was 63.6% (normal bowel 73.09%, T1/2 tumor 74.91%, T3 tumor 22.03%). For ≥T3-stage, average accuracy was 79%, and sensitivity and specificity averaged 75.13% and 87.50% respectively. On qualitative assessment, AI results were high-quality in 79% of cases (35.7% grade-3 predictions (n=15), 42.9% grade-2 (n=18)).
Conclusion: This pilot study demonstrates remarkably strong preliminary AI performance with 79% accuracy for T-stage.
Limitations: This study had a very small training set (156 images/27 patients). Ongoing testing including multicentre training data will improve the accuracy of the algorithm.
Funding for this study: Funding was provided by the Clinician Investigator Program (University of Alberta, Edmonton, Canada).

CUBE 12 - Pulmonary artery, portal vein and aorta: latest innovations

Categories: Chest, Interventional Radiology

ETC Level: LEVEL II+III

Date: March 5, 2026 | 15:30 - 16:00 CET

CME Credits: 0.5

This advanced session will explore cutting-edge developments in the management of vascular conditions affecting the pulmonary artery, portal vein, and aorta. The session contains focused presentations on pulmonary embolism thrombectomy, portal vein and double vein embolisation, and endovascular aortic repair. Each speaker will discuss recent innovations, technical considerations, and clinical outcomes to inform best practices in these complex interventions.

Moderator:

Rutger Johan Lely; Amsterdam / Netherlands

Chairperson's introduction (3 min)

ST 14 - The European Lung Cancer Screening Alliance (ELCSA): Ensuring Continuity and Impact Beyond SOLACE

Categories: Oncologic Imaging, Research

Date: March 5, 2026 | 15:30 - 16:00 CET

SESSION RECOMMENDED BY EIBIR | EUROPEAN INSTITUTE FOR BIOMEDICAL IMAGING RESEARCH

The Strengthening the Screening of Lung Cancer in Europe (SOLACE) project is a pioneering EU4Health initiative under Europe's Beating Cancer Plan. Running until the end of March 2026, SOLACE has facilitated the implementation of lung cancer screening programmes across Europe, working to remove barriers so that people from all social and economic backgrounds can access screening.
To ensure the sustainability of the progress made during the SOLACE project, ESR and ERS have agreed to establish the European Lung Cancer Screening Alliance (ELCSA). ELCSA will continue the efforts initiated by SOLACE, promoting equitable access to lung cancer screening across Europe beyond the life of the project.

EFRS 10c - Innovations in Radiotherapy: From Imaging to Patient Experience

Categories: Hybrid Imaging, Imaging Methods, Radiographers, Professional Issues

Date: March 5, 2026 | 15:45 - 16:45 CET

CME Credits: 1

This session will explore emerging innovations in radiotherapy workflows and their potential to transform clinical practice. Topics include the role of photon-counting CT in radiotherapy planning, the principles and challenges of simulation CT-free workflows, and the rationale and implementation of maskless treatments. Participants will also evaluate how these developments may reshape the entire pathway—from imaging through to treatment delivery—enhancing precision, efficiency, and patient experience.

Moderator:

Valerio Pisoni; Giussano / Italy

Chairperson's introduction (5 min)

Valerio Pisoni; Giussano / Italy

Photon-Counting CT: A New Era for Radiotherapy Planning (15 min)

Linda Rossi; Rotterdam / Netherlands

1. Explain the potential of photon-counting CT in radiotherapy planning
2. Evaluate how these innovation may reshape current radiotherapy workflows, from imaging to treatment delivery

Towards Simulation-Free Radiotherapy: Emerging Workflows and Clinical Impact (15 min)

Marco Fusella; Abano Terme (PD) / Italy

1. Describe the principles and challenges of simulation CT-free workflows
2. Evaluate how these innovation may reshape current radiotherapy workflows, from imaging to treatment delivery

Maskless Radiotherapy: Redefining Patient Comfort and Precision (15 min)

Marion Essers; Tilburg / Belgium

1. Discuss the rationale and clinical implementation of maskless treatments
2. Evaluate how these innovation may reshape current radiotherapy workflows, from imaging to treatment delivery

Panel Discussion (10 min)

CTiR 11 - Clinical Trials in Radiology: recent studies in oncology and AI

Categories: Oncologic Imaging, Genitourinary, Artificial Intelligence
Date: March 5, 2026 | 16:30 - 18:00 CET
CME Credits: 1.5

Prostate Cancer Patients Undergoing Focal Therapy: PSMA-FAB vs. PI-FAB (11 min)
Egesta Lopci; Rozzano / Italy

Author Block: E. Lopci[1], F. Mrakic Sposta[1], M. Lazzeri[1], V. Fasulo[1], P. Colombo[2], M. Rodari[1], A. Laghi[2], N. Buffi[2], G. Lughezzani[2]; [1]Rozzano/IT, [2]Pieve Emanuele/IT
Purpose: The aim of the present study is to compare in parallel mpMRI and PSMA PET/CT for the assessment of prostate cancer (PCa) patients candidate to high-intensity focused ultrasound (HIFU) ablative therapy.
Methods or Background: For this prospective study, we enrolled 55 PCa patients included in our dedicated trial (ICH-018: Focal Therapy for organ-confined prostate cancer) and assessed before and after focal therapy with HIFU. The patients were investigated at staging and 12 months after HIFU with mpMRI and PSMA PET/CT, along with biochemical assessment performed at 3, 6, and 12 months. One year after ablative therapy, patients underwent reclassification biopsy. For imaging parameters we considered PI-RADS, PRECISE, and PI-FAB for mpMRI, whereas Primary score, SUVmax, SUVratio, their variations and PSMA-FAB were analyzed for PET/CT. All clinical laboratory and imaging parameters have been analyzed with regards re-biopsy results post-HIFU.
Results or Findings: Median age of our cohort was 67 years (range 53-79), median PSA 6.7 ng/ml (range 2.1-16.4), median volume 44 cc (range 20-118), and median PSA density 0.13 (range 0.04-0.82). There was a 54.5% concordance rate between PSMA-FAB and PI-FAB scores. PSMA-FAB classification showed a sensitivity, specificity and accuracy for PCa detection at re-biopsy of 74.4%, 62.5%, and 70.9%, respectively, significantly correlating with re-biopsy results (P=0.014). On univariate analyses, also SUVmax, SUVratio and Primary score post-HIFU resulted significantly correlated to re-biopsy results, with PI-FAB resulting as independent predictive factor (P=0.0048).
Conclusion: To the best of our knowledge, this is the first study of its kind comparing PI-FAB and newly proposed PSMA-FAB in the same cohort of PCa patients. PSMA-FAB demostrated a significant correlation with re-biopsy results, although in the present cohort, PI-FAB proved an independent role in predicting biopsy results 12 months post-HIFU.
Limitations: Limited patients cohort.
Funding for this study: None.

Impact of dynamic contrast-enhanced MRI on treatment eligibility and planning in suspected prostate cancer: final analysis from the PRIME trial (11 min)
Aqua Asif; London / United Kingdom

Author Block: A. Asif, P. S. G. C. .; London/UK
Purpose: Multiparametric MRI (mpMRI) with dynamic contrast-enhanced (DCE) sequences represents the international standard for prostate cancer diagnosis. DCE may influence treatment eligibility and planning decisions, from surgical approach to radiotherapy targeting. We evaluated this in PRIME, a prospective international trial. This is the first study examining contrast sequences' impact specifically on treatment planning, made possible through within-patient design.
Methods or Background: PRIME (NCT04571840) enrolled men with suspected prostate cancer (PSA ≤20 ng/mL, no prior biopsy) across 22 centres in 12 countries (April 2022–September 2023). In this pre-specified secondary analysis, virtual multidisciplinary teams (MDTs) comprising radiologists, urologists, and oncologists reviewed 488 patients. Clinicians were initially blinded to DCE, making treatment decisions using only biparametric MRI (bpMRI: T2-weighted and diffusion-weighted imaging) with bpMRI-specific biopsy results. After unblinding to DCE (and DCE-specific biopsy if performed), treatment decisions were re-evaluated. MDTs assessed eligibility and planning for radical prostatectomy (nerve-sparing, bladder neck sparing, Retzius sparing), focal therapy (extent and energy source), and radiotherapy/brachytherapy (target volume delineation and rectal spacer use).
Results or Findings: DCE influenced treatment decisions in 31/488 patients (6.4%; 95% CI 4.4–9.0): 21 (4.3%; 95% CI 2.7–6.5) had eligibility changes, 15 (3.1%; 95% CI 1.7–5.0) had planning changes, and 5 (1.0%) had both. Among 119 radical prostatectomy candidates, nerve-sparing recommendations changed in 6 (5.0%). Of 41 focal therapy candidates, energy source changed in 1 (2.4%). Among 145 radiotherapy/brachytherapy candidates, 6 (4.1%) had target volume changes and 3 (2.1%) had rectal spacer modifications. Active surveillance eligibility changed in 7 (1.4%).
Conclusion: Overall, DCE did not substantially influence treatment eligibility or planning. However, for patients selected for specific treatment modalities, contrast affected decisions in a small subset.
Limitations: This exploratory secondary analysis was not statistically powered for treatment planning subgroup comparisons.
Funding for this study: Funded by the John Black Charitable Foundation, Prostate Cancer UK, the European Association of Urology Research Foundation, and the Wolfgang.Dieckmann Foundation. This study was sponsored by University College London. Primary funding was provided by Prostate Cancer UK (grant TLD-PF19-004) and the John Black Charitable Trust Travelling Prize Grant. Additional support for international sites was supplied by the European Association of Urology Research Foundation and the Wolfgang.Dieckmann Foundation.
Has your study been approved by an ethics committee? Yes
Ethics committee - additional information: Ethical approval was obtained from the National Research Ethics Committee West Midlands, Nottingham (21/WM/0091). The trial was approved by the ethical review board at each participating institution.
